CTRT	Control transfer stage transition interrupt	• A control transfer stage transition is detected because of one of the following: – Setup stage completed – Control write transfer status stage transition occurred – Control read transfer status stage transition occurred – Control transfer completed – Control transfer sequence error occurred	Function	INTSTS0.CTSQ[2:0]
BEMP	Buffer empty interrupt	• The buffer is empty after all FIFO buffer data is transmitted • A packet larger than the maximum packet size is received	Host or function	BEMPSTS.PIPEBEMP
NRDY	Buffer not ready interrupt	In host controller mode: • A STALL response is received from the peripheral device in response to the issued token • The response from the peripheral device in response to the issued token is not received successfully (no response three times consecutively or packet reception error three times consecutively) • An overrun or underrun error occurred during isochronous transfer In device controller mode: • NAK is returned for an IN or OUT token while the PID[1:0] bits were set to 01b (BUF) • A CRC error or bit stuffing error occurred during data reception in isochronous transfer • An interval error occurred during data reception in isochronous transfer	Host or function	NRDYSTS.PIPENRDY
BRDY	Buffer ready interrupt	• The buffer is ready (read or write state)	Host or function	BRDYSTS.PIPEBRDY
OVRCR	Overcurrent input change interrupt	• USBHS_OVRCURA pin or USBHS_OVRCURB pin state change is detected (low to high or high to low)	Host or function	SYSSTS0.OVCMON[1:0]

Table 29.18 Interrupt sources (2 of 2)

Flag to be set to 1	Interrupt name	Interrupt source	Applicable controller function	Status flag
BCHG	Bus change interrupt	• USB bus state change is detected	Host	—
DTCH	Device disconnect detection interrupt	• Peripheral device disconnect is detected	Host	—
ATTCH	Device connect detection interrupt	• J-state or K-state is detected on the USB bus for 2.5 µs continuously This interrupt can be used to check whether peripheral devices are connected.	Host	—
EOFERR	EOF error detection interrupt	• An EOF error is detected for a peripheral device	Host	—
SACK	Setup normal interrupt	• A setup transaction normal response (ACK) is received	Host	—
SIGN	Setup error interrupt	• A setup transaction error (no response or ACK packet corruption) is detected three consecutive times	Host	—
PDDETINT	PDDETSTS change detect interrupt	• PDDET pin change is detected	Host or function	BCCTRL.PDDETSTS
LPMEND	LPM transaction end interrupt	• LPM transaction is complete	Host	PL1CTRL.DVSQ[3:0]
L1RSMEND	L1 resume end interrupt	• Resume (from L1 state) processing is complete	Host	PL1CTRL.DVSQ[3:0]

Note 1. Although this interrupt can be generated in host controller mode, it is not usually used in this mode.

29.3.5.1 Selecting the USBHS interrupt detection method

Table 29.19 shows operations for an USBHS interrupt output from the USBHS. In case two or more interrupt sources are generated, the USBHS interrupt output method can be set in the SOFCFG.INTL bit. Set the USBHS interrupt output operation based on your system.

Table 29.19 USBHS interrupt operation

USBHS interrupt output (INTL setting)	When one interrupt source is generated	When two or more interrupt sources are generated
Edge detection (SOFCFG.INTL bit = 0)	Low level output until the source is cleared	When one source is cleared, the USBHS interrupt is negated for 32 clocks at 48 MHz (high pulse output)
Level detection (SOFCFG.INTL bit = 1)	Low level output until the source is cleared	Low level output until all sources are cleared

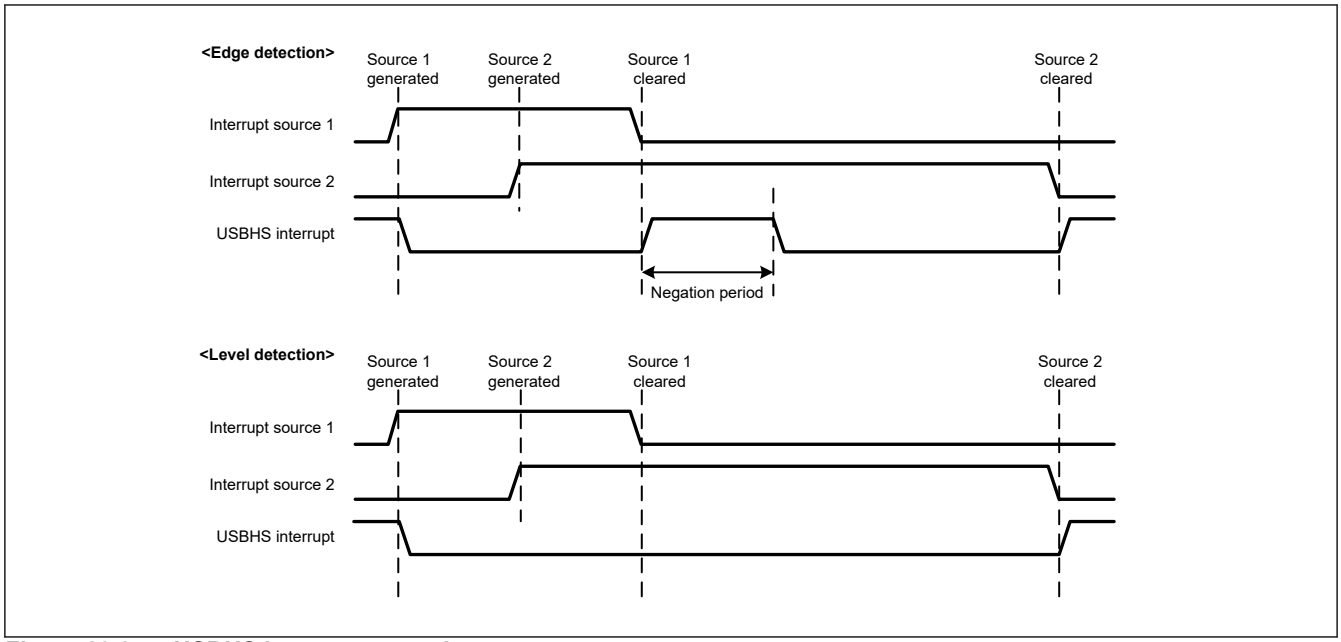

Figure 29.3 USBHS interrupt operation

Figure 29.4 shows an interrupt association chart of the USBHS.

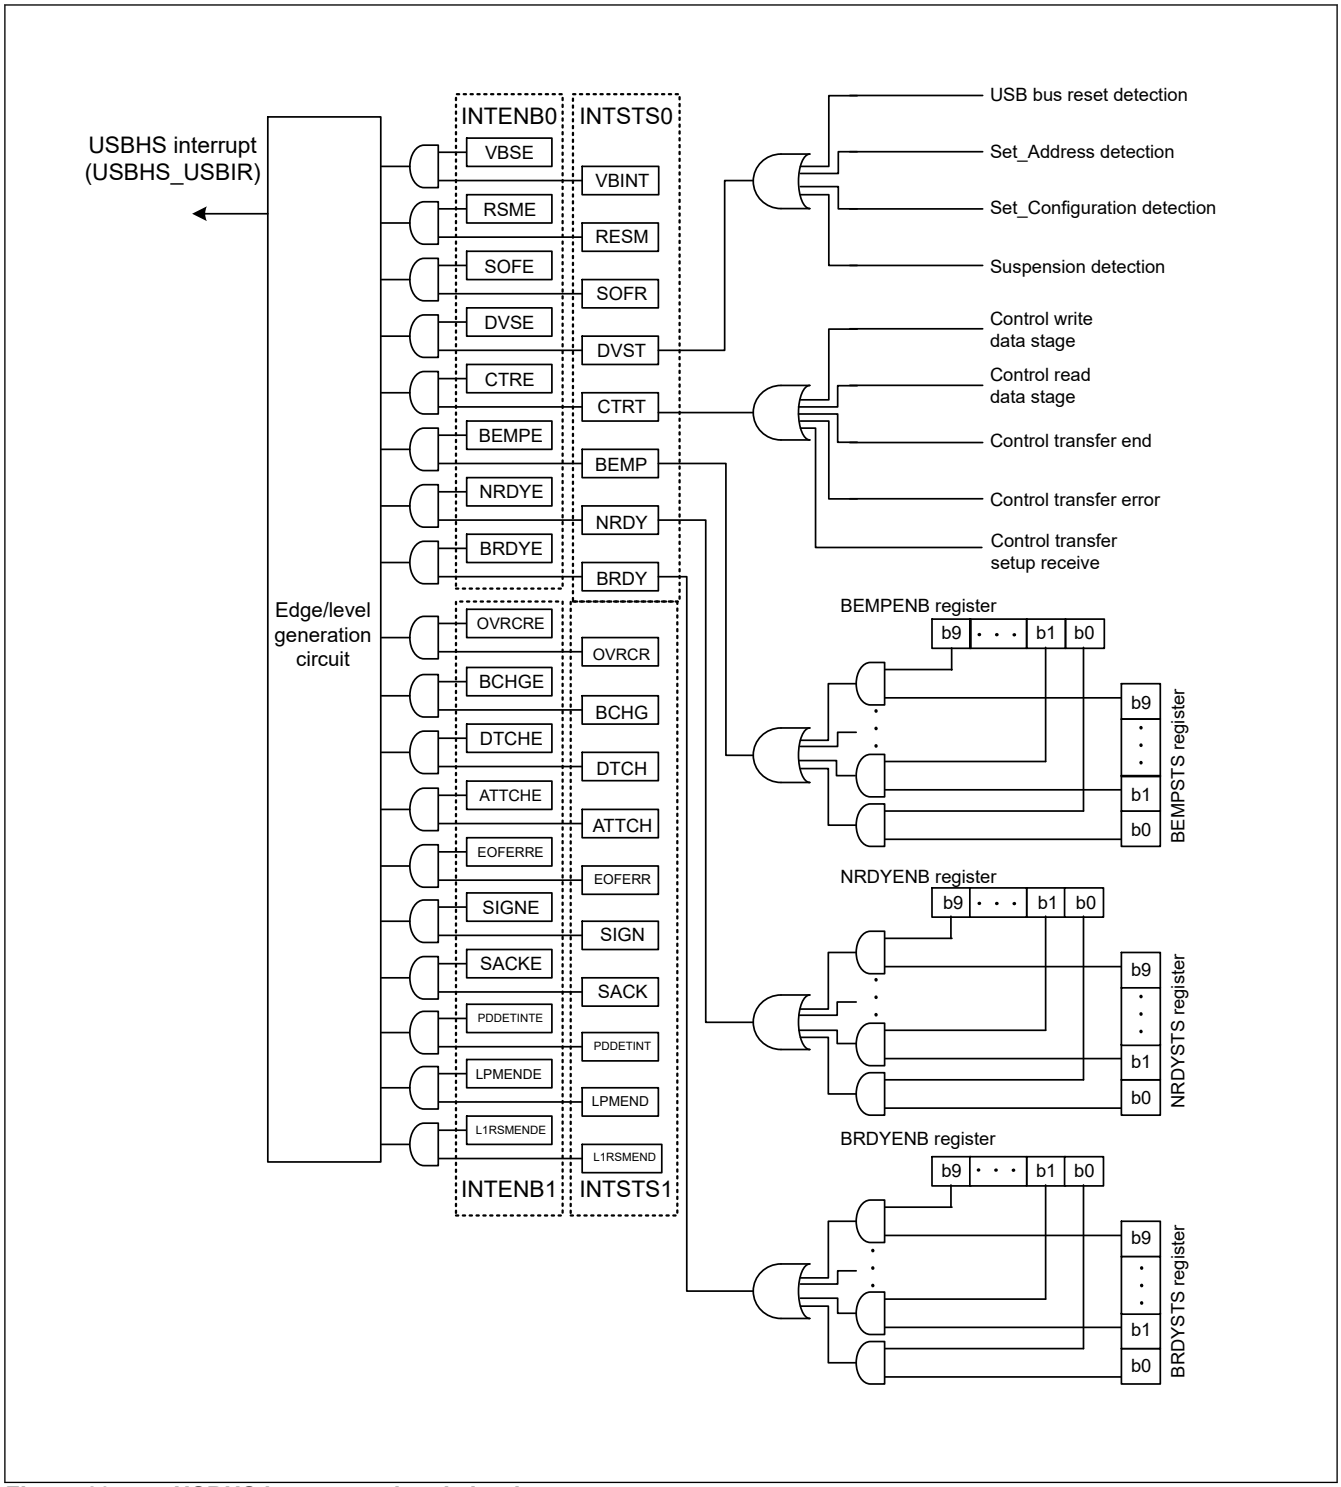

Figure 29.4 USBHS interrupt-related circuits

Table 29.20 shows the interrupts generated by the USBHS.

Table 29.20 USBHS interrupts (1 of 2)

Interrupt name	Interrupt status flag	DTC activation	DMAC activation
USBHS_D0FIFO	DMA transfer request 0	Possible	Possible
USBHS_D1FIFO	DMA transfer request 1	Possible	Possible

Table 29.20 USBHS interrupts (2 of 2)

Interrupt name	Interrupt status flag	DTC activation	DMAC activation
USBHS_USBIR	VBUS interrupt, resume interrupt, frame number update interrupt, device state transition interrupt, control transfer stage transition interrupt, buffer empty interrupt, buffer not ready interrupt, buffer ready interrupt, overcurrent interrupt, bus change interrupt, device disconnect detection interrupt, device connect detection interrupt, EOF error detection interrupt, normal setup operation interrupt, setup error interrupt, PDDETSTS change detection interrupt, LPM transaction end interrupt, and L1 resume end interrupt	Not possible	Not possible

29.3.6 Interrupt Descriptions

29.3.6.1 BRDY interrupt

The BRDY interrupt is generated in both host and device controller modes. This section describes the conditions in which the USBHS sets the associated bit in BRDYSTS to 1. Under these conditions, the USBHS generates a BRDY interrupt if the software sets the bit in BRDYENB associated with the given pipe to 1 and INTENB0.BRDYE bit to 1.

The conditions for generating and clearing the BRDY interrupt depend on the SOFCFG.BRDYM and PIPECFG.BFRE settings for each pipe as follows:

(1) When SOFCFG.BRDYM = 0 and PIPECFG.BFRE = 0

With these settings, the BRDY interrupt indicates that the FIFO port is accessible.

On any of the following conditions, the USBHS generates an internal BRDY interrupt request trigger and sets the BRDYSTS.PIPEBRDY flag associated with the pipe to 1.

For transmitting pipes

- When the DIR bit is changed from 0 to 1 by software
- When writing by the CPU to the FIFO buffer is disabled for a pipe (when the BSTS flag is read as 0) and the USBHS has completed packet transmission. In continuous transfer, a BRDY interrupt is generated on completion of the transmission of data from one FIFO buffer.
- When one FIFO buffer is empty on completion of writing data to the other FIFO buffer in double buffer mode
- No request trigger is generated until completion of writing data to the currently-written FIFO buffer even if transmission to the other FIFO buffer is complete
- When the hardware flushes the buffer of the pipe for isochronous transfers
- When 1 is written to the PIPEnCTR.ACLRM bit, which causes the FIFO buffer to transition from the write-disabled to write-enabled state.

No request trigger is generated for the DCP, that is, during data transmission for control transfers.

For receiving pipes

- When packet reception is successfully complete, enabling the FIFO buffer to be read while read-access from the CPU to the FIFO buffer for the given pipe is disabled (when the BSTS flag is read as 0). No request trigger is generated for transactions in which DATA-PID mismatch has occurred. In continuous transmission or reception mode, the request trigger is not generated when the data is of the specified maximum packet size and the buffer has available space. When a short packet is received, the request trigger is generated even if the FIFO buffer has available space. When the transaction counter is used, the request trigger is generated on receiving the specified number of packets. In this case, the request trigger is generated even if the FIFO buffer has available space.
- When one FIFO buffer is read-enabled on completion of reading data from the other FIFO buffer in double buffer mode. No request trigger is generated until completion of reading data from the currently-read FIFO buffer, even if reception by the other FIFO buffer is complete.
  In device controller mode, the BRDY interrupt is not generated in the status stage of control transfers. The PIPEBRDY interrupt status of the selected pipe can be set to 0 by writing 0 to the associated PIPEBRDY flag through the software. In this case, 1s must be written to the associated bits for the other pipes. Clear the BRDY status before accessing the FIFO buffer.

(2) When SOFCFG.BRDYM = 0 and PIPECFG.BFRE = 1

With these settings, the USBHS generates a BRDY interrupt on completion of reading all data for a single transfer using the receiving pipe, and sets the bit in BRDYSTS associated with the pipe to 1.

On any of the following conditions, the USBHS determines that the last data for a single transfer was received:

- When a short packet including a zero-length packet is received
- When the PIPEnTRN register is used and the number of packets specified in the PIPEnTRN.TRNCNT[15:0] bits are completely received

When the data is completely read after any of these conditions is satisfied, the USBHS determines that all data for a single transfer is completely read.

When a zero-length packet is received while the FIFO buffer is empty, the USBHS determines that all data for a single transfer is completely read when the FRDY flag in the FIFO port control register is 1 and the DTLN[11:0] flags are 0. In this case, to start the next transfer, write 1 to the BCLR bit in the associated port control register through software. With these settings, the USBHS does not detect a BRDY interrupt for the transmitting pipe.

The PIPEBRDY interrupt status of a pipe can be set to 0 by writing 0 to the associated BRDYSTS.PIPEBRDY flag through the software. In this case, 1s must be written to the PIPEBRDY bits for the other pipes.

In this mode, do not change the PIPECFG.BFRE bit setting until all data for a single transfer is processed. When it is necessary to change the PIPECFG.BFRE bit before completion of processing, all FIFO buffers for the pipe must be cleared using the PIPEnCTR.ACLRM bit.

(3) When SOFCFG.BRDYM = 1 and PIPECFG.BFRE = 0

With these settings, the BRDYSTS.PIPEBRDY flag values are linked to the BSTS flag setting for each pipe. In other words, the BRDY interrupt status bits are set to 1 or 0 by the USBHS depending on the FIFO buffer status.

For transmitting pipes

The BRDY interrupt status bits are set to 1 when the FIFO port is ready for write access, and are set to 0 when it is not ready. The BRDY interrupt is not generated for the DCP in the transmitting direction even when it is ready for write access.

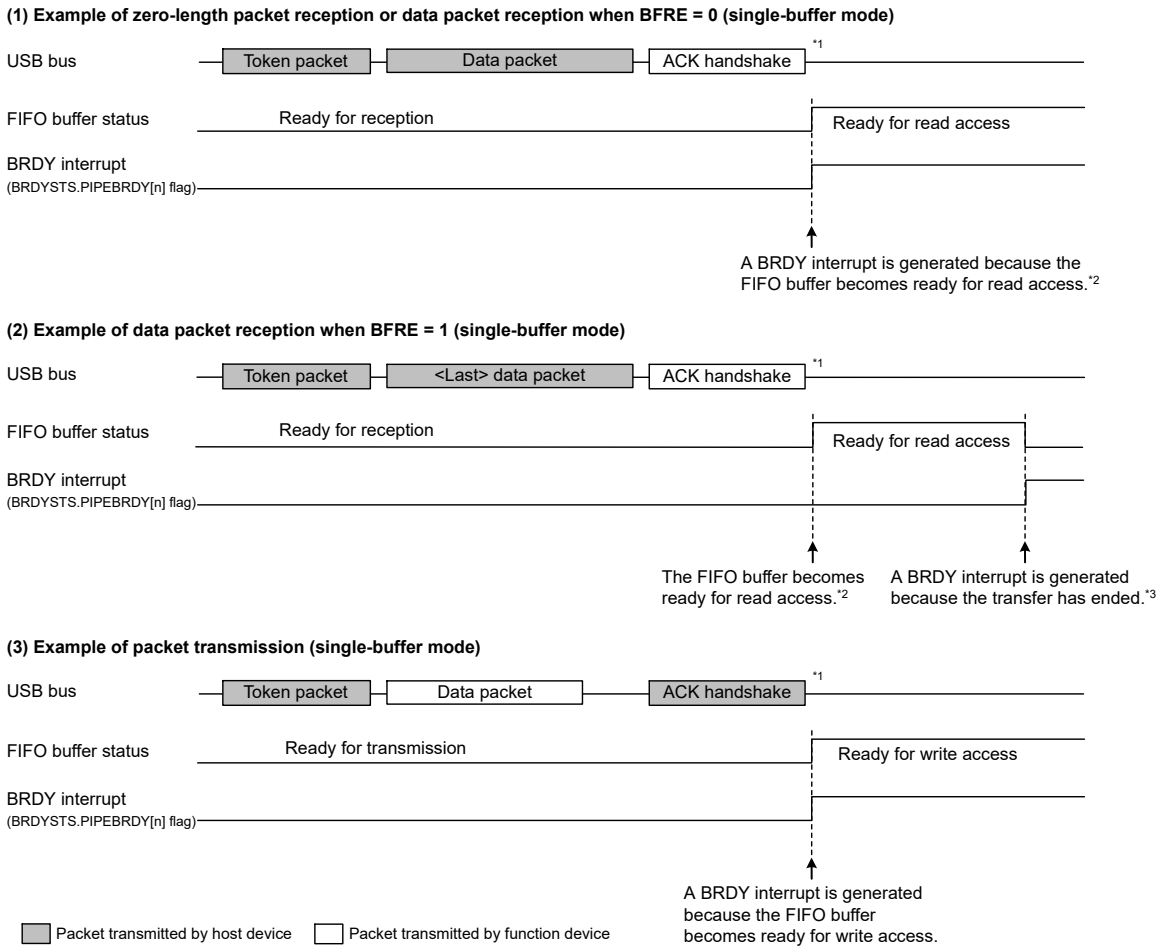
For receiving pipes

The BRDY interrupt status bits are set to 1 when the FIFO buffer is ready for read access, and are set to 0 when all data is read (not ready for read access).

When a zero-length packet is received while the FIFO buffer is empty, the associated bit is set to 1 and the BRDY interrupt is continuously generated until the software writes 1 to BCLR. With this setting, the PIPEBRDY flag cannot be set to 0 by software.

When the SOFCFG.BRDYM bit is set to 1, set the PIPECFG.BFRE bit for all pipes to 0, and the SOFCFG.INTL bit to 1 for level detection.

Figure 29.5 shows the timing of BRDY interrupt generation.



Note 1. The ACK handshake is not used in isochronous transfers.
Note 2. The FIFO buffer becomes ready for read access under the following condition:
When a packet is received while no unread data remains in the FIFO buffer in the CPU.
Note 3. A transfer ends under either of the following conditions:
1. When a short packet including a zero-length packet is received
2. When the number of packets specified in the transaction counter are received

Figure 29.5 Timing of BRDY interrupt generation

The condition for clearing the INTSTS0.BRDY flag depends on the SOFCFG.BRDYM bit setting value, as shown in Table 29.21

Table 29.21 Conditions for clearing the BRDY flag

BRDYM bit	Condition for clearing BRDY flag
0	The USBHS clears the BRDY flag to 0 when all bits in BRDYSTS are set to 0 by software
1	The USBHS clears the BRDY flag to 0 when the BSTS flags for all pipes have cleared to 0

29.3.6.2 NRDY interrupt

On generating an internal NRDY interrupt request for the pipe whose PID[1:0] bits are set to 01b (BUF response) by software, the USBHS sets the associated NRDYSTS.PIPENRDY flag to 1. If the associated bit in NRDYENB is set to 1 by software, the USBHS sets the INTSTS0.NRDY flag to 1 and generates a USBHS interrupt.

This section describes the conditions in which the USBHS generates the internal NRDY interrupt request for a given pipe.

The internal NRDY interrupt request is not generated during setup transaction execution in host controller mode. During setup transactions in host controller mode, the SACK or SIGN interrupt is detected.

The internal NRDY interrupt request is not generated during status stage execution of the control transfer in device controller mode

(1) In host controller mode when no split transactions occur in the connection

For transmitting pipes

On any of the following conditions, the USBHS detects an NRDY interrupt:

- For isochronous transfer pipes, when the time to issue an OUT token comes while there is no data to be transmitted in the FIFO buffer. In this case, the USBHS transmits a zero-length packet following the OUT token and sets the associated NRDYSTS.PIPENRDY flag and the FRMNUM.OVRN flag to 1.
- During communications other than setup transactions on pipes not used for isochronous transfers, when any combination of the following two conditions occurs three consecutive times:
  - No response is returned from the peripheral device (when timeout is detected before detection of the handshake packet from the peripheral device
  - An error is detected in the packet from the peripheral device. In this case, the USBHS sets the associated PIPENRDY flag to 1 and changes the PID[1:0] setting for the associated pipe to 00b (NAK response)
- During communications other than setup transactions, when the STALL handshake is received from the peripheral device (includes STALL for both OUT and PING). In this case, the USBHS sets the associated PIPENRDY flag to 1 and changes the PID[1:0] setting for the associated pipe to 11b (STALL response).

For receiving pipes

- For isochronous transfer pipes, when the time to issue an IN token comes but there is no space available in the FIFO buffer. In this case, the USBHS discards the received data for the IN token and sets the associated PIPENRDY flag and the OVRN flag to 1. When a packet error is detected in the received data for the IN token, the USBHS also sets the FRMNUM.CRCE flag to 1.
- For non-isochronous transfer pipes, when any combination of the following two cases occur three consecutive times:
  - No response is returned from the peripheral device for the IN token issued by the USBHS (when timeout is detected before detection of the DATA packet from the peripheral device)
  - An error is detected in the packet from the peripheral device. In this case, the USBHS sets the associated PIPENRDY flag to 1 and changes the associated PID[1:0] setting for the pipe to 00b (NAK response).
- For isochronous transfer pipes, when no response is returned from the peripheral device for the IN token (when timeout is detected before detection of the DATA packet from the peripheral device) or an error is detected in the packet from the peripheral device. In this case, the USBHS sets the associated NRDYSTS.PIPENRDY flag for each pipe to 1. The PID[1:0] setting for the pipe is not changed.
- For isochronous transfer pipes, when a CRC error or a bit stuffing error is detected in the received data packet. In this case, the USBHS sets the associated NRDYSTS.PIPENRDY flag for each pipe and the CRCE flag to 1.
- When the STALL handshake is received. In this case, the USBHS sets the associated NRDYSTS.PIPENRDY flag for each pipe to 1 and changes the PID[1:0] setting for the associated pipe to STALL.

(2) In host controller mode when split transactions occur in the connection

For transmitting pipes

On any of the following conditions, the USBHS detects an NRDY interrupt:

- For isochronous transfer pipes, when the time to issue an OUT token comes while there is no data to be transmitted in the FIFO buffer. In this case, the USBHS sets the associated RDYSTS.PIPENRDY flag for the given pipes to 1 on issuing a start-split transaction and sets the FRMNUM.OVRN flag to 1. The USBHS also transmits a zero-length packet following the OUT token.
- For non-isochronous transfer pipes, when any combination of the following two cases occurs three consecutive times:
  - No response is returned from the hub for start-split and complete-split transactions (when timeout is detected before detection of the handshake packet from the hub)

  - An error is detected in the packet from the hub. In this case, the USBHS sets the associated NRDYSTS.PIPENRDY flag for the pipe to 1 and changes the associated PID[1:0] setting for the pipe to 00b (NAK response).When an NRDY interrupt is detected on complete-split issuance, the USBHS clears the CSSTS flag to 0.

- When a STALL handshake is received for the complete-split transaction. In this case, the USBHS sets the associated NRDYSTS.PIPENRDY flag for the pipe to 1, changes the associated PID[1:0] setting for the pipe to 11b (STALL response), and clears the CSSTS flag to 0. An interrupt is not detected during setup transaction.

For receiving pipes

- For isochronous transfer pipes, when the time to issue an IN token comes but there is no space available in the FIFO buffer. In this case, the USBHS sets the associated NRDYSTS.PIPENRDY flag for the given pipe and the FRMNUM.OVRN flag to 1 on start-split issuance. The USBHS discards the received data for the IN token.
- During bulk-pipe transfers or transfers other than setup transactions with the DCP, when any combination of the following two cases occurs three consecutive times:
  - No response is returned from the hub for the IN token the USBHS issued on issuance of the start-split or complete-split transactions (when timeout is detected before detection of the data packet from the hub)
  - An error is detected in the packet from the hub. In this case, the USBHS sets the associated NRDYSTS.PIPENRDY flag for the pipe to 1 and changes the associated PID[1:0] setting for the pipe to 00b (NAK response). When this condition occurs during complete-split, the USBHS clears the CSSTS flag to 0.
- During a complete-split transaction for isochronous transfer or interrupt transfer pipes, when any combination of the following two cases occurs three consecutive times:
  - No response is returned from the hub for the IN token issued by the USBHS (when a timeout is detected before detection of the DATA packet from the hub)
  - An error is detected in the packet from the hub. On generating this condition for an interrupt transfer pipe, the USBHS sets the associated NRDYSTS.PIPENRDY flag to 1, changes the associated PID[1:0] setting for the pipe to 00b (NAK response), and clears the CSSTS flag to 0. On generating this condition for the pipe for isochronous transfers, the USBHS sets the associated NRDYSTS.PIPENRDY flag for the pipe to 1, CRCE flag to 1, and clears the CSSTS bit to 0. It does not change the PID[1:0] setting.
- During a complete-split transaction, when the STALL handshake is received for a non-isochronous transfer pipe. In this case, the USBHS sets the associated NRDYSTS.PIPENRDY flag for the pipe to 1, changes the associated PID[1:0] setting for the pipe to 11b (STALL response), and clears the CSSTS flag to 0.
- During a complete-split transaction, when the NYET handshake is received for an isochronous transfer or interrupt transfer pipe for the microframe number = 4. In this case, the USBHS sets the associated NRDYSTS.PIPENRDY flag for each pipe to 1 and the CRCE flag to 1, and clears the CSSTS flag to 0. It does not change the PID[1:0] setting.

(3) In device controller mode

For transmitting pipes

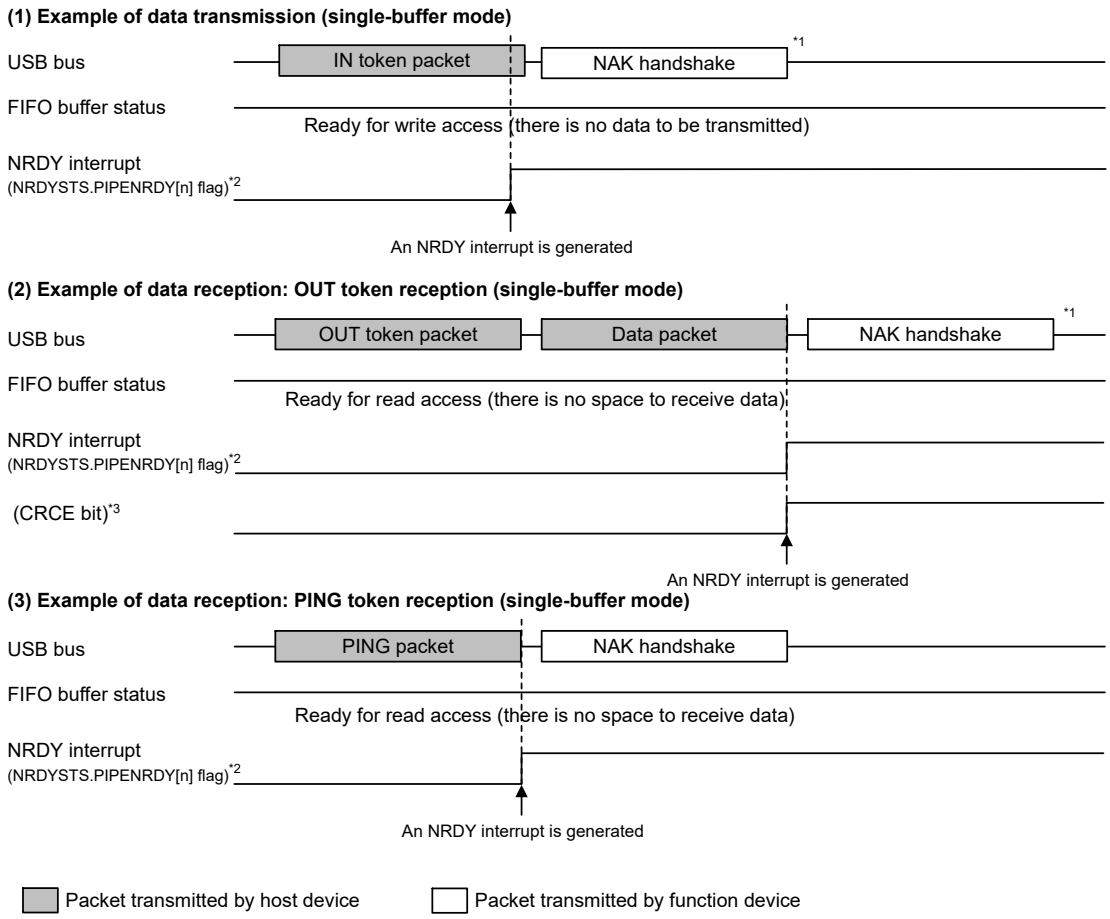
- When an IN token is received while there is no data to be transmitted in the FIFO buffer. In this case, the USBHS generates an NRDY interrupt request on reception of the IN token and sets the NRDYSTS.PIPENRDY flag to 1. For an isochronous transfer pipe in which an interrupt is generated, the USBHS transmits a zero-length packet and sets the FRMNUM.OVRN flag to 1.

For receiving pipes

- When an OUT token is received but there is no space available in the FIFO buffer. For an isochronous transfer pipe in which an interrupt is generated, the USBHS generates an NRDY interrupt request on reception of the OUT token and sets the NRDYSTS.PIPENRDY flag to 1 and the FRMNUM.OVRN flag to 1. For a non-isochronous transfer pipe in which an interrupt is generated, the USBHS generates an NRDY interrupt request when an NAK handshake is transferred after the data following the OUT token is received, and sets the NRDYSTS.PIPENRDY flag to 1. The NRDY interrupt request is not generated during retransmission because of a DATA-PID mismatch. In addition, the NRDY interrupt request is not generated if an error occurs in the DATA packet.
- On receiving a PING token when there is no space available in the FIFO buffer. The USBHS generates an NRDY interrupt request on reception of the PING token, setting the NRDYSTS.PIPENRDY flag to 1.

- For isochronous transfer pipes, when a token is not received successfully within an interval frame. In this case, the USBHS generates an NRDY interrupt request when the SOF is received, and sets the NRDYSTS.PIPENRDY flag to 1.

Figure 29.6 shows the timing of NRDY interrupt generation in device controller mode.



Note 1. The handshake is not used in isochronous transfers.
Note 2. The PIPENRDY[n] flag is changed to 1 only when PIPEnCTR.PID[1:0] bits are set to 01b (BUF response).
Note 3. The CRCE and OVRN flags change only while the target pipe is set to isochronous transfers.

Figure 29.6 Timing of NRDY interrupt generation in device controller mode

29.3.6.3 BEMP interrupt

On detecting a BEMP interrupt for the pipe whose PID[1:0] bits in the pipe control register are set to 01b (BUF response) by software, the USBHS sets the associated BEMPSTS.PIPEBEMP flag to 1. If the associated BEMPENB bit is set to 1 by software, the USBHS sets the INTSTS0.BEMP flag to 1 and generates a USB interrupt. This section describes the conditions in which the USBHS generates an internal BEMP interrupt request.

(1) For transmitting pipes

When the FIFO buffer of the associated pipe is empty on completion of transmission, including zero-length packet transmission, and in single buffer mode, an internal BEMP interrupt request is generated simultaneously with the BRDY interrupt for a non-DCP pipe. The internal BEMP interrupt request is not generated in any of the following conditions:

- When the CPU or DMA/DTC has already started writing data to the FIFO buffer of the CPU on completion of transmitting data from one FIFO buffer in double buffer mode
- When the buffer is cleared (emptied) by setting 1 to the PIPEnCTR.ACLRM or the BCLR bit in the port control register

- When an IN transfer (zero-length packet transmission) is performed during the control transfer status stage in device controller mode

(2) For receiving pipes

When a successfully-received data packet size exceeds the specified maximum packet size. In this case, the USBHS generates a BEMP interrupt request, sets the associated BEMPSTS.PIPEBEMP flag to 1, discards the received data, and changes the associated PID[1:0] setting for the pipe to STALL (11b). The USBHS returns no response in host controller mode, and returns STALL response in device controller mode.

The internal BEMP interrupt request is not generated in any of the following conditions:

- When a CRC error or a bit stuffing error is detected in the received data
- When a setup transaction is being performed:
  - Writing 0 to the BEMPSTS.PIPEBEMP flag clears the status
  - Writing 1 to the BEMPSTS.PIPEBEMP flag has no effect

Figure 29.7 shows the timing of BEMP interrupt generation in device controller mode.

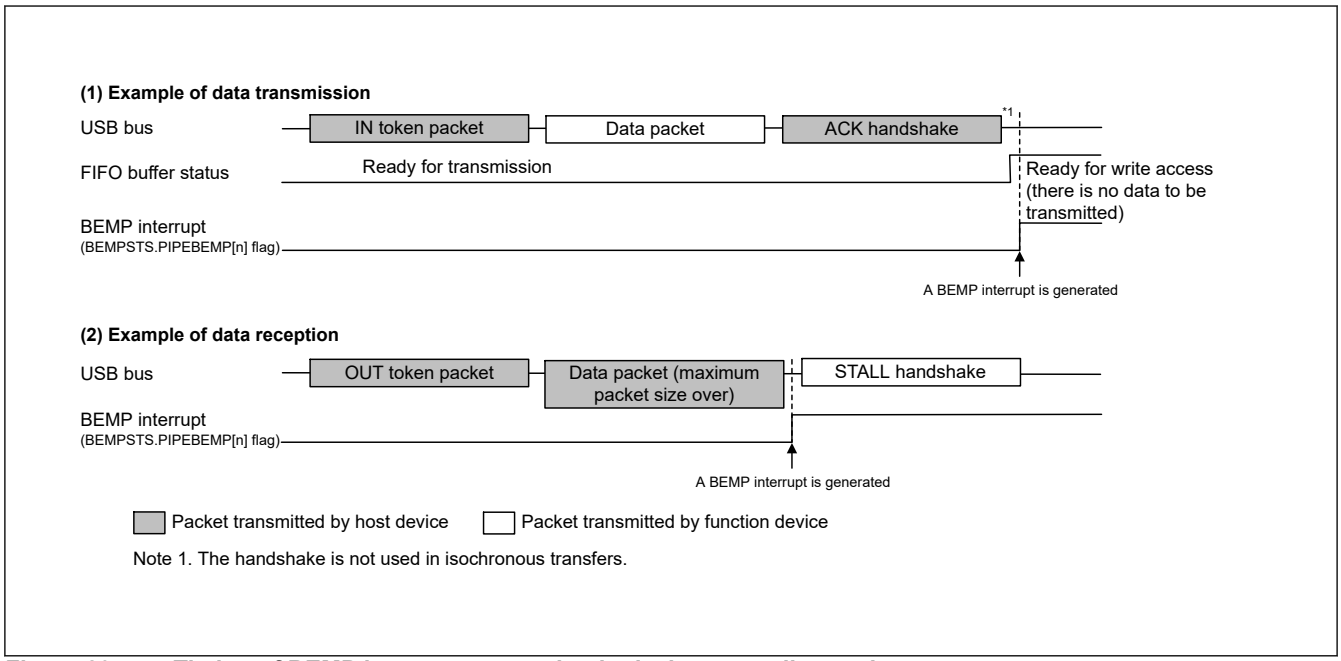


Figure 29.7 Timing of BEMP interrupt generation in device controller mode

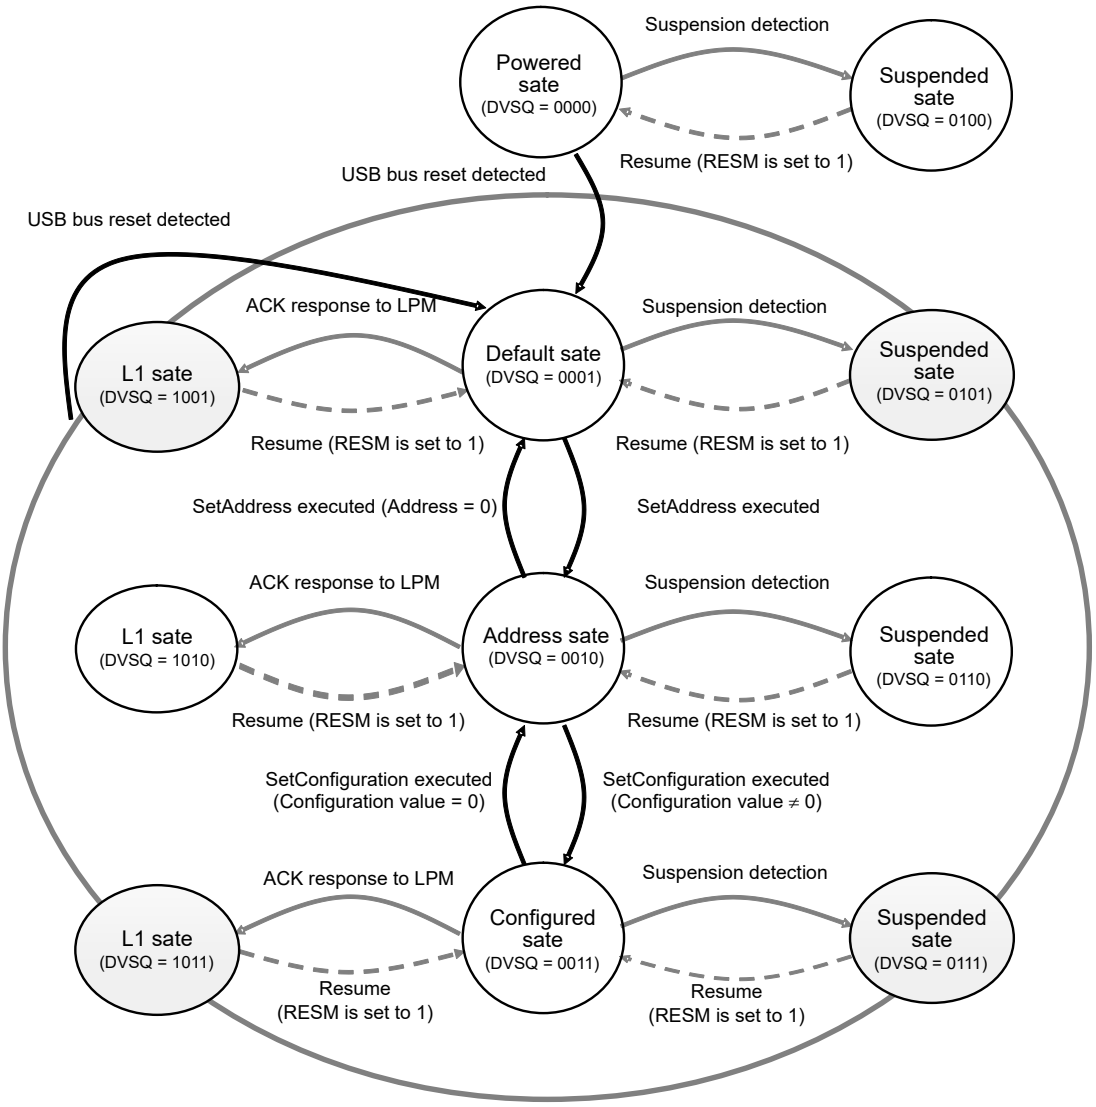
29.3.6.4 Device state transition interrupt (device controller mode)

Figure 29.8 shows a diagram of the USBHS device state transitions. The USBHS controls device states and generates device state transition interrupts. However, recovery from the Suspend state (resume signal detection) is detected by means of the resume interrupt. Device state transition interrupts can be enabled or disabled independently in INTENB0. Devices whose states have changed can be checked in the PL1CTRL.DVSQ[3:0] flags.

When a transition is made to the default state, a device state transition interrupt is generated after a USB bus reset is detected.

The USBHS controls device states, and device state transition interrupts can be generated, only in device controller mode.



Note 1. For a transition, indicated by a solid line, the DVST bit is set to 1. For a resume, indicated by a dashed line, the RESM bit is set to 1.

Figure 29.8 Device state transitions

29.3.6.5 Control transfer stage transition interrupt (device controller mode)

Figure 29.9 shows a diagram of the control transfer stage transitions of the USBHS. The USBHS controls the control transfer sequence and generates control transfer stage transition interrupts. Control transfer stage transition interrupts can be enabled or disabled independently in INTENB0. Transfer stages that have transitioned can be checked in the INTSTS0.CTSQ[2:0] bits.

Control transfer stage transition interrupts are generated only in device controller mode. This section describes control transfer sequence errors. When an error occurs, the DCPCTR.PID[1:0] bits are set to 1xb (STALL response).

- Control read transfer errors
  - An OUT token or PING token is received but no data is transferred in response to the IN token at the data stage
  - An IN token is received at the status stage

  - A data packet with DATAPID = DATA0 is received at the status stage

- Control write transfer errors
  - An IN token is received but no ACK returned in response to the OUT token in the data stage
  - A data packet with DATAPID = DATA0 is received as the first data packet at the data stage
  - An OUT token or PING token is received in the status stage
- Control write no data transfer errors
  - An OUT token or PING token is received at the status stage

At the control write transfer data stage, if the receive data length exceeds the wLength value of the USB request, it is not recognized as a control transfer sequence error. At the control read transfer status stage, packets other than zero-length packets are received by an ACK response and the transfer ends normally.

When a CTRT interrupt occurs in response to a sequence error (INTSTS0.CTRT flag = 1), the CTSQ[2:0] = 110b value is saved until CTRT flag clears to 0, clearing the interrupt status. While CTSQ[2:0] bits = 110b is being saved, no CTRT interrupt for ending the setup stage is generated, even if a new USB request is received. The USBHS saves the setup stage completion status, and it generates a CTRT interrupt after the interrupt status is cleared by software.

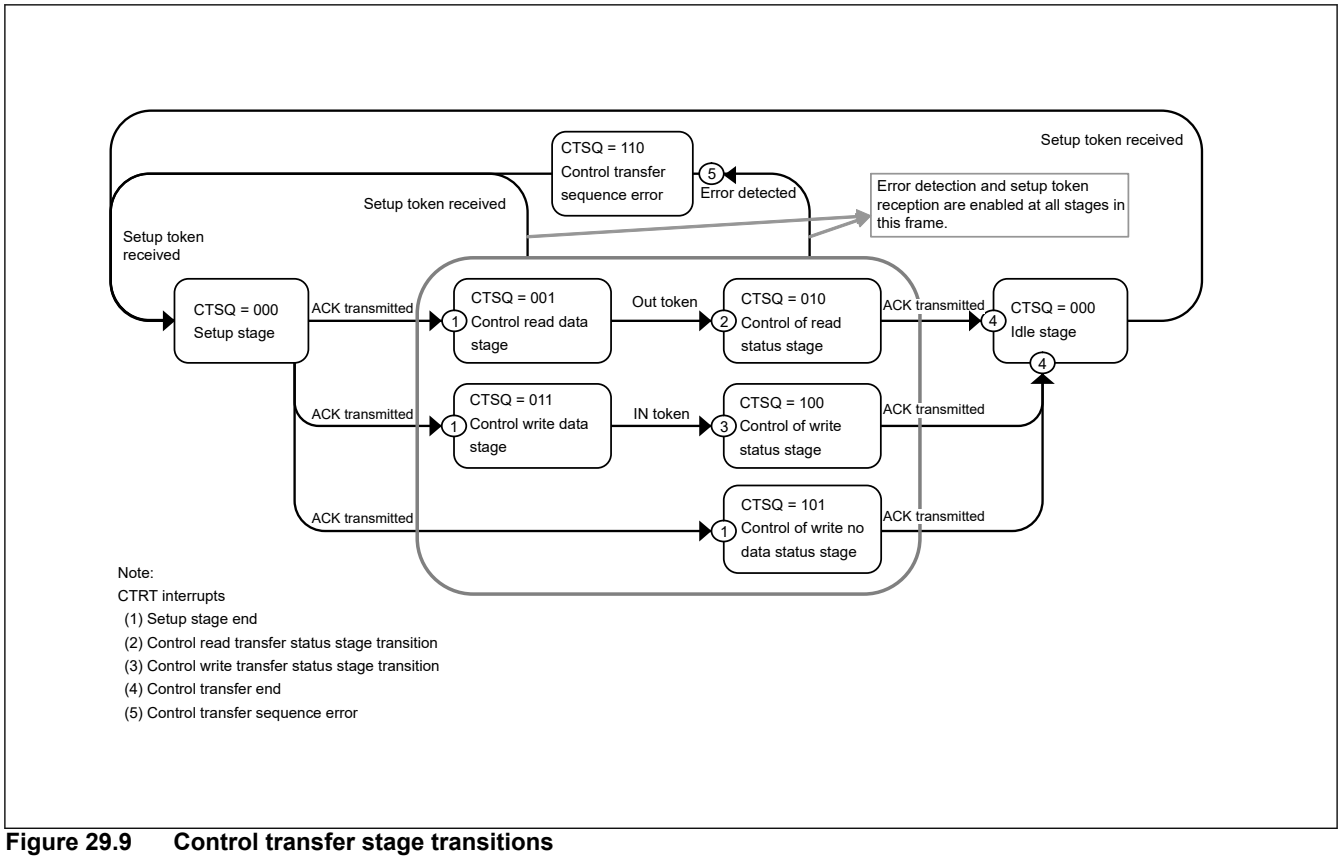


Figure 29.9 Control transfer stage transitions

29.3.6.6 Frame update interrupt

In host controller mode, an interrupt is generated when the frame number is updated.

In device controller mode, an SOFR interrupt is generated when the frame number is updated. The USBHS updates the frame number and generates an SOFR interrupt if it detects a new SOF packet during full-speed operation.

29.3.6.7 VBUS interrupt

When the USBHS_VBUS pin level changes, a VBUS interrupt is generated. The level of the USBHS_VBUS pin can be checked in the INTSTS0.VBSTS flag. Whether the host controller is connected or disconnected can be confirmed using the

VBUS interrupt. If the system is activated with the host controller connected, the first VBUS interrupt is not generated, because there is no change in the USBHS_VBUS pin level.

29.3.6.8 Resume interrupt

In device controller mode, a resume interrupt is generated when the device is in the Suspend state and the USB bus state has changed (from J-state to K-state, or from J-state to SE0). Recovery from the Suspend state is detected by means of the resume interrupt.

In host controller mode, no resume interrupt is generated. Use the BCHG interrupt to detect a change in the USB bus state.

29.3.6.9 OVRCR interrupt

An OVRCR interrupt is generated when the USBHS_OVRCURA or USBHS_OVRCURB pin level has changed. The levels of the USBHS_OVRCURA and USBHS_OVRCURB pins can be checked in the SYSSTS0.OVCMON[1:0] flags. The external power supply IC can check whether overcurrent is detected using the OVRCR interrupt.

For OTG connections, the OVRCR interrupt allows you to check whether a change is detected in the VBUS comparator.

29.3.6.10 BCHG interrupt

A BCHG interrupt is generated when the USB bus state has changed. The BCHG interrupt can be used to detect whether a peripheral device is connected. It can also be used to detect a remote wakeup in host controller mode. The BCHG interrupt is generated in both host and device controller modes.

29.3.6.11 DTCH interrupt

A DTCH interrupt occurs when a USB bus disconnect is detected in host controller mode. The USBHS detects bus disconnects in compliance with the USB 2.0 specification.

On interrupt detection, all pipes in which communications are being carried out for the relevant port must be terminated by software. The pipes enter the wait state for a bus connection to the port, waiting for an ATTCH interrupt to occur. Regardless of the value set in the associated interrupt enable bit, the USBHS hardware:

- Sets the DVSTCTR0.UACT bit for the port in which the DTCH interrupt is detected to 0
- Puts the port in which the DTCH interrupt occurred into the idle state

29.3.6.12 SACK interrupt

A SACK interrupt is generated when an ACK response for the transmitted setup packet is received from the peripheral device in host controller mode. The SACK interrupt can be used to confirm that the setup transaction is successfully complete.

29.3.6.13 SIGN interrupt

A SIGN interrupt is generated when an ACK response for the transmitted setup packet is not correctly received from the peripheral device three consecutive times in host controller mode. The SIGN interrupt can be used to detect no ACK response transmitted from the peripheral device or corruption of an ACK packet.

29.3.6.14 ATTCH interrupt

An ATTCH interrupt is generated when J-state or K-state of the full-speed signal level is detected on the USB port for 2.5 µs in host controller mode. To be more specific, an ATTCH interrupt is detected in any of the following conditions:

- When K-state, SE0, or SE1 changes to J-state, and J-state continues 2.5 µs
- When J-state, SE0, or SE1 changes to K-state, and K-state continues 2.5 µs

29.3.6.15 EOFERR interrupt

An EOFERR interrupt occurs when the USBHS detects that communication is not complete at the EOF2 timing defined in the USB 2.0 specification.

On interrupt detection, all pipes in which communications are being carried out for the relevant port must be terminated by software, and the port must be re-enumerated. Regardless of the value set in the associated interrupt enable bit, the USBHS hardware:

- Sets the DVSTCTR0.UACT bit for the port in which the EOFERR interrupt is detected to 0
- Puts the port in which the EOFERR interrupt is generated into the idle state

29.3.6.16 PDDETINT interrupt

The USBHS sets the INTSTS1.PDDETINT flag to 1 on detecting a level change (high to low or low to high) in the PDDET pin input value and generates the PDDETINT interrupt. When the PDDETINT interrupt is generated, use software to repeatedly read the BCCTRL.PDDETSTS flag until the same value is read three or more times, and perform debounce processing.

29.3.6.17 LPMEND interrupt

When the LPM transaction ends because a response from the peripheral device or a timeout is detected, the INTSTS1.LPMEND flag sets to 1 and the LPMEND interrupt is generated.

29.3.6.18 L1RSMEND interrupt

When performing resume processing when the USBHS has transitioned to the L1 state because an ACK is received in response to an LPM token, the USBHS sets the INTSTS1.L1RSMEND flag to 1 on completion of the resume processing.

29.3.7 Pipe Control

Table 29.22 lists the pipe settings for the USBHS. USB data transfer is performed through logical pipes that the software associates with endpoints. The USBHS provides 10 pipes for data transfer. Set up the pipes based on your system specifications.

Table 29.22 Pipe settings (1 of 2)

Register name	Bit name	Setting	Notes
DCPCFG PIPECFG	TYPE[1:0]	Transfer type	Pipes 1 to 9: Settable
	BFRE	BRDY interrupt mode	Pipes 1 to 5: Settable
	DBLB	Double buffer select	Pipes 1 to 5: Settable
	CNTMD	Selection of continuous transfer or discontinuous transfer	Pipes 1, 2: Settable only for bulk transfers Pipes 3 to 5: Settable
	DIR	Transfer direction select	IN or OUT settable
	EPNUM[3:0]	Endpoint number	Pipes 1 to 9: Settable Set this number to a value other than 0000 when one or more pipes are used.
	SHTNAK	Selects disabled state for pipe when transfer ends	Pipes 1, 2: Settable only for bulk transfers Pipes 3 to 5: Settable
PIPEBUF	BUFSIZE	FIFO buffer size	DCP: Setting disabled (fixed to 256 bytes) Pipes 1 to 5: Settable up to 2 KB Pipes 6 to 9: Setting disabled (fixed to 64 bytes)
	BUFNMB	FIFO buffer number	DCP: Setting disabled (fixed to 0x0-0x3 area) Pipes 1 to 5: Setting disabled (0x8-0x87 area specifiable) Pipes 6 to 9: Setting disabled (fixed to 0x4-0x7 area)
DCPMAXP PIPEMAXP	DEVSEL[3:0]	Device select	Viewable only in host controller mode
	MXPS	Maximum packet size	Setting compliant with USB specification

Table 29.22 Pipe settings (2 of 2)

Register name	Bit name	Setting	Notes
PIPEPERI	IFIS	Buffer flush	Pipes 1, 2: Settable only for isochronous transfers Pipes 3 to 5: Setting disabled Pipes 6 to 9: Setting disabled
	IITV[2:0]	Interval counter	Pipes 1, 2: Settable only for isochronous transfers Pipes 3 to 5: Setting disabled Pipes 6 to 9: Settable only in host controller mode
DCPCTR PIPEnCTR	BSTS	Buffer status	For the DCP, receive buffer status and transmit buffer status are switched with the ISEL bit
	INBUFM	IN buffer monitor	Available only for pipes 1 to 5
	SUREQ	Setup request	Settable only for the DCP and controlled in host controller mode
	SUREQCLR	SUREQ clear	Settable only for the DCP and controlled in host controller mode
	CSCLR	CSSTS clear	Controllable only in host controller mode
	CSSTS	Split status check	Viewable only in host controller mode
	ATREPM	Auto response mode	Pipes 1 to 5: Settable only in device controller mode
	ACLRM	Auto buffer clear	Pipes 1 to 9: Settable
	SQCLR	Sequence clear	Clears the data toggle bit
	SQSET	Sequence set	Sets the data toggle bit
	SQMON	Sequence check	Monitors the data toggle bit
	PBUSY	PIPE busy check	—
	PID[1:0]	Response PID	—
PIPEnTRE	TRENB	Transaction count enable	Pipes 1 to 5: Settable
	TRCLR	Current transaction counter clear	Pipes 1 to 5: Settable
PIPEnTRN	TRNCNT	Transaction counter	Pipes 1 to 5: Settable

29.3.7.1 Pipe control register switching procedures

The following bits in the pipe control registers can be changed only when USB communication is prohibited (PID[1:0] bits are 00b (NAK response)). Figure 29.10 shows pipe control register switching procedures when USB communication is enabled (PID[1:0] bits are 00b (BUF response)).

Do not change the following registers and bits when USB communication is enabled (PID[1:0] bits are 01b (BUFresponse)):

- Bits in DCPCFG and DCPMAXP
- SQCLR and SQSET bits in DCPCTR
- Bits in PIPECFG, PIPEBUF, PIPEMAXP, and PIPEPERI
- ATREPM, ACLRM, SQCLR, and SQSET bits in PIPEnCTR
- Bits in PIPEnTRE and PIPEnTRN
- Bits in DEVADDn (n = 0 to A)

To set the CSCLR bits and bits in DEVADDn (n = 0 to A), follow the procedures described in section 29.2. Register Descriptions.

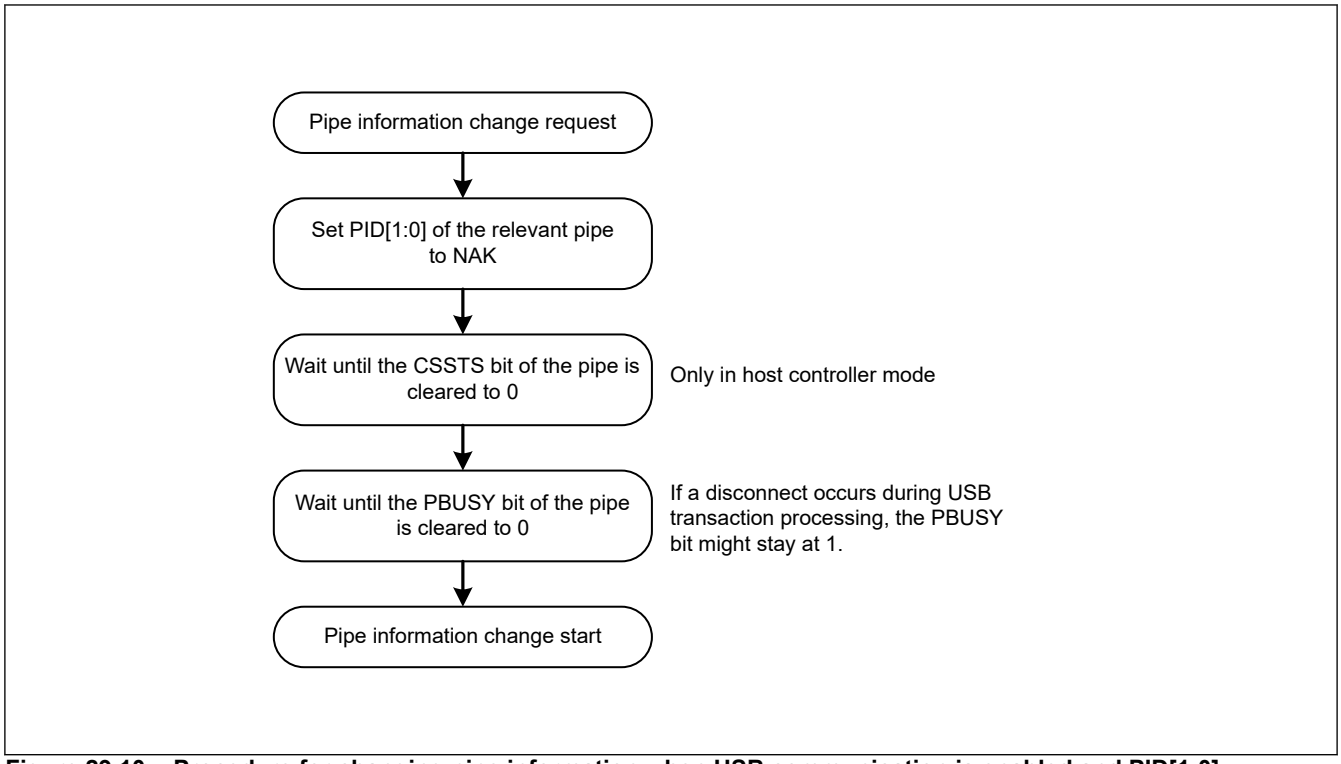

Figure 29.10 Procedure for changing pipe information when USB communication is enabled and PID[1:0] bits are 01b (BUF response)

The following bits in the pipe control registers can be changed only when the selected pipe information is not set in the CURPIPE[3:0] bits in CFIFOSEL, D0FIFOSEL, and D1FIFOSEL.

Do not set the following registers while the CURPIPE[3:0] bits are set:

- Bits in DCPCFG and DCPMAXP
- Bits in PIPECFG, PIPEBUF, PIPEMAXP, and PIPEPERI
- PIPEnCTR and ACLRM bits

To change pipe information, you must set the CURPIPE[3:0] bits to a pipe other than the one to be changed. For the DCP, the buffer must be cleared using the BCLR bit after the pipe information is changed.

29.3.7.2 Transfer types

The PIPECFG.TYPE[1:0] bits specify the following transfer types for each pipe:

- DCP: No setting necessary (fixed at control transfer)
- Pipes 1 and 2: Set to bulk transfer or isochronous transfer
- Pipes 3 to 5: Set to bulk transfer
- Pipes 6 to 9: Set to interrupt transfer

29.3.7.3 Endpoint number

The PIPECFG.EPNUM[3:0] bits are used to set the endpoint number for each pipe. The DCP is fixed at endpoint 0. The other pipes can be set from endpoint 1 to 15.

- DCP: No setting is necessary (fixed at endpoint 0)
- Pipes 1 to 9: Select and set the endpoint numbers from 1 to 15 so that the combination of the PIPECFG.DIR and EPNUM[3:0] bits is unique

29.3.7.4 Maximum packet size setting

Specify the maximum packet size for each pipe in the MXPS bits in DCPMAXP and PIPEMAXP. The DCP and pipes 1 to 5 can be set to any of the maximum pipe sizes defined in the USB 2.0 specification. For pipes 6 to 9, the maximum packet

size is 64 bytes. Set the maximum packet size as follows before starting a transfer (PID[1:0] bits are set to 01b (BUF response)):

- DCP: Set to 64 for high-speed operation
- DCP: Set to 8, 16, 32, or 64 for full-speed operation
- Pipes 1 to 5: Set to 512 for high-speed bulk transfers
- Pipes 1 to 5: Set to 8, 16, 32, or 64 for full-speed bulk transfers
- Pipes 1, 2: Set between 1 and 1024 for high-speed isochronous transfers
- Pipes 1, 2: Set between 1 and 1023 for full-speed isochronous transfers
- Pipes 6 to 9: Set between 1 and 64

High-bandwidth interrupt transfers and isochronous transfers are not supported.

29.3.7.5 Transaction counter for pipes 1 to 5 in the receiving direction

When the specified number of transactions is complete in the data packet receiving direction, the USBHS recognizes that the transfer has ended. Two transaction counters are provided. One is the PIPEnTRN register, which specifies the number of transactions to be executed, and the other is the current counter, which internally counts the number of executed transactions. If the PIPECFG.SHTNAK bit is set to 1, when the current counter value matches the specified number of transactions, the associated PIPEnCTR.PID[1:0] bits are set to 00b (NAK response) and the subsequent transfer is disabled. The transactions can be counted again from the beginning by initializing the current counter of the transaction counter function through the PIPEnTRE.TRCLR bit. The data read from PIPEnTRN differs depending on the PIPEnTRE.TRENB setting as follows:

- The TRENB bit = 0: Specified transaction counter value can be read
- The TRENB bit = 1: Current counter value indicating the internally counted number of executed transactions can be read.

The following constraints apply when working with the TRCLR bit:

- If the transactions are being counted and the PIPEnCTR.PID[1:0] bits are set to 01b (BUF response), the current counter cannot be cleared
- If there is any data left in the buffer, the current counter cannot be cleared

29.3.7.6 Response PID

Specify the response PID for each pipe in the PID[1:0] bits in DCPCTR and PIPEnCTR. This section describes the USBHS operation with different response PID settings.

Software response PID settings in host controller mode

Select the response PID to specify the execution of transactions as follows:

- NAK setting: Using pipes is disabled and no transactions are executed
- BUF setting: Transactions are executed based on the FIFO buffer state:
  OUT direction: An OUT token is issued if the FIFO buffer contains transmit data.
  IN direction: An IN token is issued if the FIFO buffer is not full and can receive data.
- STALL setting: Using pipes is disabled and no transactions are executed

Note: Use the SUREQ bit to execute setup transactions for the DCP.

Software response PID settings in device controller mode

Select the response PID to respond as follows to transactions from the host:

- NAK setting: A NAK response is returned to all generated transactions
- BUF setting: A response is returned to transactions based on the FIFO buffer
- STALL setting: A STALL response is returned to all generated transactions

Note: For setup transactions, an ACK response is always returned, regardless of the PID[1:0] bits setting, and the USB request is stored in the register.

Hardware response PID settings in host controller mode and Hardware response PID settings in device controller mode describe situations in which the USBHS writes to the PID[1:0] bits because of specific transaction results.

Hardware response PID settings in host controller mode

- NAK setting: The PID[1:0] bits are set to 00b (NAK response) in the following cases, and issuing of tokens is automatically stopped:
  - When a non-isochronous transfer is performed and an NRDY interrupt is generated. For details, see section 29.3.6.2. NRDY interrupt
  - If a short packet is received when the PIPECFG.SHTNAK bit is set to 1 for bulk transfers
  - If transaction counting ends when the SHTNAK bit is set to 1 for bulk transfers
- BUF setting: The USBHS does not write this setting
- STALL setting: The PID[1:0] bits are set to STALL in the following cases, and issuing of tokens is automatically stopped:
  - When STALL is received in response to a transmitted token
  - When a received data packet exceeds the maximum packet size

Hardware response PID settings in device controller mode

- NAK setting: The PID[1:0] bits are set to 00b (NAK response) in the following cases, and a NAK response is returned to transactions:
  - When the setup token is received normally (DCP only)
  - If transaction counting ends or a short packet is received when the PIPECFG.SHTNAK bit is set to 1 for bulk transfers
- BUF setting: The USBHS does not write this setting
- STALL setting: The PID[1:0] bits are set to STALL in the following cases, and a STALL response is returned to transactions:
  - When a received data packet exceeds the maximum packet size
  - When a control transfer sequence error is detected

29.3.7.7 Data PID sequence bit

The USBHS automatically toggles the sequence bit in the data PID when data is transferred successfully in the control transfer data stage, bulk transfer, and interrupt transfer. The sequence bit of the next data PID to be transmitted can be confirmed with the SQMON bit in DCPCTR and PIPEnCTR. When data is transmitted, the sequence bit toggles on ACK handshake reception. When data is received, the sequence bit toggles on ACK handshake transmission. The SQCLR bit in DCPCTR and the SQSET bit in PIPEnCTR can be used to change the data PID sequence bit.

In device controller mode when control transfers are used, the USBHS automatically sets the sequence bit for stage transitions. DATA1 is returned when the setup stage ends. The sequence bit is not referenced and PID = DATA1 is returned in the status stage. Therefore, no software settings are required. However, in host controller mode when control transfers are used, the sequence bit must be set by software for the stage transitions.

For ClearFeature requests for transmission or reception, the data PID sequence bit must be set by software in both host and device controller modes.

29.3.7.8 Response PID = NAK function

The USBHS provides a function for disabling pipe operation (PID[1:0] bits are set to 00b (NAK response)) when the final data packet of a transaction is received. The USBHS automatically distinguishes this based on reception of a short packet or the transaction counter. Enable this function by setting the PIPECFG.SHTNAK bit to 1.

When the double buffer mode is being used for the FIFO buffer, using this function enables reception of data packets in transfer units. If pipe operation is disabled, software must enable the pipe again (PID[1:0] bits are set to 01b (BUF response)).

The response PID = NAK function can be used only for bulk transfers.

29.3.7.9 Auto response mode

For bulk transfer pipes (1 to 5), when the PIPEnCTR.ATREPM bit is set to 1, a transition is made to auto response mode.

During an OUT transfer (PIPECFG.DIR = 0), OUT-NAK mode is invoked, and during an IN transfer (DIR = 1), null auto response mode is invoked.

29.3.7.10 OUT-NAK mode

For bulk OUT transfer pipes, NAK is returned in response to an OUT token, and an NRDY interrupt is output when the PIPEnCTR.ATREPM bit is set to 1. To transition from normal mode to OUT-NAK mode, specify OUT-NAK mode while pipe operation is disabled (PID[1:0] = 00b for NAK response). Next, enable pipe operation (PID[1:0] = 01b for BUF response), on which OUT-NAK mode becomes valid. If an OUT token is received immediately before pipe operation is disabled, the token data is normally received, and an ACK is returned to the host.

To transition from OUT-NAK mode to normal mode, cancel OUT-NAK mode while pipe operation is disabled (NAK).

Next enable pipe operation (BUF). In normal mode, reception of OUT data is enabled.

29.3.7.11 Null auto response mode

For bulk IN transfer pipes, zero-length packets are continuously transmitted when the PIPEnCTR.ATREPM bit is set to 1.

To transition from normal mode to null auto response mode, specify null auto response mode while pipe operation is disabled (PID[1:0] bits are set to 00b (NAK response)). Next, enable pipe operation (PID[1:0] bits are set to 01b (BUF response)), on which null auto response mode becomes valid. Before setting null auto response mode, check that PIPEnCTR.INBUFM = 0, because the mode can be set only when the buffer is empty. If the INBUFM bit is 1, empty the buffer using the PIPEnCTR.ACLRM bit. Do not write data from the FIFO port while a transition to null auto response mode is being made.

To transition from null auto response mode to normal mode, keep pipe operation disabled (PID[1:0] bits are set to 00b (NAK response)) for the period of the zero-length packet transmission (about 10 µs) before canceling the null auto response mode. In normal mode, data can be written from the FIFO port, so packet transmission to the host is enabled by enabling pipe operation (PID[1:0] bits are set to 01b (BUF response)).

29.3.8 FIFO Buffer

The USBHS provides a FIFO buffer for data transfers, and it manages the memory area used for each pipe. The FIFO buffer has two states depending on whether the access right is assigned to the system (CPU side) or the USBHS (SIE side).

29.3.8.1 Buffer status

Table 29.23 and Table 29.24 show the buffer status in the USBHS. The FIFO buffer status can be confirmed using the DCPCTR.BSTS and PIPEnCTR.INBUFM bits. The transfer direction for the FIFO buffer can be specified in the PIPECFG.DIR or CFIFOSEL.ISEL bit (when DCP is selected).

The INBUFM bit is valid for pipes 1 to 5 in the transmitting direction.

When a transmitting pipe uses double buffering, the software can read the BSTS bit to monitor the FIFO buffer status on the CPU side and the INBUFM bit to monitor the FIFO buffer status on the SIE side. When write access to the FIFO port by the CPU or DMA/DTC is slow and the buffer empty status cannot be determined using the BEMP interrupt, the software can use the INBUFM bit to confirm the end of transmission.

Table 29.23 Buffer status indicated in the BSTS flag (1 of 2)

ISEL or DIR	BSTS	FIFO buffer status
0 (receiving direction)	0	There is no received data, or data is being received. Reading from the FIFO port is disabled.

Table 29.23 Buffer status indicated in the BSTS flag (2 of 2)

ISEL or DIR	BSTS	FIFO buffer status
0 (receiving direction)	1	There is received data, or a zero-length packet is received. Reading from the FIFO port is allowed. When a zero-length packet is received, reading is not possible and the buffer must be cleared.
1 (transmitting direction)	0	Transmission is not complete. Writing to the FIFO port is disabled.
1 (transmitting direction)	1	Transmission is complete. CPU write is allowed.

Table 29.24 Buffer status indicated in the INBUFM bit

DIR	INBUFM	FIFO buffer status
0 (receiving direction)	Invalid	Invalid
1 (transmitting direction)	0	Transmission is complete. There is no data waiting to be transmitted.
1 (transmitting direction)	1	The FIFO port has written data to the buffer. There is data to be transmitted.

29.3.8.2 FIFO buffer clearing

Table 29.25 shows the methods for clearing the FIFO buffer. The FIFO buffer can be cleared using the BCLR bit in the port control register, DnFIFOSEL.DCLRM, or the PIPEnCTR.ACLRM bit.

Single or double buffering can be selected for pipes 1 to 5 in the PIPECFG.DBLB bit.

Table 29.25 Buffer clearing methods

FIFO buffer clearing mode	Clearing the FIFO buffer on the CPU side	Mode for automatically clearing the FIFO buffer after reading the specified pipe data	Auto buffer clear mode for discarding all received packets
Register used	• CFIFOCTR • DnFIFOCTR	DnFIFOSEL	PIPEnCTR
Bit used	BCLR	DCLRM	ACLRM
Clearing condition	Cleared by writing 1	1: Mode valid 0: Mode invalid	1: Mode valid 0: Mode invalid

Auto buffer clear mode function

The USBHS discards all received data packets if the PIPEnCTR.ACLRM bit is set to 1. If a correct data packet is received, the ACK response is returned to the host controller. The auto buffer clear mode function can only be set in the FIFO buffer reading direction.

Setting the ACLRM bit to 1 and then to 0 clears the FIFO buffer of the selected pipe regardless of the access direction. An access cycle of at least 100 ns is required for the internal hardware sequence processing between ACLRM = 1 and ACLRM = 0.

29.3.8.3 FIFO port functions

Table 29.26 shows the settings for the FIFO port functions. In write access, writing data until the maximum packet size is reached automatically enables transmission of the data. To enable transmission before the maximum packet size is reached, set the BVAL flag in the port control register to end writing. To send a zero-length packet, use the BCLR bit to clear the buffer, and then set the BVAL flag to end writing.

In reading, reception of new packets is automatically enabled when all data is read. Data cannot be read when a zerolength packet is received (DTLN[11:0] = 0), so the buffer must be cleared with the BCLR bit. The length of the receive data can be confirmed in the DTLN[11:0] flags in the port control register.

Table 29.26 FIFO port function settings

Register name	Bit name	Description
CFIFOSEL, DnFIFOSEL (n = 0, 1)	RCNT	Selects DTLN[11:0] read mode
	REW	FIFO buffer rewind (re-read, rewrite)
	DCLRM	Automatically clears receive data for a specified pipe after the data is read (only for DnFIFO)
	DREQE	Enables DMA/DTC transfers (only for DnFIFO)
	MBW[1:0]	FIFO port access bit width
	BIGEND	Selects FIFO port endian
	ISEL	FIFO port access direction (only for DCP)
	CURPIPE[3:0]	Selects the current pipe
CFIFOCTR, DnFIFOCTR (n = 0, 1)	BVAL	Ends writing to the FIFO buffer
	BCLR	Clears the FIFO buffer on the CPU side
	DTLN[11:0]	Checks the length of receive data

FIFO port selection

Table 29.27 shows the pipes that can be selected with the different FIFO ports. The pipe to be accessed must be selected in the CURPIPE[3:0] bits in the port selection register. After a pipe is selected, the software must check whether the written value can be correctly read from the CURPIPE[3:0] bits. (If the previous pipe number is read, it indicates that the USBHS is modifying the pipe.) Next, the software checks that the FRDY flag in the port control register is 1.

In addition, the software must specify the bus width to be accessed in the MBW[1:0] bits in the port selection register.

The FIFO buffer access direction conforms to the PIPECFG.DIR setting. For the DCP only, the ISEL bit in the port selection register determines the direction.

Table 29.27 FIFO port access by pipe

Pipe	Access Method	Port that can be used
DCP	CPU access	CFIFO port register
Pipes 1 to 9	CPU access	CFIFO port register D0FIFO/D1FIFO port register
	DMA/DTC access	D0FIFO/D1FIFO port register

REW bit

It is possible to temporarily stop access to a pipe being accessed, access a different pipe, and then continue processing for the first pipe again. The REW bit in the port selection register is used for this processing.

If a pipe is selected in the CURPIPE[3:0] bits in the port selection register with the REW bit set to 1, the pointer used for reading from and writing to the FIFO buffer is reset, and reading or writing can be carried out from the first byte. If a pipe is selected with the REW bit set to 0, data can be read and written in continuation from the previous selection, without the pointer being reset.

To access the FIFO port, the software must check that the FRDY bit in the port control register is 1 after selecting a pipe.

29.3.8.4 DMA/DTC transfers (D0FIFO and D1FIFO ports)

Overview of DMA/DTC transfer

For pipes 1 to 9, the FIFO port can be accessed using the DMAC/DTC. When buffer access for the pipe targeted for DMA/DTC transfer is enabled, a DMA/DTC transfer request is issued.

Select the unit of transfer to the FIFO port in the DnFIFOSEL.MBW[1:0] bits, and select the pipe targeted for the DMA/DTC transfer in the DnFIFOSEL.CURPIPE[3:0] bits. Do not change the selected pipe during the DMA transfer.

DnFIFO auto clear mode (D0FIFO and D1FIFO port reading direction)

If 1 is set in the DnFIFOSEL.DCLRM bit, the USBHS automatically clears the FIFO buffer of the selected pipe when reading of data from the FIFO buffer is complete.

Table 29.28 shows the packet reception and FIFO buffer clearing processing by software for each of the different settings. As shown in the table, the buffer clearing conditions depend on the value set in the PIPECFG.BFRE bit. Using the DnFIFOSEL.DCLRM bit eliminates the need for the buffer to be cleared by software in any situation that requires buffer clearing. This enables DMA/DTC transfers without involving software.

The DnFIFO auto clear mode can only be set in the FIFO buffer reading direction.

Table 29.28 Packet reception and FIFO buffer clearing processing by software

	Register setting			
	DCLRM = 0		DCLRM = 1	
Buffer status when packet is received	BFRE = 0	BFRE = 1	BFRE = 0	BFRE = 1
Buffer full	No clearing required	No clearing required	No clearing required	No clearing required
Zero-length packet reception	Clearing required	Clearing required	No clearing required	No clearing required
Normal short packet reception	No clearing required	Clearing required	No clearing required	No clearing required
Transaction count end	No clearing required	Clearing required	No clearing required	No clearing required

29.3.8.5 Allocating the FIFO buffer

Figure 29.11 shows an example of a memory map of the FIFO buffer. The FIFO buffer is an area shared by the USBHS and the control CPU of the application. There are two situations for the FIFO buffer: (1) access rights are given to the application (CPU side), and (2) access rights are given to the USBHS (SIE side).

An independent area is set for the FIFO buffer for each pipe. A memory area is determined by the first block number and the number of blocks (specified in the BUFNMB[7:0] and BUFSIZE[4:0] bits in PIPEBUF), where 64 bytes is regarded as one block. When the continuous transfer mode is selected in the CNTMD bit in PIPECFG, set the BUFSIZE[4:0] bits to an integral multiple of the maximum packet size. When double buffering is selected in the DBLB bit in PIPECFG, twice the memory area specified in the BUFSIZE[4:0] bits in PIPEBUF is allocated to the same pipe.

Three FIFO ports are used to access (read data from and write data to) the FIFO buffer. Specify the number of the pipe to be allocated to the FIFO port in the CURPIPE[3:0] bits in C/DnFIFOSEL.

The FIFO buffer status of each pipe can be checked in the DCPCTR.BSTS, PIPEnCTR, and INBUFM bits. The FIFO port access rights can be checked in the FRDY flag in C/DnFIFOCTR.

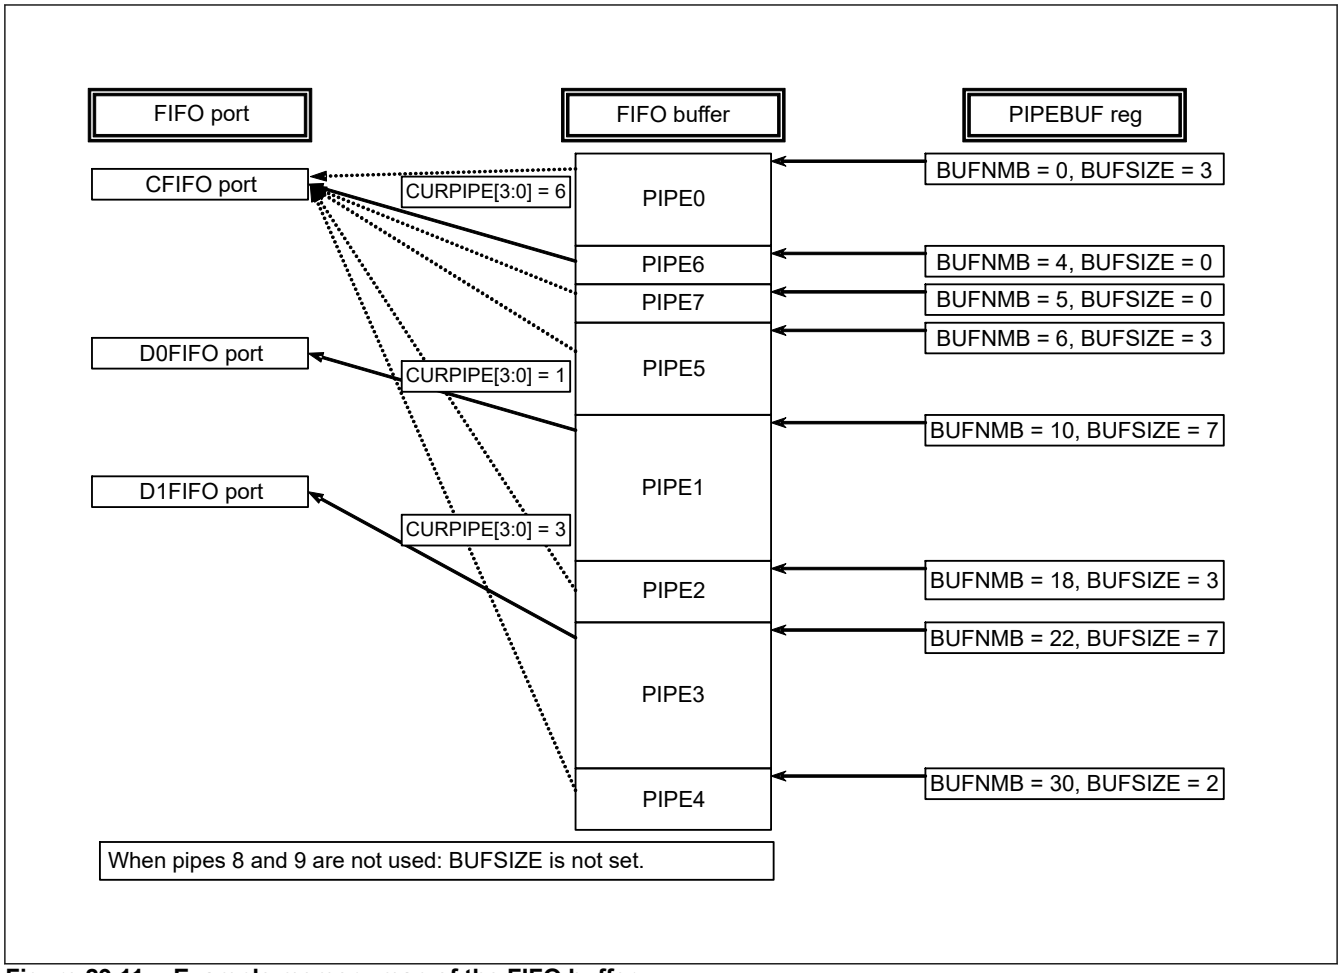

Figure 29.11 Example memory map of the FIFO buffer

29.3.9 Control Transfers Using the DCP

The Default Control Pipe (DCP) is used for data transfers in the control transfer data stage. The FIFO buffer of the DCP is a 64-byte single buffer with a fixed area for both control reads and control writes. The FIFO buffer can be accessed only through the CFIFO port.

29.3.9.1 Control transfers in host controller mode

Setup stage

The USBREQ, USBVAL, USBINDX, and USBLENG registers are used to transmit USB requests for setup transactions. Writing the setup packet data to the register and then writing 1 to the DCPCTR.SUREQ bit transmits the specified data for the setup transaction. On completion of the transaction, the SUREQ bit clears to 0. Do not change these USB request registers while SUREQ = 1.

When an attached function device is detected, the software must issue the first setup transaction for the device using this sequence with the DCPMAXP.DEVSEL[3:0] bits cleared to 0 and the DEVADD0.USBSPD[1:0] bits set appropriately.

When an attached function device is shifted to the Address state, the software must issue setup transactions using this sequence with the assigned USBAddress set in the DEVSEL[3:0] bits and the bits in DEVADDn (n = 0 to A) corresponding to the specified USBAddress set appropriately. For example, when PIPEMAXP.DEVSEL[3:0] = 0010b, make appropriate settings in DEVADD2. When PIPEMAXP.DEVSEL[3:0] = 0101b, make appropriate settings in DEVADD5.

When the setup transaction data is sent, an interrupt request is generated based on the response from the peripheral device (SIGN or SACK bit in INTSTS1). This interrupt request allows the software to check the setup transaction result.

The DATA0 data packet (USB request) for the setup transaction is always transmitted regardless of the status of the DCPCTR.SQMON flag.

Data stage

The data stage is used to transfer data using the DCP FIFO buffer.

Before accessing the DCP FIFO buffer, specify the access direction in the CFIFOSEL.ISEL bit. Specify the transfer direction in the DCPCFG.DIR bit.

For the first data packet of the data stage, the data PID must be transferred as DATA1. Set data PID to DATA1 in the DCPCTR.SQSET bit and set the PID[1:0] bits to 01b (BUF response). Completion of data transfer is detected using the BRDY or BEMP interrupt.

Data transfer of multiple packets is enabled in continuous transfer mode. However, when continuous transfer is specified in the receiving direction, the BRDY interrupt is not generated unless the buffer becomes full or a short packet is received (for 256 bytes or less, which is an integral multiple of the maximum packet size). If the transmit data size is an integral multiple of the maximum packet size, control the control write transfer through the software to transmit a zerolength packet last.

Status stage

The status stage is used for zero-length packet data transfers in the reverse direction of the data stage. As in the data stage, data is transfered using the DCP FIFO buffer. Transactions are executed using the same procedure as the data stage.

Data packets in the status stage must be transmitted and received with the data PID set to DATA1 using the DCPCTR.SQSET bit.

When a zero-length packet is received, check the receive-data length in the CFIFOCTR.DTLN[11:0] flags after a BRDY interrupt is generated, and then clear the FIFO buffer using the BCLR bit.

29.3.9.2 Control transfers in device controller mode

Setup stage

The USBHS returns an ACK response to a normal setup packet for the USBHS. The USBHS operates in the setup stage as follows:

On receiving a new setup packet, the USBHS sets the following bits:

- Sets the INTSTS0.VALID flag to 1
- Sets the DCPCTR.PID[1:0] bits to 00b (NAK response)
- Sets the DCPCTR.CCPL bit to 0

When the USBHS receives a data packet following a setup packet, it stores the USB request parameters in USBREQ, USBVAL, USBINDX, and USBLENG.

Before performing the response processing for a control transfer, set the VALID flag to 0. When the VALID flag = 1, the PID[1:0] bits cannot be set to 01b (BUF response), and the data stage cannot be terminated.

Using the VALID flag function, the USBHS can suspend a request being processed when it receives a new USB request during a control transfer and return a response to the latest request.

In addition, the USBHS automatically detects the direction bit (bmRequestType bit 8) and the request data length (wLength) in the received USB request. It distinguishes between control read transfers, control write transfers, and nodata control transfers, and it controls stage transitions. For an incorrect sequence, a sequence error occurs in the control transfer stage transition interrupt, and the interrupt is reported to the software. For a diagram of the stage control by the USBHS, see Figure 29.9.

Data stage

The DCP must be used to execute data transfers for received USB requests. Before accessing the DCP FIFO buffer, specify the access direction in the CFIFOSEL.ISEL bit.

If the transfer data is larger than the size of the DCP FIFO buffer, execute the data transfer using the BRDY interrupt for control write transfers and the BEMP interrupt for control read transfers.

In high-speed control write transfers, a NYET handshake response is returned based on the FIFO buffer status.

Status stage

Control transfers are terminated by setting the DCPCTR.CCPL bit to 1 while the DCPCTR.PID[1:0] bits are set to 01b (BUF response).Control transfers are terminated by setting the DCPCTR.CCPL bit to 1 while the DCPCTR.PID[1:0] bits are set to 01b (BUF response).

After this setting is made, the USBHS automatically executes the status stage based on the data transfer direction determined at the setup stage. The status stage is executed as follows:

- For control read transfers:
  The USBHS receives a zero-length packet from the USB host and transmits an ACK response
- For control write transfer and no data control transfer:
  The USBHS transmits a zero-length packet and receives an ACK response from the USB host.

Control transfer auto response function

The USBHS automatically responds to a normal SET_ADDRESS request. If the SET_ADDRESS request contains any of the following errors, a response must be returned by software.

- When bmRequestType is not 0x00: except control write transfer
- When wIndex is not 0x00: request error
- When wLength is not 0x00: except no data control transfer
- When wValue is larger than 0x7F: request error
- When PL1CTRL.DVSQ[3:0] flags are 0011b (Configured): control transfer of device state error

A response by the corresponding software is required to all requests other than SET_ADDRESS.

29.3.10 Bulk Transfers (Pipes 1 to 5)

The FIFO buffer usage (setting of single buffer/double buffer or continuous/discontinuous transfer mode) is configurable for bulk transfers. The FIFO buffer size can be set up to 2 KB. The USBHS manages the FIFO buffer state and automatically responds to the PING packet and the NYET handshake.

29.3.10.1 PING packet control in host controller mode

In the OUT direction, a PING packet is automatically transmitted by the USBHS. The USBHS starts communication in the transmitting direction beginning with the PING packet. When it receives an ACK handshake in response to the PING packet, the USBHS transmits an OUT packet. The USBHS returns to the PING transmission state on receiving a NAK or NYET response during an OUT transaction. The procedure is as follows:

Starting OUT data transmission

(1) Transmit PING packet
(2) Receive NAK handshake
(3) Transmit PING packet
(4) Receive ACK handshake
(5) Transmit OUT data packet
(6) Receive ACK handshake
(7) Transmit OUT data packet
⋮
(8) Return to (1) on receiving a NAK/NYET handshake

The USBHS returns to the PING packet transmission state when a hardware reset is issued, the NYET or NAK handshake is received, the sequence toggle bit is cleared (SQCLR), or the buffer clear bit (ACLRM) is set.

29.3.10.2 NYET handshake control in device controller mode

Table 29.29 lists responses to received tokens during bulk and control transfers. The USBHS returns a NYET response when an available area for only one packet is left in the FIFO buffer when the USBHS has received an OUT token during a bulk or control transfer. When the USBHS receives a short packet, however, it returns an ACK response instead of NYET even when this condition occurs.

Table 29.29 Responses to received tokens

PID[1:0] bit setting	FIFO buffer state	Received token	Response	Note
NAK/STALL	—	SETUP	ACK	—
	—	IN/OUT/PING	NAK/STALL	—
BUF	—	SETUP	ACK	—
	RCV-BRDY	OUT/PING	ACK	When OUT token is received, data packet is received.*1
	RCV-BRDY	OUT	NYET	Data packet is received*2
	RCV-BRDY	OUT (Short)	ACK	Data packet is received*2
	RCV-BRDY	PING	ACK	*2
	RCV-NRDY	OUT/PING	NAK	—
	TRN-BRDY	IN	DATA0/1	Data packet is transmitted
	TRN-NRDY	IN	NAK	—

Note 1. RCV-BRDY: An available area for two packets is left in the FIFO buffer when an OUT token or a PING token is received.
Note 2. RCV-BRDY: An available area for only one packet is left in the FIFO buffer when an OUT token is received.
RCV-NRDY: No available area is left in the FIFO buffer when a PING token is received.
TRN-BRDY: The FIFO buffer contains transmit data when an IN token is received.
TRN-NRDY: The FIFO buffer contains no transmit data when an IN token is received.

29.3.11 Interrupt Transfers (Pipes 6 to 9)

In device controller mode, the USBHS performs interrupt transfers based on the timing dictated by the host controller. In the interrupt transfer, the USBHS ignores PING packets (no response) and does not transmit the NYET handshake, but returns an ACK, NAK, or STALL response.

In host controller mode, the software can set the timing for issuing tokens using the interval counter. The USBHS does not issue a PING token but issues an OUT token, including for transfers in the OUT direction.

The USBHS does not support high-bandwidth interrupt transfers.

29.3.11.1 Interval counter for interrupt transfers in host controller mode

Specify the transaction interval for interrupt transfers in the PIPEPERI.IITV[2:0] bits. The USBHS issues interrupt transfer tokens based on this interval.

(1) Initializing the counter

The USBHS initializes the interval counter under the following conditions:

- Power-on reset:
  This initializes the IITV[2:0] bits
- FIFO buffer initialization using the PIPEnCTR.ACLRM bit:
  This does not initialize the IITV[2:0] bits, but does initialize the count value. Setting the PIPEnCTR.ACLRM bit to 0 starts counting from the value set in IITV[2:0].

(2) Operation when tokens cannot be transmitted or received even on token generation

No token is generated in the following cases even at token generation time. In these cases, the USBHS tries to execute the transaction in the next interval.

- When the PID[1:0] bits are set to NAK or STALL
- When the FIFO buffer is full at token transmit time in the receiving (IN) direction
- When there is no data to be transmitted in the FIFO buffer at token transmit time in the transmitting (OUT) direction

29.3.12 Isochronous Transfers (Pipes 1 and 2)

The USBHS does not support high-bandwidth isochronous transfers but provides the following functions for isochronous transfers:

- Notification of isochronous transfer error

- Interval counter (specified in the PIPEPERI.IITV[2:0] bits)
- Isochronous IN transfer data setup control (IDLY function)
- Isochronous IN transfer buffer flush function (specified in the PIPEPERI.IFIS bit)
- SOF pulse output function

29.3.12.1 Error detection in isochronous transfers

The USBHS provides a function for detecting the errors described in this section, so that when errors occur in isochronous transfers, they can be controlled by software. Table 29.30 and Table 29.31 show the priority order for errors detected by the USBHS and the associated interrupts.

PID errors

- The PID value of the received packet is invalid

CRC errors and bit stuffing errors

- A CRC error is found in a received packet or the bit stuffing is illegal

Maximum packet size exceeded

- The data size of the received packet exceeds the specified maximum packet size

Overrun and underrun errors

In host controller mode:

- The FIFO buffer is full at token transmit time in the IN (receiving) direction
- There is no data to be sent in the FIFO buffer at token transmit time in the OUT (transmitting) direction

In device controller mode:

- There is no data to be sent in the FIFO buffer at token receive time in the IN (transmitting) direction
- The FIFO buffer is full at token receive time in the OUT (receiving) direction

Interval error

In device controller mode, the following cases are treated as an interval error:

- Failure to receive an IN token in the interval frame during an isochronous IN transfer
- Failure to receive an OUT token in the interval frame during an isochronous OUT transfer

Table 29.30 Error detection for token transmission and reception

Detection priority	Error type	Interrupt generated at error detection and status
1	PID error	No interrupts are generated in either host or device controller mode. (Ignored as a corrupted packet.)
2	CRC or bit stuffing error	No interrupts are generated in either host or device controller mode. (Ignored as a corrupted packet.)
3	Overrun or underrun error	An NRDY interrupt is generated to set the OVRN flag to 1 in both host and device controller modes. In device controller mode, a zero-length packet is transmitted in response to an IN token. No data packets are received in response to the OUT token.
4	Interval error	An NRDY interrupt is generated in device controller mode. No interrupt is generated in host controller mode.

Table 29.31 Error detection for data packet reception (1 of 2)

Detection priority	Error type	Interrupt generated at error detection and status
1	PID error	No interrupt is generated. (Ignored as a corrupted packet.)
2	CRC or bit stuffing error	An NRDY interrupt is generated and the FRMNUM.CRCE bit sets to 1 in both host and device controller modes.

Table 29.31 Error detection for data packet reception (2 of 2)

Detection priority	Error type	Interrupt generated at error detection and status
3	Maximum packet size exceeded error	A BEMP interrupt is generated and the PID[1:0] bits set to STALL in both host and device controller modes.

29.3.12.2 DATA PID

The USBHS does not support high-bandwidth transfers. In device controller mode, the USBHS responds as follows to a received PID:

IN direction

- DATA0: Transmitted as data packet PID
- DATA1: Not transmitted
- DATA2: Not transmitted
- mDATA: Not transmitted

OUT direction (full-speed operation)

- DATA0: Received normally as data packet PID
- DATA1: Received normally as data packet PID
- DATA2: Packets ignored
- mDATA: Packets ignored

OUT direction (high-speed operation)

- DATA0: Received normally as data packet PID
- DATA1: Received normally as data packet PID
- DATA2: Received normally as data packet PID
- mDATA: Received normally as data packet PID

29.3.12.3 Interval counter

The isochronous transfer interval can be set in the PIPEPERI.IITV[2:0] bits. In device controller mode, the interval counter enables functions as shown in Table 29.32. In host controller mode, the USBHS generates the token issuance timing, and the interval counter operation is the same as that for interrupt transfers.

Table 29.32 Interval counter functions in device controller mode

Transfer direction	Function	Conditions for detection
IN	Transmit buffer flush	Failure to receive an IN token successfully in the interval frame during an isochronous IN transfer
OUT	Notification of no reception of token	Failure to receive an OUT token successfully in the interval frame during an isochronous OUT transfer

The interval count is performed when an SOF is received or for complemented SOFs, so the isochronism can be maintained even if an SOF is corrupt. The frame interval can be set to 2IITV (μ) frames.

(1) Counter initialization in device controller mode

The USBHS initializes the interval counter under the following conditions:

- Power-on reset:
  This initializes the PIPEPERI.IITV[2:0] bits
- FIFO buffer initialization using the ACLRM bit:
  This does not initialize the IITV[2:0] bits, but does initialize the count value.

After the interval counter is initialized, the interval count starts under either of the following conditions when a packet is transferred successfully:

- An SOF is received after data is transmitted in response to an IN token, with the PID[1:0] bits set to 01b (BUF response)
- An SOF is received after data is received in response to an OUT token, with PID[1:0] bits set to 01b (BUF response)

The interval counter is not initialized under the following conditions:

- When the PID[1:0] bits are set to NAK or STALL
  This does not stop the interval timer. The USBHS attempts the transaction in the next interval.
- USB bus reset and USB suspension
  This does not initialize the IITV[2:0] bits. When an SOF is received, the interval counter starts counting from the value set before SOF was received.

(2) Interval counting and transfer control in host controller mode

The USBHS controls the interval between token issuance operations based on the PIPEPERI.IITV[2:0] bit settings. Specifically, the USBHS issues a token for a selected pipe once every 2IITV frames.

The USBHS starts counting the token issuance interval at the frame following the frame in which the PID[1:0] bits are set to 01b (BUF response) by software.

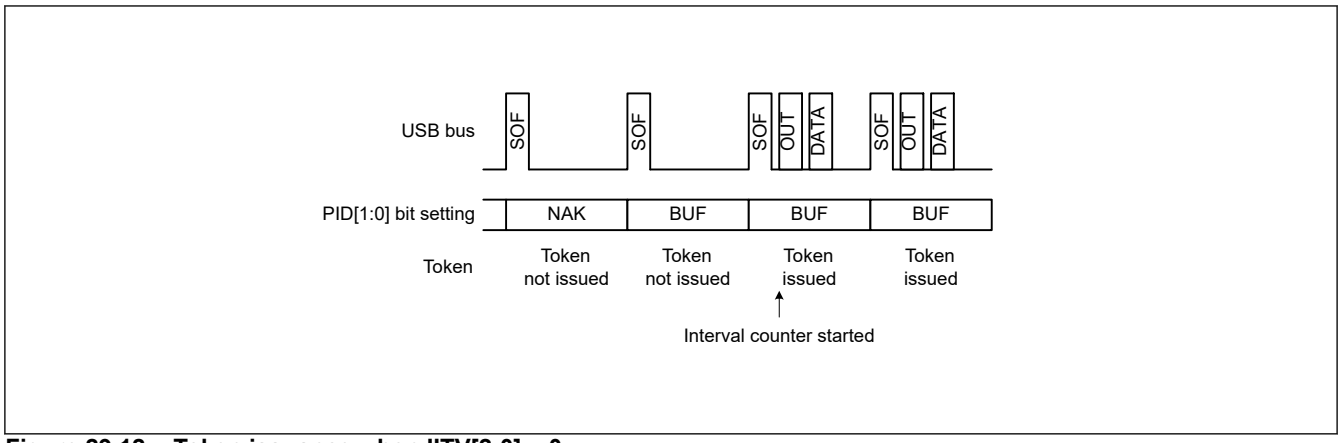

Figure 29.12 Token issuance when IITV[2:0] = 0

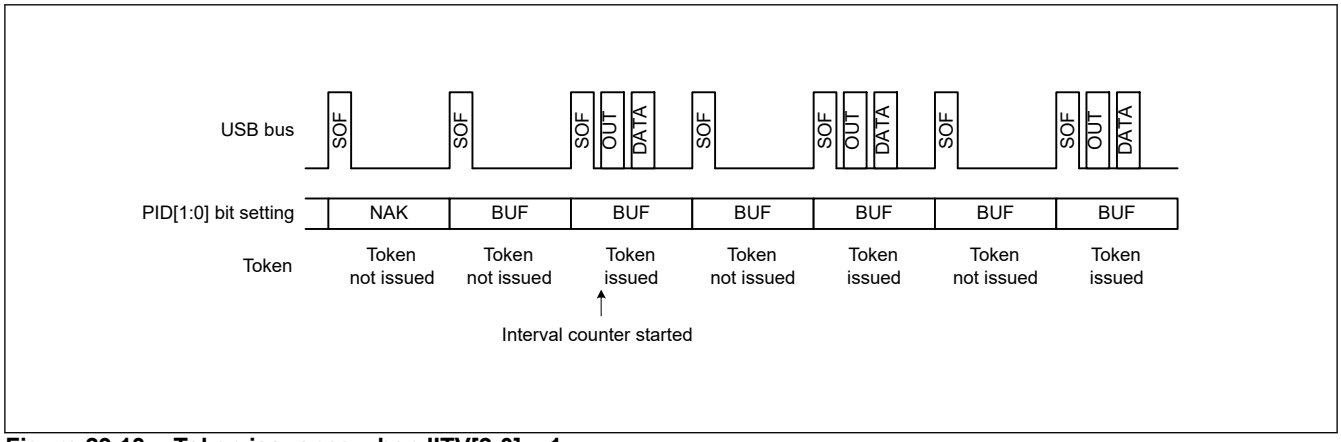

Figure 29.13 Token issuance when IITV[2:0] = 1

When the selected pipe is set for isochronous transfers, the USBHS carries out the following operation in addition to controlling the token issuance interval. The USBHS issues a token even when the NRDY interrupt generation condition is satisfied.

When the selected pipe is for isochronous IN transfers

The USBHS generates an NRDY interrupt when the USBHS issues an IN token but does not receive a packet successfully from a peripheral device (no response or packet error).

When the selected pipe is for isochronous OUT transfers

The USBHS sets the OVRN flag to 1, generating an NRDY interrupt and transmitting a zero-length packet, when the time to issue an OUT token comes while there is no data to be transmitted in the FIFO buffer, because the CPU or DMA/DTC is too slow in writing data to the FIFO buffer.

The token issuance interval is reset on any of the following conditions:

- When the MCU is reset
  This initializes the IITV[2:0] bits
- When the PIPEnCTR.ACLRM bit is set to 1 by software

(3) Interval counting and transfer control in device controller mode

When the selected pipe is for isochronous OUT transfers

The USBHS generates an NRDY interrupt when it fails to receive a data packet within the interval set in the PIPEPERI.IITV[2:0] bits.

The USBHS also generates an NRDY interrupt when it fails to receive data because of a CRC error or other errors contained in the data packet or because of the FIFO buffer is full.

The NRDY interrupt is generated on SOF packet reception. Even if the SOF packet is corrupted, internal complementation allows the interrupt to be generated when the SOF packet is received. However, when the IITV[2:0] bits are set to a value other than 0, the USBHS generates an NRDY interrupt on receiving an SOF packet for every interval after interval counting starts.

When the PID[1:0] bits are set to 00b (NAK response) by software after starting the interval timer, the USBHS does not generate an NRDY interrupt on receiving an SOF packet.

The timing for starting interval counting depend on the IITV[2:0] setting as follows:

- When the IITV[2:0] bits = 0:
  The interval counting starts when the PID[1:0] bits of the selected pipe are changed to BUF
- When the IITV[2:0] bits ≠ 0:
  The interval counting starts on completion of successful reception of the first data packet after the PID[1:0] bits for the selected pipe are changed to 01b (BUF response)

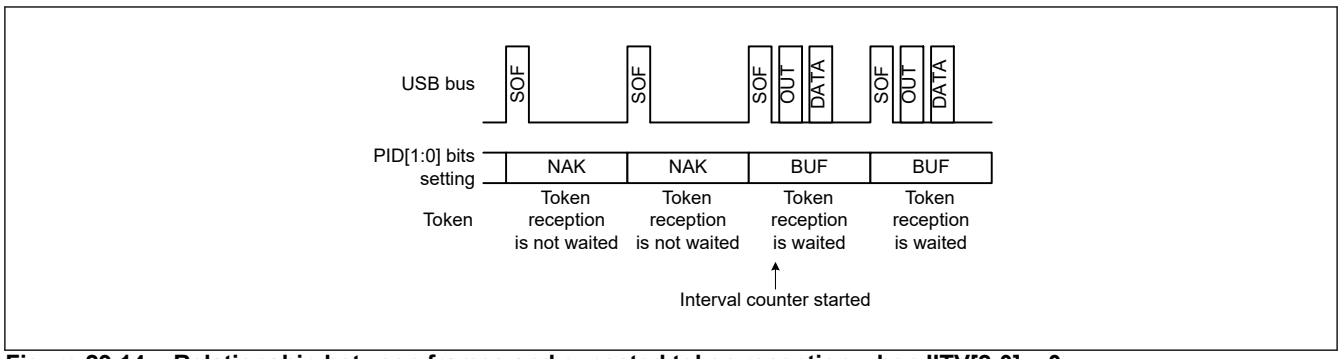

Figure 29.14 Relationship between frames and expected token reception when IITV[2:0] = 0

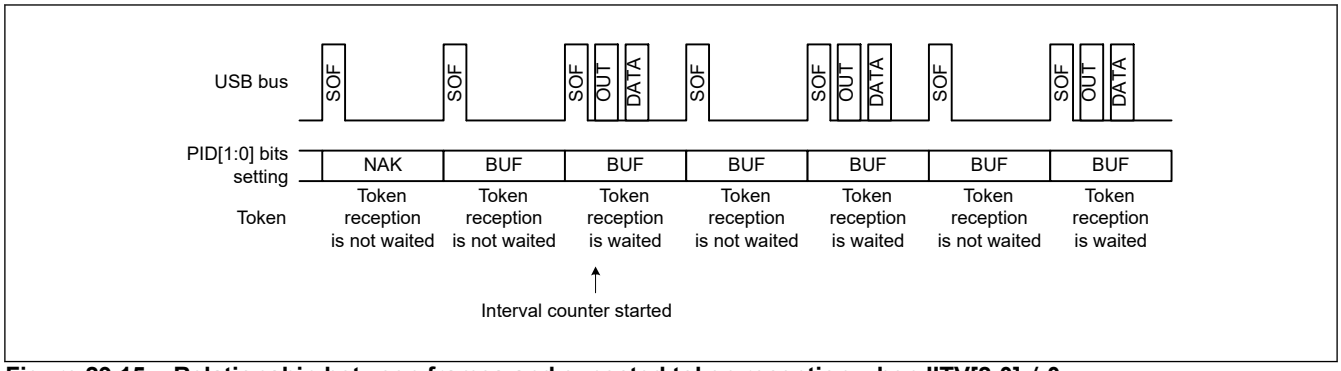

Figure 29.15 Relationship between frames and expected token reception when IITV[2:0] ≠ 0

When the selected pipe is for isochronous IN transfers

The PIPEPERI.IFIS bit must be 1 for this use case. When the IFIS bit is cleared to 0, the USBHS transmits a data packet in response to a received IN token, regardless of the PIPEPERI.IITV[2:0] setting.

When IFIS is 1 and there is data to be transmitted in the FIFO buffer, the USBHS clears the FIFO buffer when it fails to receive an IN token in the frame at the interval set in the IITV[2:0] bits.

The USBHS also clears the FIFO buffer when it fails to receive an IN token successfully because of a bus error, such as a CRC error, contained in the IN token.

The FIFO buffer is cleared on SOF packet reception. Even if the SOF packet is corrupted, the internal complementation allows the FIFO buffer to be cleared when the SOF packet is received.

The timing to start interval counting depends on the IITV[2:0] setting, as with OUT transfers.

The interval is counted on any of the following conditions in device controller mode:

- When a hardware reset is applied to the USBHS (which also sets the IITV[2:0] bits to 000b)
- When the PIPEnCTR.ACLRM bit is set to 1 by software
- When the USBHS detects a USB bus reset

(4) Transmit data setup for isochronous transfers in device controller mode

With isochronous data transmission using the USBHS in device controller mode, after data is written to the FIFO buffer, a data packet can be transmitted in the first frame after the SOF packet is detected. This isochronous transfer transmit data setup function can identify the frame that started transmission.

When the double buffering is used, transmission is only enabled for the buffer in which data writing was completed first, even after the data write to both buffers is complete. Accordingly, even if multiple IN tokens are received, only the one packet of FIFO buffer data is transmitted.

When the FIFO buffer is ready to transmit data when an IN token is received, the data is transferred and a normal response is returned. However, if the FIFO buffer cannot transmit data, a zero-length packet is transmitted and an underrun error occurs.

Figure 29.16 shows an example of transmission using the isochronous transfer transmit data setup function when the IITV[2:0] bits are set to 0 (every frame).

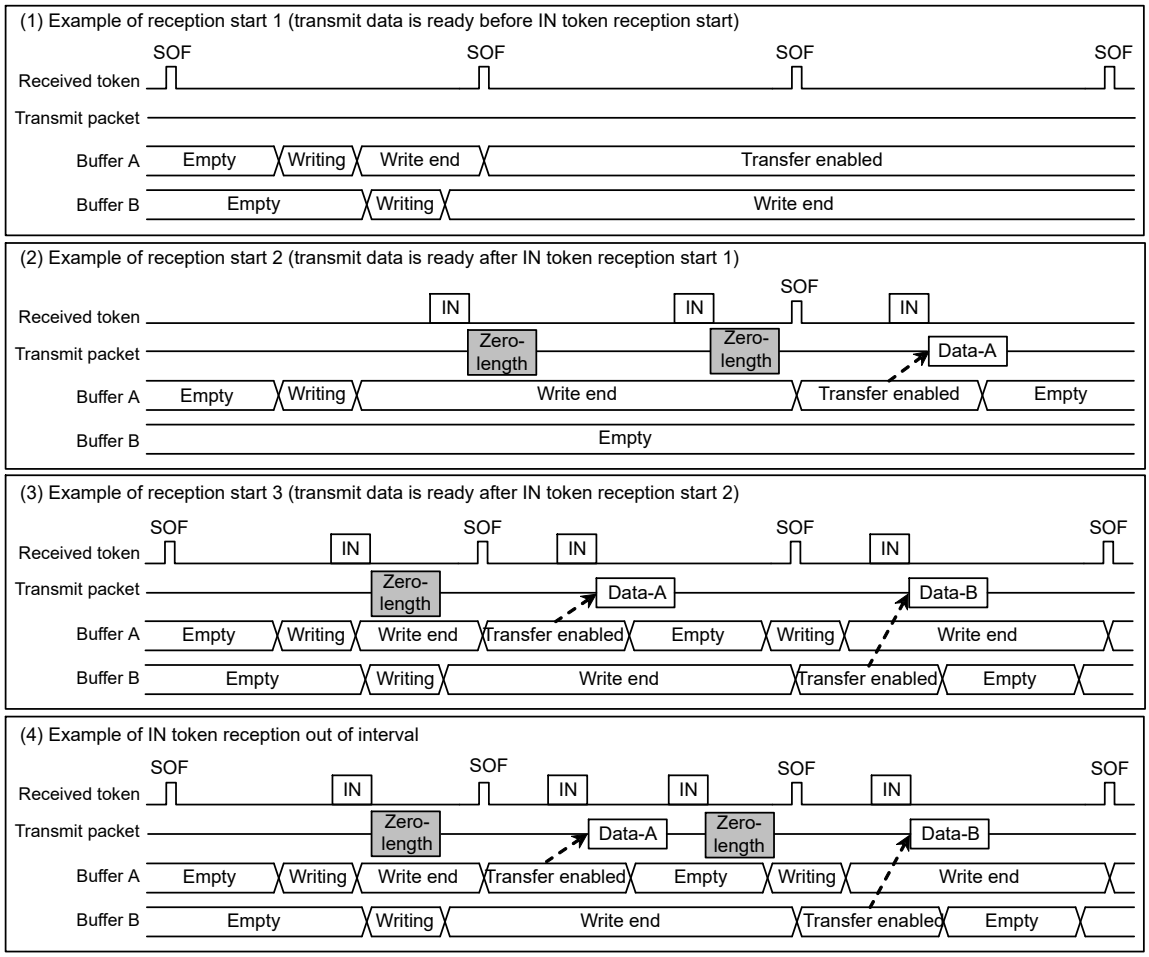

Figure 29.16 Example data setup operation

(5) Isochronous transfer transmit buffer flush in device controller mode

In device controller mode during isochronous data transmission, if the USBHS receives an SOF packet for the next frame without receiving an IN token in the interval frame, it operates as if the IN token is corrupt and clears the buffer that is enabled for transmission, putting that buffer in the writing enabled state.

When double buffering is used and writing to both buffers is complete, the cleared FIFO buffer is assumed to be the one where the data was transmitted in the interval frame, and transmission is enabled for the FIFO buffer that was not cleared on SOF packet reception.

The timing of the buffer flush function depends on the PIPEPERI.IITV[2:0] setting as follows:

- When IITV[2:0] = 0:
  The buffer flush operation starts from the first frame after the pipe is enabled
- When IITV[2:0] ≠ 0:
  The buffer flush operation starts after the first normal transaction

Figure 29.17 shows an example buffer flush. When an unanticipated token is received before the interval frame, the USBHS sends the write data or a zero-length packet as an underrun error, depending on the data setup status.

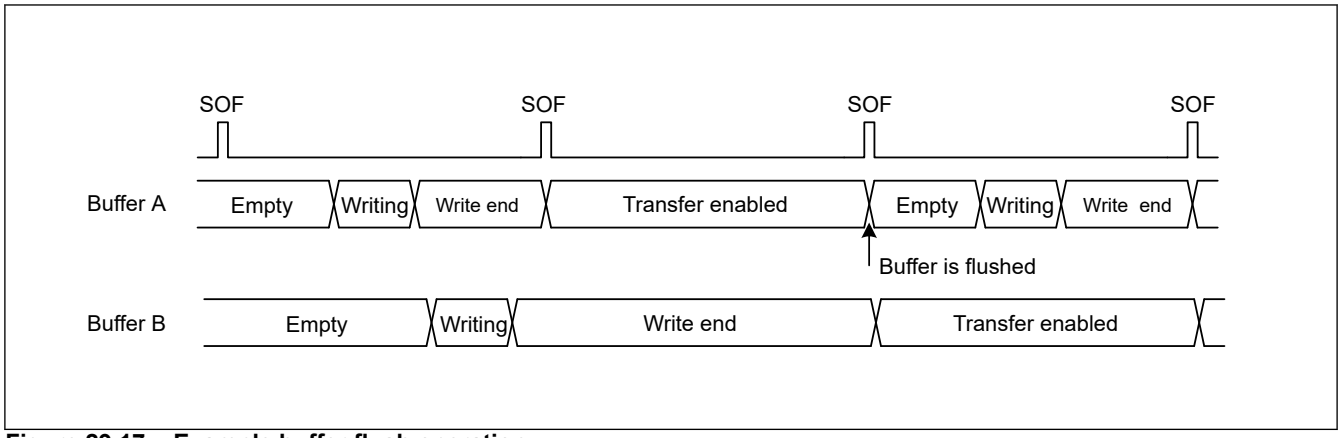

Figure 29.17 Example buffer flush operation

Figure 29.18 shows an example interval error occurrence. There are five types of interval errors, as shown in the figure. An interval error occurs at timing ①, and the buffer flush function is activated.

If an interval error occurs during an IN transfer, the buffer flush function is activated. If it occurs during an OUT transfer, an NRDY interrupt is generated. Use the FRMNUM.OVRN bit to distinguish between this and NRDY interrupts triggered by received packet errors and overrun errors.

For tokens that are shaded in the figure, responses are returned based on the FIFO buffer status.

- IN direction:
  - If the buffer is ready to transfer data, the data is transferred and a normal response is returned
  - If the buffer is not ready to transfer data, a zero-length packet is transmitted and an underrun error occurs
- OUT direction:
  - If the buffer is ready to receive data, the data is received and a normal response is returned
  - If the buffer is not ready to receive data, the received data is discarded and an overrun error occurs

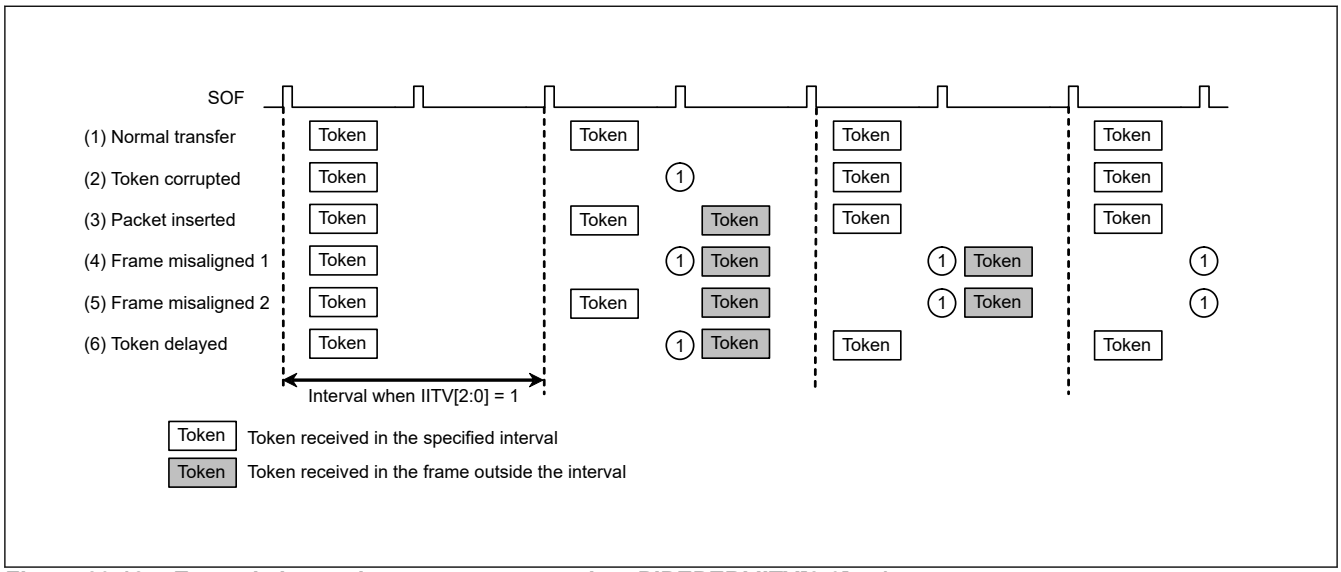

Figure 29.18 Example interval error occurrence when PIPEPERI.IITV[2:0] = 1

29.3.13 SOF Complementation Function

In device controller mode, if packet reception is disabled at intervals of 1 ms in full-speed mode or 125 µs in high-speed mode because the SOF packet is missing or corrupted, the USBHS complements the SOF. SOF complementation begins when the SYSCFG.USBE and LPSTS.SUSPENDM bits are set to 1 and an SOF packet is received. The complementation function is initialized under the following conditions:

- Power-on reset

- USB bus reset
- Suspend state detection

The SOF complementation function operates as follows:

- The frame interval (125 µs or 1 ms) is determined by the reset handshake protocol result
- The complementation function is not activated until an SOF packet is received
- When the first SOF packet is received, complementation is performed by counting 125 µs or 1 ms on the 48-MHz internal clock
- When the second or subsequent SOF packets are received, complementation is performed at the previous reception interval
- Complementation is not performed in the Suspend state or on reception of a USB bus reset. During high-speed operation, complementation continues for 3 ms from the last packet on transition to the Suspend state

The USBHS supports the following functions controlled by SOF packet reception. These functions operate normally with SOF complementation if the SOF packet is missing:

- Updating of the frame number and micro frame number
- SOFR interrupt and micro-SOF lock
- SOF pulse output
- Isochronous transfer interval count

If an SOF packet is missing during full-speed operation, the FFRMNUM.FRNM[10:0] flags are not updated. If a micro-SOF packet is missing during high-speed operation, the URMNUM.UFRNM[2:0] bits are updated.

However, if a micro-SOF packet is missing while the UFRNM[2:0] bits are set to 000b, the FRNM bits are not updated. In this case, even if a subsequent micro-SOF packet with a value other than UFRNM[2:0] bits = 000b is received successfully while UFRNM[2:0] bits are set to the value other than 000b, the FRNM bits are not updated.

29.3.14 Pipe Schedule

29.3.14.1 Conditions for generating transactions

In host controller mode and when the DVSTCTR0.UACT bit is set to 1, the USBHS generates transactions under the conditions as shown in Table 29.33.

Table 29.33 Conditions for generating transactions

Transaction	Conditions for generation				
	DIR	PID[1:0]	IITV0	Buffer state	SUREQ
Setup	—*1	—*1	—*1	—*1	1 setting
Control transfer data stage, status stage, bulk transfer	IN	BUF	—*1	Receive area exists	—*1
	OUT	BUF	—*1	Transmit data exists	—*1
Interrupt transfer	IN	BUF	Valid*2	Receive area exists	—*1
	OUT	BUF	Valid*2	Transmit data exists	—*1
Isochronous transfer	IN	BUF	Valid*2	*3	—*1
	OUT	BUF	Valid*2	*4	—*1

Note 1. An em dash (—) in the table indicates that the condition is unrelated to the generating of tokens.
Note 2. “Valid” indicates that, for interrupt transfers and isochronous transfers, a transaction is generated only in transfer frames that are based on the interval counter.
Note 3. This indicates that a transaction is generated regardless of whether there is a receive area. If there is no receive area, however, the received data is discarded.
Note 4. This indicates that a transaction is generated regardless of whether there is any data to be transmitted. If there is no data to be transmitted, however, a zero-length packet is transmitted.

29.3.14.2 Transfer schedule

This section describes the transfer scheduling within a frame of the USBHS. After the USBHS sends an SOF, the transfer is carried out in the following sequence:

1. Execution of periodic transfers:
   A pipe is searched for in the order of pipe 1 → pipe 2 → pipe 6 → pipe 7 → pipe 8 → pipe 9, and then if there is a pipe for which an isochronous or interrupt transfer transaction can be generated, the transaction is generated.
2. Setup transactions for control transfers:
   The DCP is checked, and if a setup transaction is possible, it is sent.
3. Execution of bulk transfers, control transfer data stages, and control transfer status stages:
   A pipe is searched for in the order of DCP → pipe 1 → pipe 2 → pipe 3 → pipe 4 → pipe 5, and then if there is a pipe for which a transaction for a bulk transfer, a control transfer data stage, or a control transfer status stage can be generated, the transaction is generated.
   When a transaction is generated, processing moves to the next pipe transaction regardless of whether the response from the peripheral device is ACK or NAK. If there is time for transfer within the frame, step 3 is repeated.

29.3.14.3 Enabling USB communication

Setting the DVSTCTR0.UACT bit to 1 initiates an SOF transmission, and transaction generation is enabled. Setting the UACT bit to 0 stops SOF transmission, and the Suspend state is invoked. If the UACT setting is changed from 1 to 0, processing stops after the next SOF is sent.

29.3.15 Battery charging detection processing

The USBHS provides control over the data contact detection processing (D+ line contact checking), primary detection processing (charger detection processing), and secondary detection processing (charger determination processing) as defined in the Battery Charging Specification.

This section describes operations required in device and host controller modes.

29.3.15.1 Processing in device controller mode

To operate a function device as a battery charging portable device:

1. Start primary detection processing after detecting contact with the D+ and D- lines. The Battery Charging Specification describes two processing methods for Data Contact Detection. The USBHS supports both methods as follows:
   - Software processing
     After a VBINT interrupt or polling of the VBSTS flag indicates a change in the state of the USBHS_VBUS input pin, software controls a wait from 300 to 900 ms. The BCCTRL.VDPSRCE and IDMSINKE bits are then both set to 1, enabling the VDP_SRC and IMP_SINK circuits, respectively, to start primary detection processing.
   - Hardware processing
     Apply 7 to 13 µA of current to the D+ line to hold the D+ line at the logical high level. This is done to detect the D+ and D- lines going to the logical low level because of pull-down resistors on the host device side when the D+ and D- lines come in contact with those of the host. Monitor the SYSSTS0.LNST[1:0] flags while the BCCTRL.IDPSRCE bit is set to 1, enabling the IDP_SRC circuit, to see when the level on the D+ line changes from high to low. After detecting a low level on the D+ line, clear the BCCTRL.IDPSRCE bit to 0, disabling the IDP_SRC circuit, and set both the BCCTRL.VDPSRCE and IDMSINKE bits to 1, enabling the VDP_SRC and IDM_SINK circuits, respectively, to start primary detection processing. The VDPSRCE and IDMSINKE bits must be set to 1 simultaneously.
2. After the start of primary detection processing followed by a software-controlled wait of 40 ms, check the BCCTRL.CHGDETSTS flag. A value of 1 indicates detection of a charger, and secondary detection processing starts.[*1]
3. To start secondary detection processing, clear both the BCCTRL.VDPSRCE and IDMSINKE bits to 0, disabling the VDP_SRC and IDM_SINK circuits, respectively. Next, set both the BCCTRL.VDMSRCE and IDPSINKE bits to 1, enabling the VDM_SRC and IDP_SINK circuits, respectively.
4. After the start of secondary detection processing followed by a software-controlled wait of 40 ms, check the BCCTRL.PDDETSTS flag. A value of 1 indicates that secondary detection processing is complete.

Note 1. In primary detection processing, detection of a voltage above the range from 0.25 to 0.4 V and below the range from 0.8 to 2.0 V on the D-Line indicates that the other device is a host device that supports battery charging (charging downstream port). The BCCTRL.CHGDETSTS flag in the PHY block only indicates whether the voltage on the D-line is higher than the range from 0.25 to 0.4 V, so add processing as required to read the SYSSTS0.LNST[1:0] flags and confirm that the voltage on the D- line is also below the range from 0.8 to 2.0 V.

Figure 29.19 illustrates this processing flow.

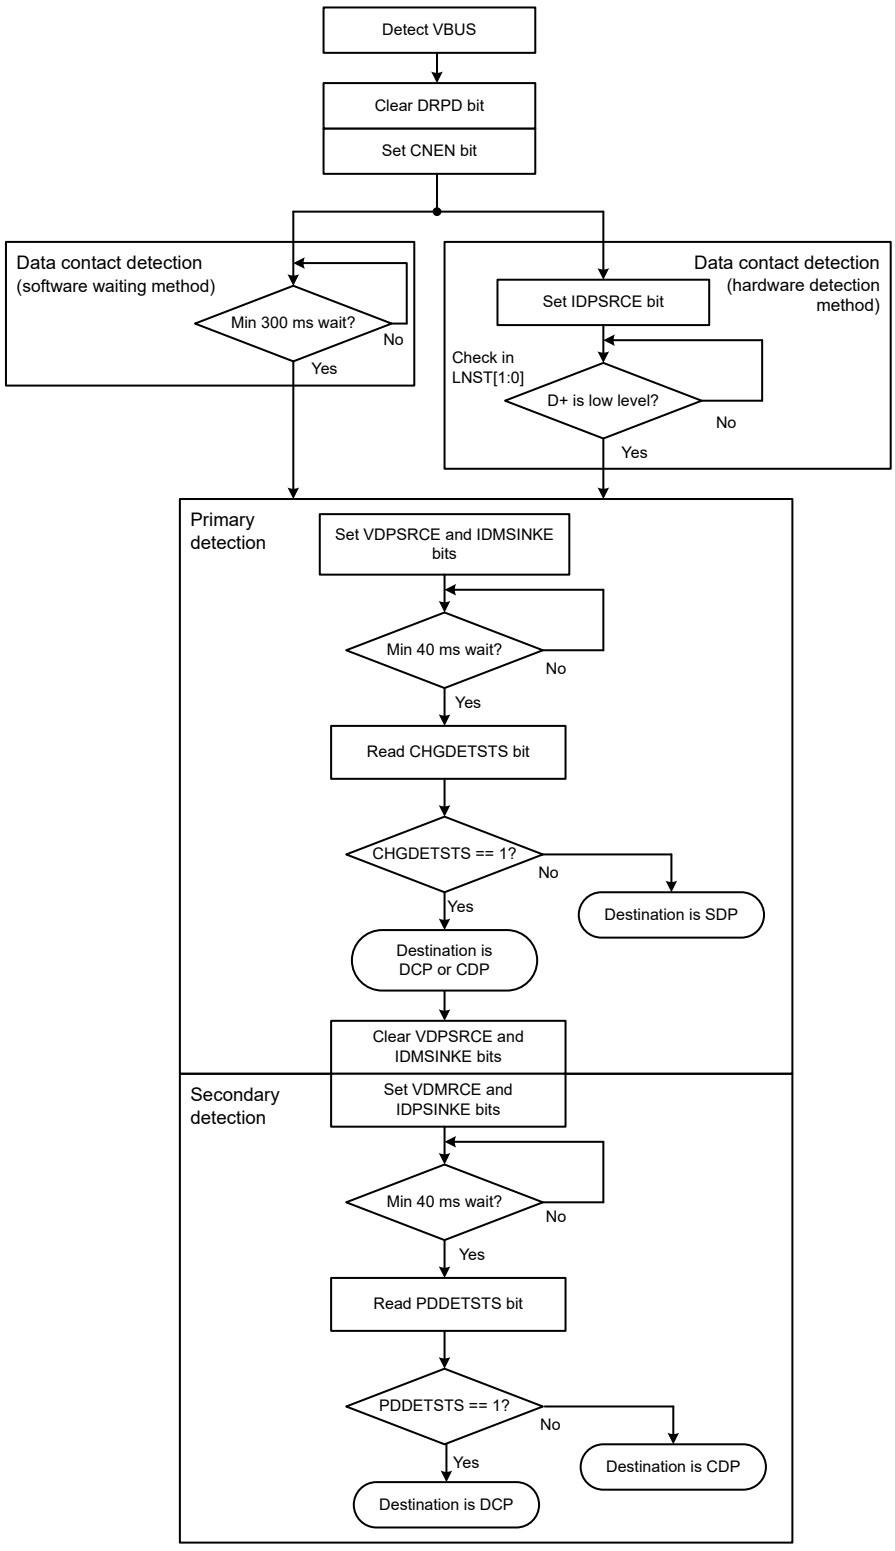

Figure 29.19 Processing flow as portable device

29.3.15.2 Processing in host controller mode

In host controller mode, driving the D- line is required for a portable device to perform primary detection. The USBHS supports the following two primary detection methods:

- When the hardware has a portable device detection function
- When the hardware does not have the function or the function is present but not used

Figure 29.20 and Figure 29.21 show the processing flows for these methods.

(1) When the hardware has a portable device detection function

a. Start driving the USBHS_VBUS input pin.

b. Set the BCCTRL.IDMSINKE bit to 1 to enable the portable device detection circuit.

c. Monitor the portable device detection signal and start driving the D-line when the level of the portable device detection signal is high*1.

d. Stop driving the D-line when the portable device detection signal is at the low level*1.

Note 1. The PDDETINT interrupt indicates a change in the level of the portable device detection signal (EUH_CPDDET), and the current level can be obtained by reading the PDDETSTS flag.

(2) When the hardware does not have a portable device detection function or the function is not used

Software handles the timing of steps a. and b.

a. After a disconnect is detected, start driving the D-line within 200 ms.

b. After a connect is detected, stop driving the D-line within 10 ms.

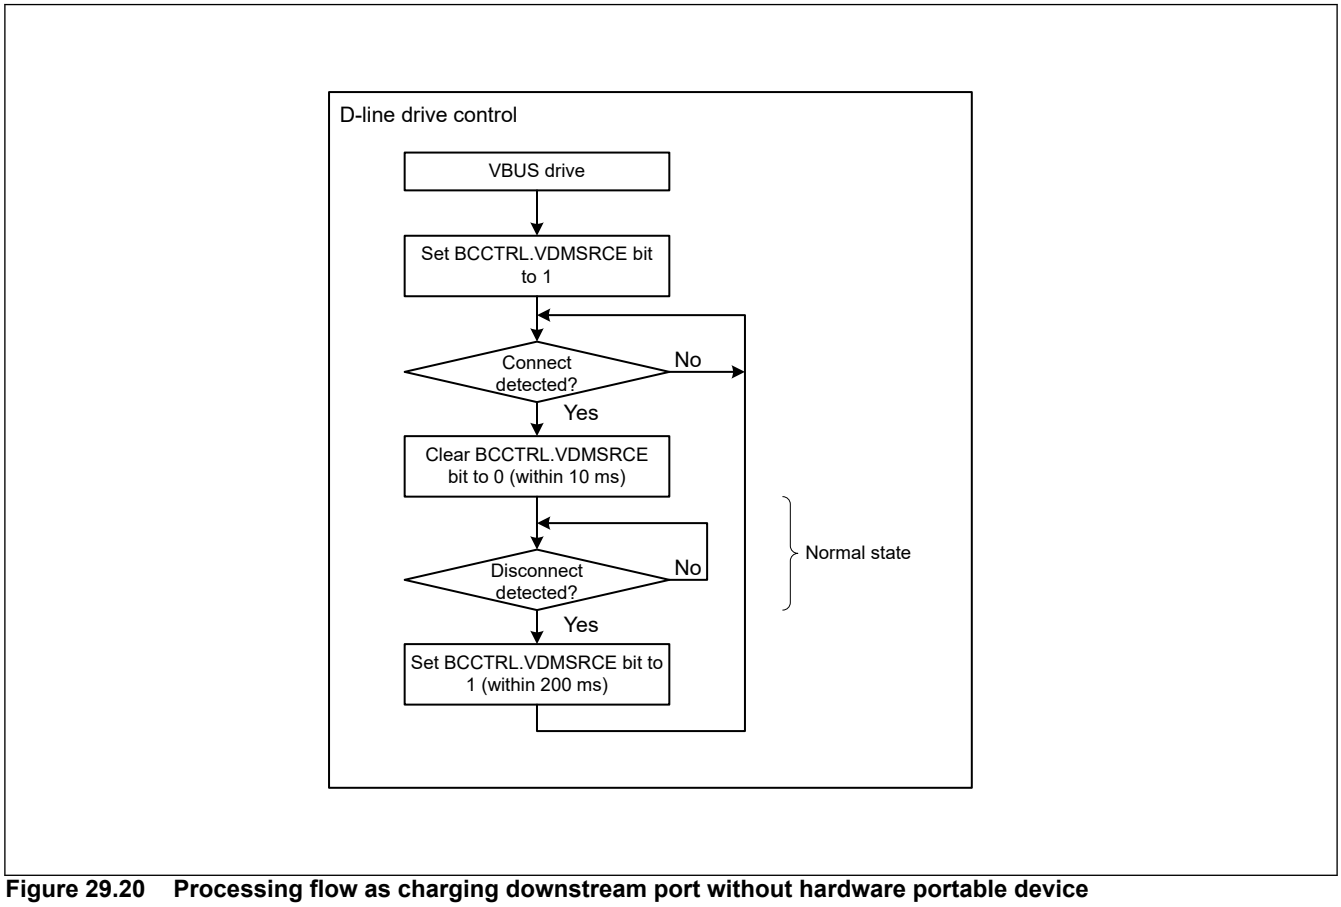

Figure 29.20 Processing flow as charging downstream port without hardware portable device detectionfunction or when function is not used

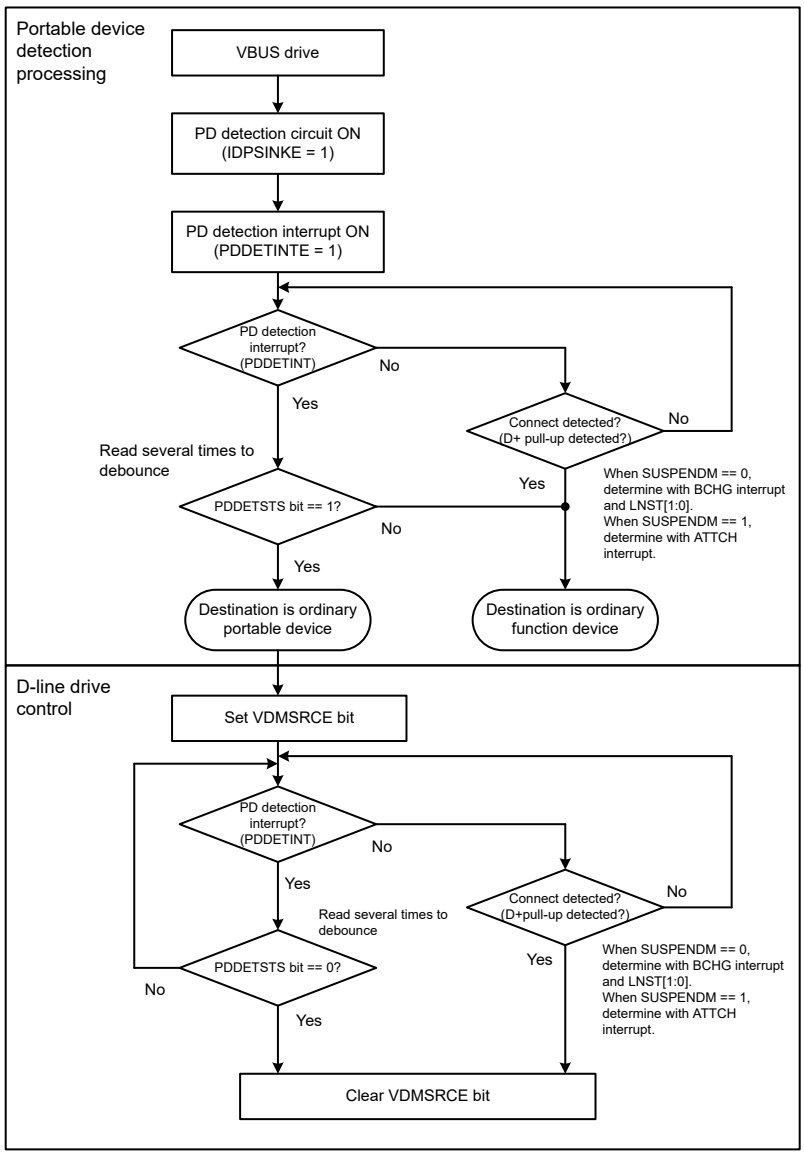

Figure 29.21 Processing flow as charging downstream port with hardware portable device detection function

29.3.16 Link Power Management Processing

The Link Power Management standard defines the existing Suspend state as the L2 state and also defines the L1 state as a state that allows transition and return with lower latency than the L2 state (Suspend). Table 29.34 provides a comparison between the L2 (Suspend) and L1 states.

Table 29.34 Comparison between L2 (Suspend) state and L1 state (1 of 2) (1 of 2)

Parameter	L1 state	L2 (Suspend) state
Transition	LPM transaction	Idle for 3 ms

Table 29.34 Comparison between L2 (Suspend) state and L1 state (1 of 2) (2 of 2)

Parameter	L1 state	L2 (Suspend) state
Return caused by host	Host: Minimum drive period (75 µs to 1.175 ms) can be specified by the host. Function: 10-µs K drive	Host: Minimum 20-ms K drive Function: 10-ms K drive
Return caused by function	Device: 50-µs K drive Function: 60- to 990-µs K drive Device: 10-µs K drive	Function: 1- to 15-ms K drive Host: Minimum 20-ms K drive Function: 10-ms K drive
Signaling	Low- and full-speed idle	Low- and full-speed idle

29.3.16.1 Processing in device controller mode

(1) Descriptor contents

In device controller mode, the USBHS must return its descriptor on receiving the GetDescriptor command.

Change the content of the descriptor to be returned depending on whether the transition to and return from the L1 state corresponds to the processing for the LPM transaction. The following table shows the relationship between LPM correspondence and the descriptor.

Table 29.35 Relationship between LPM correspondence and descriptor

Correspondence with LPM	bcdUSB field	USB2.0 extension descriptor		Response to received LPM request	Notes
		Provided/ not provided	Value of LPM bit		
Does not correspond	0x0200	Not provided	—	No response	Normal operation when the LPM is not supported
	0x0201	Provided	0	STALL	Setting for clear non-correspondence to LPM. In this case, a STALL response must be returned.
Corresponds	0x0201	Provided	1	ACK or NYET	Normal operation when the LPM is supported

Declare whether to correspond to the transition to and return from L1 in the LPM bit in the USB 2.0 extension descriptor. To provide the USB2.0 extension descriptor, the bcdUSB field of the device descriptor must be set to a value of 0x0201 or larger.

When the LPM is not supported, the USB2.0 extension descriptor is not provided and the bcdUSB field value must be 0x0200. If an LPM token is received in this case, it must be ignored. It is also possible to set the bcdUSB field value to 0x0201 and the LPM bit in the USB2.0 extension descriptor to 0 (LPM tokens not supported). In this case, the LPM token cannot be ignored and a STALL response must be returned.

When the LPM token is supported, set the bcdUSB field value to 0x0201 and set the LPM bit in the USB 2.0 extension descriptor to 1 (LPM tokens supported). This allows acknowledgment when returning a NYET or ACK response to the LPM token.

(2) Processing during LPM token reception

Transition to and return from the L1 state in device controller mode is as follows:

a. When the USBHS receives an LPM token from the host, the L1RESPEN, L1RESPMD[1:0], and L1NEGOMD settings in PL1CTRL1 determine whether a response packet is sent or the token is ignored and, if a response is to be sent, whether it is an ACK, NYET, or STALL packet.

b. If an ACK response to the LPM token is sent and the host does not transmit another LPM token in 8 µs, the USBHS enters the L1 state. The USBHS handles detection of the newly transmitted packet and the transition to the L1 state. The DVST interrupt can be used to detect the transition.

c. Two types of processing can return the USBHS from the L1 state:

- When the host drives the D-line in the K-state:
  The function device detects the K-state and starts processing the return from the L1 state in response to an RESM interrupt request
- When the function device outputs a remote wakeup signal:
  If the software on the function device sets the DVSTCTR0.WKUP bit to 1, it sends a remote wakeup signal to the host

The software clears the DVSTCTR0.WKUP bit to 0 on returning from the L2 (Suspend) state, and the USBHS clears the DVSTCTR0.WKUP bit to 0 for return from the L1 state.

(3) HIRD field value negotiation function

The HIRD field value included in the LPM token indicates the host K-drive period on return from the L1 state. The HIRD field value can be adjusted according to the requirements of the target system. For example, a small HIRD field value is better for systems focusing on higher transfer efficiency, while a large HIRD field value is better for systems focusing on low power consumption.

Based on the L1NEGOMD and HIRDTHR[3:0] settings in PL1CTRL1, an ACK response is returned when the received HIRD field value is in the expected range, and otherwise a NYET response is returned, requesting the host to change the HIRD field value.

Note: This HIRD field value negotiation function at the host must also support negotiation processing.

29.3.16.2 Processing in host controller mode

(1) Processing during LPM token transmission

Transition to and return from the L1 state in host controller mode is as follows:

a. When the HL1CTRL.L1REQ bit is set to 1, an LPM token is sent to the function device from the host device.

b. If an ACK response is received from the function device, a transition to the L1 state starts within 10 µs and is complete within 50 µs. If a transaction error is detected, another LPM token is transmitted within 8 µs. Retransmission can proceed up to two times. The USBHS handles all of this processing.

c. Two types of processing can return the USBHS from the L1 state:

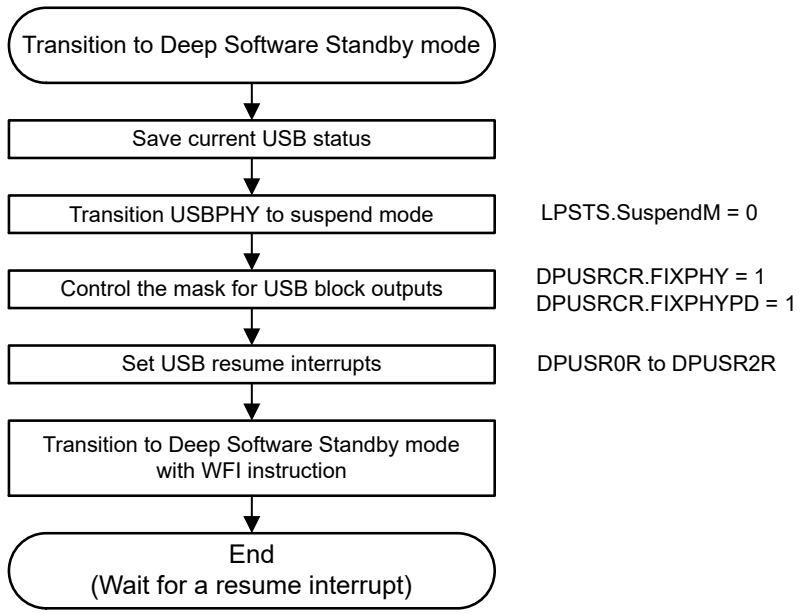
- When the host drives the D-line for the K state:
  When the DVSTCTR0.RESUME bit is set to 1, the host device starts driving the D-line for the K-state and starts processing the return
- When the function device generates a remote wakeup signal:
  When the host device detects a remote wakeup signal from the function device, it sets the DVSTCTR0.RESUME bit to 1 and starts driving the D-line for the K-state

Unlike when returning from the Suspend (L2) state, the USBHS clears the DVSTCTR0.RESUME bit to 0. After clearing the RESUME bit, it sets the DVSTCTR0.UACT bit to 1 and issues an L1RSMEND interrupt request.

29.3.17 Release from Deep Software Standby Mode Because of USB Suspend/Resume Interrupts

Deep Software Standby mode can be canceled by a USB suspend/resume interrupt. USB suspend/resume interrupts are detected by the USB resume detecting unit, which controls and monitors the USB I/O pins to detect the interrupts.

Figure 29.22 shows the flow for setting the USBHS when entering Deep Software Standby mode from either host or device controller mode. Figure 29.23 and Figure 29.24 show the flows for setting the USBHS when canceling Deep Software Standby mode from host controller mode. Figure 29.25 shows the flow for setting the USBHS when canceling Deep Software Standby mode from device controller mode.



Note 1. When connected to an external device, transition to Deep Software Standby mode is enabled only on USB Suspend.
Note 2. Never invoke Deep Software Standby mode in the following cases:
- In an L1 Suspend status with the USB-LPM protocol.
- When remote wakeup is enabled in host controller mode.

Figure 29.22 USBHS setup flow for transition to Deep Software Standby mode as a host or device controller

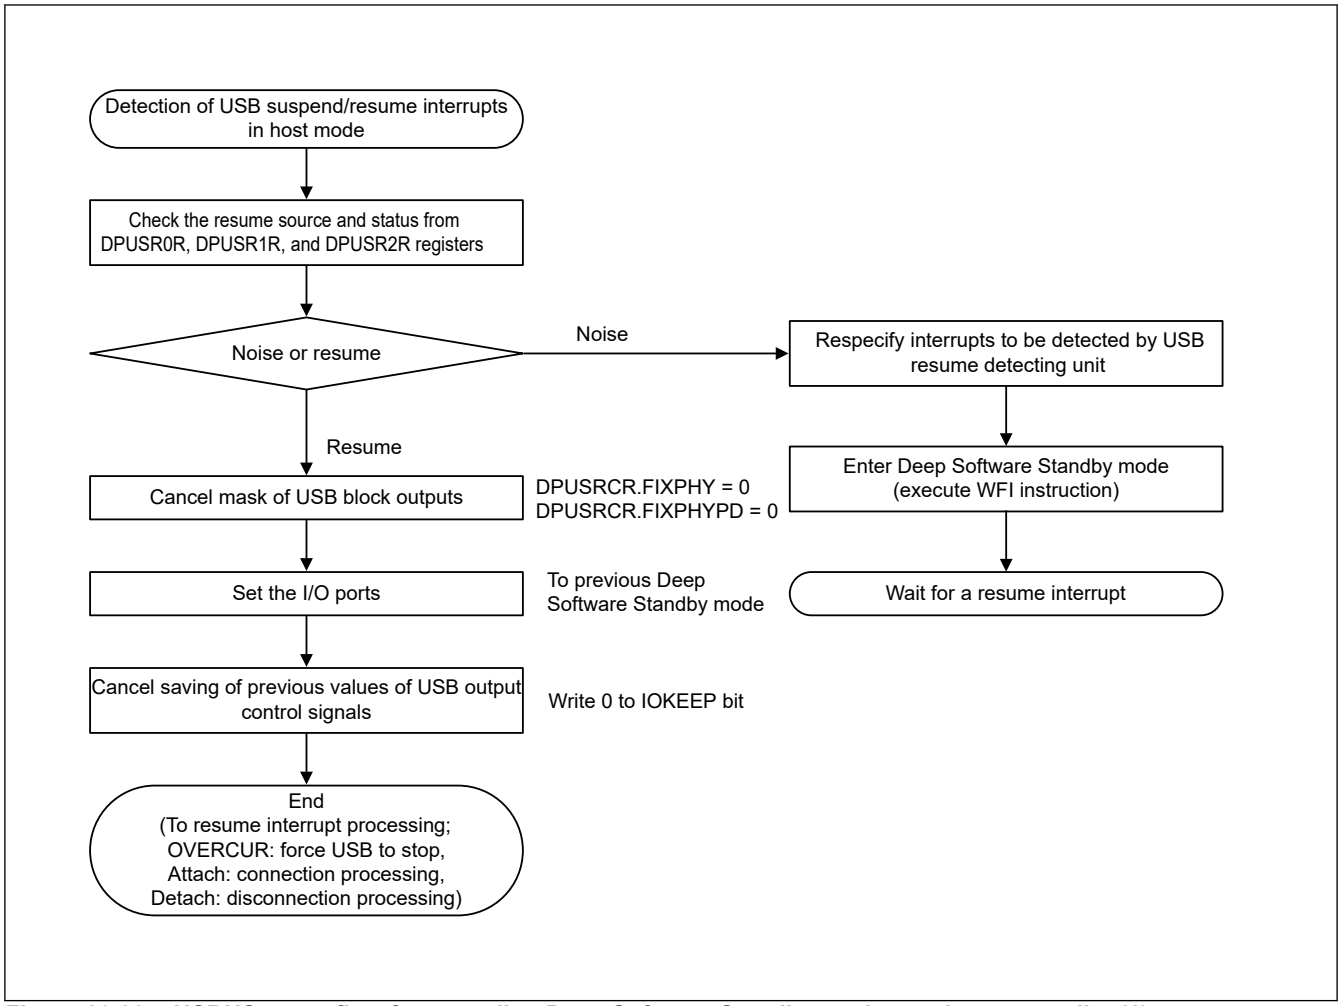


Figure 29.23 USBHS setup flow for canceling Deep Software Standby mode as a host controller (1)

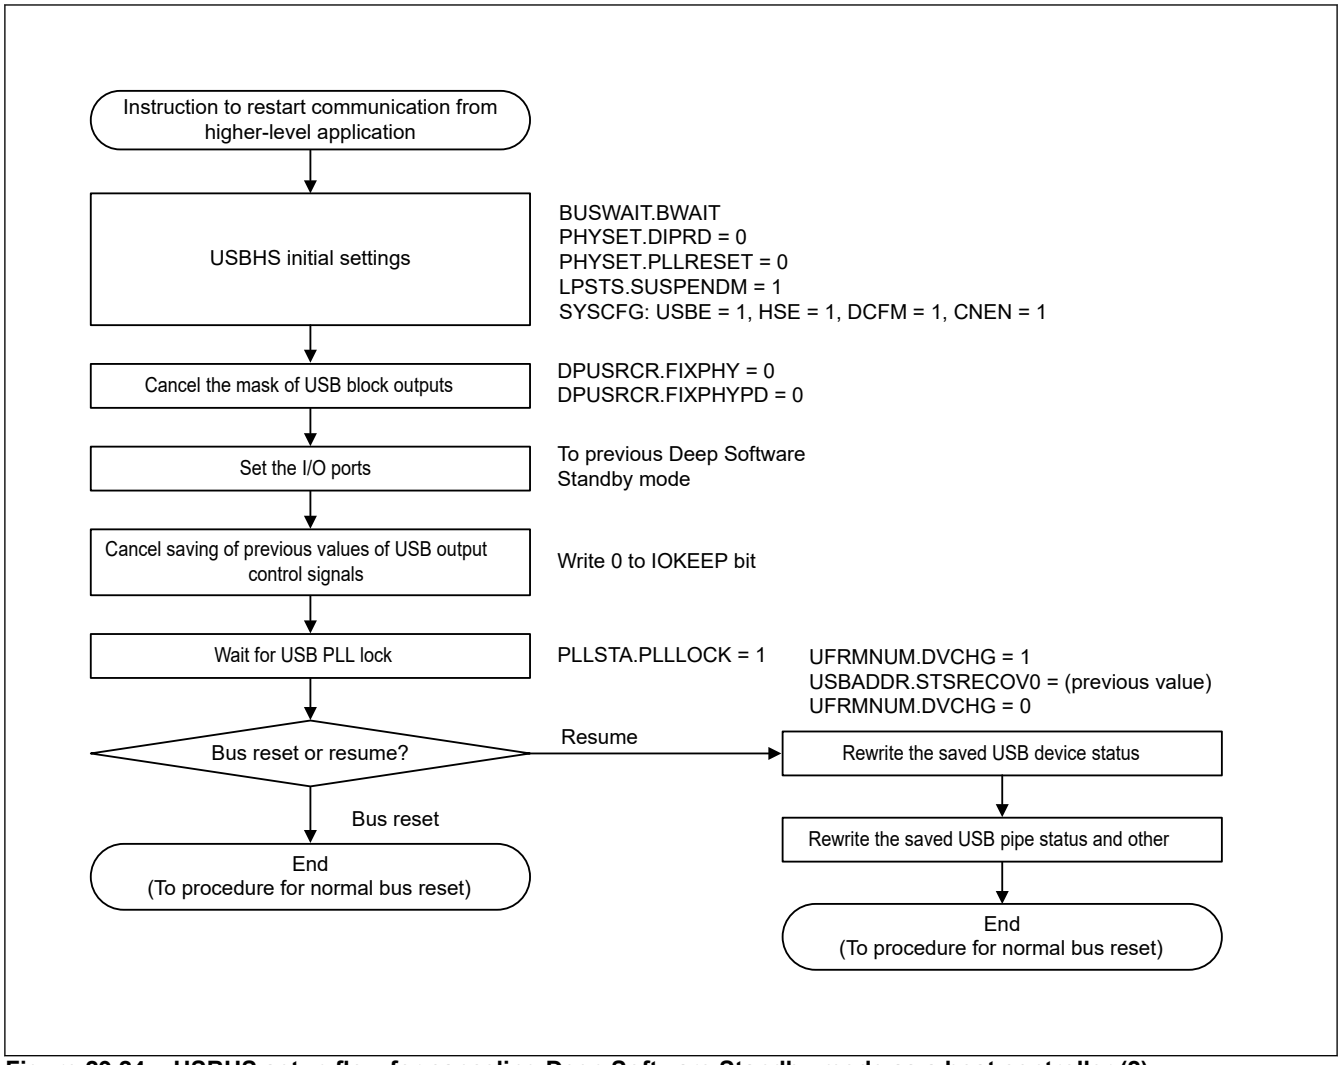

Figure 29.24 USBHS setup flow for canceling Deep Software Standby mode as a host controller (2)

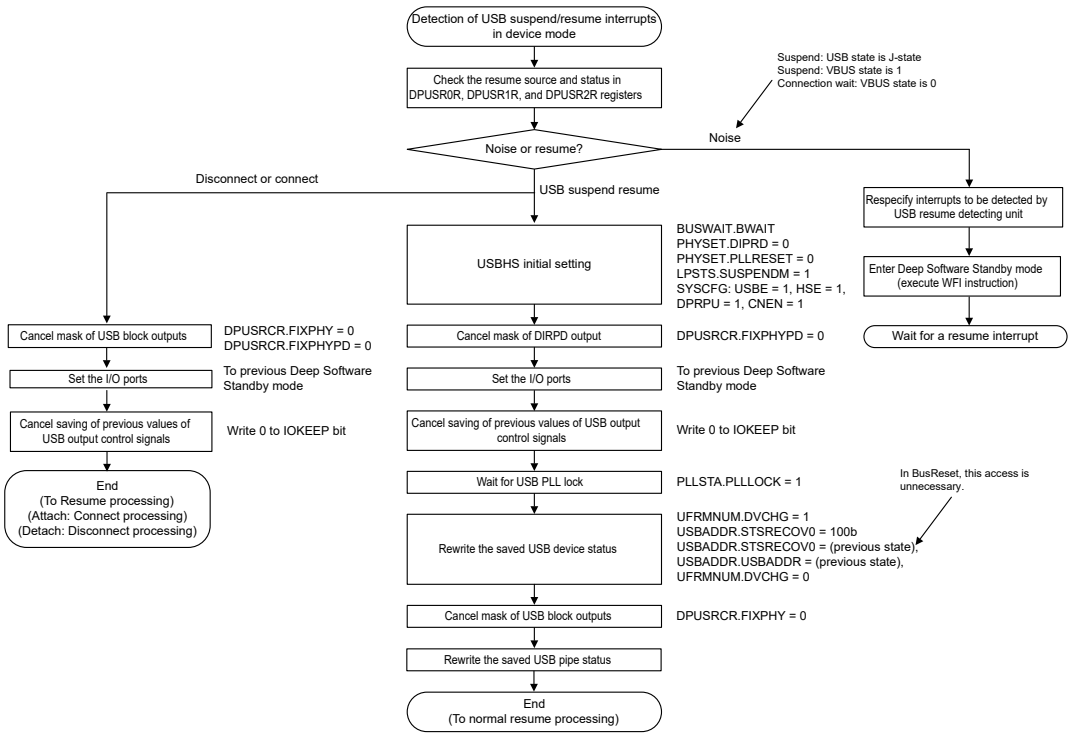

Note 1. In BusReset return, the write to the STSRECOV0 bit must be within 2.5 µS of USBHS-PHY PLL oscillation start.

Figure 29.25 USBHS setup flow for transition to Deep Software Standby mode as a host or device controller

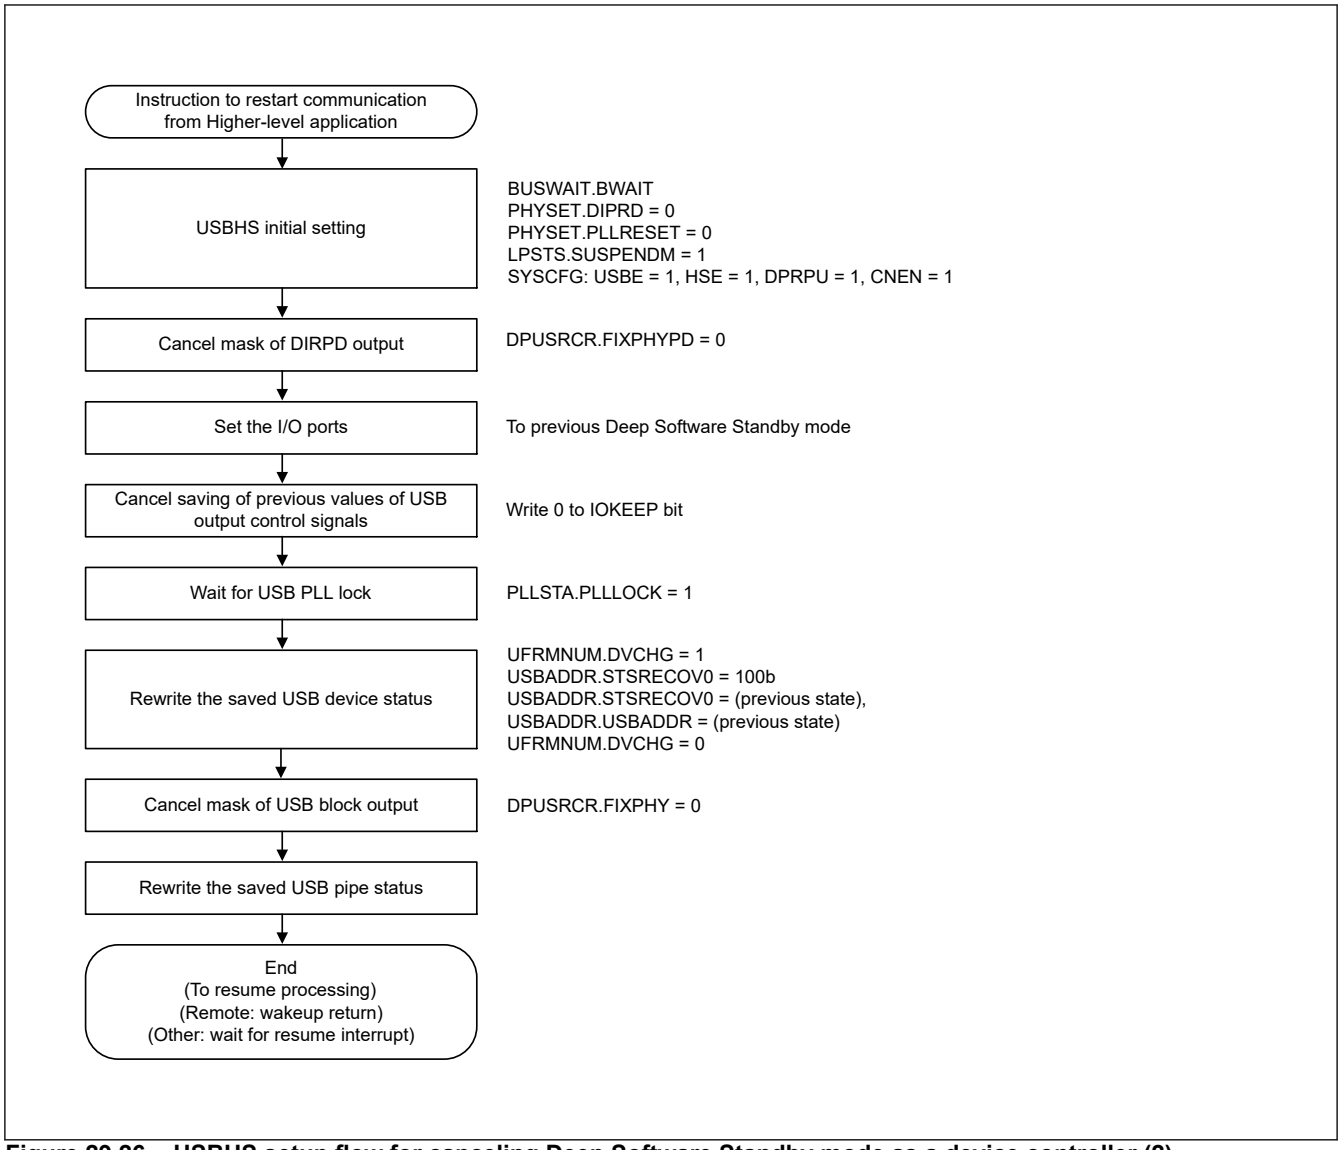

Figure 29.26 USBHS setup flow for canceling Deep Software Standby mode as a device controller (2)

29.3.18 Example External Connection Circuits

Figure 29.27 shows an example OTG connection in a self-powered system. The USBHS controls the pull-up resistor of the D+ line and the pull-down resistor of D+ and D- lines. Select pull-up and pull-down for the lines in the SYSCFG.DPRPU and SYSCFG.DRPD bits. In device controller mode, the pull-up resistor of USB data line is disabled if SYSCFG.DPRPU bit is set to 0 while communicating with the USB host. The USBHS can use this to notify the USB host of a device disconnect.

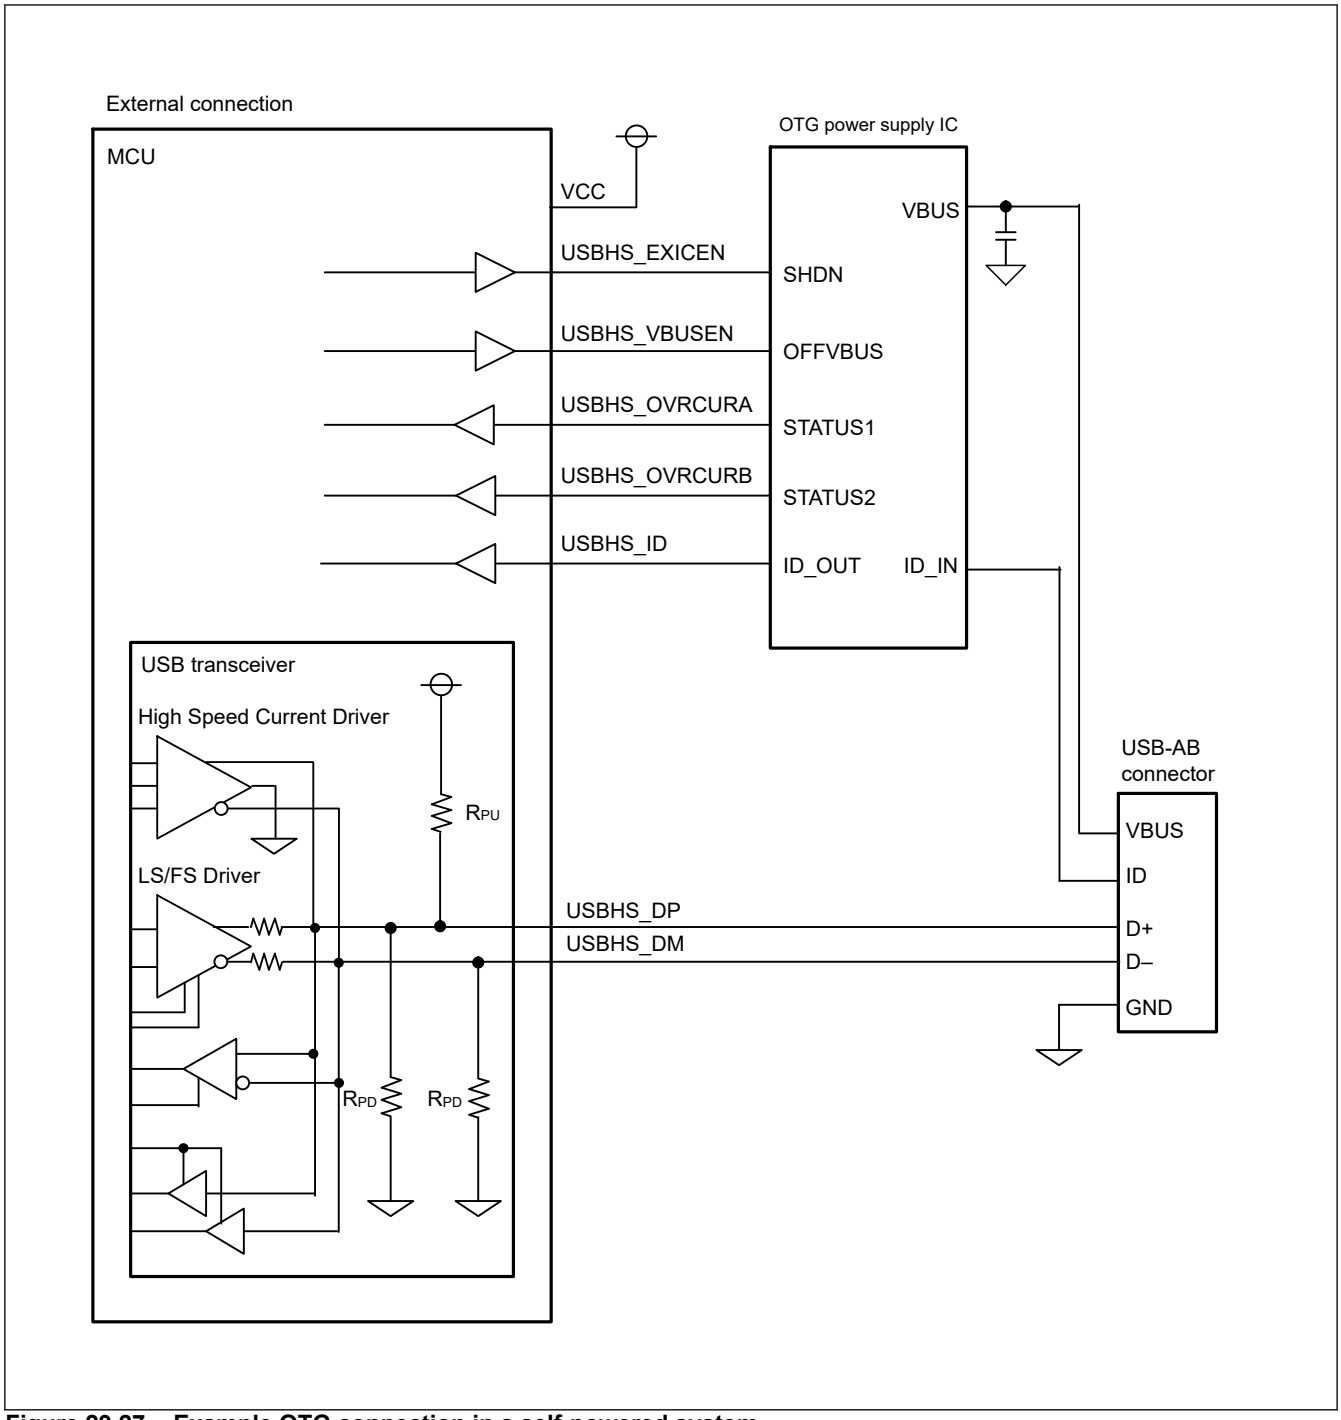

Figure 29.27 Example OTG connection in a self-powered system

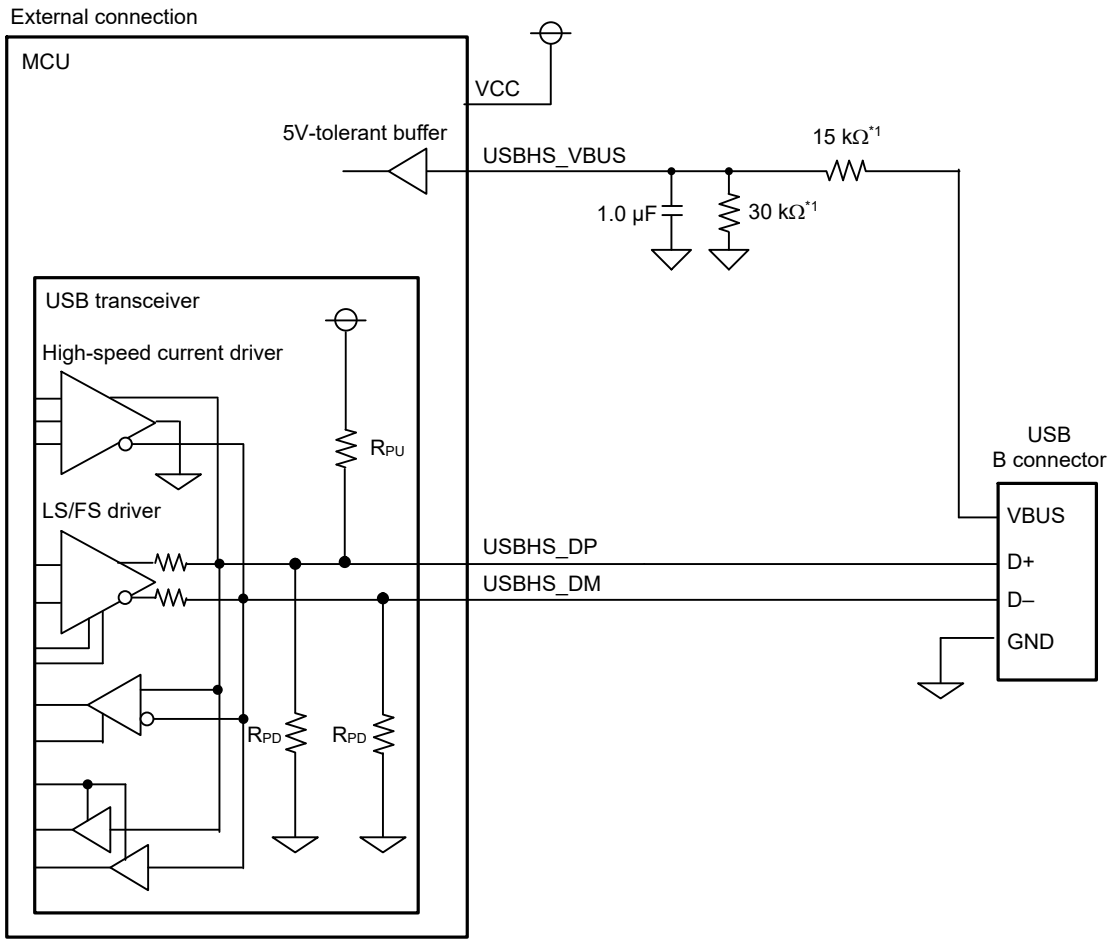
Figure 29.28Figure 33.28 shows an example USB device connection in a self-powered system.



Note 1. The VBUS (5 V) can be directly connected to the MCU if the VCC power supply of the MCU is not turned off when the USB is connected. If the VCC power supply of the MCU is turned off, the VBUS should be less than 3.6 V.

29.4 Usage Notes

29.4.1 Settings for the Module-Stop Function

USBHS operation can be disabled or enabled using Module Stop Control Register B (MSTPCRB). The USBHS is initially stopped after reset. Releasing the module-stop state enables access to the registers. After releasing module stop, make settings required to activate the PHY circuit, including the input system clock frequency setting, and then clear the PHYSET.DIRPD bit to 0. For details, see section 10, Low Power Modes .

29.4.2 Setup for Transitioning to Deep Software Standby Mode

Before transitioning to Deep Software Standby mode, clear the DVSTCTR0.VBUSEN bit to 0.

29.4.3 Clearing the Interrupt Status Register on Exiting Software Standby Mode

Because the input buffer is always enabled in Software Standby mode, an unexpected interrupt might occur under the following conditions:

- When the interrupt is enabled in Normal mode

- When the interrupt is disabled in Software Standby mode
- When the input level of the pin that cancels Software Standby is changed in Software Standby mode

These conditions might cause the associated interrupt flag in the Interrupt Status Register to set unexpectedly. After the MCU exits the Software Standby mode, the unexpected interrupt might be sent to the interrupt controller. To avoid this, always clear the INTSTS0 and INTSTS1 registers in the canceling sequence.

29.4.4 Clearing the Interrupt Status Register after Setting Up the Port Function

The input buffer is disabled before the PmnPFS.PSEL and PmnPFS.PMR ports are set up, so the internal signal is fixed high or low. The input buffer is enabled after the port is set so that the external pin state is propagated to the MCU. An unexpected interrupt might occur at this time, causing the VBINT and OVRCR bits in INTSTS0 and INTSTS1, or other interrupt status flags to set to 1. To avoid a malfunction, always clear the INTSTS0 and INTSTS1 registers after setting up the port.

30. Serial Communications Interface (SCI)

30.1 Overview

The Serial Communications Interface (SCI) × 10 channels have asynchronous and synchronous serial interfaces:

- Asynchronous interfaces (UART and Asynchronous Communications Interface Adapter (ACIA))
- 8-bit clock synchronous interface
- Simple IIC (master-only)
- Simple SPI
- Smart card interface
- Manchester interface
- Extended Serial interface

The smart card interface complies with the ISO/IEC 7816-3 standard for electronic signals and transmission protocol. SCIn (n = 0, 3 to 9) has FIFO buffers to enable continuous and full-duplex communication, and the data transfer speed can be configured independently using an on-chip baud rate generator.

In this section, PCLK refers to PCLKA.

Table 30.1 lists the SCI specifications, Figure 30.1 shows a block diagram of SCI, and Table 30.3 lists the I/O pins.

Table 30.1 SCI specifications (1 of 3)

Parameter		Specifications
Number of modules		10 (SCIn (n = 0 to 9))
Serial communication modes		• Asynchronous • Clock synchronous • Simple IIC • Simple SPI • Smart card interface • Manchester interface (SCIn (n = 3, 4)) • Extended Serial interface (SCIn (n = 1, 2))
Transfer speed		Bit rate specifiable with the on-chip baud rate generator
Full-duplex communications		• Transmitter: Continuous transmission possible using double-buffering • Receiver: Continuous reception possible using double-buffering
Data transfer		Selectable as LSB-first or MSB-first transfer
Inverter for communication terminals (RXDn, TXDn)		Selectable inverter for each terminals (RXDn, TXDn) (SCIn (n = 0, 3 to 9)
Interrupt sources		Transmit end, transmit data empty, receive data full, receive error, receive data ready*, address match*. (* SCIn (n = 0, 3 to 9) support) Completion of generation of a start condition, restart condition, or stop condition. (for simple IIC mode)
Module-stop function		Module-stop state can be set for each channel
Snooze end request		SCI0 address mismatch (SCI0_DCUF)
Clock synchronous mode	Data length	8 bits
	Receive error detection	Overrun error
	Clock source	Selectable to internal clock (master mode) or external clock (slave mode)
	Hardware flow control	Transmission and reception controllable with CTSn_RTSn pins
	Transmission and reception	Selectable to 1-stage register or 16-stage FIFO (only SCIn (n = 0, 3 to 9) supports FIFO)
Asynchronous mode	Data length	7, 8, or 9 bits
	Transmission stop bit	1 or 2 bits
	Adjustment of receive sampling timing	Adjustable receive sampling timing before/after the default timing

Table 30.1 SCI specifications (2 of 3)

Parameter		Specifications
	Adjustment of transmit timing	Adjustable edge timing of transmit waveform controlled by the setting value of registers.
	Parity	Even parity, odd parity, or no parity
	Receive error detection	• Parity error • Overrun error • Framing error
	Hardware flow control	Transmission and reception controllable with CTSn_RTSn pins
	Transmission and reception	Selectable to 1-stage register or 16-stage FIFO (SCIn (n = 0, 3 to 9) supports FIFO)
	Address match	Interrupt request/event output can be issued upon detecting a match between received data and the value in the compare match register (SCIn (n = 0, 3 to 9) support)
	Address mismatch (SCI0 only) receive data	Snooze end request can be issued when detecting a mismatch between the received data and the value in the compare match register
	Start-bit detection	Selectable to low level or falling edge detection
	Break detection	Breaks from framing errors detectable by read from SPTR register
	Clock source	Selectable to internal or external clock Transfer rate clock input from the GPT can be used. (SCIn (n = 1, 2))
	Double-speed mode	Baud rate generator double-speed mode is selectable
	Multi-processor communications function	Serial communication enabled among multiple processors
	Noise cancellation	Digital noise filters included on signal paths from the RXDn pin inputs
Smart card interface mode	Error processing	Error signal can be automatically transmitted upon detecting a parity error during reception
		Data can be automatically retransmitted upon receiving an error signal during transmission
	Data type	Both direct and inverse convention supported
Manchester mode	Communication format	Manchester code with the preface and the Start Bit added
	Data length	7,8, or 9 bits
	Transmission stop bit	1 or 2 bits
	Parity function	Even parity, odd parity, or no parity
	Receive error detection	Parity, overrun, framing, Manchester errors
	Hardware flow control	CTSn and RTSn pins can be used in controlling transmission
	Clock source	Only internal clock can be used.
	Double-speed mode	Baud rate generator double-speed mode is selectable
	Multi-processor communication function	Serial communication among multiple processors
	Noise cancellation	The signal paths from input on the RXDn pins incorporate digital noise filters
	Preface setting / detection function	The function outputs the configured the preface pattern and detects it.
	Start Bit setting / detection function	The function outputs the configured the Start Bit pattern and detects it.
	Reception retiming function	Timing correction is performed for each bit of the received signal
Simple IIC mode	Transfer format	I^2C bus format (MSB-first only)
	Operating mode	Master (single-master operation only)
	Transfer rate	Up to 400 kbps

Table 30.1 SCI specifications (3 of 3)

Parameter		Specifications
	Noise cancellation	The signal paths from input on the SCLn and SDAn pins incorporate digital noise filters and provide an adjustable interval for noise cancellation
Simple SPI mode	Data length	8 bits
	Error detection	Overrun error
	Clock source	Selectable to internal clock (master mode) or external clock (slave mode)
	SSn input pin function	High impedance state can be invoked on the output pins by driving the SSn pin high.
	Clock settings	Configurable among four clock phase and clock polarity settings
Extended serial mode	Start Frame transmission	• Output of a low level as the Break Field over a specified width and generation of interrupts on completion • Detection of bus collisions and the generation of interrupts on detection
	Start Frame reception	• Detection of the Break Field low width and generation of an interrupt on detection • Comparison of Control Fields 0 and 1 and generation of an interrupt when the two match • Two kinds of data for comparison (primary and secondary) can be set in Control Field 1. • A priority interrupt bit can be set in Control Field 1. • Handling of Start Frames that do not include a Break Field • Handling of Start Frames that do not include a Control Field 0 • Function for measuring bit rates
	I/O control function	• Selectable polarity for TXDXn and RXDXn signals • Selection of a digital filter for the RXDXn signal • Half-duplex operation employing RXDXn and TXDXn signals multiplexed on the same pin • Selectable timing for the sampling of data received through RXDXn • Signals received on RXDXn can be passed though to SCIn (n = 1, 2) when the extended serial mode control section is off.
	Timer function	• Usable as a reloading timer
Bit rate modulation function		Error reduction through correction of outputs from the on-chip baud rate generator
Event link function		Error event output for receive error or error signal detection (SCIn_ERI) (n = 0 to 9)
		Receive data full event output (SCIn_RXI) (n = 0 to 9)
		Transmit data empty event output (SCIn_TXI) (n = 0 to 9)
		Address match event output (SCIn_AM) (n = 0, 3 to 9)
		Transmit end event output (SCIn_TEI) (n = 0 to 9)
TrustZone Filter		Security attribution can be set for each channels

Function	Pin name	Input/ Output	Description
SCIn (n = 0 to 9)	RXDn/SCLn/MISOn	Input/ Output	SCIn receive data input SCIn I^2C clock input/output SCIn slave transmit data input/output
	TXDn/SDAn/MOSIn	Input/ Output	SCIn transmit data output SCIn I^2C data input/output SCIn master transmit data input/output
	SSn/CTSn_RTSn	Input/ Output	SCIn chip select input, active-low SCIn transfer start control input/output, active-low
	CTSn (n = 0, 3 to 9)	Input	SCIn transfer start control input, active-low
	RXDXn (n = 1, 2)	Input/ Output	SCIn receive data input (Extended Serial Mode)
	TXDXn/SIOXn (n = 1, 2)	Input/ Output	SCIn transmit data output (Extended Serial Mode) SCIn transmit data input/output (Extended Serial Mode)
	SCKn	Input/ Output	SCIn clock input/output

30.2 Register Descriptions

30.2.1 RSR : Receive Shift Register

RSR is a shift register that receives serial data input from the RXDn pin and converts it into parallel data. When one frame of data is received, the data is automatically transferred to the RDR, RDRHL, or the receive FIFO register. The RSR register cannot be directly accessed by the CPU.

30.2.2 RDR : Receive Data Register

Base address: SCIn = 0x4011_8000 + 0x0100 × n (n = 0, 5 to 9)
SCIk = 0x4011_8000 + 0x0100 × k (k = 3, 4)
SCIm = 0x4011_8000 + 0x0100 × m (m = 1, 2)

Offset address: 0x05

Bit position:	7	6	5	4	3	2	1	0
Bit field:								
Value after reset:	0	0	0	0	0	0	0	0

RDR is an 8-bit register that stores received data. When one frame of serial data is received, it is transferred from RSR to RDR, and the RSR register can receive more data. Because RSR and RDR function as a double buffer, continuous received operations can be performed.

Read the RDR only once after a receive data full interrupt (SCIn_RXI) occurs.

Note: If the next frame of data is received before reading the received data from RDR, an overrun error occurs. The CPU cannot write to the RDR.

30.2.3 RDRHL : Receive Data Register for Non-Manchester mode (MMR.MANEN = 0)

Base address: SCIn = 0x4011_8000 + 0x0100 × n (n = 0, 5 to 9)
SCIk = 0x4011_8000 + 0x0100 × k (k = 3, 4)
SCIm = 0x4011_8000 + 0x0100 × m (m = 1, 2)

Offset address: 0x10

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	RDAT[8:0]								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
8:0	RDAT[8:0]	Serial Receive Data	R
15:9	—	These bits are read as 0.	R

RDRHL is a 16-bit register that stores received data. Use this register when asynchronous mode and 9-bit data length are selected.

The lower 8 bits of RDRHL are the shadow register of RDR, so access to RDRHL affects the RDR register. Access to the RDRHL register is prohibited if 7-bit or 8-bit data length is selected.

After one frame of data is received, the received data is transferred from the RSR register to the RDR/RDRHL registers, allowing the RSR register to receive more data.

The RSR and RDRHL registers form a double-buffered structure to enable continuous reception. RDRHL should be read only when a receive data full interrupt (SCIn_RXI) request is issued. An overrun error occurs when the next frame of data is received before the received data is read from RDRHL. The CPU cannot write to the RDRHL register.

30.2.4 RDRHL_MAN : Receive Data Register for Manchester mode (MMR.MANEN = 1)

Base address: SCIk = 0x4011_8000 + 0x0100 × k (k = 3, 4)

Offset address: 0x10

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	RSYNC	—	—	MPB	RDAT[8:0]								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
8:0	RDAT[8:0]	Serial receive data It can read serial receive data	R
9	MPB	Multi-processor bit It can read multi-processor bit corresponded to serial receive data (RDATA[8:0]) 0: Data transmission cycles 1: ID transmission cycles	R
11:10	—	These bits are read as 0. The write value should be 0.	R
12	RSYNC	Receive SYNC data bit It is valid when MMR.SBSEL = 1 in Manchester mode, 0 is read otherwise. 0: The received the Start Bit is DATA SYNC 1: The received the Start Bit is COMMAND SYNC	R
15:13	—	These bits are read as 0. The write value should be 0.	R

RDRHL_MAN is a 16-bit register that stores received data. Use this register when asynchronous mode and 9-bit data length are selected. The lower 8 bits of RDRHL_MAN are the shadow register of RDR, so access to RDRHL_MAN affects the RDR register. Access to the RDRHL_MAN register is prohibited if 7-bit or 8-bit data length is selected.

After one frame of data is received, the received data is transferred from the RSR register to the RDR/RDRHL_MAN registers, allowing the RSR register to receive more data.

The RSR and RDRHL_MAN registers form a double-buffered structure to enable continuous reception.

RDRHL_MAN should be read only when a receive data full interrupt (SCIn_RXI) request is issued. An overrun error occurs when the next frame of data is received before the received data is read from RDRHL_MAN.

The CPU cannot write to the RDRHL_MAN register.

RDAT[8:0] bit (Serial receive data)

It can read serial receive data.

MPB bit (Multi-processor bit)

Holds the value of the multi-processor bit in the reception frame. This bit does not change when the SCR.RE bit is 0.

RSYNC bit (Receive SYNC data bit)

When Manchester mode and MMR.SBSEL = 1, this bit indicates the type of SYNC of the received the Start Bit. For other settings, it is fixed to 0.

30.2.5 FRDRHL/FRDRH/FRDRL : Receive FIFO Data Register

Base address: SCIn = 0x4011_8000 + 0x0100 × n (n = 0, 5 to 9)
SCIk = 0x4011_8000 + 0x0100 × k (k = 3, 4)

Offset address: 0x10 (FRDRHL/FRDRH)
0x11 (FRDRL)

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	RDF	ORER	FER	PER	DR	MPB	RDAT[8:0]								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
8:0	RDAT[8:0]	Serial receive data Stores the serial receive data. Valid only in asynchronous mode, including multi-processor mode, and clock synchronous mode, and with FIFO selected.	R
9	MPB	Multi-Processor Bit Flag Stores the value of the multi-processor bit in the serial receive data, RDAT[8:0]. Valid only in asynchronous mode with SMR.MP = 1, and with FIFO selected. 0: Data transmission cycle 1: ID transmission cycle	R
10	DR	Receive Data Ready Flag This flag is the same as SSR_FIFO.DR. 0: Receiving is in progress, or no received data remains in the FRDRH and FRDRL registers after successfully completed reception 1: Next receive data is not received for a period after successfully completed reception	R*1
11	PER	Parity Error Flag 0: No parity error occurred in the first data of FRDRH and FRDRL 1: Parity error occurred in the first data of FRDRH and FRDRL	R
12	FER	Framing Error Flag 0: No framing error occurred in the first data of FRDRH and FRDRL 1: Framing error occurred in the first data of FRDRH and FRDRL	R
13	ORER	Overrun Error Flag This flag is the same as SSR_FIFO.ORER. 0: No overrun error occurred 1: Overrun error occurred	R*1
14	RDF	Receive FIFO Data Full Flag This flag is the same as SSR_FIFO.RDF. 0: The amount of receive data written in FRDRH and FRDRL is less than the specified receive triggering number 1: The amount of receive data written in FRDRH and FRDRL is equal to or greater than the specified receive triggering number	R*1
15	—	This bit is read as 0.	R

Note 1. If this flag is read, it indicates the same value as that read from the SSR_FIFO register. Write 0 to the SSR_FIFO register to clear the flag.

FRDRHL is a 16-bit register that consists of the 8-bit FRDRH and FRDRL registers. FRDRH is assigned to the FRDRHL[15:8] bits, and allocated to the same address as FRDRHL. FRDRL is assigned to the FRDRHL[7:0] bits, and allocated to (the address of FRDRHL + 1) address.

FRDRH and FRDRL constitute a 16-stage FIFO register that stores serial receive data and related status information readable by software. This register is only valid in asynchronous mode, including multi-processor mode, or clock synchronous mode.

The SCI completes reception of one frame of serial data by transferring the received data from the Receive Shift Register (RSR) into FRDRH and FRDRL for storage. Continuous reception is executed until 16 stages are stored. If data is read when there is no received data in FRDRH and FRDRL, the value is undefined. When FRDRH and FRDRL are full, subsequent serial receive data is lost. The CPU can read from the FRDRH and FRDRL registers but cannot write to them.

Reading 1 from the RDF, ORER, or DR flags of the FRDRH register is the same as reading from those bits in the SSR_FIFO register. When writing 0 to clear a flag in the SSR_FIFO register after reading the FRDRH register, write 0 only to the flag that is to be cleared and write 1 to the other flags.

When reading both the FRDRH and FRDRL registers, read in order from FRDRH to FRDRL. The FRDRHL register can be accessed in 16-bit units.

30.2.6 TDR : Transmit Data Register

Base address: SCIn = 0x4011_8000 + 0x0100 × n (n = 0, 5 to 9)
SCIk = 0x4011_8000 + 0x0100 × k (k = 3, 4)
SCIm = 0x4011_8000 + 0x0100 × m (m = 1, 2)

Offset address: 0x03

Bit position:	7	6	5	4	3	2	1	0
Bit field:								
Value after reset:	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
7:0	n/a	Serial Transmit Data	R/W

TDR is an 8-bit register that stores transmit data.

When the SCI detects that the TSR register is empty, it transfers the transmit data written in the TDR register to the TSR register and starts transmission.

The double-buffered structure of the TDR and TSR registers enables continuous serial transmission. If the next transmit data is already written to TDR when one frame of data is transmitted, the SCI transfers the written data to the TSR register to continue transmission.

The CPU can read from or write to TDR at any time. Only write transmit data to TDR once after each instance of the transmit data empty interrupt (SCIn_TXI).

30.2.7 TDRHL : Transmit Data Register for Non-Manchester mode (MMR.MANEN = 0)

Base address: SCIn = 0x4011_8000 + 0x0100 × n (n = 0, 5 to 9)
SCIk = 0x4011_8000 + 0x0100 × k (k = 3, 4)
SCIm = 0x4011_8000 + 0x0100 × m (m = 1, 2)

Offset address: 0x0E

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	TDAT[8:0]								
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
8:0	TDAT[8:0]	Serial Transmit Data	R/W
15:9	—	This bit is read as 1. The write value should be 1.	R/W

TDRHL is a 16-bit register that stores transmit data. Use this register when asynchronous mode and 9-bit data length are selected.

The lower 8 bits of TDRHL are the shadow register of TDR, so access to TDRHL affects the TDR register. Access to the TDRHL register is prohibited if 7-bit or 8-bit data length is selected.

When empty space is detected in the TSR register, the transmit data stored in the TDRHL registers is transferred to TSR and transmission starts.

The TSR and TDRHL registers have a double-buffered structure to support continuous transmission. When the next data to be transmitted is stored in TDRHL after one frame of data is transmitted, the transmitting operation continues by transferring the data to the TSR register.

The CPU can read and write to the TDRHL register. Bits [15:9] in TDRHL are fixed to 1. These bits are read as 1. The write value should be 1.

Write transmit data to theTDRHL register only once when a transmit data empty interrupt (SCIn_TXI) request is issued.

30.2.8 TDRHL_MAN : Transmit Data Register for Manchester mode (MMR.MANEN = 1)

Base address: SCIk = 0x4011_8000 + 0x0100 × k (k = 3, 4)

Offset address: 0x0E

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	TSYNC	—	—	MPBT	TDAT[8:0]								
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
8:0	TDAT[8:0]	Serial transmit data It can set serial transmit data	R/W
9	MPBT	Multi-processor transfer bit flag Value of the multi-processor bit in the transmission frame 0: Data transmission cycles 1: ID transmission cycles	R/W
11:10	—	The write value should be 1.	R
12	TSYNC	Transmit SYNC data bit It is valid when MMR.SBSEL = 1 and MMR.SYNSEL = 1 in Manchester mode. 0: The Start Bit is transmitted as DATA SYNC. 1: The Start Bit is transmitted as COMMAND SYNC.	R/W
15:13	—	The write value should be 1.	R

TDRHL_MAN is a 16-bit register that stores transmit data. Use this register when asynchronous mode and 9-bit data length are selected.

The lower 8 bits of TDRHL_MAN are the shadow register of TDR, so access to TDRHL_MAN affects the TDR register. Access to the TDRHL_MAN register is prohibited if 7-bit or 8-bit data length is selected.

When empty space is detected in the TSR register, the transmit data stored in the TDRHL_MAN registers is transferred to TSR and transmission starts.

The TSR and TDRHL_MAN registers have a double-buffered structure to support continuous transmission. When the next data to be transmitted is stored in TDRHL_MAN after one frame of data is transmitted, the transmitting operation continues by transferring the data to the TSR register.

Write transmit data to theTDRHL_MAN register only once when a transmit data empty interrupt (SCIn_TXI) request is issued.

TDAT[8:0] bit (Serial transmit data)

This register sets serial transmission data.

MPBT bit (Multi-processor transfer bit flag)

Selects the multi processor bit of transmit frame.

TSYNC bit (Transmit SYNC data bit)

When Manchester mode and MMR.SBSEL = "1" and MMR.SYNSEL = "1",the type of SYNC selected according to this bit becames the Start Bit of the transmission frame.

30.2.9 FTDRHL/FTDRH/FTDRL : Transmit FIFO Data Register

Base address: SCIn = 0x4011_8000 + 0x0100 × n (n = 0, 5 to 9)
SCIk = 0x4011_8000 + 0x0100 × k (k = 3, 4)

Offset address: 0x0E (FTDRHL/FTDRH)
0x0F (FTDRL)

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	MPBT	TDAT[8:0]								
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
8:0	TDAT[8:0]	Serial transmit data Specifies the serial transmit data. Valid only in asynchronous mode, including multi-processor mode, and clock synchronous mode, and with FIFO selected.	W
9	MPBT	Multi-Processor Transfer Bit Flag Specifies the multi-processor bit in the transmission frame. Valid only in asynchronous mode and SMR.MP = 1, and with FIFO selected.Valid only in asynchronous mode, including multi-processor mode, and clock synchronous mode, and with FIFO selected. 0: Data transmission cycle 1: ID transmission cycle	W
15:10	—	The write value should be 1.	W

FTDRHL is a 16-bit register that consists of the 8-bit FTDRH and FTDRL registers. FTDRH is assigned to the FTDRHL[15:8] bits, and allocated to the same address as FTDRHL. FTDRL is assigned to the FTDRHL[7:0] bits, and allocated to (the address of FTDRHL + 1) address.

FTDRH and FTDRL constitute a 16-stage FIFO register that stores data for serial transmission and a multi-processor transfer bit. This register is only valid in asynchronous mode, including multi-processor mode, or clock synchronous mode.

When the SCI detects that the Transmit Shift Register (TSR) is empty, it transfers data written in the FTDRH and FTDRL registers to the TSR register and starts serial transmission. Continuous serial transmission is executed until no transmit data is left in FTDRH and FTDRL. When FTDRHL is full of transmit data, no more data can be written. If writing new data is attempted, the data is ignored. The CPU can write to the FTDRH and FTDRL registers but cannot read them.

When writing to both the FTDRH and FTDRL registers, write in order from FTDRH to FTDRL.

TDAT[8:0] bits (Serial transmit data)

The TDAT[8:0] bits set the serial transmission data. This is valid only when FIFO is selected in asynchronous mode (including multiprocessor) or clock synchronous mode.

MPBT flag (Multi-Processor Transfer Bit Flag)

The MPBT flag specifies the value of the multi-processor bit of the transmit frame. When FCR.FM = 1, SSR.MPBT is invalid.

30.2.10 TSR : Transmit Shift Register

TSR is a shift register that transmits serial data. To perform serial data transmission, the SCI first automatically transfers transmit data from TDR, TDRHL, or transmit FIFO to TSR, then sends the data to the TXDn pin. The CPU cannot directly access the TSR.

30.2.11 SMR : Serial Mode Register for Non-Smart Card Interface Mode (SCMR.SMIF = 0)

Base address: SCIn = 0x4011_8000 + 0x0100 × n (n = 0, 5 to 9)
SCIk = 0x4011_8000 + 0x0100 × k (k = 3, 4)
SCIm = 0x4011_8000 + 0x0100 × m (m = 1, 2)

Offset address: 0x00

Bit position:	7	6	5	4	3	2	1	0
Bit field:	CM	CHR	PE	PM	STOP	MP	CKS[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	CKS[1:0]	Clock Select 0 0: PCLK clock (n = 0)*1 0 1: PCLK/4 clock (n = 1)*1 1 0: PCLK/16 clock (n = 2)*1 1 1: PCLK/64 clock (n = 3)*1	R/W*4
2	MP	Multi-Processor Mode Valid only in asynchronous mode. 0: Disable multi-processor communications function 1: Enable multi-processor communications function	R/W*4
3	STOP	Stop Bit Length Valid only in asynchronous mode. 0: 1 stop bit 1: 2 stop bits	R/W*4
4	PM	Parity Mode Valid only when the PE bit is 1. 0: Even parity 1: Odd parity	R/W*4
5	PE	Parity Enable Valid only in asynchronous mode. 0: When transmitting: Do not add parity bit When receiving: Do not check parity bit 1: When transmitting: Add parity bit When receiving: Check parity bit	R/W*4
6	CHR	Character Length Valid only in asynchronous mode.*2 Selects the transmit/receive character length in combination with the SCMR.CHR1 bit. 0: SCMR.CHR1 = 0: Transmit/receive in 9-bit data length SCMR.CHR1 = 1: Transmit/receive in 8-bit data length (initial value) 1: SCMR.CHR1 = 0: Transmit/receive in 9-bit data length SCMR.CHR1 = 1: Transmit/receive in 7-bit data length*3	R/W*4
7	CM	Communication Mode 0: Asynchronous mode or simple IIC mode 1: Clock synchronous mode or simple SPI mode	R/W*4

Note 1. n is the decimal notation of the value of n in the BRR register. See section 30.2.20. BRR : Bit Rate Register.
Note 2. In any mode other than asynchronous mode, this bit setting is invalid and a fixed data length of 8 bits is used.
Note 3. LSB-first is fixed and the MSB (bit [7]) in the TDR register is not transmitted in transmit mode.
Note 4. Writable only when SCR.TE = 0 and SCR.RE = 0 (both serial transmission and reception are disabled).

The SMR register sets the communication format and clock source for the on-chip baud rate generator.

CKS[1:0] bits (Clock Select)

The CKS[1:0] bits select the clock source for the on-chip baud rate generator. For the relationship between the settings of these bits and the baud rate, see section 30.2.20. BRR : Bit Rate Register.

MP bit (Multi-Processor Mode)

The MP bit disables or enables the multi-processor communications function. The PE and PM bit settings are invalid in multi-processor mode.

STOP bit (Stop Bit Length)

The STOP bit selects the stop bit length in transmission.

In reception, only the first stop bit is checked regardless of this bit setting. If the second stop bit is 0, it is treated as the start bit of the next transmit frame.

PM bit (Parity Mode)

The PM bit selects the parity mode (even or odd) for transmission and reception. The PM bit setting is invalid in multiprocessor mode.

PE bit (Parity Enable)

When the PE bit is set to 1, the parity bit is added to transmit data, and the parity bit is checked in reception. Regardless of the PE bit setting, the parity bit is not added or checked in multi-processor format.

CHR bit (Character Length)

The CHR bit selects the data length for transmission and reception in combination with the SCMR.CHR1 bit. In modes other than asynchronous, a fixed data length of 8 bits is used.

CM bit (Communication Mode)

The CM bit selects the communication mode:

- Asynchronous mode or simple IIC mode
- Clock synchronous mode or simple SPI mode

30.2.12 SMR_SMCI : Serial Mode Register for Smart Card Interface Mode (SCMR.SMIF = 1)

Base address: SCIn = 0x4011_8000 + 0x0100 × n (n = 0, 5 to 9)
SCIk = 0x4011_8000 + 0x0100 × k (k = 3, 4)
SCIm = 0x4011_8000 + 0x0100 × m (m = 1, 2)

Offset address: 0x00

Bit position:	7	6	5	4	3	2	1	0
Bit field:	GM	BLK	PE	PM	BCP[1:0]		CKS[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	CKS[1:0]	Clock Select 0 0: PCLK clock (n = 0)*1 0 1: PCLK/4 clock (n = 1)*1 1 0: PCLK/16 clock (n = 2)*1 1 1: PCLK/64 clock (n = 3)*1	R/W*2
3:2	BCP[1:0]	Base Clock Pulse Selects the number of base clock cycles in combination with the SCMR.BCP2 bit. Table 30.4 lists the combinations of the SCMR.BCP2 and SMR.BCP[1:0] bits.	R/W*2
4	PM	Parity Mode Valid only when the PE bit is 1. 0: Even parity 1: Odd parity	R/W*2
5	PE	Parity Enable When this bit is set to 1, a parity bit is added to transmit data, and the parity of received data is checked. Set this bit to 1 in smart card interface mode.	R/W*2

Bit	Symbol	Function	R/W
6	BLK	Block Transfer Mode 0: Normal mode operation 1: Block transfer mode operation	R/W*2
7	GM	GSM Mode 0: Normal mode operation 1: GSM mode operation	R/W*2

Note 1. n is the decimal notation of the value of n in the BRR register. See section 30.2.20. BRR : Bit Rate Register.
Note 2. Writable only when SCR_SMCI.TE = 0 and SCR_SMCI.RE = 0 (both serial transmission and reception are disabled).

The SMR_SMCI register sets the communication format and clock source for the on-chip baud rate generator.

CKS[1:0] bits (Clock Select)

The CKS[1:0] bits select the clock source for the on-chip baud rate generator. For the relationship between the settings of these bits and the baud rate, see section 30.2.20. BRR : Bit Rate Register.

BCP[1:0] bits (Base Clock Pulse)

The BCP[1:0] bits select the number of base clock cycles in a 1-bit data transfer time in smart card interface mode. Set these bits in combination with the SCMR.BCP2 bit.

For details, see section 30.7.4. Receive Data Sampling Timing and Reception Margin.

Table 30.4 Combinations of SCMR.BCP2 and SMR_SMCI.BCP[1:0] bits

SCMR.BCP2 bit	SMR_SMCI.BCP[1:0] bits	Number of base clock cycles for 1-bit transfer period*1
0	00b	93 clock cycles (S = 93)
0	01b	128 clock cycles (S = 128)
0	10b	186 clock cycles (S = 186)
0	11b	512 clock cycles (S = 512)
1	00b	32 clock cycles (S = 32) (initial value)
1	01b	64 clock cycles (S = 64)
1	10b	372 clock cycles (S = 372)
1	11b	256 clock cycles (S = 256)

Note 1. S is the value of S in BRR (see section 30.2.20. BRR : Bit Rate Register).

PM bit (Parity Mode)

The PM bit selects the parity mode for transmission and reception (even or odd). For details on the usage of this bit in smart card interface mode, see section 30.7.2. Data Format (Except in Block Transfer Mode).

PE bit (Parity Enable)

Set the PE bit to 1. The parity bit is added to transmit data before transmission, and the parity bit is checked in reception.

BLK bit (Block Transfer Mode)

Setting the BLK bit to 1 enables block transfer mode operation. For details, see section 30.7.3. Block Transfer Mode.

GM bit (GSM Mode)

Setting the GM bit to 1 enables GSM mode operation. In GSM mode, the SSR_SMCI.TEND flag set timing is moved forward to 11.0 etus (elementary time unit = 1-bit transfer time) from the start bit, and clock output control is added. For details, see section 30.7.6. Serial Data Transmission (Except in Block Transfer Mode) and section 30.7.8. Clock Output Control.

30.2.13 SCR : Serial Control Register for Non-Smart Card Interface Mode (SCMR.SMIF = 0)

Base address: SCIn = 0x4011_8000 + 0x0100 × n (n = 0, 5 to 9)
SCIk = 0x4011_8000 + 0x0100 × k (k = 3, 4)
SCIm = 0x4011_8000 + 0x0100 × m (m = 1, 2)

Offset address: 0x02

Bit position:	7	6	5	4	3	2	1	0
Bit field:	TIE	RIE	TE	RE	MPIE	TEIE	CKE[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	CKE[1:0]	Clock Enable 0 0: In asynchronous mode, the SCKn pin is available for use as an I/O port based on the I/O port settings. In clock synchronous mode, the SCKn pin functions as the clock output pin. 0 1: In asynchronous mode, a clock with the same frequency as the bit rate is output from the SCKn pin. In clock synchronous mode, the SCKn pin functions as the clock output pin. Others: In asynchronous mode, input a clock with a frequency 16 times the bit rate from the SCKn pin when the SEMR.ABCS bit is 0. Input a clock signal with a frequency eight times the bit rate when the SEMR.ABCS bit is 1. The SCKn pin is available for use as an I/O port based on the I/O port settings when the GPT clock*4 is used. In clock synchronous mode, the SCKn pin functions as the clock input pin.	R/W*1
2	TEIE	Transmit End Interrupt Enable 0: Disable SCIn_TEI interrupt requests 1: Enable SCIn_TEI interrupt requests	R/W
3	MPIE	Multi-Processor Interrupt Enable Valid in asynchronous mode when SMR.MP = 1. 0: Normal reception 1: When data with the multi-processor bit set to 0 is received, the data is not read, and setting the status flags RDRF, ORER, and FER in SSR to 1 and the status flags SYER, PFER, and SBER in MESR are disabled. When data with the multi-processor bit set to 1 is received, the MPIE bit is automatically set to 0, and normal reception is resumed.	R/W*3
4	RE	Receive Enable 0: Disable serial reception 1: Enable serial reception	R/W*2
5	TE	Transmit Enable 0: Disable serial transmission 1: Enable serial transmission	R/W*2
6	RIE	Receive Interrupt Enable 0: Disable SCIn_RXI and SCIn_ERI interrupt requests 1: Enable SCIn_RXI and SCIn_ERI interrupt requests	R/W
7	TIE	Transmit Interrupt Enable 0: Disable SCIn_TXI interrupt requests 1: Enable SCIn_TXI interrupt requests	R/W

Note 1. Writable only when TE = 0 and RE = 0.
Note 2. 1 can be written only when TE = 0 and RE = 0, when the SMR.CM bit is 1. After setting TE or RE to 1, only 0 can be written to TE and RE. When the SMR.CM bit is 0 and the SIMR1.IICM bit is 0, writing is enabled under any condition.
Note 3. When writing a new value to a bit other than the MPIE bit of this register in multi-processor mode (SMR.MP bit = 1), write 0 to the MPIE bit using the store instruction to avoid accidentally setting the MPIE bit to 1 by a read-modify-write operation when using a bit manipulation instruction.
Note 4. GPT clock is selectable for SCI1 and SCI2.

The SCR register controls operation and clock source selection for transmission and reception.

CKE[1:0] bits (Clock Enable)

The CKE[1:0] bits select the clock source and the SCKn pin function.

TEIE bit (Transmit End Interrupt Enable)

The TEIE bit enables or disables SCIn_TEI interrupt requests. Set TEIE to 0 to disable an SCIn_TEI interrupt request.

In simple IIC mode, SCIn_TEI is allocated to the interrupt on completion of issuing a start, restart, or stop condition (STIn). In this case, the TEIE bit can be used to enable or disable the STI.

MPIE bit (Multi-Processor Interrupt Enable)

When the MPIE bit is set to 1 and data with the multi-processor bit set to 0 is received, the data is not read and setting the status flags RDRF, ORER, FER, RDF, and DR in SSR/SSR_FIFO to 1 is disabled. When data with the multi-processor bit set to 1 is received, the MPIE bit is automatically set to 0, and normal reception resumes. For details, see section 30.4. Multi-Processor Communication Function.

When the MPB bit in the SSR register is 0, the receive data is not transferred from the RSR register to the RDR register, a receive error is not detected, and setting the flags ORER and FER to 1 is disabled.

When the MPB bit is set to 1, the MPIE bit is automatically set to 0, SCIn_RXI and SCIn_ERI interrupt requests are enabled (if the RIE bit in SCR is set to 1), and setting of the ORER and FER flags to 1 is enabled.

Set MPIE to 0 if the multi-processor communications function is not used.

RE bit (Receive Enable)

The RE bit enables or disables serial reception. When the RE bit is set to 1, serial reception starts by detecting the start bit in asynchronous mode or the synchronous clock input in clock synchronous mode. Set the reception format in the SMR register before setting the RE bit to 1.

In non-FIFO operation, when reception is halted by setting the RE bit to 0, the RDRF, ORER, FER, and PER flags in the SSR register are not affected, and the previous values are retained.

When FIFO operation is selected and reception is halted by setting the RE bit to 0, the RDF, ORER, FER, PER, and DR flags in SSR_FIFO are not affected and the previous values are retained.

TE bit (Transmit Enable)

The TE bit enables or disables serial transmission.

When the TE bit is set to 1, serial transmission is started by writing transmit data to the TDR register. Set the transmission format in the SMR register before setting the TE bit to 1.

RIE bit (Receive Interrupt Enable)

The RIE bit enables or disables SCIn_RXI and SCIn_ERI interrupt requests.

SCIn_RXI and SCIn_ERI interrupt requests are disabled by setting the RIE bit to 0.

An SCIn_ERI interrupt request can be canceled by reading 1 from the ORER, FER, or PER flag in SSR/SSR_FIFO then setting the flag to 0, or by setting the RIE bit to 0.

TIE bit (Transmit Interrupt Enable)

The TIE bit enables or disables SCIn_TXI interrupt requests. SCIn_TXI interrupt requests are disabled by setting the TIE bit to 0.

Note: To switch the TIE bit value from 0 to 1 in FIFO mode, set the TIE and TE bits to 1 simultaneously or set the TIE bit to 1 when TE = 1. When TE = 0 in FIFO mode, setting the TIE bit to 1 is prohibited.

30.2.14 SCR_SMCI : Serial Control Register for Smart Card Interface Mode (SCMR.SMIF = 1)

Base address: SCIn = 0x4011_8000 + 0x0100 × n (n = 0, 5 to 9)
SCIk = 0x4011_8000 + 0x0100 × k (k = 3, 4)
SCIm = 0x4011_8000 + 0x0100 × m (m = 1, 2)

Offset address: 0x02

Bit position:	7	6	5	4	3	2	1	0
Bit field:	TIE	RIE	TE	RE	MPIE	TEIE	CKE[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	CKE[1:0]	Clock Enable 0 0: When SMR_SMCI.GM = 0: Disable output The SCKn pin is available for use as an I/O port if set up in the I/O port settings When SMR_SMCI.GM = 1: Fix output low 0 1: When SMR_SMCI.GM = 0: Output clock When SMR_SMCI.GM = 1: Output clock 1 0: When SMR_SMCI.GM = 0: Setting prohibited When SMR_SMCI.GM = 1: Fix output high 1 1: When SMR_SMCI.GM = 0: Setting prohibited When SMR_SMCI.GM = 1: Output clock	R/W*1
2	TEIE	Transmit End Interrupt Enable Set this bit to 0 in smart card interface mode	R/W
3	MPIE	Multi-Processor Interrupt Enable Set this bit to 0 in smart card interface mode	R/W
4	RE	Receive Enable 0: Disable serial reception 1: Enable serial reception	R/W*2
5	TE	Transmit Enable 0: Disable serial transmission 1: Enable serial transmission	R/W*2
6	RIE	Receive Interrupt Enable 0: Disable SCIn_RXI and SCIn_ERI interrupt requests 1: Enable SCIn_RXI and SCIn_ERI interrupt requests	R/W
7	TIE	Transmit Interrupt Enable 0: Disable SCIn_TXI interrupt requests 1: Enable SCIn_TXI interrupt requests	R/W

Note 1. Writable only when TE = 0 and RE = 0.
Note 2. 1 can be written only when TE = 0 and RE = 0. After setting TE or RE to 1, only 0 can be written to TE and RE.

The SCR_SMCI register sets transmission and reception control, interrupt control, and clock source selection for transmission and reception.

For details on interrupt requests, see section 30.12. Interrupt Sources.

CKE[1:0] bits (Clock Enable)

The CKE[1:0] bits control the clock output from the SCKn pin. In GSM mode, clock output can be dynamically switched. For details, see section 30.7.8. Clock Output Control.

TEIE bit (Transmit End Interrupt Enable)

Set the TEIE bit to 0 in smart card interface mode.

MPIE bit (Multi-Processor Interrupt Enable)

Set the MPIE bit to 0 in smart card interface mode.

RE bit (Receive Enable)

The RE bit enables or disables serial reception. When the RE bit is set to 1, serial reception starts by detecting the start bit. Set the reception format in the SMR_SMCI register before setting the RE bit to 1.

If reception is halted by setting the RE bit to 0, the ORER, FER, and PER flags in SSR_SMCI are not affected and the previous values are retained.

TE bit (Transmit Enable)

The TE bit enables or disables serial transmission. When the TE bit is set to 1, serial transmission is started by writing transmit data to TDR. Set the transmission format in the SMR_SMCI register before setting the TE bit to 1.

RIE bit (Receive Interrupt Enable)

The RIE bit enables or disables SCIn_RXI and SCIn_ERI interrupt requests.

SCIn_RXI and SCIn_ERI interrupt requests are disabled by setting the RIE bit to 0.

An SCIn_ERI interrupt request can be canceled by reading 1 from the ORER, FER, or PER flag in the SSR_SMCI register, and then setting the flag to 0, or by setting the RIE bit to 0.

TIE bit (Transmit Interrupt Enable)

The TIE bit enables or disables SCIn_TXI interrupt requests. SCIn_TXI interrupt requests are disabled by setting the TIE bit to 0.

30.2.15 SSR : Serial Status Register for Non-Smart Card Interface and Non-FIFO Mode (SCMR.SMIF = 0, FCR.FM = 0, and MMR.MANEN = 0)

Base address: SCIn = 0x4011_8000 + 0x0100 × n (n = 0, 5 to 9)
SCIk = 0x4011_8000 + 0x0100 × k (k = 3, 4)
SCIm = 0x4011_8000 + 0x0100 × m (m = 1, 2)

Offset address: 0x04

Bit position:	7	6	5	4	3	2	1	0
Bit field:	TDRE	RDRF	ORER	FER	PER	TEND	MPB	MPBT
Value after reset:	1	0	0	0	0	1	0	0

Bit	Symbol	Function	R/W
0	MPBT	Multi-Processor Bit Transfer Sets the value of the multi-processor bit in the transmission frame. 0: Data transmission cycle 1: ID transmission cycle	R/W
1	MPB	Multi-Processor Value of the multi-processor bit in the reception frame. 0: Data transmission cycle 1: ID transmission cycle	R
2	TEND	Transmit End Flag 0: A character is being transmitted 1: Character transfer is complete	R
3	PER	Parity Error Flag 0: No parity error occurred 1: Parity error occurred	R/(W)*1
4	FER	Framing Error Flag 0: No framing error occurred 1: Framing error occurred	R/(W)*1
5	ORER	Overrun Error Flag 0: No overrun error occurred 1: Overrun error occurred	R/(W)*1

Bit	Symbol	Function	R/W
6	RDRF	Receive Data Full Flag 0: No received data in RDR register 1: Received data in RDR register	R/(W)*1
7	TDRE	Transmit Data Empty Flag 0: Transmit data in TDR register 1: No transmit data in TDR register	R/(W)*1

Note 1. Only 0 can be written to clear the flag after reading 1.

The SSR register provides SCI status flags and transmission and reception multi-processor bits.

MPBT bit (Multi-Processor Bit Transfer)

The MPBT bit sets the value of the multi-processor bit in the transmit frame.

MPB bit (Multi-Processor)

The MPB bit holds the value of the multi-processor bit in the reception frame. This bit does not change when the SCR.RE bit is 0.

TEND flag (Transmit End Flag)

The TEND flag indicates completion of transmission.

[Setting conditions]

- When the SCR.TE bit is set to 0 (serial transmission is disabled) and the FCR.FM bit is set to 0 (non-FIFO selected). When the SCR.TE bit is set to 1, the TEND flag is not affected and retains the value 1.
- When the TDR register is not updated on transmission of the tail-end bit of a character being transmitted.

[Clearing conditions]

- When transmit data is written to the TDR register while the SCR.TE bit is 1
- When 0 is written to TDRE after reading TDRE = 1 while the SCR.TE bit is 1

PER flag (Parity Error Flag)

The PER flag indicates that a parity error occurred during reception in asynchronous mode and the reception ended abnormally.

[Setting condition]

- When a parity error is detected during reception in asynchronous mode when the address match function is disabled (DCCR.DCME = 0).

  Although receive data is transferred to the RDR register when the parity error occurs, no SCIn_RXI interrupt request occurs. When the PER flag is set to 1, the subsequent receive data is not transferred to the RDR register.

[Clearing condition]

- When 0 is written to PER after reading PER = 1. After writing 0 to the PER flag, read the PER flag to check that it is actually set to 0.

When the SCR.RE bit is set to 0 (serial reception is disabled), the PER flag is not affected and retains its previous value.

FER flag (Framing Error Flag)

The FER flag indicates that a framing error occurred during reception in asynchronous mode and the reception ended abnormally.

[Setting condition]

- When 0 is sampled as the stop bit during reception in asynchronous mode when the address match function is disabled (DCCR.DCME = 0).

  In 2-stop-bit mode, only the first stop bit is checked. The second stop bit is not checked. Although receive data is transferred to the RDR register when the framing error occurs, no SCIn_RXI interrupt request occurs. When the FER flag is to 1, the subsequent receive data is not transferred to the RDR register.

[Clearing condition]

- When 0 is written to FER after reading FER = 1. After writing 0 to the FER flag, read the FER flag to check that it is actually set to 0.

When the SCR.RE bit is set to 0 (serial reception is disabled), the FER flag is not affected and retains its previous value.

ORER flag (Overrun Error Flag)

The ORER flag indicates that an overrun error occurred during reception and the reception ended abnormally.

[Setting condition]

- When the next data is received before receive data that does not have a parity error and a framing error is read from the RDR register.

  The data received before an overrun error occurred is saved in the RDR register, but data received after the error is lost. When the ORER flag is set to 1, receive data is not forwarded to the RDR register. In clock synchronous mode, serial transmission and reception are stopped.

[Clearing condition]

- When 0 is written to ORER after reading ORER = 1. After writing 0 to the ORER flag, read the ORER flag to check that it is actually set to 0.

When the SCR.RE bit is set to 0 (serial reception is disabled), the ORER flag is not affected and retains its previous value.

RDRF flag (Receive Data Full Flag)

The RDRF flag indicates the presence of receive data in the RDR register.

[Setting condition]

- When the reception ends normally, and receive data is forwarded from the RSR register to the RDR register.

[Clearing conditions]

- When 0 is written to RDRF after reading RDRF = 1
- When data is forwarded from the RDR register

TDRE flag (Transmit Data Empty Flag)

The TDRE flag indicates the presence of transmit data in the TDR register.

[Setting conditions]

- When the SCR.TE bit is 0
- When data is transmitted from the TDR register to the TSR register

[Clearing conditions]

- When 0 is written to TDRE after reading TDRE = 1
- When the SCR.TE bit is 1 and data is written to the TDR register

30.2.16 SSR_FIFO : Serial Status Register for Non-Smart Card Interface and FIFO Mode (SCMR.SMIF = 0, FCR.FM = 1, and MMR.MANEN = 0)

Base address: SCIn = 0x4011_8000 + 0x0100 × n (n = 0, 5 to 9)
SCIk = 0x4011_8000 + 0x0100 × k (k = 3, 4)

Offset address: 0x04

Bit position:	7	6	5	4	3	2	1	0
Bit field:	TDFE	RDF	ORER	FER	PER	TEND	—	DR
Value after reset:	1	0	0	0	0	0	x	0

Bit	Symbol	Function	R/W
0	DR	Receive Data Ready Flag 0: Receiving is in progress, or no received data remains in FRDRHL after successfully completed reception (receive FIFO empty) 1: Next receive data is not received for a period after normal receiving is complete, when the amount of data stored in the FIFO is equal to or less than the receive triggering number	R/W*1
1	—	The read value is undefined. The write value should be 1.	R/W
2	TEND	Transmit End Flag 0: A character is being transmitted 1: Character transfer is complete	R/W*1
3	PER	Parity Error Flag 0: No parity error occurred 1: Parity error occurred	R/W*1
4	FER	Framing Error Flag 0: No framing error occurred 1: Framing error occurred	R/W*1
5	ORER	Overrun Error Flag 0: No overrun error occurred 1: Overrun error occurred	R/W*1
6	RDF	Receive FIFO Data Full Flag 0: The amount of receive data written in FRDRHL is less than the specified receive triggering number 1: The amount of receive data written in FRDRHL is equal to or greater than the specified receive triggering number	R/W*1
7	TDFE	Transmit FIFO Data Empty Flag 0: The amount of transmit data written in FTDRHL exceeds the specified transmit triggering number 1: The amount of transmit data written in FTDRHL is equal to or less than the specified transmit triggering number	R/W*1

Note 1. Only 0 can be written, to clear the flag after reading 1.

The SSR_FIFO register provides the SCI with FIFO mode status flags.

DR flag (Receive Data Ready Flag)

The DR flag indicates that the amount of data stored in the Receive FIFO Data Register (FRDRHL) falls below the specified receive triggering number, and that no next data is received after 15 etus (elementary time units) from the last stop bit in asynchronous mode. This flag is valid only in asynchronous mode, including multi-processor mode, when FIFO operation is selected.

In clock synchronous mode, the DR flag is not set to 1.

[Setting condition]

- When FRDRHL contains less data than the specified receive triggering number, and no next data is received after 15 etus*1 from the last stop bit, and the SSR_FIFO.FER and SSR_FIFO.PER flags are 0.

[Clearing conditions]

- When 1 is read from DR, after all received data is read
- When the FCR.FM bit is changed from 0 to 1

Note 1. This is equivalent to 1.5 frames in the 8-bit format with one stop bit.

The DR flag is only set to 1 when FIFO is selected in asynchronous mode, including multi-processor mode. It is not set to 1 in other operation modes.

TEND flag (Transmit End Flag)

The TEND flag indicates that FTDRHL does not contain valid data when transmitting the last bit of a serial character, so the transmission is halted.

[Setting condition]

- When FTDRHL does not contain transmit data when the last bit of a 1-byte serial character is transmitted.

[Clearing conditions]

- When transmit data is written to FTDRHL[*1] while the SCR.TE bit is 1
- When 0 is written to TEND after 1 is read from TEND, when the SCR.TE bit is 1
- When the FCR.FM bit is changed from 0 to 1

Note 1. Do not use the TEND bit as a transmit end flag when the DTC writes data to FTDRHL in response to an SCIn_TXI interrupt request.

PER flag (Parity Error Flag)

The PER flag indicates whether there is a parity error in the data read from the FRDRHL register in asynchronous mode when the address match function is disabled (DCCR.DCME = 0).

[Setting condition]

- When data is received and a parity error is detected, when the address match function is disabled (DCCR.DCME = 0).

[Clearing condition]

- When 0 is written to PER after reading PER = 1.

The reception operation is continuous, and the receive data is stored in the FRDRHL register, even when a parity error occurs during reception.

When the SCR.RE bit is set to 0 (serial reception is disabled), the PER flag is not affected and retains its previous value.

FER flag (Framing Error Flag)

The FER flag indicates whether there is a framing error in the data read from the FRDRHL register in asynchronous mode when the address match function is disabled (DCCR.DCME = 0).

[Setting condition]

- When 0 is sampled as the stop bit during reception when the address match function is disabled (DCCR.DCME = 0).

[Clearing condition]

- When 0 is written to FER after reading FER = 1.

The reception operation is continuous, and the receive data is stored in the FRDRHL register, even when a framing error occurs during reception.

When the SCR.RE bit is set to 0 (serial reception is disabled), the FER flag is not affected and retains its previous value.

ORER flag (Overrun Error Flag)

The ORER flag indicates that the receive operation stopped abnormally because an overrun error occurred.

[Setting condition]

- When the next serial reception completes while the receive FIFO is full with 16-byte receive data.

[Clearing condition]

- When 0 is written to ORER after reading ORER = 1.

When the SCR.RE bit is set to 0 (serial reception is disabled), the ORER flag is not affected and retains its previous value.

RDF flag (Receive FIFO Data Full Flag)

The RDF flag indicates that receive data was transferred to the FRDRHL register, and the amount of data in FRDRHL is equal to or exceeds the specified receive triggering number. When RTRG is set to 0, the RDF flag is not set even when the amount of data in the receive FIFO is equal to 0.

[Setting condition]

- When the amount of receive data equal to or greater than the specified receive triggering number is stored in FRDRHL,[*1] and the FIFO is not empty.

[Clearing conditions]

- When 0 is written to RDF after reading RDF = 1
- When FRDRHL is read by the DTC, but only when the block transfer is the last transmission
- When the setting and clearing conditions occur at the same time, the RDF bit is set to 0. After that, when the amount of data stored in the FRDRHL register is the same as or greater than the RTRG value, RDF is set to 1 after 1 PCLK.

Note 1. Because FRDRHL is a 16-stage FIFO register, the maximum amount of data that can be read when RDF is 1 is equivalent to the specified receive triggering number. If an attempt is made to read after all the data in FRDRHL is read, the data is undefined.

TDFE flag (Transmit FIFO Data Empty Flag)

The TDFE flag indicates that data is transferred from the FTDRHL register into the TSR register, the amount of data in FTDRHL is below the specified transmit triggering number, and writing of transmit data to FTDRHL is enabled.

[Setting conditions]

- When the TE bit in SCR is 0
- When the amount of transmit data written in FTDRHL is equal to or less than the specified transmit triggering number*1

[Clearing conditions]

- When writing to FTDRHL is executed on the last transmission while the DTC is activated
- When 0 is written to the TDFE flag after reading TDFE = 1.*2
  The setting conditions are given priority when TE = 0. When the setting condition and clearing condition occur at the same time, the TDFE flag is set to 0. After that, when the amount of data stored in the FTDRHL register is equal to or less than the TTRG value, TDFE is set to 1 after 1 PCLK.

Note 1. Because the FTDRHL register is a 16-stage FIFO register, when the TDFE flag is 1, the maximum amount of data that can be written to the FTDRHL register is 16 minus FDR.T[4:0] bytes. If more data is written, data is discarded.
Note 2. Do not clear the TDFE flag during block transfer processing by the DTC.

30.2.17 SSR_SMCI : Serial Status Register for Smart Card Interface Mode (SCMR.SMIF = 1, and MMR.MANEN = 0)

Base address: SCIn = 0x4011_8000 + 0x0100 × n (n = 0, 5 to 9)
SCIk = 0x4011_8000 + 0x0100 × k (k = 3, 4)
SCIm = 0x4011_8000 + 0x0100 × m (m = 1, 2)

Offset address: 0x04

Bit position:	7	6	5	4	3	2	1	0
Bit field:	TDRE	RDRF	ORER	ERS	PER	TEND	MPB	MPBT
Value after reset:	1	0	0	0	0	1	0	0

Bit	Symbol	Function	R/W
0	MPBT	Multi-Processor Bit Transfer Set this bit to 0 in smart card interface mode	R/W
1	MPB	Multi-Processor Set this bit to 0 in smart card interface mode	R
2	TEND	Transmit End Flag 0: A character is being transmitted 1: Character transfer is complete	R
3	PER	Parity Error Flag 0: No parity error occurred 1: Parity error occurred	R/W*1
4	ERS	Error Signal Status Flag 0: No low error signal response 1: Low error signal response occurred	R/W*1

Bit	Symbol	Function	R/W
5	ORER	Overrun Error Flag 0: No overrun error occurred 1: Overrun error occurred	R/W*1
6	RDRF	Receive Data Full Flag 0: No received data in RDR register 1: Received data in RDR register	R/W*1
7	TDRE	Transmit Data Empty Flag 0: Transmit data in TDR register 1: No transmit data in TDR register	R/W*1

Note 1. Only 0 can be written, to clear the flag after reading 1.

The SSR_SMCI register provides the SCI with smart card interface mode status flags.

TEND flag (Transmit End Flag)

When there is no error signal from the receiving side, the TEND flag is set to 1 when more data for transfer is ready to be transferred to the TDR register.

[Setting conditions]

- When the SCR_SMCI.TE bit = 0 (serial transmission is disabled).
  When the SCR_SMCI.TE bit is changed from 0 to 1, the TEND flag is not affected and retains the value 1.
- When a specified period elapses after the latest transmission of 1 byte, the ERS flag is 0, and the TDR register is not updated.

  The set timing is determined by the following register settings:
  - When SMR_SMCI.GM = 0 and SMR_SMCI.BLK = 0, 12.5 etus after the start of transmission
  - When SMR_SMCI.GM = 0 and SMR_SMCI.BLK = 1, 11.5 etus after the start of transmission
  - When SMR_SMCI.GM = 1 and SMR_SMCI.BLK = 0, 11.0 etus after the start of transmission
  - When SMR_SMCI.GM = 1 and SMR_SMCI.BLK = 1, 11.0 etus after the start of transmission

[Clearing conditions]

- When transmit data is written to the TDR register while the SCR_SMCI.TE bit is 1
- When 0 is written to TDRE after reading TDRE = 1 while the SCR_SMCI.TE bit is 1

PER flag (Parity Error Flag)

The PER flag indicates that a parity error occurred during reception in asynchronous mode and the reception ended abnormally.

[Setting condition]

- When a parity error is detected during reception. Although receive data is transferred to RDR when a parity error occurs, no SCIn_RXI interrupt request occurs. After the PER flag is set to 1, the subsequent receive data is not transferred to RDR.

[Clearing condition]

- When 0 is written to PER after reading PER = 1. After writing 0 to the PER flag, read the flag to check that it is actually set to 0.

When the RE bit in SCR_SMCI is set to 0 (serial reception is disabled), the PER flag is not affected and retains its previous value.

ERS flag (Error Signal Status Flag)

[Setting condition]

- When a low error signal is sampled.

[Clearing condition]

- When 0 is written to ERS after reading ERS = 1.

ORER flag (Overrun Error Flag)

The ORER flag indicates that an overrun error occurred during reception and the reception ended abnormally.

[Setting condition]

- When the next data is received before receive data that does not have a parity error is read from the RDR register. The data received before an overrun error occurred is saved in the RDR, but data received after the error is lost. When the ORER flag is set to 1, receive data is not forwarded to the RDR register.

[Clearing condition]

- When 0 is written to ORER after reading ORER = 1. After writing 0 to the ORER flag, read the flag to check that it is actually set to 0.

When the RE bit in SCR_SMCI is set to 0, the ORER flag is not affected and retains its previous value.

RDRF flag (Receive Data Full Flag)

The RDRF flag indicates the presence of receive data in the RDR register.

[Setting condition]

- When the reception ends normally, and receive data is forwarded from the RSR register to the RDR register.

[Clearing conditions]

- When 0 is written to RDRF after reading RDRF = 1
- When data is forwarded from the RDR register

TDRE flag (Transmit Data Empty Flag)

The TDRE flag indicates the presence of transmit data in the TDR register.

[Setting conditions]

- When the SCR_SMCI.TE bit is 0
- When data is transmitted from the TDR register to the TSR register

[Clearing conditions]

- When 0 is written to TDRE after reading TDRE = 1
- When the SCR_SMCI.TE bit is 1 and data is written to the TDR register

30.2.18 SSR_MANC : Serial Status Register for Manchester Mode (SCMR.SMIF = 0, and MMR.MANEN = 1)

Base address: SCIk = 0x4011_8000 + 0x0100 × k (k = 3, 4)

Offset address: 0x04

Bit position:	7	6	5	4	3	2	1	0
Bit field:	TDRE	RDRF	ORER	FER	PER	TEND	MPB	MER
Value after reset:	1	0	0	0	0	1	0	0

Bit	Symbol	Function	R/W
0	MER	Manchester Error Flag Valid for Manchester mode only 0: No Manchester error occurred 1: Manchester error has occurred	R/(W)*1

Bit	Symbol	Function	R/W
1	MPB	Multi-Processor Value of the multi-processor bit in the reception frame 0: Data transmission cycles 1: ID transmission cycles	R
2	TEND	Transmit End Flag 0: A character is being transmitted 1: Character transfer has been completed.	R
3	PER	Parity Error Flag 0: No parity error occurred 1: A parity error has occurred	R/(W)*1
4	FER	Framing Error Flag 0: No framing error occurred 1: A framing error has occurred	R/(W)*1
5	ORER	Overrun Error Flag 0: No overrun error occurred 1: An overrun error has occurred	R/(W)*1
6	RDRF	Receive Data Full Flag 0: No received data is in RDR register 1: Received data is in RDR register	R/(W)*1
7	TDRE	Transmit Data Empty Flag 0: Transmit data is in TDR register 1: No transmit data is in TDR register	R/(W)*1

Note 1. Only 0 can be written to this bit, to clear the flag after confirmed(read) the flag is set to 1.

SSR is constructed in the status flag of SCI and reception multi processor bits.

MER flag (Manchester Error Flag)

When data is received in Manchester mode, Manchester error is detected and it is displayed.

[Setting conditions]

- When receiving in Manchester mode and detecting Manchester code error in data area of received frame.
  Received data when an error occurs is transferred to the RDR register, but the RXI interrupt request is not generatedand the ERI interrupt request is generated.
  When the Manchester error flag is set to “1”, subsequent receive data is not transferred to the RDR register.
  For details on Manchester error, see section 30.5.11. Errors in Manchester Mode.

[Clearing conditions]

- When 0 is written to MER after reading MER = 1 (after writing 0 to it, read the MER bit to check that it has actually been set to 0.)
  Even when the RE bit in SCR is set to 0 (serial reception is disabled), the MER flag is not affected and retains its previous value.

MPB flag (Multi-Processor)

Holds the value of the multi-processor bit in the reception frame. This bit does not change when the SCR.RE bit is 0.

TEND flag (Transmit End Flag)

Indicates completion of transmission.

[Setting conditions]

- When the SCR.TE bit is set to 0 (serial transmission is disabled) and FCR.FM bit is set to 0 (non-FIFO selected).
  When the SCR.TE bit is changed from 0 to 1, the TEND flag is not affected and retains the value 1.
- When the TDR register is not updated at the time of transmission of the tail-end bit of a character being transmitted

[Clearing conditions]

- When transmit data are written to the TDR register while the SCR.TE bit is 1.
- When 0 is written to TDRE after reading TDRE = 1 while the SCR.TE bit is 1.

PER flag (Parity Error Flag)

Indicates that a parity error has occurred during reception in asynchronous mode and the reception ends abnormally.

[Setting condition]

- When a parity error is detected during reception in Asynchronous Mode and the state of Address Match function invalidity (DCCR.DCME = 0).
  Although receive data when the parity error occurs is transferred to RDR, no RXI interrupt request occurs. Note that when the PER flag is being set to 1, the subsequent receive data is not transferred to RDR.

[Clearing condition]

- When 0 is written to PER after reading PER = 1 (after writing 0 to it, read the PER bit to check that it has actually been set to 0.)

Even when the RE bit in SCR is set to 0 (serial reception is disabled), the PER flag is not affected and retains its previous value.

FER flag (Framing Error Flag)

Indicates that a framing error has occurred during reception in asynchronous mode and the reception ends abnormally.

[Setting condition]

- When 0 is sampled as the stop bit during reception in Asynchronous Mode and the state of Address Match function invalidity (DCCR.DCME = 0).
  In 2-stop-bit mode, only the first stop bit is checked whether it is 1 but the second stop bit is not checked. Note that although receive data when the framing error occurs is transferred to RDR, no RXI interrupt request occurs. In addition, when the FER flag is being set to 1, the subsequent receive data is not transferred to RDR.

[Clearing condition]

- When 0 is written to FER after reading FER = 1 (after writing 0 to it, read the FER bit to check that it has actually been set to 0.)
  .

Even when the RE bit in SCR is set to 0, the FER flag is not affected and retains its previous value.

ORER flag (Overrun Error Flag)

Indicates that an overrun error has occurred during reception and the reception ends abnormally.

[Setting condition]

- When the next data is received before receive data is read from RDR which don’t have any valid reception error.
  In RDR, receive data prior to an overrun error occurrence is retained, but data received after the overrun error occurrence is lost. When the ORER flag is set to 1, reception data isn’t forwarded to RDR register. Note that, in clock synchronous mode, serial transmission and reception will be stop.

[Clearing condition]

- When 0 is written to ORER after reading ORER = 1 (after writing 0 to it, read the ORER bit to check that it has actually been set to 0.)

Even when the RE bit in SCR is set to 0, the ORER flag is not affected and retains its previous value.

RDRF flag (Receive Data Full Flag)

Indicates the presence of receive data in the RDR register.

[Setting condition]

- When the reception ends normally, and receive data is forwarded from the RSR register to the RDR register

[Clearing conditions]

- When it’s written to “0" after the state of “1" is read
- When it’s read the data from the RDR register

TDRE flag (Transmit Data Empty Flag)

Indicates the presence of transmit data in the TDR register.

[Setting conditions]

- When the SCR.TE bit is 0
- When data is transmitted from the TDR register to the TSR register

[Clearing conditions]

- When it's written to 0 after the state of 1 is read
- When the SCR.TE bit is 1, it's written to the TDR register

Note: RDRF and TDRE should not be cleared by SSR register access unless communication is interrupted.

30.2.19 SCMR : Smart Card Mode Register

Base address: SCIn = 0x4011_8000 + 0x0100 × n (n = 0, 5 to 9)
SCIk = 0x4011_8000 + 0x0100 × k (k = 3, 4)
SCIm = 0x4011_8000 + 0x0100 × m (m = 1, 2)

Offset address: 0x06

Bit position:	7	6	5	4	3	2	1	0
Bit field:	BCP2	—	—	CHR1	SDIR	SINV	—	SMIF
Value after reset:	1	1	1	1	0	0	1	0

Bit	Symbol	Function	R/W
0	SMIF	Smart Card Interface Mode Select 0: Non-smart card interface mode (asynchronous mode, clock synchronous mode, simple SPI mode, or simple IIC mode) 1: Smart card interface mode	R/W*1
1	—	This bit is read as 1. The write value should be 1.	R/W
2	SINV	Transmitted/Received Data Invert Set the SINV bit to 0 for operation in simple IIC mode. The level of communication terminals (RXD, TXD) are controlled by combination of this bit and SPTR.TINV/RINV. For details, see Figure 30.5. The SINV bit can be used in the following modes: ● Smart card interface mode ● Asynchronous mode (including multi-processor mode) ● Clock synchronous mode ● Simple SPI mode 0: TDR contents are transmitted as they are. Received data is stored as received in the RDR register. 1: TDR register contents are inverted before transmission. Receive data is stored in inverted form in the RDR register.	R/W*1
3	SDIR	Transmitted/Received Data Transfer Direction Set the SDIR bit to 1 for operation in simple IIC mode. The SDIR bit can be used in the following modes: ● Smart card interface mode ● Asynchronous mode (including multi-processor mode) ● Clock synchronous mode ● Simple SPI mode 0: Transfer LSB-first 1: Transfer MSB-first	R/W*1
4	CHR1	Character Length 1 Valid only in asynchronous mode.*2 Selects the transmit/receive character length in combination with the SMR.CHR bit. 0: SMR.CHR = 0: Transmit/receive in 9-bit data length SMR.CHR = 1: Transmit/receive in 9-bit data length 1: SMR.CHR = 0: Transmit/receive in 8-bit data length (initial value) SMR.CHR = 1: Transmit/receive in 7-bit data length*3	R/W*1

Bit	Symbol	Function	R/W
6:5	—	These bits are read as 1. The write value should be 1.	R/W
7	BCP2	Base Clock Pulse 2 Selects the number of base clock cycles in combination with the SMR_SMCI.BCP[1:0] bits. Table 30.5 lists the combinations of the SCMR.BCP2 and SMR_SMCI.BCP[1:0] bits.	R/W*1

Note 1. Writable only when the TE and RE bits in SCR/SCR_SMCI are 0 (both serial transmission and reception are disabled).
Note 2. The setting is invalid and a fixed data length of 8 bits is used in modes other than asynchronous mode.
Note 3. LSB-first must be selected and the value of the MSB (bit [7]) in TDR cannot be transmitted.

The SCMR register selects the smart card interface and communication format.

SMIF bit (Smart Card Interface Mode Select)

Setting the SMIF bit to 1 selects smart card interface mode. Setting it to 0 selects all other modes:

- Asynchronous mode, including multi-processor mode
- Clock synchronous mode
- Simple SPI mode
- Simple IIC mode

SINV bit (Transmitted/Received Data Invert)

The SINV bit inverts the transmit and receive data logic level. It does not affect the logic level of the parity bit. To invert the parity bit, invert the PM bit in SMR or SMR_SMCI.

CHR1 bit (Character Length 1)

The CHR1 bit selects the data length of transmit and receive data in combination with the CHR bit in the SMR register. A fixed data length of 8 bits is used in modes other than asynchronous mode.

BCP2 bit (Base Clock Pulse 2)

The BCP2 bit selects the number of base clock cycles in a 1-bit data transfer time in smart card interface mode. Set this bit in combination with the SMR_SMCI.BCP[1:0] bits.

Table 30.5 Combinations of the SCMR.BCP2 and SMR_SMCI.BCP[1:0] bits

SCMR.BCP2 bit	SMR_SMCI.BCP[1:0] bits	Number of base clock cycles for 1-bit transfer period
0	00b	93 clock cycles (S = 93)*1
0	01b	128 clock cycles (S = 128)*1
0	10b	186 clock cycles (S = 186)*1
0	11b	512 clock cycles (S = 512)*1
1	00b	32 clock cycles (S = 32) (Initial Value)*1
1	01b	64 clock cycles (S = 64)*1
1	10b	372 clock cycles (S = 372)*1
1	11b	256 clock cycles (S = 256)*1

Note 1. S is the value of S in section 30.2.20. BRR : Bit Rate Register.

30.2.20 BRR : Bit Rate Register

Base address: SCIn = 0x4011_8000 + 0x0100 × n (n = 0, 5 to 9)
SCIk = 0x4011_8000 + 0x0100 × k (k = 3, 4)
SCIm = 0x4011_8000 + 0x0100 × m (m = 1, 2)

Offset address: 0x01

Bit position:	7	6	5	4	3	2	1	0
Bit field:								
Value after reset:	1	1	1	1	1	1	1	1

BRR is an 8-bit register that adjusts the bit rate.

As each SCI channel has independent baud rate generator control, different bit rates can be set for each channel. Table 30.6 shows the relationship between the setting (N) in the BRR and the bit rate (B) for normal asynchronous mode, multi-processor transfer, clock synchronous mode, smart card interface mode, simple SPI mode, and simple IIC mode.

The initial value of the BRR register is 0xFF. The BRR register can be read by the CPU, but it can be written to only when the TE and RE bits in SCR/SCR_SMCI are 0.

Table 30.6 Relationship between N setting in BRR and bit rate B

Mode	SEMR settings			BRR setting	Error
	BGDM bit	ABCS bit	ABCS E bit		
Asynchronous, multi-processor transfer	0	0	0	$N = \frac{PCLK \times 10^6}{64 \times 2^{2n-1} \times B} - 1$	$Error\ (\%) = \left\{\frac{PCLK \times 10^6}{B \times 64 \times 2^{2n-1} \times (N+1)} - 1\right\} \times 100$
	1	0	0	$N = \frac{PCLK \times 10^6}{32 \times 2^{2n-1} \times B} - 1$	$Error\ (\%) = \left\{\frac{PCLK \times 10^6}{B \times 32 \times 2^{2n-1} \times (N+1)} - 1\right\} \times 100$
	0	1	0		
	1	1	0	$N = \frac{PCLK \times 10^6}{16 \times 2^{2n-1} \times B} - 1$	$Error\ (\%) = \left\{\frac{PCLK \times 10^6}{B \times 16 \times 2^{2n-1} \times (N+1)} - 1\right\} \times 100$
	Don't care	Don't care	1	$N = \frac{PCLK \times 10^6}{12 \times 2^{2n-1} \times B} - 1$	$Error\ (\%) = \left\{\frac{PCLK \times 10^6}{B \times 12 \times 2^{2n-1} \times (N+1)} - 1\right\} \times 100$
Clock synchronous, simple SPI				$N = \frac{PCLK \times 10^6}{8 \times 2^{2n-1} \times B} - 1$	—
Smart card interface				$N = \frac{PCLK \times 10^6}{S \times 2^{2n+1} \times B} - 1$	$Error\ (\%) = \left\{\frac{PCLK \times 10^6}{B \times S \times 2^{2n+1} \times (N+1)} - 1\right\} \times 100$
Simple IIC*1				$N = \frac{PCLK \times 10^6}{64 \times 2^{2n-1} \times B} - 1$	—

Note: B: Bit rate (bps)
N: BRR setting for on-chip baud rate generator (0 ≤ N ≤ 255)
PCLK: Operating frequency (MHz)
n and S: Determined by the SMR/SMR_SMCI and SCMR register settings as listed in Table 30.8 and Table 30.9.

Note 1. Adjust the bit rate so that the widths of high and low level of the SCLn output in simple IIC mode satisfy the I^2C bus standard.

Table 30.7 Calculating widths of SCLn high and low levels

Mode	SCLn	Formula (result in seconds)
IIC	Width at high level (minimum value)	$(N+1) \times 4 \times 2^{2n-1} \times 7 \times \frac{1}{PCLK \times 10^6}$
	Width at low level (minimum value)	$(N+1) \times 4 \times 2^{2n-1} \times 8 \times \frac{1}{PCLK \times 10^6}$

Table 30.8 Clock source settings

SMR or SMR_SMCI.CKS[1:0] bits setting		
CKS[1:0] bits	Clock source	n
00b	PCLK clock	0
01b	PCLK/4 clock	1
10b	PCLK/16 clock	2
11b	PCLK/64 clock	3

Table 30.9 Base clock settings in smart card interface mode

SCMR.BCP2 bit setting	SMR_SMCI.BCP[1:0] bits setting		
BCP2 bit	BCP[1:0] bits	Base clock cycles for 1-bit period	S
0	00b	93 clock cycles	93
0	01b	128 clock cycles	128
0	10b	186 clock cycles	186
0	11b	512 clock cycles	512
1	00b	32 clock cycles	32
1	01b	64 clock cycles	64
1	10b	372 clock cycles	372
1	11b	256 clock cycles	256

Table 30.10 and Table 30.11 list examples of BRR (N) settings in normal asynchronous mode. Table 30.12 lists the maximum bit rate settable for each operating frequency. Table 30.16 lists examples of BRR (N) settings in smart card interface mode.

In smart card interface mode, the number of base clock cycles S in a 1-bit data transfer time can be selected. For details, see section 30.7.4. Receive Data Sampling Timing and Reception Margin. Table 30.13 and Table 30.15 list the maximum bit rates with external clock input.

When either the Asynchronous Mode Base Clock Select bit (ABCS) or the Baud Rate Generator Double-speed Mode Select bit (BGDM) in the Serial Extended Mode Register (SEMR) is set to 1 in asynchronous mode, the bit rate becomes twice the value listed in Table 30.17. When both of those registers are set to 1, the bit rate becomes four times the listed value.

Table 30.10 Examples of BRR settings for different bit rates in asynchronous mode (1) (1 of 2)

38400	—	—	—	0	12	0.16	0	13	0.00	0	14	-2.34	0	15	0.00

Note: In this example, SEMR.ABCS = 0, SEMR.ABCSE = 0, and SEMR.BGDM = 0.
When either the ABCS or BGDM bit is set to 1, the bit rate doubles.
When both ABCS and BGDM are set to 1, the bit rate increases four times.

Table 30.11 Examples of BRR settings for different bit rates in asynchronous mode (2) (1 of 3)

10 M															0	0*1						
15 M																			0	0*1		

Note: Space: Setting prohibited.
—: Can be set, but an error occurs.

Note 1. Continuous transmission or reception is not possible. After transmitting or receiving one frame of data, a 1-bit period elapses before starting to transmit or receive the next frame of data. The output of the synchronization clock is stopped for a 1-bit period. Therefore, it takes 9 bits worth of time to transfer one frame (8 bits) of data, and the average transfer rate is 8/9 times the bit rate. When the FIFO is selected, this setting (BRR = 0x00 and SMR.CKS[1:0] = 00b) is not available.

Table 30.15 Maximum bit rate with external clock input in clock synchronous and simple SPI modes (1 of 2)

PCLK (MHz)	External input clock (MHz)	Maximum bit rate (Mbps)

30.2.21 MDDR : Modulation Duty Register

Base address: SCIn = 0x4011_8000 + 0x0100 × n (n = 0, 5 to 9)
SCIk = 0x4011_8000 + 0x0100 × k (k = 3, 4)
SCIm = 0x4011_8000 + 0x0100 × m (m = 1, 2)

Offset address: 0x12

Bit position:	7	6	5	4	3	2	1	0
Bit field:								
Value after reset:	1	1	1	1	1	1	1	1

MDDR corrects the bit rate adjusted by the BRR register.

When the BRME bit in SEMR is set to 1, the bit rate generated by the on-chip baud rate generator is evenly corrected using the settings in MDDR (M/256). Table 30.20 shows the relationship between the MDDR setting (M) and the bit rate (B).

The initial value of MDDR is 0xFF. Bit [7] in this register is fixed to 1.

The CPU can read the MDDR register, but this register is only writable when the TE and RE bits in SCR/SCR_SMCI are 0.

Table 30.20 Relationship between MDDR setting (M) and bit rate (B) when bit rate modulation function is used

B: Bit rate (bps)
M: MDDR setting (128 ≤ MDDR ≤ 256)
N: BRR setting for baud rate generator (0 ≤ N ≤ 255)
PCLK: Operating frequency (MHz)
n and S: Determined by the SMR/SMR_SMCI and SCMR register settings as listed in Table 30.8 and Table 30.9 in section 30.2.20. BRR : Bit Rate Register.

Mode	SEMR settings			BRR setting	Error
	BGDM bit	ABCS bit	ABCSE bit		
Asynchronous multiprocessor transfer	0	0	0	$N = \frac{PCLK \times 10^6}{64 \times 2^{2n-1} \times (256/M) \times B} - 1$	$Error(\%) = \left\{\frac{PCLK \times 10^6}{B \times 64 \times 2^{2n-1} \times (256/M) \times (N+1)} - 1\right\} \times 100$
	1	0	0	$N = \frac{PCLK \times 10^6}{32 \times 2^{2n-1} \times (256/M) \times B} - 1$	$Error(\%) = \left\{\frac{PCLK \times 10^6}{B \times 32 \times 2^{2n-1} \times (256/M) \times (N+1)} - 1\right\} \times 100$
	0	1	0		
	1	1	0	$N = \frac{PCLK \times 10^6}{16 \times 2^{2n-1} \times (256/M) \times B} - 1$	$Error(\%) = \left\{\frac{PCLK \times 10^6}{B \times 16 \times 2^{2n-1} \times (256/M) \times (N+1)} - 1\right\} \times 100$
	×	×	1	$N = \frac{PCLK \times 10^6}{12 \times 2^{2n-1} \times (256/M) \times B} - 1$	$Error(\%) = \left\{\frac{PCLK \times 10^6}{B \times 12 \times 2^{2n-1} \times (256/M) \times (N+1)} - 1\right\} \times 100$
Clock synchronous, simple SPI*1				$N = \frac{PCLK \times 10^6}{8 \times 2^{2n-1} \times (256/M) \times B} - 1$	—
Smart card interface				$N = \frac{PCLK \times 10^6}{S \times 2^{2n+1} \times (256/M) \times B} - 1$	$Error(\%) = \left\{\frac{PCLK \times 10^6}{B \times S \times 2^{2n+1} \times (256/M) \times (N+1)} - 1\right\} \times 100$
Simple IIC*2				$N = \frac{PCLK \times 10^6}{64 \times 2^{2n-1} \times (256/M) \times B} - 1$	—

Note 1. Do not use this function in clock synchronous mode or in the highest speed settings in simple SPI mode (SMR.CKS[1:0] = 00b, SCR.CKE[1] = 0, and BRR = 0).

Note 2. Adjust the bit rate so that the widths at high and low level of the SCLn output in simple IIC mode satisfy the IIC standard.

Table 30.21 and Table 30.22 list examples of N settings in BRR and M settings in MDDR in normal asynchronous mode.

Table 30.21 Examples of the BRR and MDDR settings for different bit rates in asynchronous mode (1) (1 of 3)

Note 1. In this example, the ABCS and ABCSE bits in the SEMR register are 0.
SEMR.BRME = 0 (M = 256) disables the bit rate modulation function.

30.2.22 SEMR : Serial Extended Mode Register

Base address: SCIn = 0x4011_8000 + 0x0100 × n (n = 0, 5 to 9)
SCIk = 0x4011_8000 + 0x0100 × k (k = 3, 4)
SCIm = 0x4011_8000 + 0x0100 × m (m = 1, 2)

Offset address: 0x07

Bit position:	7	6	5	4	3	2	1	0
Bit field:	RXDESEL	BGDM	NFEN	ABCS	ABCSE	BRME	PADIS	ACS0
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	ACS0	Asynchronous Mode Clock Source Select Valid only in asynchronous mode 0: External clock input 1: Logical AND of compare matches output from the internal GPT. These bit for the other SCI channels than SCIn (n = 1, 2) are reserved.	R/W*1
1	PADIS	Preamble function Disable Valid only in asynchronous mode 0: Preamble output function is enabled 1: Preamble output function is disabled These bits for the other SCI channels than SCIn (n = 0, 3 to 9) are reserved.	R/W
2	BRME	Bit Rate Modulation Enable 0: Disable bit rate modulation function 1: Enable bit rate modulation function	R/W*1

Bit	Symbol	Function	R/W
3	ABCSE	Asynchronous Mode Extended Base Clock Select 1 Valid only in asynchronous mode with SCR.CKE[1] = 0. 0: Clock cycles for 1-bit period determined by combination of the BGDM and ABCS bits in the SEMR register 1: Baud rate is 6 base clock cycles for 1-bit period These bits for the other SCI channels than SCIn (n = 0, 3 to 9) are reserved.	R/W*1
4	ABCS	Asynchronous Mode Base Clock Select Valid only in asynchronous mode. 0: Select 16 base clock cycles for 1-bit period 1: Select 8 base clock cycles for 1-bit period	R/W*1
5	NFEN	Digital Noise Filter Function Enable The NFEN bit must be 0 in all other modes. 0: In asynchronous mode: Disable noise cancellation function for RXDn input signal In simple I2C mode: Disable noise cancellation function for SCLn and SDAn input signals 1: In asynchronous mode: Enable noise cancellation function for RXDn input signal In simple I2C mode: Enable noise cancellation function for SCLn and SDAn input signals	R/W*1
6	BGDM	Baud Rate Generator Double-Speed Mode Select Valid only in asynchronous mode with SCR.CKE[1] = 0. 0: Output clock from baud rate generator with normal frequency 1: Output clock from baud rate generator with doubled frequency	R/W*1
7	RXDESEL	Asynchronous Start Bit Edge Detection Select Valid only in asynchronous mode. 0: Detect low level on RXDn pin as start bit 1: Detect falling edge of RXDn pin as start bit	R/W*1

Note 1. Writable only when the TE and RE bits in SCR/SCR_SMCI are 0 (both serial transmission and reception are disabled).

The SEMR register selects the clock source for the 1-bit period in asynchronous mode.

ACS0 bit (Asynchronous Mode Clock Source Select)

Selects the clock source in the asynchronous mode.

The ACS0 bit is valid in asynchronous mode (SMR.CM bit = 0) and when an external clock input is selected (SCR.CKE[1:0] bits = 10b or 11b). This bit is used to select an external clock input or the logical AND of compare matches output from the internal GPT.

Set the ACS0 bit to 0 in other than asynchronous mode.

For SCI1 and SCI2, the GTIOCnA output (n = 3, 4, 6, 7) of GPT can be set as the serial transfer base clock. For details, see Table 30.23.

These bits for the other SCI channels than SCI1 and SCI2 are reserved. The write values to these bits for other than SCI1 and SCI2 should be 0.

Table 30.23 Correspondence between SCI Channels and Compare Match Outputs

SCI	GPT	Compare Match Output
SCI1	GPT3	GTIOC3A
	GPT4	GTIOC4A
SCI2	GPT6	GTIOC6A
	GPT7	GTIOC7A

Figure 30.3, Figure 30.4 show a setting example of when GTIOC3A and GTIOC4A are selected for output.

This figure shows an example when GPT clock is input to SCI1.

When generating 187.5 kbps of GPT average transfer rate for PCLKD = 32 MHz:

1. Generate a frequency of 4 MHz using GTIOC3A as the base clock.
2. Generate 3/4 clock enable of base clock to set an average transfer rate of 3 MHz/16 = 187.5 kbps using GTIOC4A.

Setting examples of GPT and SCI

- GPT3.GTSSR = 0x80000000, GPT4.GTSSR = 0x80000000 (Enable software counter start)
- GPT3.GTPR = 0x00000007, GPT4.GTPR = 0x0000001F (Maximum count value of GTCNT)
- GPT3.GTCCRA = 0x00000003, GPT4.GTCCRA = 0x00000007 (Compare match value)
- GPT3.GTCR = 0x00000000, GPT4.GTCR = 0x00000000 (Saw-wave PWM mode, timer prescaler is PCLKD/1)
- GPT3.GTIOR = 0x00000306, GPT4.GTIOR = 0x00000306

(Initial output low, output high at GTCCRA compare match, output low at cycle end)

- SCR.SCK[1:0] = 10b (External clock input or GPT clock input is selected)
- SEMR = 0x01 (TMR clock input is selected with 16 base clock cycles for 1-bit period)
- GPT3.GTSTR = 0x00000018 (Software start GTCNT counter)

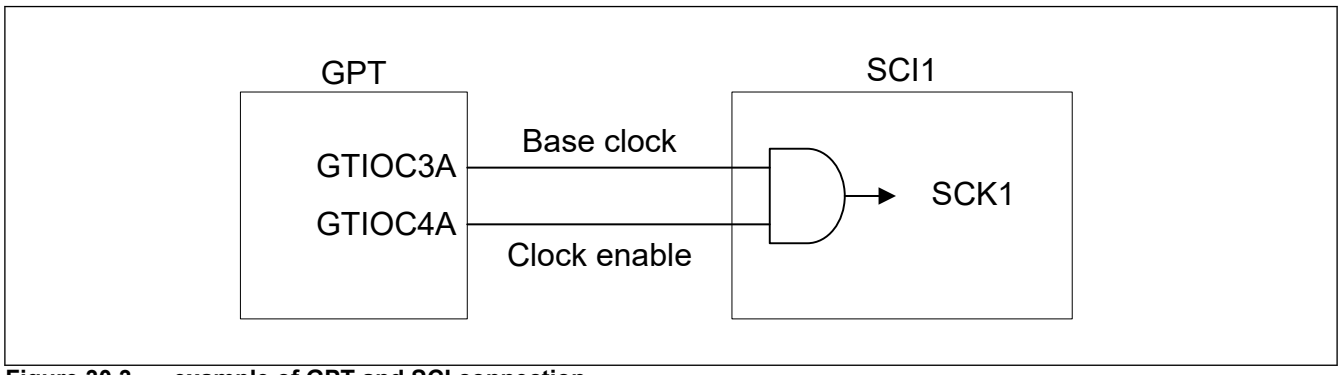

Figure 30.3 example of GPT and SCI connection

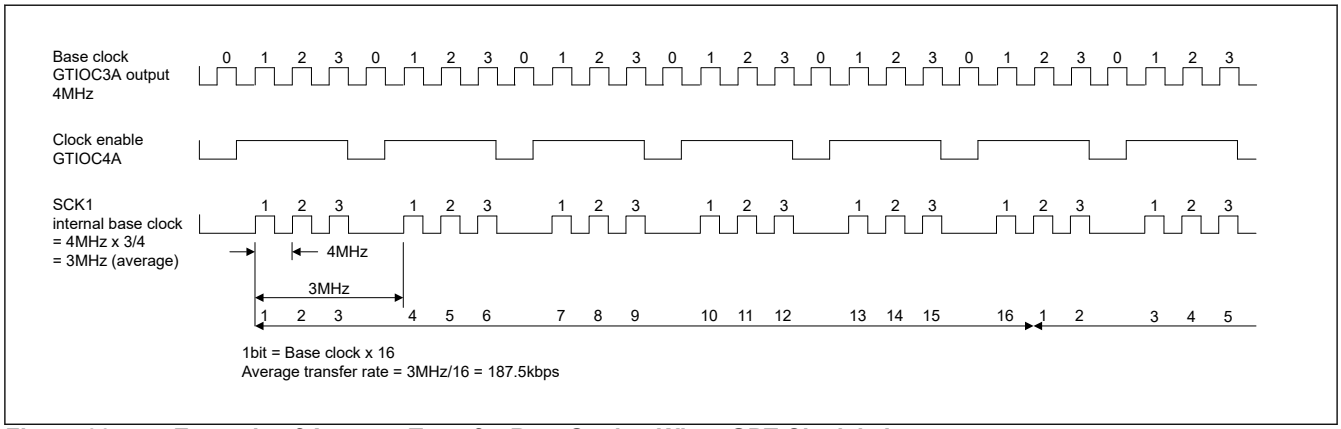

Figure 30.4 Example of Average Transfer Rate Setting When GPT Clock is Input

PADIS bit (Preamble function Disable)

In asynchronous mode, select enable / disable of preamble function. In Manchester mode, preamble is not output regardless of this bit setting

BRME bit (Bit Rate Modulation Enable)

The BRME bit enables or disables the bit rate modulation function. The bit rate generated by the on-chip baud rate generator is evenly corrected when this function is enabled. Set to 0 in Manchester mode.

ABCSE bit (Asynchronous Mode Extended Base Clock Select 1)

The ABCSE bit sets the pulse number for the base clock in a 1-bit period to 6, and the double-frequency clock is output from the baud rate generator. When the bit rate is set to 6 while dividing the bus clock frequency, use this bit and set SMR.CKS[1:0] = 00b and BRR = 0.

Set it to 0 in modes other than asynchronous mode. Even in asynchronous mode, set it to 0 when using external clock.

ABCS bit (Asynchronous Mode Base Clock Select)

The ABCS bit selects the number of clock cycles for a 1-bit period.

Set it to 0 in modes other than asynchronous mode and Manchester mode.

NFEN bit (Digital Noise Filter Function Enable)

The NFEN bit enables or disables the digital noise filter function.

When the digital noise filter function is enabled:

- Noise cancellation is applied to the RXDn input signal in asynchronous mode
- Noise cancellation is applied to the SDAn and SCLn input signals in simple I^2C mode

In all other modes, set the NFEN bit to 0 to disable the digital noise filter function. When the function is disabled, input signals are transferred as received.

BGDM bit (Baud Rate Generator Double-Speed Mode Select)

The BGDM bit selects whether or not to double the base clock frequency output from the baud rate generator.

The BGDM bit is valid when the on-chip baud rate generator is selected as the clock source (SCR.CKE[1] = 0) in asynchronous mode (SMR.CM = 0) or Manchester mode (MMR.MANEN = 1). When external clock is selected (SCR.CKE[1] = 1), set it to 0. The base clock is generated by the clock output from the baud rate generator. When the BGDM bit is set to 1, the base clock cycle is halved and the bit rate is doubled.

Set this bit to 0 in modes other than asynchronous mode or Manchester mode.

RXDESEL bit (Asynchronous Start Bit Edge Detection Select)

The RXDESEL bit selects the detection method of the start bit for reception in asynchronous mode. When a break occurs, data reception operation depends on the setting of this bit. Set this bit to 1 when reception must be stopped while a break occurs or when reception must be started without keeping the RXDn pin input at the high level for the period of one data frame or longer after completion of the break.

Set this bit to 0 in modes other than asynchronous mode.

30.2.23 SNFR : Noise Filter Setting Register

Base address: SCIn = 0x4011_8000 + 0x0100 × n (n = 0, 5 to 9)
SCIk = 0x4011_8000 + 0x0100 × k (k = 3, 4)
SCIm = 0x4011_8000 + 0x0100 × m (m = 1, 2)

Offset address: 0x08

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	NFCS[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	NFCS[2:0]	Noise Filter Clock Select In asynchronous mode, selects the standard setting for the base clock. In simple I^2C mode, selects the standard settings for the clock source of the on-chip baud rate generator selected in the SMR.CKS[1:0] bits. 0 0 0: In asynchronous mode: Use clock signal divided by 1 with noise filter In simple I^2C mode: Setting prohibited 0 0 1: In asynchronous mode: Setting prohibited In simple I^2C mode: Use clock signal divided by 1 with noise filter 0 1 0: In asynchronous mode: Setting prohibited In simple I^2C mode: Use clock signal divided by 2 with noise filter 0 1 1: In asynchronous mode: Setting prohibited In simple I^2C mode: Use clock signal divided by 4 with noise filter 1 0 0: In asynchronous mode: Setting prohibited In simple I^2C mode: Use clock signal divided by 8 with noise filter Others: Setting prohibited	R/W*1

Bit	Symbol	Function	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Writing to these bits is only possible when the RE and TE bits in SCR/SCR_SMCI are 0 (serial reception and transmission disabled).

The SNFR register sets the digital noise filter clock.

NFCS[2:0] bits (Noise Filter Clock Select)

The NFCS[2:0] bits select the sampling clock for the digital noise filter. To use the noise filter in asynchronous mode, set these bits to 000b. In simple I^2C mode, when 32 clocks are selected as one bit period in the basic clock selection bits of the SEMR register, set the NFCS [2: 0] bits in the range from 001b to 100b. When any other value is selected for the basic clock selection bit, set the NFCS bit to 001b.

30.2.24 SIMR1 : IIC Mode Register 1

Base address: SCIn = 0x4011_8000 + 0x0100 × n (n = 0, 5 to 9)
SCIk = 0x4011_8000 + 0x0100 × k (k = 3, 4)
SCIm = 0x4011_8000 + 0x0100 × m (m = 1, 2)

Offset address: 0x09

Bit position:	7	6	5	4	3	2	1	0
Bit field:	IICDL[4:0]					—	—	IICM
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	IICM	Simple IIC Mode Select 0: SCMR.SMIF = 0: Asynchronous mode (including multi-processor mode), clock synchronous mode, or simple SPI mode SCMR.SMIF = 1: Smart card interface mode 1: SCMR.SMIF = 0: Simple IIC mode SCMR.SMIF = 1: Setting prohibited	R/W*1
2:1	—	These bits are read as 0. The write value should be 0.	R/W
7:3	IICDL[4:0]	SDAn Delay Output Select SDAn signal output delay in cycles of the clock signal from the on-chip baud rate generator. 0x00: No output delay Others: (IICDL - 1) to (IICDL) cycles	R/W*1

Note 1. Writing to these bits is only possible when the RE and TE bits in the SCR register are 0 (both serial transmission and reception are disabled).

SIMR1 selects simple IIC mode and the number of delay stages for the SDAn output.

IICM bit (Simple IIC Mode Select)

In combination with the SCMR.SMIF bit, the IICM bit selects the operating mode.

IICDL[4:0] bits (SDAn Delay Output Select)

The IICDL[4:0] bits specify an output delay on the SDAn pin relative to the falling edge of the output on the SCLn pin.

The available delay settings range from no delay to 31 cycles, with the clock signal from the on-chip baud rate generator as the base. The signal obtained by frequency-dividing PCLK by the divisor set in SMR.CKS[1:0] is supplied as the clock signal from the on-chip baud rate generator. Set 00000b to IICDL[4:0] bits unless operation is in simple IIC mode. In simple IIC mode, set the bits to a value in the range from 00001b to 11111b.

Table 30.24 Settable value of IICDL[4: 0] bits in each communication mode (1 of 2)

Communication mode	ABCS	Settable value of IICDL[4:0] bits
Other than simple IIC mode	Don't care	00000b

Table 30.24 Settable value of IICDL[4: 0] bits in each communication mode (2 of 2)

Communication mode	ABCS	Settable value of IICDL[4:0] bits
Simple IIC mode	0	00001b to 11111b
	1	00001b to 00100b

30.2.25 SIMR2 : IIC Mode Register 2

Base address: SCIn = 0x4011_8000 + 0x0100 × n (n = 0, 5 to 9)
SCIk = 0x4011_8000 + 0x0100 × k (k = 3, 4)
SCIm = 0x4011_8000 + 0x0100 × m (m = 1, 2)

Offset address: 0x0A

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	IICACKT	—	—	—	IICSCC	IICINTM
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	IICINTM	IIC Interrupt Mode Select 0: Use ACK/NACK interrupts 1: Use reception and transmission interrupts	R/W*1
1	IICCSC	Clock Synchronization 0: Do not synchronize with clock signal 1: Synchronize with clock signal	R/W*1
4:2	—	These bits are read as 0. The write value should be 0.	R/W
5	IICACKT	ACK Transmission Data 0: ACK transmission 1: NACK transmission and ACK/NACK reception	R/W
7:6	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Writing to these bits is only possible when the RE and TE bits in the SCR register are 0 (serial reception and transmission disabled).

SIMR2 selects how reception and transmission are controlled in simple IIC mode.

IICINTM bit (IIC Interrupt Mode Select)

The IICINTM bit selects the sources of interrupt requests in simple IIC mode.

IICCSC bit (Clock Synchronization)

Set the IICCSC bit to 1 if the internally generated SCLn clock signal is to be synchronized when the SCLn pin is driven low because a wait was inserted by another other device.

The SCLn clock signal is not synchronized if the IICCSC bit is 0. The SCLn clock signal is generated according to the rate selected in the BRR register regardless of the level being input on the SCLn pin.

Set the IICCSC bit to 1 except during debugging.

IICACKT bit (ACK Transmission Data)

Transmitted data contains ACK bits. Set the IICACKT bit to 1 when ACK and NACK bits are received.

30.2.26 SIMR3 : IIC Mode Register 3

Base address: SCIn = 0x4011_8000 + 0x0100 × n (n = 0, 5 to 9)
SCIk = 0x4011_8000 + 0x0100 × k (k = 3, 4)
SCIm = 0x4011_8000 + 0x0100 × m (m = 1, 2)

Offset address: 0x0B

Bit position:	7	6	5	4	3	2	1	0
Bit field:	IICSCLS[1:0]		IICSDAS[1:0]		IICSTIF	IICSTPREQ	IICRSTAREQ	IICSTAREQ
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	IICSTAREQ	Start Condition Generation 0: Do not generate start condition 1: Generate start condition*1 *3 *5 *6	R/W
1	IICRSTAREQ	Restart Condition Generation 0: Do not generate restart condition 1: Generate restart condition*2 *3 *5 *6	R/W
2	IICSTPREQ	Stop Condition Generation 0: Do not generate stop condition 1: Generate stop condition*2 *3 *5 *6	R/W
3	IICSTIF	Issuing of Start, Restart, or Stop Condition Completed Flag 0: No requests are being made for generating conditions, or a condition is being generated 1: Generation of start, restart, or stop condition is complete. When 0 is written to IICSTIF, it is set to 0*4	R/W*4
5:4	IICSDAS[1:0]	SDAn Output Select 0 0: Output serial data 0 1: Generate start, restart, or stop condition 1 0: Output low on SDAn pin 1 1: Drive SDAn pin to high-impedance state	R/W
7:6	IICSCLS[1:0]	SCLn Output Select 0 0: Output serial clock 0 1: Generate start, restart, or stop condition 1 0: Output low on SCLn pin 1 1: Drive SCLn pin to high-impedance state	R/W

Note 1. Only generate a start condition after checking the bus state and confirming that the bus is free.
Note 2. Generate a restart or stop condition after checking the bus state and confirming that the bus is busy.
Note 3. Do not set more than one of the IICSTAREQ, IICRSTAREQ, and IICSTPREQ bits to 1 at a given time.
Note 4. Write only 0. When 1 is written, the value is ignored.
Note 5. Execute the generation of a condition after the value of the IICSTIF flag is 0.
Note 6. Do not write 0 to this bit while it is 1. Generation of a condition is suspended by writing 0 to this bit while it is 1.

The SIMR3 register is used to control the start, restart, and stop conditions in the simple I^2C mode, and to hold the SSDAn and SSCLn pins at fixed levels.

IICSTAREQ bit (Start Condition Generation)

When a start condition is to be generated, set both IICSDAS[1:0] and IICSCLS[1:0] to 01b in addition to setting the IICSTAREQ bit to 1.

[Setting condition]

- On writing 1 to the bit.

[Clearing condition]

- On completion of start condition generation.

IICRSTAREQ bit (Restart Condition Generation)

When a restart condition is to be generated, set both IICSDAS[1:0] and IICSCLS[1:0] to 01b in addition to setting the IICRSTAREQ bit to 1.

[Setting condition]

- On writing 1 to the bit.

[Clearing condition]

- On completion of restart condition generation.

IICSTPREQ bit (Stop Condition Generation)

When a stop condition is to be generated, set both IICSDAS[1:0] and IICSCLS[1:0] to 01b in addition to setting the IICSTPREQ bit to 1.

[Setting condition]

- On writing 1 to the bit.

[Clearing condition]

- On completion of stop condition generation.

IICSTIF flag (Issuing of Start, Restart, or Stop Condition Completed Flag)

After generating a condition, the IICSTIF flag indicates that the condition generation is complete. When using the IICSTAREQ, IICRSTAREQ, or IICSTPREQ bit to cause generation of a condition, do so after setting the IICSTIF flag to 0.

When the IICSTIF flag is 1 while an interrupt request is enabled by setting the SCR.TEIE bit, an STI request is output.

[Setting condition]

- On completion of a start, restart, or stop condition generation.

  If the setting condition conflicts with any of the clearing conditions for the flag, the clearing condition takes precedence.

[Clearing conditions]

- On writing 0 to the bit. After writing 0 to the IICSTIF bit, read the bit to check that it is actually set to 0.
- On writing 0 to the SIMR1.IICM bit when operation is not in simple IIC mode.
- On writing 0 to the SCR.TE bit.

IICSDAS[1:0] bits (SDAn Output Select)

The IICSDAS[1:0] bits control output from the SDAn pin. Set IICSDAS[1:0] and IICSCLS[1:0]to the same value during normal operations.

IICSCLS[1:0] bits (SCLn Output Select)

The IICSCLS[1:0] bits control output from the SCLn pin. Set IICSDAS[1:0] and IICSCLS[1:0] to the same value during normal operations.

30.2.27 SISR : IIC Status Register

Base address: SCIn = 0x4011_8000 + 0x0100 × n (n = 0, 5 to 9)
SCIk = 0x4011_8000 + 0x0100 × k (k = 3, 4)
SCIm = 0x4011_8000 + 0x0100 × m (m = 1, 2)

Offset address: 0x0C

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	IICACKR
Value after reset:	0	0	x	x	0	x	0	0

Bit	Symbol	Function	R/W
0	IICACKR	ACK Reception Data Flag 0: ACK received 1: NACK received	R
1	—	This bit is read as 0.	R
2	—	The read value is undefined.	R
3	—	This bit is read as 0.	R
5:4	—	The read value is undefined.	R
7:6	—	These bits are read as 0.	R

SISR monitors the state in simple IIC mode.

IICACKR flag (ACK Reception Data Flag)

Received ACK and NACK bits can be read from the IICACKR flag. The IICACKR flag is updated on the rising edge of the SCLn clock for the received ACK/NACK bit.

30.2.28 SPMR : SPI Mode Register

Base address: SCIn = 0x4011_8000 + 0x0100 × n (n = 0, 5 to 9)
SCIk = 0x4011_8000 + 0x0100 × k (k = 3, 4)
SCIm = 0x4011_8000 + 0x0100 × m (m = 1, 2)

Offset address: 0x0D

Bit position:	7	6	5	4	3	2	1	0
Bit field:	CKPH	CKPOL	—	MFF	CTSPEN	MSS	CTSE	SSE
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SSE	SSn Pin Function Enable 0: Disable SSn pin function 1: Enable SSn pin function	R/W*1
1	CTSE	CTS Enable 0: Disable CTS function (enable RTS output function) 1: Enable CTS function	R/W*1
2	MSS	Master Slave Select 0: Transmit through TXDn pin and receive through RXDn pin (master mode) 1: Receive through TXDn pin and transmit through RXDn pin (slave mode)	R/W*1
3	CTSPEN	CTS external pin Enable 0: Alternate setting to use CTS and RTS functions as either one terminal 1: Dedicated setting for separately using CTS and RTS functions with 2 terminals These bits for the other SCI channels than SCIn (n = 0, 3 to 9) are reserved.	R/W
4	MFF	Mode Fault Flag 0: No mode fault error 1: Mode fault error	R/W*2
5	—	This bit is read as 0. The write value should be 0.	R/W
6	CKPOL	Clock Polarity Select 0: Do not invert clock polarity 1: Invert clock polarity	R/W*1
7	CKPH	Clock Phase Select 0: Do not delay clock 1: Delay clock	R/W*1

Note 1. Writing to these bits is only possible when the RE and TE bits in the SCR register are 0 (both serial transmission and reception are disabled).
Note 2. Only 0 can be written to this bit, to clear the flag.

SPMR selects the extension settings in asynchronous and clock synchronous modes.

SSE bit (SSn Pin Function Enable)

Set the SSE bit to 1 to use the SSn pin to control transmission and reception in simple SPI mode. Set this bit to 0 in all other modes. In simple SPI mode, when master mode is selected (SCR.CKE[1:0] = 00b and SPMR.MSS = 0) and there is a single master, the SSn pin on the master side is not required to control reception and transmission. In such a case, set the SSE bit to 0. Do not set both the SSE and CTSE bits to 1. If this setting is made, operation is the same as that when these bits are set to 0.

CTSE bit (CTS Enable)

Set the CTSE bit to 1 if the SSn pin is to be used for inputting the CTS control signal to control transmission and reception. The RTS signal is output when this bit is set to 0. Set this bit to 0 in smart card interface mode, simple SPI mode, and simple IIC mode. Do not set both the CTSE and SSE bits to 1. If this setting is made, operation is the same as that when these bits are set to 0.

MSS bit (Master Slave Select)

The MSS bit selects master or slave operation in simple SPI mode. The functions of the TXDn and RXDn pins are reversed when this bit is set to 1, so that data is received through the TXDn pin and transmitted through the RXDn pin.

Set this bit to 0 in modes other than simple SPI mode.

CTSPEN bit (CTS external pin Enable)

Select the terminals usage method when using the CTS and RTS functions.

MFF flag (Mode Fault Flag)

The MFF flag indicates mode fault errors. In a multi-master configuration, determine the mode fault error occurrence by reading this flag.

[Setting condition]

- When input on the SSn pin is low during master operation in simple SPI mode (SSE bit = 1 and MSS bit = 0).

[Clearing condition]

- On writing 0 to the bit after it is read as 1.

CKPOL bit (Clock Polarity Select)

The CKPOL bit selects the polarity of the clock signal output through the SCKn pin. See Figure 30.99 for details. Set the CKPOL bit to 0 in all modes other than simple SPI mode and clock synchronous mode.

CKPH bit (Clock Phase Select)

The CKPH bit selects the phase of the clock signal output through the SCKn pin. See Figure 30.99 for details. Set the CKPH bit to 0 in all modes other than simple SPI mode and clock synchronous mode.

30.2.29 FCR : FIFO Control Register

Base address: SCIn = 0x4011_8000 + 0x0100 × n (n = 0, 5 to 9)
SCIk = 0x4011_8000 + 0x0100 × k (k = 3, 4)

Offset address: 0x14

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	RSTRG[3:0]				RTRG[3:0]				TTRG[3:0]				DRES	TFRST	RFRST	FM
Value after reset:	1	1	1	1	1	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	FM	FIFO Mode Select Valid only in asynchronous mode, including multi-processor mode, or clock synchronous mode. 0: Non-FIFO mode. Selects TDR/RDR or TDRHL/RDRHL for communication. 1: FIFO mode. Selects FTDRHL/FRDRHL for communication.	R/W*1
1	RFRST	Receive FIFO Data Register Reset Valid only when FCR.FM = 1. 0: Do not reset FRDRHL 1: Reset FRDRHL	R/W
2	TFRST	Transmit FIFO Data Register Reset Valid only when FCR.FM = 1. 0: Do not reset FTDRHL 1: Reset FTDRHL	R/W
3	DRES	Receive Data Ready Error Select Selects the interrupt requested when detecting receive data ready. 0: Receive data full interrupt (SCIn_RXI) 1: Receive error interrupt (SCIn_ERI)	R/W
7:4	TTRG[3:0]	Transmit FIFO Data Trigger Number Valid only in asynchronous mode, including multi-processor mode, or clock synchronous mode. The trigger number is specified in the TTRG[3:0] bits.	R/W
11:8	RTRG[3:0]	Receive FIFO Data Trigger Number Valid only in asynchronous mode, including multi-processor mode, or clock synchronous mode. The trigger number is specified in the RTRG[3:0] bits.	R/W
15:12	RSTRG[3:0]	RTS Output Active Trigger Number Select Valid only in asynchronous mode, including multi-processor mode, or clock synchronous mode, when FCR.FM = 1, SPMR.CTSE = 0, and SPMR.SSE = 0. The trigger number is specified in the RSTRG[3:0] bits.	R/W

Note 1. Writable only when TE = 0 and RE = 0.

FCR selects FIFO mode, resets FTDRHL and FRDRHL, selects the FIFO data trigger number for transmission or reception, and selects the RTS output active trigger number.

FM bit (FIFO Mode Select)

When the FM bit is set to 1, FTDRHL and FRDRHL are selected for communication. When the FM bit is set to 0, TDR and RDR, or TDRHL and RDRHL are selected for communication.

RFRST bit (Receive FIFO Data Register Reset)

When the RFRST bit is set to 1, the FRDRHL register is reset and the received data count resets to 0. When 1 is written to the RFRST bit, it clears to 0 after 1 PCLK.

TFRST bit (Transmit FIFO Data Register Reset)

When the TFRST bit is set to 1, the FTDRHL register is reset and the transmit data count resets to 0. When 1 is written to the TFRST bit, it clears to 0 after 1 PCLK.

DRES bit (Receive Data Ready Error Select)

When detecting a receive data ready error, the selection can be made from an SCIn_RXI interrupt request or an SCIn_ERI interrupt request.

TTRG[3:0] bits (Transmit FIFO Data Trigger Number)

The TDFE flag is set to 1 when the amount of transmit data in FTDRHL is equal to or less than the transmit triggering number specified in the TTRG[3:0] bits, and software can write data to FTDRHL. If SCR.TIE = 1, an SCIn_TXI interrupt request occurs.

RTRG[3:0] bits (Receive FIFO Data Trigger Number)

The RDF flag is set to 1 when the amount of receive data in FRDRHL is equal to or greater than the receive triggering number specified in the RTRG[3:0] bits, and software can read data from FRDRHL. If SCR.RIE = 1, an SCIn_RXI interrupt request occurs.

When RTRG[3:0] is 0, the RDF flag is not set even when the amount of data in the receive FIFO is equal to 0, and an SCIn_RXI interrupt does not occur.

RSTRG[3:0] bits (RTS Output Active Trigger Number Select)

When the amount of receive data stored in FRDRHL is equal to or greater than the receive triggering number specified in the RSTRG[3:0] bits, the RTS signal goes high.

When RSTRG[3:0] is 0, the RTS signal does not go high even when the amount of data in FRDRHL is equal to 0.

30.2.30 FDR : FIFO Data Count Register

Base address: SCIn = 0x4011_8000 + 0x0100 × n (n = 0, 5 to 9)
SCIk = 0x4011_8000 + 0x0100 × k (k = 3, 4)

Offset address: 0x16

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	T[4:0]					—	—	—	R[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
4:0	R[4:0]	Receive FIFO Data Count Valid only in asynchronous mode, including multi-processor mode, or clock synchronous mode, when FCR.FM = 1. Indicates the amount of receive data stored in FRDRHL.	R
7:5	—	These bits are read as 0.	R
12:8	T[4:0]	Transmit FIFO Data Count Valid only in asynchronous mode, including multi-processor mode, or clock synchronous mode, when FCR.FM = 1. Indicates the amount of non-transmitted data stored in FTDRHL.	R
15:13	—	These bits are read as 0.	R

The FDR register indicates the amount of data stored in FRDRHL and FTDRHL.

R[4:0] bits (Receive FIFO Data Count)

The R[4:0] bits indicate the amount of receive data stored in FRDRHL. 0x00 means no receive data, and 0x10 means that the maximum received data is stored in FRDRHL.

T[4:0] bits (Transmit FIFO Data Count)

The T[4:0] bits indicate the amount of non-transmitted data stored in FTDRHL. 0x00 means no transmit data, and 0x10 means that all (maximum amount) of the data to be transmitted is stored in FTDRHL.

30.2.31 LSR : Line Status Register

Base address: SCIn = 0x4011_8000 + 0x0100 × n (n = 0, 5 to 9)
SCIk = 0x4011_8000 + 0x0100 × k (k = 3, 4)

Offset address: 0x18

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	PNUM[4:0]					—	FNUM[4:0]					—	ORER
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	ORER	Overrun Error Flag Valid only in asynchronous mode, including multi-processor mode, or clock synchronous mode, and when FIFO is selected. 0: No overrun error occurred 1: Overrun error occurred	R*1
1	—	This bit is read as 0.	R
6:2	FNUM[4:0]	Framing Error Count Indicates the amount of data with a framing error in the receive data stored in FRDRHL.	R
7	—	This bit is read as 0.	R
12:8	PNUM[4:0]	Parity Error Count Indicates the amount of data with a parity error in the receive data stored in FRDRHL.	R
15:13	—	These bits are read as 0.	R

Note 1. Write 0 to SSR_FIFO.ORER to clear the flag.

The LSR register indicates the receive error status.

ORER flag (Overrun Error Flag)

The ORER flag reflects the value in SSR_FIFO.ORER.

FNUM[4:0] bits (Framing Error Count)

The FNUM[4:0] value indicates the amount of data with a framing error stored in the FRDRHL register.

PNUM[4:0] bits (Parity Error Count)

The PNUM[4:0] value indicates the amount of data with a parity error stored in the FRDRHL register.

30.2.32 CDR : Compare Match Data Register

Base address: SCIn = 0x4011_8000 + 0x0100 × n (n = 0, 5 to 9)
SCIk = 0x4011_8000 + 0x0100 × k (k = 3, 4)

Offset address: 0x1A

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	CMPD[8:0]								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
8:0	CMPD[8:0]	Compare Match Data Holds compare data pattern for address match wakeup function.	R/W
15:9	—	These bits are read as 0. The write value should be 0.	R/W

The CDR register sets the compare data for the address match function.

CMPD[8:0] bits (Compare Match Data)

The CMPD[8:0] bits set the data to be compared to receive data for the address match function, when the address match function is enabled (DCCR.DCME = 1).

Three bit lengths are available:

- CMPD[6:0] with 7-bit length
- CMPD[7:0] with 8-bit length
- CMPD[8:0] with 9-bit length

30.2.33 DCCR : Data Compare Match Control Register

Base address: SCIn = 0x4011_8000 + 0x0100 × n (n = 0, 5 to 9)
SCIk = 0x4011_8000 + 0x0100 × k (k = 3, 4)

Offset address: 0x13

Bit position:	7	6	5	4	3	2	1	0
Bit field:	DCME	IDSEL	—	DFER	DPER	—	—	DCMF
Value after reset:	0	1	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	DCMF	Data Compare Match Flag 0: Not matched 1: Matched	R/(W)*1
2:1	—	These bits are read as 0. The write value should be 0.	R/W
3	DPER	Data Compare Match Parity Error Flag 0: No parity error occurred 1: Parity error occurred	R/(W)*1
4	DFER	Data Compare Match Framing Error Flag 0: No framing error occurred 1: Framing error occurred	R/(W)*1
5	—	This bit is read as 0. The write value should be 0.	R/W
6	IDSEL	ID Frame Select Valid only in asynchronous mode, including multi-processor mode. 0: Always compare data regardless of the MPB bit value 1: Only compare data when MPB bit = 1 (ID frame)	R/W
7	DCME	Data Compare Match Enable Valid only in asynchronous mode, including multi-processor mode. 0: Disable address match function 1: Enable address match function	R/W

Note 1. Only 0 can be written, to clear the flag after reading 1.

The DCCR register controls the address match function.

DCMF flag (Data Compare Match Flag)

The DCMF flag indicates that the SCI detected a receive data match with the comparison data (CDR.CMPD).

[Setting condition]

- On match of the comparison data (CDR.CMPD) with the receive data when DCCR.DCME = 1.

[Clearing condition]

- When 0 is written after 1 is read from DCMF.

Clearing the SCR.RE bit to 0 does not affect the DCMF flag, which retains its previous value.

DPER flag (Data Compare Match Parity Error Flag)

The DPER flag indicates that a parity error occurred on address match detection (receive data match detection).

[Setting condition]

- When a parity error is detected in a frame in which an address match is detected.

[Clearing conditions]

- When 0 is written after 1 is read from DPER.

When the SCR.RE bit is set to 0 (serial reception is disabled), the DPER flag is not affected and retains its previous value.

DFER flag (Data Compare Match Framing Error Flag)

The DFER flag indicates that a framing error occurred on address match detection (receive data match detection).

[Setting conditions]

- When a stop bit of a frame in which an address match is detected is 0.

  When in 2-stop-bit mode, only the first bit of the stop bits is checked for a value of 1 (the second stop bit is not checked).

[Clearing conditions]

- When 0 is written after 1 is read from DFER.

When the SCR.RE bit is set to 0 (serial reception is disabled), the DFER flag is not affected and retains its previous value.

IDSEL bit (ID Frame Select)

The IDSEL bit selects whether to compare data regardless of the MPB bit value or to compare data only when MPB = 1 (ID frame), when the address match function is enabled.

DCME bit (Data Compare Match Enable)

The DCME bit enables or disables the address match function (data compare match function).

If the SCI detects a match to the comparison data (CDR.CMPD) with the receive data, the DCME bit clears automatically, after which SCI operation mode is in normal receive mode. See section 30.3.6. Address Match (Receive Data Match Detection) Function.

The write value must be 0 for all modes other than asynchronous mode.

30.2.34 SPTR : Serial Port Register

Base address: SCIn = 0x4011_8000 + 0x0100 × n (n = 0, 5 to 9)
SCIk = 0x4011_8000 + 0x0100 × k (k = 3, 4)

Offset address: 0x1C

Bit position:	7	6	5	4	3	2	1	0
Bit field:	ATEN	ASEN	TINV	RINV	—	SPB2IO	SPB2DT	RXDMON
Value after reset:	0	0	0	0	0	0	1	1

Bit	Symbol	Function	R/W
0	RXDMON	Serial Input Data Monitor Indicates the state of the RXDn pin. 0: When RINV = 0, RXDn terminal is the low level. When RINV = 1, RXDn terminal is the High level. 1: When RINV = 0, RXDn terminal is the High level. When RINV = 1, RXDn terminal is the Low level.	R
1	SPB2DT	Serial Port Break Data Select Selects the output level of the TXDn pin when SCR.TE = 0. 0: When TINV = 0, Low level is output in TXDn terminal. When TINV = 1, High level is output in TXDn terminal. 1: When TINV = 0, High level is output in TXDn terminal. When TINV = 1, Low level is output in TXDn terminal.	R/W
2	SPB2IO	Serial Port Break I/O*1 Selects whether the value of SPB2DT is output to TXDn pin. 0: Do not output value of SPB2DT bit on TXDn pin 1: Output value of SPB2DT bit on TXDn pin	R/W
3	—	These bits are read as 0. The write value should be 0.	R/W
4	RINV	RXD invert bit 0: Received data from RXDn is not inverted and input.*2 1: Received data from RXDn is inverted and input.	R/W*3

Bit	Symbol	Function	R/W
5	TINV	TXD invert bit 0: Transmit data is not inverted and output to TXDn.*2 1: Transmit data is inverted and output to TXDn.	R/W*3
6	ASEN	Adjust receive sampling timing enable (This bit enables in asynchronous mode using internal clock) This function can adjust the receive sampling timing. In asynchronous mode using internal clock, see section 30.3.10. The function of adjust receive sampling timing (Asynchronous Mode) for details. 0: Adjust sampling timing disable. 1: Adjust sampling timing enable.	R/W*3
7	ATEN	Adjust transmit timing enable (This bit enables in asynchronous mode using internal clock) This function can adjust the transmit edge of TXDn waveform. See section 30.3.11. The function of adjust transmit timing (Asynchronous Mode) for details. 0: Adjust transmit timing disable. 1: Adjust transmit timing enable.	R/W*3

Note 1. Please use this bit in asynchronous mode and manchester mode. Movement by other mode isn't guaranteed.
Note 2. RINV/TINV should be set to 0 in smart card interface mode and simple I2C mode.
Note 3. Change the value of these bits only at SCR.TE = SCR.RE = 0.

The SPTR register provides confirmation of the serial reception pin (RXDn pin) status and sets the transmission and receive pin status.

And SPTR register has enable bits for adjust functions of receive sampling timing and transmit timing.

The TXDn pin status is determined by the combination of SCR.TE, SPTR.SPB2IO, and SPTR.SPB2DT settings, as shown in Table 30.25.

The data of RDR is controlled by RINV and SCMR.SINV. And the data from TXDn terminal is controlled by TINV and SCMR.SINV. The control by RINV/TINV are done to communication terminals (RXDn/TXDn), so they can control not only data-bits but also other bits (start bit, stop bit, parity bit). For details, see Figure 30.5.

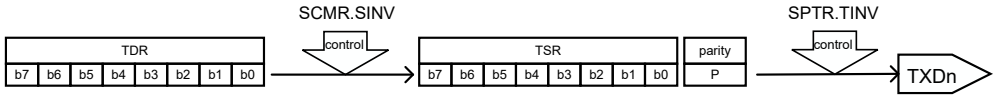
Table 30.25 TXDn pin status

Value of SCR.TE	Value of SPTR.SPB2IO	Value of SPTR.SPB2DT	TXDn pin status
0	0	—	Hi-Z (initial value)
0	1	0	Low level output
0	1	1	High level output
1	—	—	Serial transmit data is output

Note: —: Do not care.
Note: Use the SPTR register in asynchronous mode only. Using this register in any other mode is not guaranteed.

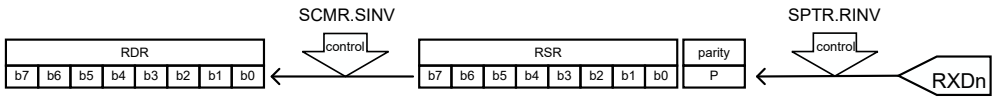
The receive/transmit data control (Data size=8bits, Even parity, MSB first)

The transmit data is controlled by SPTR.TINV and SCMR.SINV.



SCMR .SINV	SPTR. TINV	TDR	TSR	Prity (even)	TXDn waveform
0	0	0xBE	0xBE	0	S b7 b6 b5 b4 b3 b2 b1 b0 P
0	1	0xBE	0xBE	0	S b7 b6 b5 b4 b3 b2 b1 b0 P
1	0	0xBE	0x41	0	S b7 b6 b5 b4 b3 b2 b1 b0 P
1	1	0xBE	0x41	0	S b7 b6 b5 b4 b3 b2 b1 b0 P

The received data is controlled by SPTR.RINV and SCMR.SINV.



SCMR .SINV	SPTR. TINV	RDR	RSR	parity (even)	RXDn waveform
0	0	0xBE	0xBE	0	S b7 b6 b5 b4 b3 b2 b1 b0 P
1	0	0x41	0xBE	0	
0	1	0xBE	0xBE	0	S b7 b6 b5 b4 b3 b2 b1 b0 P
1	1	0x41	0xBE	0	

Figure 30.5 Example of the receive/transmit data control

30.2.35 ACTR : Adjustment Communication Timing Register

Base address: SCIn = 0x4011_8000 + 0x0100 × n (n = 0, 5 to 9)
SCIk = 0x4011_8000 + 0x0100 × k (k = 3, 4)

Offset address: 0x1D

Bit position:	7	6	5	4	3	2	1	0
Bit field:	AET	ATT[2:0]			AJD	AST[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	AST	Adjustment value for receive Sampling Timing The sampling timing of RXD terminal is adjusted from the middle of bit by the following formula. Adjustment sampling timing = base clock × the setting value of AST[2:0]. This bit is effective only at SPTR.ASEN = 1. This setting timing is limited by setting the base clock cycles. For details, see section 30.3.10. The function of adjust receive sampling timing (Asynchronous Mode).	R/W*1
3	AJD	Adjustment Direction for receive sampling timing Adjustment direction for RXD receive sampling timing is determined by this bit. 0: The sampling timing is adjusted backward to the middle of bit. 1: The sampling timing is adjusted forward to the middle of bit. This bit is effective only at SPTR.ASEN = 1. For details, see section 30.3.10. The function of adjust receive sampling timing (Asynchronous Mode).	R/W*1
6:4	ATT	Adjustment value for Transmit timing The selected edge timing of TXD is adjusted by the following formula. Adjustment edge timing = base clock × the setting value of ATT[2:0]. This bit is effective only at SPTR.ATEN = 1. This setting timing is limited by setting the base clock cycles. For details, see section 30.3.11. The function of adjust transmit timing (Asynchronous Mode).	R/W*2
7	AET	Adjustment edge for transmit timing The adjustable edge is set by this bit. When SPTR.TINV is 0, 0: Adjust the rising edge timing. 1: Adjust the falling edge timing. When SPTR.TINV is 1, 0: Adjust the falling edge timing. 1: Adjust the rising edge timing. This bit is effective only at SPTR.ATEN = 1. For details, see section 30.3.11. The function of adjust transmit timing (Asynchronous Mode).	R/W*2

Note 1. Write this bit only when SPTR.ASEN = 0.
Note 2. Write this bit only when SPTR.ATEN = 0.

This register controls adjustment of receive sampling timing and transmit timing. This register is effective only when asynchronous mode using internal clock.

For details of adjustment receive sampling timing by this register, see section 30.3.10. The function of adjust receive sampling timing (Asynchronous Mode).

For details of adjustment transmit timing by this register, see section 30.3.11. The function of adjust transmit timing (Asynchronous Mode).

Note: Sentences and a timing chart of the IP operation explanation (except section 30.1. Overview, section 30.2. Register Descriptions, section 30.3.10. The function of adjust receive sampling timing (Asynchronous Mode) and section 30.3.11. The function of adjust transmit timing (Asynchronous Mode)) are mentioned by the condition that the receive sampling timing and transmit timing adjustments are disabled (SPTR.ASEN = 0, SPTR.ATEN = 0).

30.2.36 MMR : Manchester Mode Register

Base address: SCIk = 0x4011_8000 + 0x0100 × k (k = 3, 4)

Offset address: 0x20

Bit position:	7	6	5	4	3	2	1	0
Bit field:	MANEN	SBSEL	SYNSEL	SYNVAL	—	ERTEN	TMPOL	RMPOL
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	RMPOL	Polarity of Received Manchester Code Sets the polarity of the received Manchester code 0: Logic 0 is coded as a zero-to-one transition in Manchester code Logic 1 is coded as a one-to-zero transition in Manchester code 1: Logic 0 is coded as a one-to-zero transition in Manchester code Logic 1 is coded as a zero-to-one transition in Manchester code	R/W*1
1	TMPOL	Polarity of Transmit Manchester Code Sets the polarity of the transmit Manchester code 0: Logic 0 is coded as a zero-to-one transition in Manchester code Logic 1 is coded as a one-to-zero transition in Manchester code 1: Logic 0 is coded as a one-to-zero transition in Manchester code Logic 1 is coded as a zero-to-one transition in Manchester code	R/W*1
2	ERTEN	Manchester Edge Retiming Enable Sets the receive retiming function 0: Disables the receive retiming function 1: Enables the receive retiming function	R/W*1
3	—	This bit is read as 0. The write value should be 0.	R
4	SYNVAL	SYNC value Setting Sets the SYNC type of the start bit(s) in the Manchester code When the start bit area consists of one bit. (SBSEL = 0) ● when transmitting 0: The start bit is added as a zero-to-one transition. 1: The start bit is added as a one-to-zero transition. ● when receiving 0: Only when the start bit is a zero-to-one transition, the data is received. The other cases are judged as an error. 1: Only when the start bit is a one-to-zero transition, the data is received. The other cases are judged as an error. When the start bit area consists of three bits. (SBSEL = 1) ● when transmitting 0: The start bits are added as a zero-to-one transition. (DATA SYNC) 1: The start bits are coded as a one-to-zero transition. (COMMAND SYNC) ● when receiving When the start bit area consists of three bits, data is received regardless of the value of this bit.	R/W*1
5	SYNSEL	SYNC Select 0: The start bit pattern is set with the SYNVAL bit 1: The start bit pattern is set with the TSYNC bit.	R/W*1
6	SBSEL	Start Bit Select 0: The start bit area consists of one bit. 1: The start bit area consists of three bits (COMMAND SYNC or DATA SYNC)	R/W*1
7	MANEN	Manchester Mode Enable Sets the Manchester mode 0: Disables the Manchester mode 1: Enables the Manchester mode	R/W*1

Note: Bits 6 to 0 in this register are valid only when the Manchester mode is enabled.(MANEN = ”1”) in bit 7.
Note 1. Writing to these bits is only possible when the RE and TE bits in SCR are 0 (both serial transmission and reception are disabled).

This register is used to enable or disable the Manchester mode, set the start bit area, and set the logic polarity.

RMPOL bit (Polarity of Received Manchester Code)

This bit sets the polarity of the received Manchester code. For details, see section 30.5.7. Serial Data Reception in Manchester Mode.

TMPOL bit (Polarity of Transmit Manchester Code)

This bit sets the polarity of the transmit Manchester code. For details, see section 30.5.6. Serial data transmission in Manchester mode.

ERTEN bit (Manchester Edge Retiming Enable)

This bit sets the receive retiming function in Manchester mode.

For information on the receive retiming function, see section 30.5.9. Receive Retiming.

SYNVAL bit (SYNC value Setting)

This bit is valid when the SYNSEL bit of this register is set to 0.

The SYNC type can be set by combining this bit and the SBSEL bit.

For the start bit area determined by the combination of this bit and the SBSEL bit, see Figure 30.52 and Figure 30.53.

SYNSEL bit (SYNC Select)

This bit is valid when the SBSEL bit of this register is set to 1. This bit determines the destination to be referred to for setting the SYNC type of the start bit area added to Manchester frames.

When this bit is set to 0, the SYNVAL bit of this register is referred to.

When this bit is set to 1, the TSYNC bit in the TDRH register is referred to.

For detail, see the bit table in section 30.2.36. MMR : Manchester Mode Register.

SBSEL bit (Start Bit Select)

This bit sets the start bit area in Manchester frames.

When this bit is set to 1, the start bit area added to each frame consists of three bits, and the SYNSEL and SYNVAL bits in this register are valid.

When this bit is set to 0, the start bit area added to each frame consists of one bit.

MANEN bit (Manchester Mode Enable)

This bit sets the Manchester mode.

When this bit is set to 0, the Manchester mode is disabled.

When this bit is set to 1, the Manchester mode is enabled.

30.2.37 TMPR : Transmit Manchester Preface Setting Register

Base address: SCIk = 0x4011_8000 + 0x0100 × k (k = 3, 4)

Offset address: 0x22

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	TPPAT[1:0]		TPLEN[3:0]			
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	TPLEN	Transmit preface length Set the preface length of the transmit data in Manchester mode 0x0: Disables the transmit preface generation Others: Transmit preface length (bit length)	R/W*1
5:4	TPPAT	Transmit preface pattern Set the preface pattern of the transmit data 0 0: ALL ZERO 0 1: ZERO ONE 1 0: ONE ZERO 1 1: ALL ONE	R/W*1
7:6	—	The read value is undefined. The write value should be 0.	R

Note: This register is valid only when the Manchester mode is enabled (MMR.MANEN = 1).
Note 1. Writing to these bits is only possible when the RE and TE bits in SCR are 0 (both serial transmission and reception are disabled).

This register is used to set the preface length and preface pattern of the transmit data in Manchester mode.

TPLEN bit (Transmit preface length)

These bits set the preface bit length of the transmit data in Manchester mode.

The settable range is 0x0 to 0xF (0 to 15). 0x0 disables the transmit preface, which is not added.

TPPAT bit (Transmit preface pattern)

These bits set one of the four preface patterns in Manchester mode.

When these bits are set to 00b, the preface area is set to all zeros.

When these bits are set to 01b, the preface area is set to the zero-one-zero-one pattern.

When these bits are set to 10b, the preface area is set to the one-zero-one-zero pattern.

When these bits are set to 11b, the preface area is set to all ones.

Note: For the transmit and receive data when the TPPAT bits are set, see Figure 30.51.

30.2.38 RMPR : Receive Manchester Preface Setting Register

Base address: SCIk = 0x4011_8000 + 0x0100 × k (k = 3, 4)

Offset address: 0x23

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	RPPAT[1:0]		RPLEN[3:0]			
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	RPLEN	Receive Preface Length Set the preface length in received frames when Manchester mode is enabled 0: Disables the receive preface generation Others: Receive preface length (bit length)	R/W*1
5:4	RPPAT	Receive Preface Pattern Set the preface pattern of received frames 0 0: ALL ZERO 0 1: ZERO ONE 1 0: ONE ZERO 1 1: ALL ONE	R/W*1
7:6	—	These bits are read as 0. The write value should be 0.	R

Note: This register is valid only when the Manchester mode is enabled (MMR.MANEN = 1).
Note 1. Writing to these bits is only possible when the RE and TE bits in SCR are 0 (both serial transmission and reception are disabled).

This register is used to set the preface length and preface pattern of the received frames in Manchester mode.

RPLEN bit (Receive Preface Length)

These bits set the preface bit length of the received frames in Manchester mode.

The settable range is 0x0 to 0xF (0 to 15). 0x0 disables the receive preface, which is not added. When 0x1 to 0xF is set, the set value is handled as the receive preface bit length.

RPPAT bit (Receive Preface Pattern)

These bits set one of the four preface patterns in Manchester mode.

When these bits are set to 00b, the preface area is handled as all zeros.

When these bits are set to 01b, the preface area is handled as the zero-one-zero-one pattern.

When these bits are set to 10b, the preface area is handled as the one-zero-one-zero pattern.

When these bits are set to 11b, the preface area is handled as all ones.

Note: For the transmit and receive data when the RPPAT bits are set, see Figure 30.51.

30.2.39 MESR : Manchester Extended Error Status Register

Base address: SCIk = 0x4011_8000 + 0x0100 × k (k = 3, 4)

Offset address: 0x24

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	SBER	SYER	PFER
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PFER	Preface Error flag This bit is set when a preface error (pattern mismatch) is detected 0: No preface error detected 1: Preface error detected	R/(W)*1
1	SYER	SYNC Error flag This bit is set when no edge is detected in the adjustable range during receive retiming 0: No receive SYNC error detected 1: Receive SYNC error detected	R/(W)*1
2	SBER	Start Bit Error flag This bit is set when a pattern mismatch in the start bit area is detected 0: No start bit error detected 1: Start bit error detected	R/(W)*1
7:3	—	These bits are read as 0. The write value should be 0.	R

Note: This register is valid only when the Manchester mode is enabled (MMR.MANEN = 1).
Note 1. Only 0 can be written to this bit, to clear the flag. To clear the flag, confirm that the flag is 1 before setting it to 0.

This register indicates an error status when receiving frames in Manchester mode.

A preface error, receive SYNC error or start bit error was detected.

PFER bit (Preface Error flag)

This bit indicates that a preface error was detected when receiving frames in Manchester mode.

[Setting condition]

- When detecting a preface error when receiving frames in Manchester mode
  The following operations are performed when a preface error occurs.
  When MECR.PFEREN = 1
  The received data is not transferred to the RDR register and no RXI interrupt request occurs. Instead, an ERI interrupt request occurs. Note that when the PFER flag is being set to 1, the subsequently received data is not transferred to the RDR register.
  When MECR.PFEREN = 0
  The received data is transferred to the RDR register and an RXI interrupt request occurs. An ERI interrupt request is not generated. The subsequent receive operations are not affected even with the PFER flag being set to 1.

[Clearing condition]

- When 0 is written to the bit after it was read as 1

Even if the SCR.RE bit is cleared, the PFER flag is not affected, and the previous state is retained.

SYER bit (SYNC Error flag)

This bit indicates that a receive SYNC error was detected when receiving frames in Manchester mode with

MMR.ERTEN = 1 (Manchester edge retiming enabled).

[Setting condition]

- When detecting a receive SYNC error when receiving frames in Manchester mode
  The following operations are performed when a receive SYNC error occurs.
  When MECR.SYEREN = 1

Although the received data is transferred to the RDR register, no RXI interrupt request occurs. Instead, an ERI interrupt request occurs. Note that when the SYER flag is being set to 1, the subsequently received data is not transferred to the RDR register.
When MECR.SYEREN = 0
The received data is transferred to the RDR register and an RXI interrupt request occurs. An ERI interrupt request is not generated. The subsequent receive operations are not affected even with the SYER flag being set to 1.

[Clearing condition]

- When 0 is written to the bit after it was read as 1

Even if the SCR.RE bit is cleared, the SYER flag is not affected, and the previous state is retained.

SBER bit (Start Bit Error flag)

This bit indicates that a start bit error was detected when receiving frames in Manchester mode.

[Setting condition]

- When detecting a start bit error when receiving frames in Manchester mode
The following operations are performed when a start bit error occurs.
When MECR.SBEREN = 1
The received data is not transferred to the RDR register and no RXI interrupt request occurs. Instead, an ERI interrupt request occurs. Note that when the SBER flag is being set to 1, the subsequently received data is not transferred to the RDR register.
When MECR.SBEREN = 0
The received data is transferred to the RDR register and an RXI interrupt request occurs. An ERI interrupt request is not generated. The subsequent receive operations are not affected even with the SBER flag being set to 1.

[Clearing condition]

- When 0 is written to the bit after it was read as 1

Even if the SCR.RE bit is cleared, the SBER flag is not affected, and the previous state is retained.

30.2.40 MECR : Manchester Extended Error Control Register

Base address: SCIk = 0x4011_8000 + 0x0100 × k (k = 3, 4)

Offset address: 0x25

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	SBEREN	SYEREN	PFEREN
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PFEREN	Preface Error Enable Specifies whether to handle a preface error as an interrupt source 0: Does not handle a preface error as an interrupt source 1: Handles a preface error as an interrupt source	R/W
1	SYEREN	Receive SYNC Error Enable Specifies whether to handle a receive SYNC error as an interrupt source 0: Does not handle a receive SYNC error as an interrupt source 1: Handles a receive SYNC error as an interrupt source	R/W
2	SBEREN	Start Bit Error Enable Specifies whether to handle a start bit error as an interrupt source 0: Does not handle a start bit error as an interrupt source 1: Handles a start bit error as an interrupt source	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R

Note: This register is valid only when the Manchester mode is enabled (MMR.MANEN = 1).

This register is used to specify whether to handle a preface error, receive SYNC error, or a start bit error as an interrupt source in Manchester mode. If those errors are handled as interrupt sources, interrupt requests and event requests are generated at the occurrence of each error, and the next reception is not performed until the corresponding error flag is cleared.

Set this register when MMR.MANEN = 0. However, do not change this register during communication.

PFEREN bit (Preface Error Enable)

This bit specifies whether to handle a preface error as an interrupt source.

When it is set to 0, a preface error is not handled as an interrupt source. When it is set to 1, a preface error is handled as an interrupt source.

SYEREN bit (Receive SYNC Error Enable)

This bit specifies whether to handle a receive SYNC error as an interrupt source.

When it is set to 0, a receive SYNC error is not handled as an interrupt source. When it is set to 1, a receive SYNC error is handled as an interrupt source.

SBEREN bit (Start Bit Error Enable)

This bit specifies whether to handle a start bit error as an interrupt source.

When it is set to 0, a start bit error is not handled as an interrupt source. When it is set to 1, a start bit error is handled as an interrupt source.

30.2.41 ESMER : Extended Serial Module Enable Register

Base address: SCIm = 0x4011_8000 + 0x0100 × m (m = 1, 2)

Offset address: 0x20

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	ESME
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	ESME	Extended Serial Mode Enable 0: The extended serial mode is disabled. 1: The extended serial mode is enabled.	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W

ESME bit (Extended Serial Mode Enable)

When the ESME bit is 1, the facilities of the extended serial mode control section are enabled.

When the ESME bit is 0, the extended serial mode control section is initialized.

Table 30.26 Settings of the ESME Bit and Timer Operation Mode

ESME Bit	Timer Mode	Break Field Low Width Determination Mode	Break Field Low Width Output Mode
0	Available*1	Not available	Not available
1	Available	Available	Available

Note 1. Operation is only possible with PCLK selected.

30.2.42 CR0 : Control Register 0

Base address: SCIm = 0x4011_8000 + 0x0100 × m (m = 1, 2)

Offset address: 0x21

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	BRME	RXDSF	SFSF	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	—	This bit is read as 0. The write value should be 0.	R/W
1	SFSF	Start Frame Status Flag 0: Start Frame detection function is disabled. 1: Start Frame detection function is enabled.	R
2	RXDSF	RXDXn Input Status Flag 0: RXDXn input is enabled. 1: RXDXn input is disabled.	R
3	BRME	Bit Rate Measurement Enable 0: Measurement of bit rate is disabled. 1: Measurement of bit rate is enabled.	R/W
7:4	—	These bits are read as 0. The write value should be 0.	R/W

30.2.43 CR1 : Control Register 1

Base address: SCIm = 0x4011_8000 + 0x0100 × m (m = 1, 2)

Offset address: 0x22

Bit position:	7	6	5	4	3	2	1	0
Bit field:	PIBS[2:0]			PIBE	CF1DS[1:0]		CF0RE	BFE
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	BFE	Break Field Enable 0: Break Field detection is disabled. 1: Break Field detection is enabled.	R/W
1	CF0RE	Control Field 0 Reception Enable 0: Reception of Control Field 0 is disabled. 1: Reception of Control Field 0 is enabled.	R/W
3:2	CF1DS[1:0]	Control Field 1 Data Register Select 0 0: Selects comparison with the value in PCF1DR. 0 1: Selects comparison with the value in SCF1DR. 1 0: Selects comparison with the values in PCF1DR and SCF1DR. 1 1: Setting prohibited.	R/W
4	PIBE	Priority Interrupt Bit Enable 0: The priority interrupt bit is disabled. 1: The priority interrupt bit is enabled.	R/W

Bit	Symbol	Function	R/W
7:5	PIBS[2:0]	Priority Interrupt Bit Select 0 0 0: 0th bit of Control Field 1 0 0 1: 1st bit of Control Field 1 0 1 0: 2nd bit of Control Field 1 0 1 1: 3rd bit of Control Field 1 1 0 0: 4th bit of Control Field 1 1 0 1: 5th bit of Control Field 1 1 1 0: 6th bit of Control Field 1 1 1 1: 7th bit of Control Field 1	R/W

30.2.44 CR2 : Control Register 2

Base address: SCIm = 0x4011_8000 + 0x0100 × m (m = 1, 2)

Offset address: 0x23

Bit position:	7	6	5	4	3	2	1	0
Bit field:	RTS[1:0]		BCCS[1:0]		—	DFCS[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	DFCS[2:0]	RXDXn Signal Digital Filter Clock Select 0 0 0: Filter is disabled. 0 0 1: Filter clock is SCI base clock*1 *2 0 1 0: Filter clock is PCLK/8 0 1 1: Filter clock is PCLK/16 1 0 0: Filter clock is PCLK/32 1 0 1: Filter clock is PCLK/64 1 1 0: Filter clock is PCLK/128 1 1 1: Setting prohibited	R/W
3	—	This bit is read as 0. The write value should be 0.	R/W
5:4	BCCS[1:0]	Bus Collision Detection Clock Select ● When SEMR.BGDM = 0 or SEMR.BGDM = 1 and SMR.CKS[1:0] = a value other than 00b 0 0: SCI base clock 0 1: SCI base clock frequency divided by 2 1 0: SCI base clock frequency divided by 4 1 1: Setting prohibited ● When SEMR.BGDM = 1 and SMR.CKS[1:0] = 00b 0 0: SCI base clock frequency divided by 2 0 1: SCI base clock frequency divided by 4 1 0: Setting prohibited 1 1: Setting prohibited	R/W
7:6	RTS[1:0]	RXDXn Reception Sampling Timing Select ● When SCIn.SEMR.ABCS = 0 0 0: Rising edge of the 8th cycle of SCI base clock 0 1: Rising edge of the 10th cycle of SCI base clock 1 0: Rising edge of the 12th cycle of SCI base clock 1 1: Rising edge of the 14th cycle of SCI base clock ● When SCIn.SEMR.ABCS = 1 0 0: Rising edge of the 4th cycle of SCI base clock 0 1: Rising edge of the 5th cycle of SCI base clock 1 0: Rising edge of the 6th cycle of SCI base clock 1 1: Rising edge of the 7th cycle of SCI base clock	R/W

Note: The period of the SCI base clock is 1/16 of a single bit period when the SCIn.SEMR.ABCS is 0, and 1/8 of a single bit period when the SCIn.SEMR.ABCS is 1.

Note 1. To use the SCI base clock, set the SCIn.SCR.TE bit to 1.

Note 2. The SCI base clock divided by 2 is the filter clock when the SEMR.BGDM bit is 1 and the SMR.CKS[1:0] bits are 00b.

30.2.45 CR3 : Control Register 3

Base address: SCIm = 0x4011_8000 + 0x0100 × m (m = 1, 2)

Offset address: 0x24

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	SDST
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SDST	Start Frame Detection Start 0: Detection of Start Frame is not performed. 1: Detection of Start Frame is performed.	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W

SDST bit (Start Frame Detection Start)

Detection of a Start Frame begins when this bit is set to 1. The bit is read as 0.

30.2.46 PCR : Port Control Register

Base address: SCIm = 0x4011_8000 + 0x0100 × m (m = 1, 2)

Offset address: 0x25

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	SHARPS	—	—	RXDXPS	TXDXPS
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TXDXPS	TXDXn Signal Polarity Select 0: The polarity of TXDXn signal is not inverted for output. 1: The polarity of TXDXn signal is inverted for output.	R/W
1	RXDXPS	RXDXn Signal Polarity Select 0: The polarity of RXDXn signal is not inverted for input. 1: The polarity of RXDXn signal is inverted for input.	R/W
3:2	—	These bits are read as 0. The write value should be 0.	R/W
4	SHARPS	TXDXn/RXDXn Pin Multiplexing Select 0: The TXDXn and RXDXn pins are independent. 1: The TXDXn and RXDXn signals are multiplexed on the same pin.	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W

SHARPS bit (TXDXn/RXDXn Pin Multiplexing Select)

When this bit is set to 1, the TXDXn and RXDXn signals are multiplexed on the same pin so that half-duplex communications become possible.

30.2.47 ICR : Interrupt Control Register

Base address: SCIm = 0x4011_8000 + 0x0100 × m (m = 1, 2)

Offset address: 0x26

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	AEDIE	BCDIE	PIBDIE	CF1MIE	CF0MIE	BFDIE
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	BFDIE	Break Field Low Width Detected Interrupt Enable 0: Interrupts on detection of the low width for a Break Field are disabled. 1: Interrupts on detection of the low width for a Break Field are enabled.	R/W
1	CF0MIE	Control Field 0 Match Detected Interrupt Enable 0: Interrupts on detection of a match with Control Field 0 are disabled. 1: Interrupts on detection of a match with Control Field 0 are enabled.	R/W
2	CF1MIE	Control Field 1 Match Detected Interrupt Enable 0: Interrupts on detection of a match with Control Field 1 are disabled. 1: Interrupts on detection of a match with Control Field 1 are enabled.	R/W
3	PIBDIE	Priority Interrupt Bit Detected Interrupt Enable 0: Interrupts on detection of the priority interrupt bit are disabled. 1: Interrupts on detection of the priority interrupt bit are enabled.	R/W
4	BCDIE	Bus Collision Detected Interrupt Enable 0: Interrupts on detection of a bus collision are disabled. 1: Interrupts on detection of a bus collision are enabled.	R/W
5	AEDIE	Valid Edge Detected Interrupt Enable 0: Interrupts on detection of a valid edge are disabled. 1: Interrupts on detection of a valid edge are enabled.	R/W
7:6	—	These bits are read as 0. The write value should be 0.	R/W

30.2.48 STR : Status Register

Base address: SCIm = 0x4011_8000 + 0x0100 × m (m = 1, 2)

Offset address: 0x27

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	AEDF	BCDF	PIBDF	CF1MF	CF0MF	BFDF
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	BFDF	Break Field Low Width Detection Flag [Setting conditions] ● Detection of the low width for a Break Field ● Completion of the output of the low width for a Break Field ● Underflow of the timer [Clearing condition] ● Writing 1 to the BFDCL bit in STCR	R
1	CF0MF	Control Field 0 Match Flag [Setting conditions] ● A match between the value received in Control Field 0 and the set value. [Clearing condition] ● Writing 1 to the CF0MCL bit in STCR	R
2	CF1MF	Control Field 1 Match Flag [Setting conditions] ● A match between the data received in Control Field 1 and the set values. [Clearing condition] ● Writing 1 to the CF1MCL bit in STCR	R
3	PIBDF	Priority Interrupt Bit Detection Flag [Setting conditions] ● Detection of the priority interrupt bit [Clearing condition] ● Writing 1 to the PIBDCL bit in STCR	R

Bit	Symbol	Function	R/W
4	BCDF	Bus Collision Detected Flag [Setting conditions] ● Detection of the bus collision [Clearing condition] ● Writing 1 to the BCDCL bit in STCR	R
5	AEDF	Valid Edge Detection Flag [Setting conditions] ● Detection of a valid edge [Clearing condition] ● Writing 1 to the AEDCL bit in STCR	R
7:6	—	These bits are read as 0. The write value should be 0.	R

30.2.49 STCR : Status Clear Register

Base address: SCIm = 0x4011_8000 + 0x0100 × m (m = 1, 2)

Offset address: 0x28

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	AEDCL	BCDCL	PIBDCL	CF1MCL	CF0MCL	BFDCL
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	BFDCL	BFDF Clear Setting this bit to 1 clears the STR.BFDF flag. This bit is read as 0.	R/W
1	CF0MCL	CF0MF Clear Setting this bit to 1 clears the STR.CF0MF flag. This bit is read as 0.	R/W
2	CF1MCL	CF1MF Clear Setting this bit to 1 clears the STR.CF1MF flag. This bit is read as 0.	R/W
3	PIBDCL	PIBDF Clear Setting this bit to 1 clears the STR.PIBDF flag. This bit is read as 0.	R/W
4	BCDCL	BCDF Clear Setting this bit to 1 clears the STR.BCDF flag. This bit is read as 0.	R/W
5	AEDCL	AEDF Clear Setting this bit to 1 clears the STR.AEDF flag. This bit is read as 0.	R/W
7:6	—	These bits are read as 0. The write value should be 0.	R/W

30.2.50 CF0DR : Control Field 0 Data Register

Base address: SCIm = 0x4011_8000 + 0x0100 × m (m = 1, 2)

Offset address: 0x29

Bit position:	7	6	5	4	3	2	1	0
Bit field:								
Value after reset:	0	0	0	0	0	0	0	0

The CF0DR register is an 8-bit readable and writable register that holds a value for comparison with Control Field 0.

30.2.51 CF0CR : Control Field 0 Compare Enable Register

Base address: SCIm = 0x4011_8000 + 0x0100 × m (m = 1, 2)

Offset address: 0x2A

Bit position:	7	6	5	4	3	2	1	0
Bit field:	CF0CE7	CF0CE6	CF0CE5	CF0CE4	CF0CE3	CF0CE2	CF0CE1	CF0CE0
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CF0CE0	Control Field 0 Bit 0 Compare Enable 0: Comparison with bit 0 of Control Field 0 is disabled. 1: Comparison with bit 0 of Control Field 0 is enabled.	R/W
1	CF0CE1	Control Field 1 Bit 0 Compare Enable 0: Comparison with bit 1 of Control Field 0 is disabled. 1: Comparison with bit 1 of Control Field 0 is enabled.	R/W
2	CF0CE2	Control Field 2 Bit 0 Compare Enable 0: Comparison with bit 2 of Control Field 0 is disabled. 1: Comparison with bit 2 of Control Field 0 is enabled.	R/W
3	CF0CE3	Control Field 3 Bit 0 Compare Enable 0: Comparison with bit 3 of Control Field 0 is disabled. 1: Comparison with bit 3 of Control Field 0 is enabled.	R/W
4	CF0CE4	Control Field 4 Bit 0 Compare Enable 0: Comparison with bit 4 of Control Field 0 is disabled. 1: Comparison with bit 4 of Control Field 0 is enabled.	R/W
5	CF0CE5	Control Field 5 Bit 0 Compare Enable 0: Comparison with bit 5 of Control Field 0 is disabled. 1: Comparison with bit 5 of Control Field 0 is enabled.	R/W
6	CF0CE6	Control Field 6 Bit 0 Compare Enable 0: Comparison with bit 6 of Control Field 0 is disabled. 1: Comparison with bit 6 of Control Field 0 is enabled.	R/W
7	CF0CE7	Control Field 7 Bit 0 Compare Enable 0: Comparison with bit 7 of Control Field 0 is disabled. 1: Comparison with bit 7 of Control Field 0 is enabled.	R/W

30.2.52 CF0RR : Control Field 0 Receive Data Register

Base address: SCIm = 0x4011_8000 + 0x0100 × m (m = 1, 2)

Offset address: 0x2B

Bit position:	7	6	5	4	3	2	1	0
Bit field:								
Value after reset:	0	0	0	0	0	0	0	0

CF0RR is a readable register that holds the value received in Control Field 0.

30.2.53 PCF1DR : Primary Control Field 1 Data Register

Base address: SCIm = 0x4011_8000 + 0x0100 × m (m = 1, 2)

Offset address: 0x2C

Bit position:	7	6	5	4	3	2	1	0
Bit field:								
Value after reset:	0	0	0	0	0	0	0	0

PCF1DR is an 8-bit readable and writable register that holds the 8-bit primary value for comparison with Control Field 1.

30.2.54 SCF1DR : Secondary Control Field 1 Data Register

Base address: SCIm = 0x4011_8000 + 0x0100 × m (m = 1, 2)

Offset address: 0x2D

Bit position:	7	6	5	4	3	2	1	0
Bit field:								
Value after reset:	0	0	0	0	0	0	0	0

SCF1DR is an 8-bit readable and writable register that holds the 8-bit secondary value for comparison with Control Field 1.

30.2.55 CF1CR : Control Field 1 Compare Enable Register

Base address: SCIm = 0x4011_8000 + 0x0100 × m (m = 1, 2)

Offset address: 0x2E

Bit position:	7	6	5	4	3	2	1	0
Bit field:	CF1CE7	CF1CE6	CF1CE5	CF1CE4	CF1CE3	CF1CE2	CF1CE1	CF1CE0
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CF1CE0	Control Field 1 Bit 0 Compare Enable 0: Comparison with bit 0 of Control Field 1 is disabled. 1: Comparison with bit 0 of Control Field 1 is enabled.	R/W
1	CF1CE1	Control Field 1 Bit 1 Compare Enable 0: Comparison with bit 1 of Control Field 1 is disabled. 1: Comparison with bit 1 of Control Field 1 is enabled.	R/W
2	CF1CE2	Control Field 1 Bit 2 Compare Enable 0: Comparison with bit 2 of Control Field 1 is disabled. 1: Comparison with bit 2 of Control Field 1 is enabled.	R/W
3	CF1CE3	Control Field 1 Bit 3 Compare Enable 0: Comparison with bit 3 of Control Field 1 is disabled. 1: Comparison with bit 3 of Control Field 1 is enabled.	R/W
4	CF1CE4	Control Field 1 Bit 4 Compare Enable 0: Comparison with bit 4 of Control Field 1 is disabled. 1: Comparison with bit 4 of Control Field 1 is enabled.	R/W
5	CF1CE5	Control Field 1 Bit 5 Compare Enable 0: Comparison with bit 5 of Control Field 1 is disabled. 1: Comparison with bit 5 of Control Field 1 is enabled.	R/W
6	CF1CE6	Control Field 1 Bit 6 Compare Enable 0: Comparison with bit 6 of Control Field 1 is disabled. 1: Comparison with bit 6 of Control Field 1 is enabled.	R/W

Bit	Symbol	Function	R/W
7	CF1CE7	Control Field 1 Bit 7 Compare Enable 0: Comparison with bit 7 of Control Field 1 is disabled. 1: Comparison with bit 7 of Control Field 1 is enabled.	R/W

30.2.56 CF1RR : Control Field 1 Receive Data Register

Base address: SCIm = 0x4011_8000 + 0x0100 × m (m = 1, 2)

Offset address: 0x2F

Bit position:	7	6	5	4	3	2	1	0
Bit field:								
Value after reset:	0	0	0	0	0	0	0	0

CF1RR is a readable register that holds the value received in Control Field 1.

30.2.57 TCR : Timer Control Register

Base address: SCIm = 0x4011_8000 + 0x0100 × m (m = 1, 2)

Offset address: 0x30

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	TCST
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TCST	Timer Count Start 0: Stops the timer counting 1: Starts the timer counting	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W

30.2.58 TMR : Timer Mode Register

Base address: SCIm = 0x4011_8000 + 0x0100 × m (m = 1, 2)

Offset address: 0x31

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	TCSS[2:0]			TWRC	—	TOMS[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	TOMS[1:0]	Timer Operating Mode Select*1 0 0: Timer mode 0 1: Break Field low width determination mode 1 0: Break Field low width output mode 1 1: Setting prohibited	R/W
2	—	This bit is read as 0. The write value should be 0.	R/W
3	TWRC	Counter Write Control 0: Data is written to the reload register and counter 1: Data is written to the reload register only	R/W

Bit	Symbol	Function	R/W
6:4	TCSS[2:0]	Timer Count Clock Source Select*1 0 0 0: PCLK 0 0 1: PCLK/2 0 1 0: PCLK/4 0 1 1: PCLK/8 1 0 0: PCLK/16 1 0 1: PCLK/32 1 1 0: PCLK/64 1 1 1: PCLK/128	R/W
7	—	This bit is read as 0. The write value should be 0.	R/W

Note 1. Rewrite the TOMS[1:0] and TCSS[2:0] bits only when the timer is stopped (TCST = 0).

TWRC bit (Counter Write Control)

This bit determines whether a value written to TPRE or TCNT is written to the reload register only or is written to both the reload register and the counter.

30.2.59 TPRE : Timer Prescaler Register

Base address: SCIm = 0x4011_8000 + 0x0100 × m (m = 1, 2)

Offset address: 0x32

Bit position:	7	6	5	4	3	2	1	0
Bit field:								
Value after reset:	1	1	1	1	1	1	1	1

TPRE consists of an 8-bit reload register, a read buffer, and a counter, each of which has 0xFF as its initial value. The counter counts down in synchronization with the counter clock selected by the TMR.TCSS[2:0] bits, and is reloaded with the value in the reload register when it underflows. Underflows of this register provide the clock source to drive counting by the TCNT register. The reload register and read buffer are allocated to the same address. Data is written to the reload register in writing, and the counter value that has been transferred to the read buffer is returned in reading.

It takes one PCLK cycle to load a value from the reload register to the counter.

30.2.60 TCNT : Timer Count Register

Base address: SCIm = 0x4011_8000 + 0x0100 × m (m = 1, 2)

Offset address: 0x33

Bit position:	7	6	5	4	3	2	1	0
Bit field:								
Value after reset:	1	1	1	1	1	1	1	1

TCNT consists of an 8-bit reload register, a read buffer, and a counter, each of which has 0xFF as its initial value. This down-counter counts underflows of the TPRE register until the TCNT register underflows, and is then reloaded with the value from the reload register. The reload register and read buffer are allocated to the same address. Data is written to the reload register in writing, and the counter value that has been transferred to the read buffer is returned in reading.

It takes one PCLK cycle to load a value from the reload register to the counter.

30.3 Operation in Asynchronous Mode

Figure 30.6 shows the general format for asynchronous serial communications. One frame consists of a start bit (low level), transmit or receive data, a parity bit, and stop bits (high level). In asynchronous serial communications, the communications line is usually held in the mark state (high level).

The SCI monitors the communications line. When the SCI detects a low, it regards that as a start bit and starts serial communication.

Inside the SCI, the transmitter and receiver are independent units, enabling full-duplex communications. Both the transmitter and receiver have a double-buffered structure in addition to FIFO mode, so that data can be read or written during transmission or reception, enabling continuous data transmission and reception.

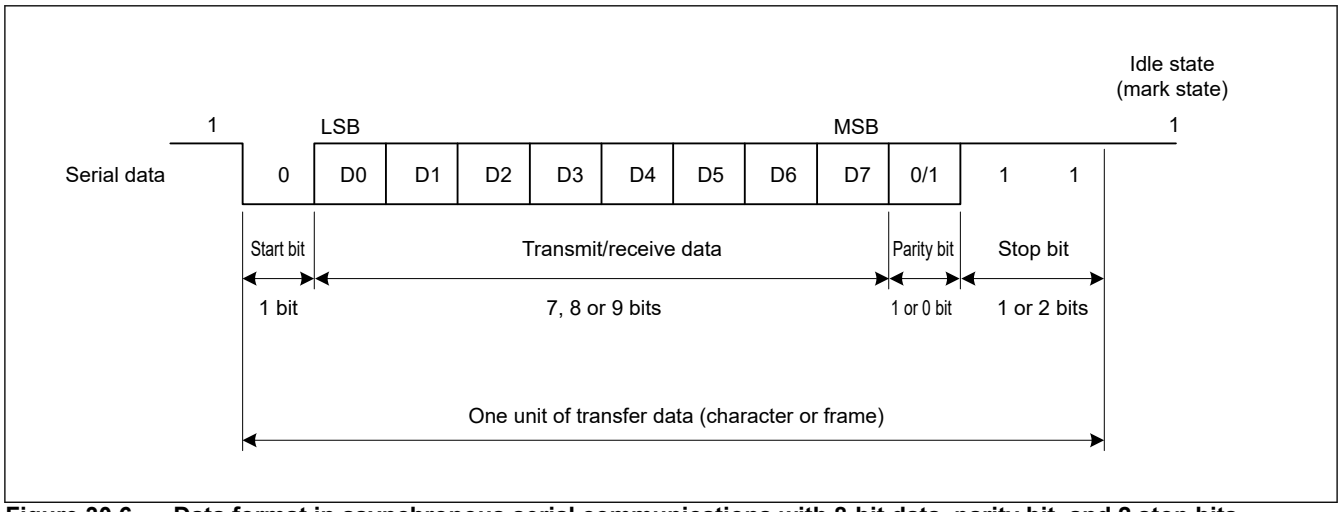


Figure 30.6 Data format in asynchronous serial communications with 8-bit data, parity bit, and 2 stop bits

30.3.1 Serial Data Transfer Format

Table 30.27 lists the serial data transfer formats that can be used in asynchronous mode. Any of 18 transfer formats can be selected with the SMR and SCMR settings. For details on the multi-processor function, see section 30.4. Multi-Processor Communication Function.

Table 30.27 Serial transfer formats in asynchronous mode (1 of 2)

SCMR setting	SMR setting				Serial transfer format and frame length
CHR1	CHR	PE	MP	STOP	1 2 3 4 5 6 7 8 9 10 11 12 13
0	0	0	0	0	ST 9-bit data SP
0	0	0	0	1	ST 9-bit data SP SP
0	0	1	0	0	ST 9-bit data P SP
0	0	1	0	1	ST 9-bit data P SP SP
1	0	0	0	0	ST 8-bit data SP
1	0	0	0	1	ST 8-bit data SP SP
1	0	1	0	0	ST 8-bit data P SP
1	0	1	0	1	ST 8-bit data P SP SP
1	1	0	0	0	ST 7-bit data SP
1	1	0	0	1	ST 7-bit data SP SP

Table 30.27 Serial transfer formats in asynchronous mode (2 of 2)

SCMR setting	SMR setting				Serial transfer format and frame length
CHR1	CHR	PE	MP	STOP	1 2 3 4 5 6 7 8 9 10 11 12 13
1	1	1	0	0	ST | 7-bit data | P | SP
1	1	1	0	1	ST | 7-bit data | P | SP | SP
0	0	—	1	0	ST | 9-bit data | MPB | SP
0	0	—	1	1	ST | 9-bit data | MPB | SP | SP
1	0	—	1	0	ST | 8-bit data | MPB | SP
1	0	—	1	1	ST | 8-bit data | MPB | SP | SP
1	1	—	1	0	ST | 7-bit data | MPB | SP
1	1	—	1	1	ST | 7-bit data | MPB | SP | SP

ST: Start bit
SP: Stop bit
P: Parity bit
MPB: Multi-processor bit

30.3.2 Receive Data Sampling Timing and Reception Margin in Asynchronous Mode

In asynchronous mode, the SCI operates on a base clock with a frequency of 16 times[*1] the bit rate.

In reception, the SCI samples the falling edge of the start bit using the base clock, and performs internal synchronization.[*2]

Because receive data is sampled on the rising edge of the 8th pulse[*1] of the base clock, data is latched at the middle of each bit (when sampling timing does not adjust (SPTR.ASEN = 0)), as shown in Figure 30.7 The reception margin in asynchronous mode is determined by the following formula (1):

$$M = \left|\left(0.5 - \frac{1}{2N}\right) - (L - 0.5)F - \frac{|D - 0.5|}{N}(1 + F)\right| \times 100\ [\%] \quad \ldots \quad \text{Formula (1)}$$

Note: M: Reception margin
N: Ratio of bit rate to clock
(N = 16 when SEMR.ABCSE = 0 and SEMR.ABCS = 0,
N = 8 when SEMR.ABCS = 1,
N = 6 when SEMR.ABCSE = 1)
D: Duty cycle of clock (D = 0.5 to 1.0)
L: Frame length (L = 9 to 13)
F: Absolute value of clock frequency deviation

Assuming values of F = 0 and D = 0.5 in formula (1), the reception margin is determined using the following formula:
$M = \{0.5 - 1/(2 \times 16)\} \times 100\ (\%) = 46.875\ \%$

This represents the computed value. Renesas recommends a margin of 20% to 30% in system design.

Note 1. In this example, the SEMR.ABCS bit is 0 and the SEMR.ABCSE is 0. When the ABCS bit is 1 and the ABCSE bit is 0, a frequency of 8 times the bit rate is used as a base clock, and receive data is sampled on the rising edge of the 4th pulse of the base clock.

When the ABCSE bit is 1, a sextuple frequency of a bit rate is used as a base clock, and receive data is sampled on the rising edge of the 3rd pulse of the base clock.

Note 2. The determination condition of the start bit is as follows.

The function of adjust sampling timing is OFF (ASEN = 0):

The determination condition of a start bit is that Low beyond half bit length continues. It is same as the sampling timing. In Figure 30.7, Low period should be kept over 8-cycles to detect a start bit. If Low period does not keep over 8-cycles, the IP judges this as a noise. So, the IP does not start reception and wait start bit.

The function of adjust sampling timing is ON (ASEN = 1):

The determination condition of a start bit is that Low keeps up until the sampling timing. Adjusting the sampling timing forward (AJD = 1) increases the possibility of erroneously determining a noise as the start bit.

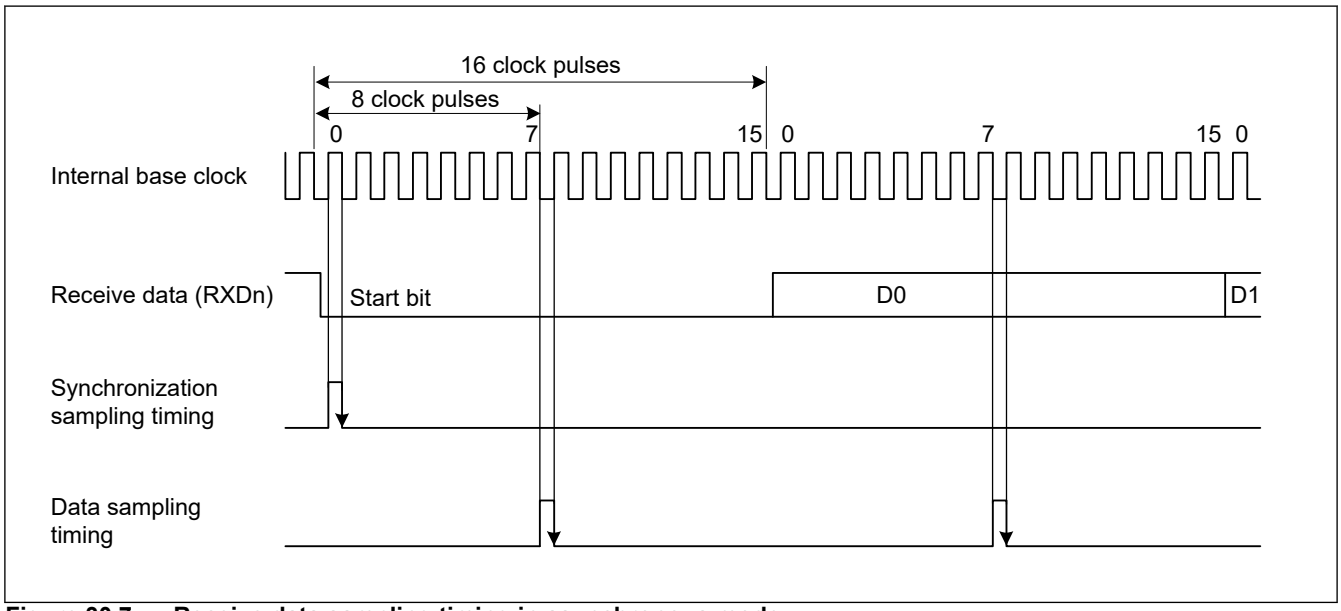

Figure 30.7 Receive data sampling timing in asynchronous mode

30.3.3 Clock

Either an internal clock generated by the on-chip baud rate generator or an external clock input to the SCKn pin can be selected as the transfer clock of the SCI, based on the SMR.CM and SCR.CKE[1:0] settings.

When an external clock is input to the SCKn pin, the clock frequency must be 16 times the bit rate (when SEMR.ABCS = 0) or 8 times the bit rate (when SEMR.ABCS = 1).

When the SCI uses its internal clock, the clock can be output from the SCKn pin. The frequency of the clock output in this case is equal to the bit rate, and the phase is configured so that the rising edge of the clock is in the middle of the transmit data, as shown in Figure 30.8.

When clock output is enabled, the clock is output after setting the SCR.TE or SCR.RE bit to 1.

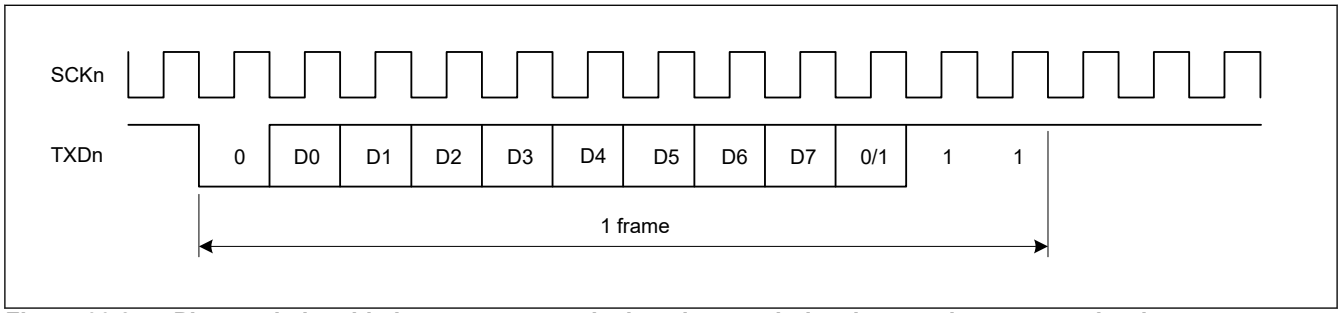

Figure 30.8 Phase relationship between output clock and transmit data in asynchronous mode when SMR.CHR = 0, PE = 1, MP = 0, and STOP = 1

30.3.4 Double-Speed Operation and Frequency of 6 Times the Bit Rate

When the SEMR.ABCS bit is set to 1 and eight pulses of the base clock for a 1-bit period is selected, the SCI operates on the bit rate twice that of when ABCS is set to 0. When the SEMR.BGDM bit is set to 1, the cycle of the base clock is half and the bit rate is double that of when BGDM is set to 0. When the SCR.CKE[1] bit is set to 0 and the on-chip baud rate generator is selected, setting the ABCS and BGDM bits to 1 allows the SCI to operate at a bit rate four times that when the ABCS and BGDM bits are set to 0.

When the SEMR.ABCSE bit is set to 1, the number of base clock pulses is 6 during a period of 1 bit, and the SCI operates at a bit rate 16/3 times that when SEMR.ABCS = 0, SEMR.BGDM = 0, and SEMR.ABCSE = 0.

As shown by Formula (1) in section 30.3.2. Receive Data Sampling Timing and Reception Margin in Asynchronous Mode, the reception margin decreases when the SEMR.ABCS or SEMR.ABCSE bit is set to 1. Therefore, if the target bit rate can be obtained with ABCS or ABCSE set to 0, it is recommended that you use the SCI with ABCS and ABCSE set to 0.

30.3.5 CTS and RTS Functions

The CTS function uses input on the CTSn_RTSn pin in transmission control. Setting the SPMR.CTSE bit to 1 enables the CTS function. For the functions of CTS and RTS, you can select the alternate setting that uses either function with one terminal and the dedicated setting that uses each function independently with two terminals. This setting is done with the SPMR.CTSPEN bit.

When the CTS function is enabled, placing a low level on the CTSn_RTSn pin causes transmission to start.

Driving the CTSn_RTSn pin high while transmission is in progress does not affect transmission of the current frame.

In the RTS function, which uses output on the CTSn_RTSn pin, a low level is output when reception becomes possible. Conditions for output of the low and high levels are shown in this section.

[Conditions for low level output]

Satisfaction of all conditions are listed in this section.

Non-FIFO selected

- The value of the SCR.RE bit is 1
- Reception is not in progress
- There is no received data yet to be read
- The ORER, FER, and PER flags in the SSR register are all 0

FIFO selected

- The value of the SCR.RE bit is 1
- The amount of receive data written in FRDRHL is equal to or less than the setting value of FCRH.RSTRG[3:0]
- The ORER flag in the SSR_FIFO register (ORER in FRDRH) is 0

[Condition for high level output]

- The conditions for low-level output are not satisfied

30.3.6 Address Match (Receive Data Match Detection) Function

The address match function can be used only in asynchronous mode.

If the DCCR.DCME bit is set to 1, when one frame of data is received, the SCI compares that received data with the data set in CDR.CMPD. If the SCI detects a match to the comparison data (CDR.CMPD[*1]) with the received data, the SCI can issue the SCIn_RXI interrupt request.

If the SMR.MP bit is set to 0, comparison occurs only for valid data in receive format. In multi-processor mode (SMR.MP bit = 1), if the DCCR.IDSEL bit is set to 1, receive data where the MPB bit is 1 is subject to comparison for address match and receive data where the MPB bit is 0 is always treated as a non-match.

If the DCCR.IDSEL bit is set to 0, SCI performs address match detection regardless of the MPB bit value of the received data.

Until SCI detects a match to the comparison data (CDR.CMPD[*1]) with receive data, received data is skipped (discarded), and the SCI cannot detect a parity error or framing error.

When SCI detects a match, the DCCR.DCME bit is automatically cleared, and the DCCR.DCMF flag is set to 1. If the DCCR.IDSEL bit is set to 1, the SCR.MPIE bit is automatically cleared. If DCCR.IDSEL is set to 0, the value of the SCR.MPIE bit is retained. If the SCR.RIE bit is set to 1, the SCI issues an SCIn_RXI interrupt request.

If the SCI detects a framing error in the receive data for which a match is detected, the DCCR.DFER flag is set to 1, and if the SCI detects a parity error in that frame, the DCCR.DPER flag is set to 1. The compared receive data is not stored in the RDR register, and SSR.RDRF remains 0. When FCR.FM = 1, the RDR register indicates the FRDRHL register, and the SSR.RDRF flag indicates the SSR_FIFO.RDF flag.

After the SCI detects a match, and DCCR.DCME is automatically cleared, the SCI receives the next data continuously based on the current register setting.

When the DCCR.DFER or DCCR.DPER flag is set, the address match is not performed. Before enabling the address match function, set the DCCR.DFER and DCCR.DPER flags to 0.

Examples of the address match function are shown in Figure 30.9 and Figure 30.10.

Note 1. This comparative target can select one length of 3 types: CMPD[6:0] with 7-bit length, CMPD[7:0] with 8-bit length, and CMPD[8:0] with 9-bit length.

(b) Example of compare matched between receive data and CDR (8-bit length/IDSEL = 1/multi-processor mode)

Figure 30.10 Example of address match (2) multi-processor mode

30.3.7 SCI Initialization in Asynchronous Mode

Before transmitting and receiving data, start by writing the initial value 0x00 to the SCR register, then continue through the SCI initialization procedure (select non-FIFO or FIFO) shown in Table 30.28 and Table 30.29. Whenever the operating mode or transfer format is to be changed, the SCR register must be initialized before the change is made.

When the external clock is used in asynchronous mode, ensure that the clock signal is supplied during initialization.

Note: Setting the SCR.RE bit to 0 initializes neither the ORER, FER, RDRF, RDF, PER, and DR flags in SSR/SSR_FIFO nor RDR and RDRHL. When the TE bit is set to 0, the TEND flag for the selected FIFO buffer is not initialized.

Note: In non-FIFO mode, switching the value of the SCR.TE bit from 1 to 0 or 0 to 1 while the SCR.TIE bit is 1 leads to the generation of an SCIn_TXI interrupt request.

Table 30.28 Example flow of SCI initialization in asynchronous mode with non-FIFO selected

No.	Step Name	Description
1	Start initialization	
2	Set the SCR.TIE, RIE, TE, RE, and TEIE bits to 0	
3	Set the FCR.FM bit to 0	Set the FCR.FM bit to 0.
4	Set the SCR.CKE[1:0] bits	Set the clock selection in SCR. When the clock output is selected in asynchronous mode, the clock is output immediately after SCR settings are made.
5	Set the SIMR1.IICM bit to 0. Set the SPMR.CKPH and CKPOL bits to 0.	Set the SIMR1.IICM bit to 0. Set the SPMR.CKPH and CKPOL bits to 0. Step 5 can be skipped if the values have not been changed from the initial values.
6	Set the data transmission/ reception format in SMR, SCMR, and SEMR	Set data transmission/reception format in SMR, SCMR, and SEMR.
7	Set a value in SPTR and ACTR	Set the communication terminals status in SPTR and adjustable sampling values in ACTR.
8	Set a value in BRR	Write a value corresponding to the bit rate to BRR. This step is not necessary if an external clock is used.
9	Set a value in MDDR	Write the value obtained by correcting a bit rate error in MDDR. This step is not necessary if the BRME bit in SEMR is set to 0 or an external clock is used.
10	Set the I/O port functions	Make I/O port settings to enable input and output functions as required for TXDn, RXDn, and SCKn pins.
11	Set the SCR.TE or RE bit to 1, and set the SCR.TIE and RIE bits	Set the SCR.TE or RE bit to 1. Also set the SCR.TIE and RIE bits. Setting the TE and RE bits allows TXDn and RXDn to be used.
12	Initialization completion	

Table 30.29 Example flow of SCI initialization in asynchronous mode with FIFO selected (1 of 2)

No.	Step Name	Description
1	Start initialization	
2	Set the SCR.TIE, RIE, TE, RE, and TEIE bits to 0	
3	Set the FCR.FM, TFRST, and RFRST bits to 1. Set the FCR.TTRG[3:0], RTRG[3:0], and RSTRG[3:0] bits.	Set the FCR.FM, TFRST, and RFRST bits to 1 (FIFO mode enabled, transmit/receive FIFOs empty). Set the FCR.TTRG[3:0], RTRG[3:0], and RSTRG[3:0] bits.
4	Set the SCR.CKE[1:0] bits	Set the clock selection in SCR. When the clock output is selected in asynchronous mode, the clock is output immediately after SCR settings are made.
5	Set the SIMR1.IICM bit to 0. Set the SPMR.CKPH and CKPOL bits to 0.	Set the SIMR1.IICM bit to 0. Set the SPMR.CKPH and CKPOL bits to 0. Step 5 can be skipped if the values have not been changed from the initial values.
6	Set the data transmission/ reception format in SMR, SCMR, and SEMR	Set data transmission/reception format in SMR, SCMR, and SEMR.
7	Set a value in SPTR and ACTR	Set the communication terminals status in SPTR and adjustable sampling values in ACTR.

Table 30.29 Example flow of SCI initialization in asynchronous mode with FIFO selected (2 of 2)

No.	Step Name	Description
8	Set a value in BRR	Write a value corresponding to the bit rate to BRR. This step is not necessary if an external clock is used.
9	Set a value in MDDR	Write the value obtained by correcting a bit rate error in MDDR. This step is not necessary if the BRME bit in SEMR is set to 0 or an external clock is used.
10	Set the FCR.TFRST and RFRST bits to 0	Set the FCR.TFRST and RFRST bits to 0.
11	Set the I/O port functions	Make I/O port settings to enable input and output functions as required for TXDn, RXDn, and SCKn pins.
12	Set the SCR.TE or RE bit to 1, and set the SCR.TIE and RIE bits	Set the SCR.TE or RE bit to 1. Also set the SCR.TIE and RIE bits. Setting the TE and RE bits allows TXDn and RXDn to be used.
13	Initialization completion	

30.3.8 Serial Data Transmission in Asynchronous Mode

(1) Non-FIFO selected

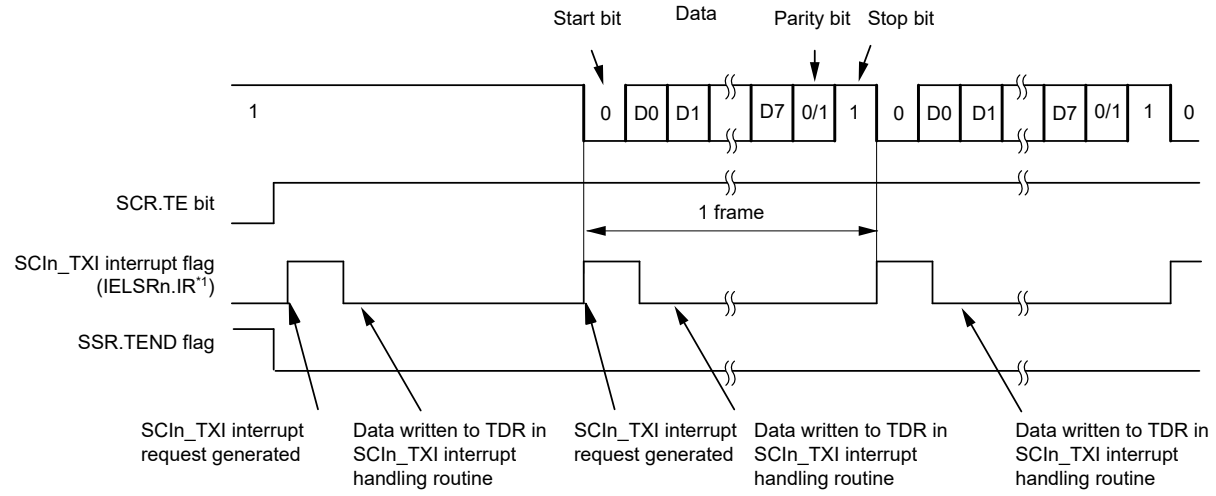
Figure 30.11, Figure 30.12, and Figure 30.13 show examples of serial transmission in asynchronous mode.

In serial transmission, the SCI operates as described in this section. When the SCR.TE bit is set to 1, the high level is output to TXDn for one frame. However, when SEMR.PADIS is set to "1", this preamble will not be output. An example of operation when preamble is not output is shown in Figure 30.14.

1. The SCI transfers data from the TDR[*1] register to the TSR register when data is written to TDR[*1] in the SCIn_TXI interrupt handling routine.
   The SCIn_TXI interrupt request at the beginning of transmission is generated when the SCR.TE and SCR.TIE bits are set to 1 simultaneously by a single instruction.
2. Transmission starts after the SPMR.CTSE bit is set to 0 (CTS function is disabled) or a low level on the CTSn_RTSn pin causes data transfer from the TDR[*1] register to the TSR register. If the SCR.TIE bit is 1, an SCIn_TXI interrupt request is generated. Continuous transmission is possible by writing the next transmit data to the TDR[*1] register in the SCIn_TXI interrupt handling routine before transmission of the current transmit data is complete. When SCIn_TEI interrupt requests are in use, set the SCR.TIE bit to 0 (SCIn_TXI interrupt requests are disabled) and the SCR.TEIE bit to 1 (an SCIn_TEI interrupt request is enabled) after the last of the data to be transmitted is written to the TDR[*1] register from the handling routine for SCIn_TXI requests.
3. Data is sent from the TXDn pin in the following order:
   - Start bit
   - Transmit data
   - Parity bit or multi-processor bit (can be omitted depending on the format)
   - Stop bit
4. The SCI checks for update of the TDR register on output of the stop bit.
5. When the TDR register is updated, setting the SPMR.CTSE bit to 0 (CTS function is disabled) or a low level input on the CTSn_RTSn pin causes transfer of the next transmit data from the TDR[*1] register to the TSR register and transmission of the stop bit, after which serial transmission of the next frame starts.
6. If the TDR register is not updated, the SSR.TEND flag is set to 1, the stop bit is sent, and the mark state is entered, in which 1 is output. If the SCR.TEIE bit is 1, the SSR.TEND flag is set to 1 and an SCIn_TEI interrupt request is generated.

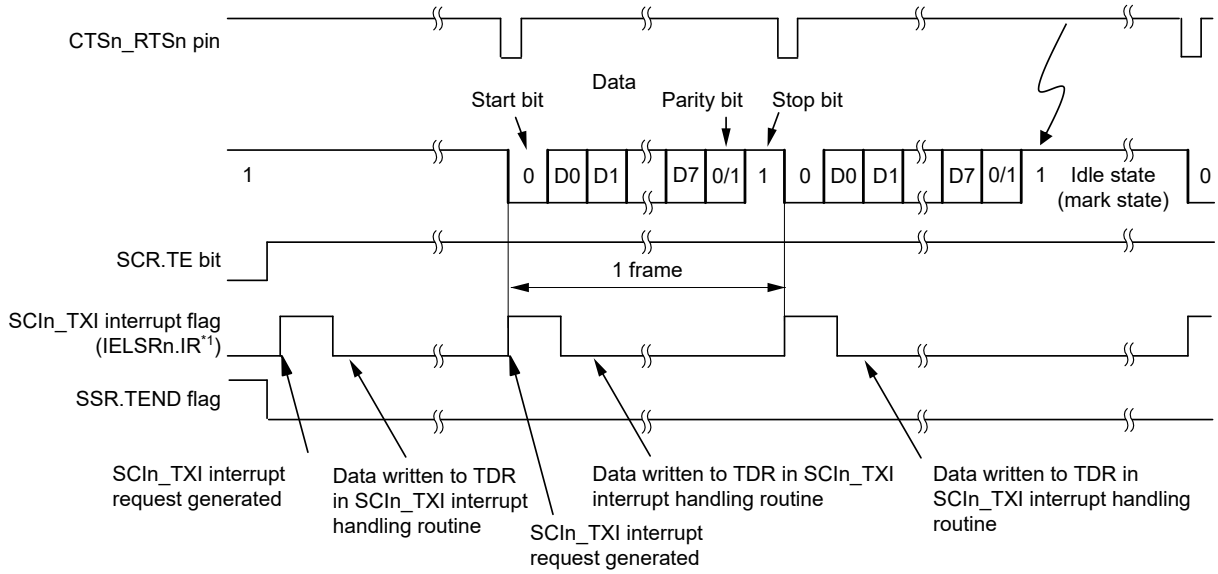
Note 1. The TDRHL register when 9-bit data length is selected.

Figure 30.11, Figure 30.12, and Figure 30.13 show examples of serial transmission in asynchronous mode.



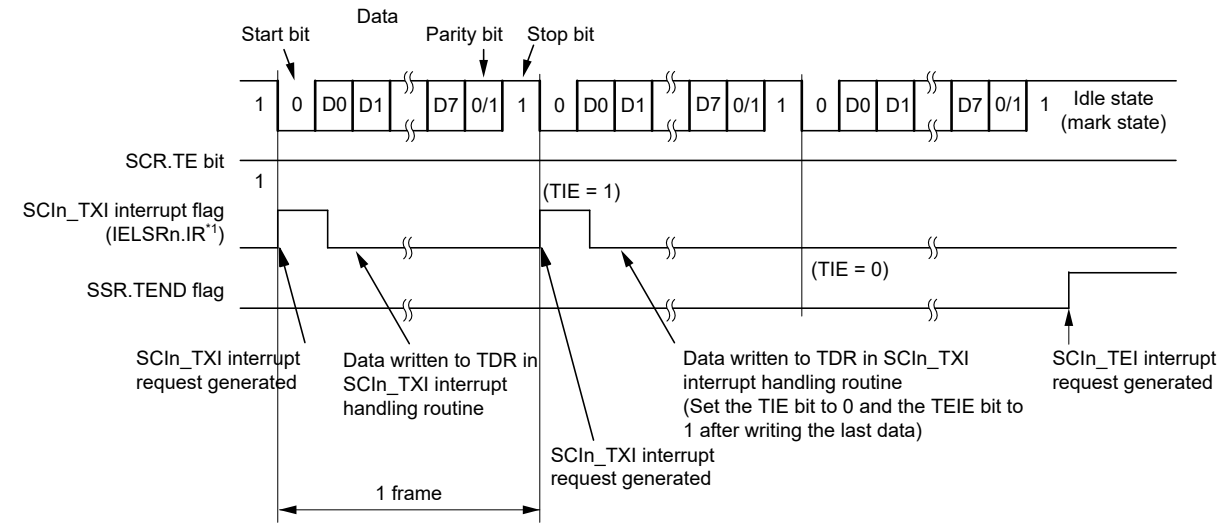
Note 1. See section 13, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 30.11 Example operation for serial transmission in asynchronous mode (1) with 8-bit data, parity bit, 1 stop bit, CTS function not used, and at the beginning of transmission



Note 1. See section 13, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 30.12 Example operation for serial transmission in asynchronous mode (2) with 8-bit data, parity bit, one stop bit, CTS function used, and at the beginning of transmission



Note 1. See section 13, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 30.13 Example operation for serial transmission in asynchronous mode (3) with 8-bit data, parity bit, one stop bit, CTS function not used, and from the middle of transmission until transmission completion

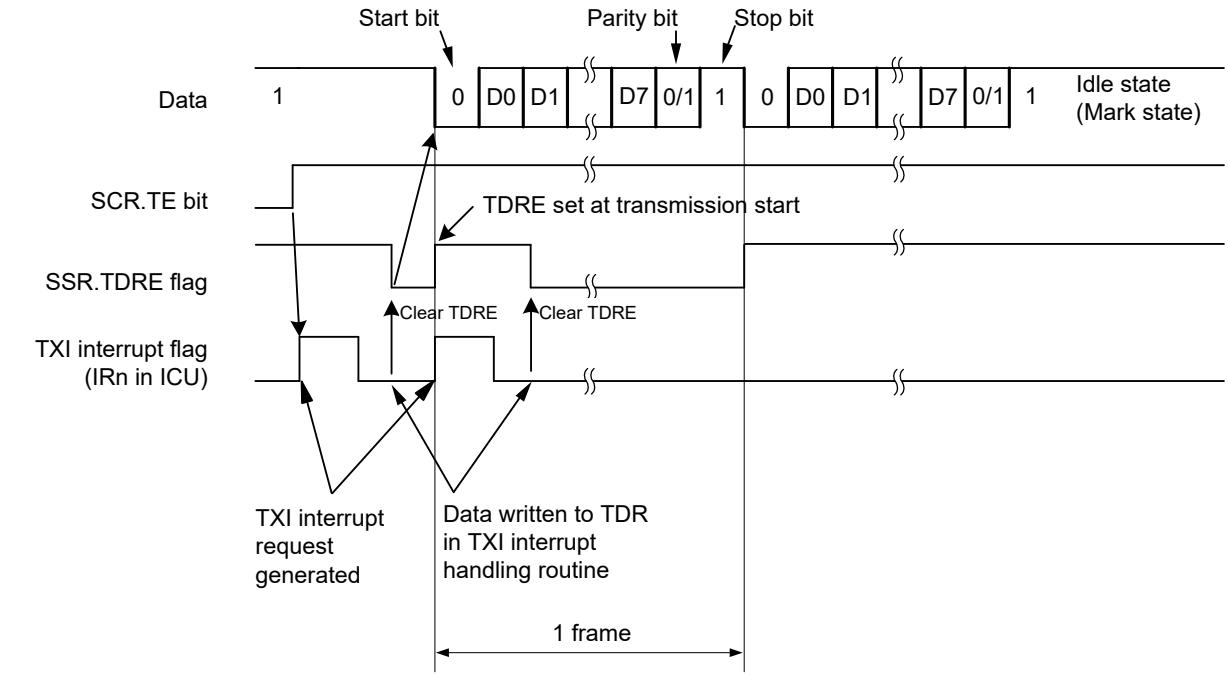


Figure 30.14 Example of Operation for Serial Transmission in Asynchronous Mode (4)(with 8-Bit Data, Parity, 1 Stop Bit, CTS Function Not Used, from the Middle of Transmission until Transmission Completion, stop preamble)

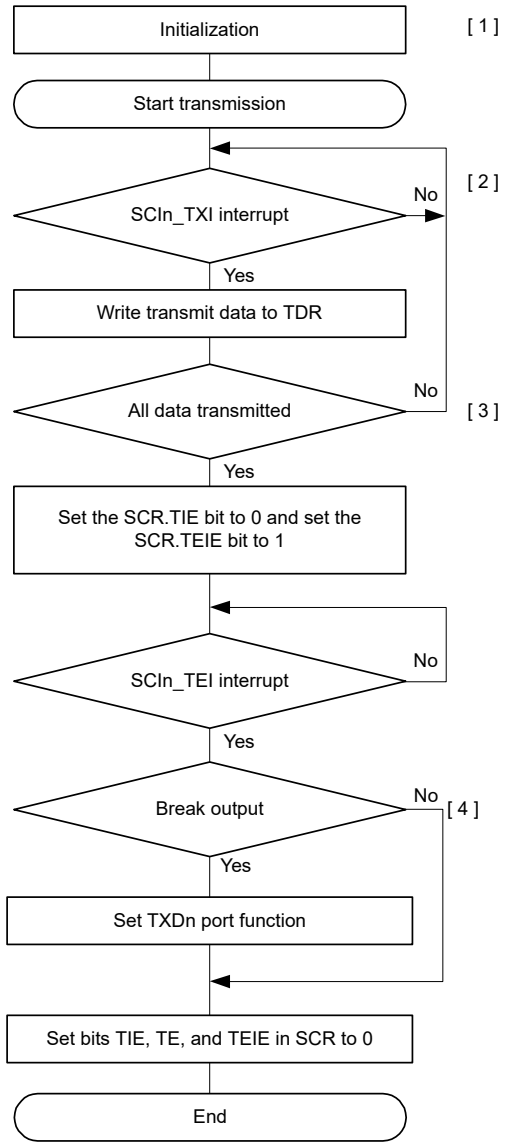


[1] SCI Initialization:
Set data transmission.
After the SCR.TE bit is set to 1, 1 is output for a frame, and transmission is enabled.

[2] Transmit data write to TDR by an SCIn_TXI interrupt request. When transmit data is transferred from TDR to TSR, a transmit data empty interrupt (SCIn_TXI) request is generated. Write transmit data to TDR once in the SCIn_TXI interrupt processing routine.

[3] Serial transmission continuation procedure:
To continue serial transmission write transmit data to TDR once using an SCIn_TXI interrupt request. Transmit data can also be written to TDR by activating the DMAC or DTC.
When SCIn_TEI interrupt requests are in use, set the SCR.TIE bit to 0 and the SCR.TEIE bit to 1 after the last of the data to be transmitted is written to TDR.

[4] Break output at the end of serial transmission:
To output a break in serial transmission, after setting the output state (LOW level output) of TXDn pin by SPTR.SPB2IO and SPTR.SPB2DT bits, set the SCR.TE bit to 0.

Figure 30.15 Example flow of serial transmission in asynchronous mode with non-FIFO selected

(2) FIFO selected

Figure 30.16 shows an example of a data format that is written to FTDRH and FTDRL register in asynchronous mode.

Data corresponding to the data length is set to FTDRH and FTDRL. Write 0 for unused bits. Write in order from FTDRH to FTDRL.

Data Length	Register Setting		Transmit data in FTDRH, FTDRL															
			FTDRHL															
			FTDRH								FTDRL							
	SCMR.CHR1	SMR.CHR	b7	b6	b5	b4	b3	b2	b1	b0	b7	b6	b5	b4	b3	b2	b1	b0
7 bits	1	0	—	—	—	—	—	—	—	—	—	7-bit transmit data						
8 bits	1	1	—	—	—	—	—	—	—	—	8-bit transmit data							
9 bits	0	Don't care	—	—	—	—	—	—	—	9-bit transmit data								

Note: —: Invalid. The write value should be 0.

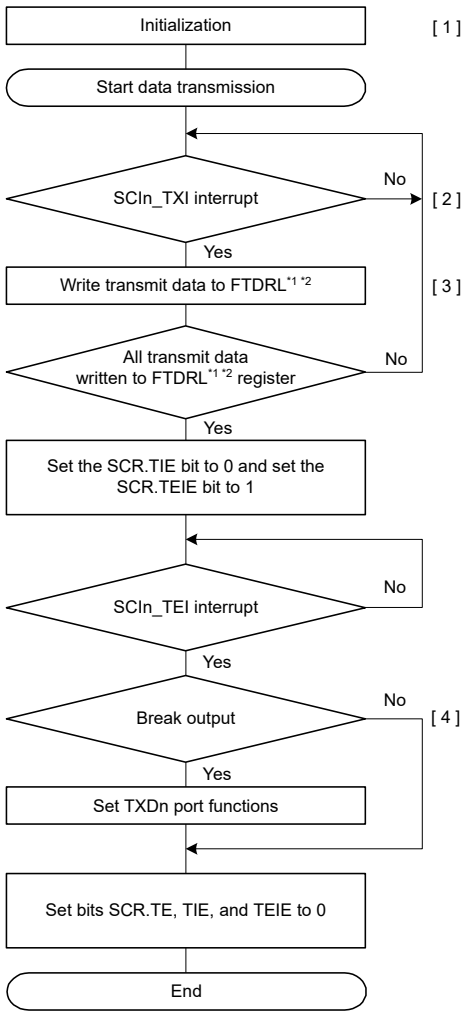
Figure 30.16 Data format written to FTDRH and FTDRL with FIFO selected

In serial transmission, the SCI operates as described in this section. When the TE bit is set to 1, the high level is output to TXDn for one frame (preamble).

1. The SCI transfers data from the FTDRL*1 register to the TSR register when data is written to FTDRL*1 in the SCIn_TXI interrupt handling routine. The amount of data that can be written to FTDRL is 16 minus FDR.T[4:0] bytes. The SCIn_TXI interrupt request at the beginning of transmission is generated when the SCR.TE and SCR.TIE bits are set to 1 simultaneously by a single instruction.
2. Transmission starts after the SPMR.CTSE bit is set to 0 (CTS function is disabled) or a low level on the CTSn_RTSn pin causes data transfer from the FTDRL*1 register to the TSR register. When the amount of transmit data written in FTDRL is equal to or less than the specified transmit triggering number, SSR_FIFO.TDFE is set to 1. If the SCR.TIE bit is 1, an SCIn_TXI interrupt request is generated. Continuous transmission is possible by writing the next transmit data to FTDRL*1 in the SCIn_TXI interrupt handling routine before transmission of the current transmit data is complete. When SCIn_TEI interrupt requests are in use, set the SCR.TIE bit to 0 (SCIn_TXI interrupt requests are disabled) and the SCR.TEIE bit to 1 (an SCIn_TEI interrupt request is enabled) after the last of the data to be transmitted is written to the FTDRL*1*2 register from the handling routine for SCIn_TXI requests.
3. Data is sent from the TXDn pin in the following order:
   - Start bit
   - Transmit data
   - Parity bit or multi-processor bit (can be omitted depending on the format)
   - Stop bit
4. On output of the stop bit, the SCI checks whether non-transmitted data remains in the FTDRL*3 register.
5. When data is set to FTDRL*3, setting the SPMR.CTSE bit to 0 (CTS function is disabled) or a low level input on the CTSn_RTSn pin causes transfer of the next transmit data from FTDRL*1 to TSR and transmission of the stop bit, after which serial transmission of the next frame starts.
6. If data is not set in FTDRL*3, the TEND flag in SSR_FIFO is set to 1, the stop bit is sent, and the mark state is entered in which 1 is output. If the SCR.TEIE bit is 1, the SSR_FIFO.TEND flag is set to 1 and an SCIn_TEI interrupt request is generated.

Note 1. Write data not to FTDRL but to the FTDRH and FTDRL registers.
Note 2. Write data in order from FTDRH to FTDRL when 9-bit data length is selected.
Note 3. The SCI only checks for update to the FTDRL register and not the FTDRH register when 9-bit data length is selected.

Figure 30.17 shows an example flow of serial transmission in asynchronous mode with FIFO selected.



[1] SCI initialization:
Set data transmission.
After the SCR.TE bit is set to 1, 1 is output for a frame, and transmission is enabled.

[2] Transmit data write to FTDRL*1 by an SCIn_TXI interrupt request:
When transmit data is transferred from FTDRL to TSR, when the quantity of transmit data written in FTDRL is equal to or less than the specified transmit triggering number, a transmit data FIFO empty interrupt (SCIn_TXI) request is generated. Write transmit data to FTDRL*1 *2 once in the SCIn_TXI interrupt handling routine.

[3] Serial transmission continuation procedure:
To continue serial transmission, write all transmit data to FTDRL using an SCIn_TXI interrupt request and clear the SSR_FIFO.TDFE flag to 0. The number of transmission data it is possible to write in is 16 - (the number of stored transmit FIFO data). Transmit data can also be written to FTDRL by activating the DTC or DMAC. When writing the data to FTDRL by DTC or DMAC, the TDFE flag is cleared automatically, so do not write to the TDFE flag.
When SCIn_TEI interrupt requests are in use, set the SCR.TIE bit to 0 and the SCR.TEIE bit to 1 after the last of the data to be transmitted is written to FTDRL.

[4] Break output at the end of serial transmission:
To output a break in serial transmission, after setting the output state (LOW level output) of TXD pin by SPTR.SPB2IO and SPTR.SPB2DT bits, set the SCR.TE bit to 0.

Note 1. When data length is 9 bits, this refers to FTDRH and FTDRL registers.
Note 2. When data length is 9 bits, write in order from FTDRH to FTDRL.

Figure 30.17 Example flow of serial transmission in asynchronous mode with FIFO selected

30.3.9 Serial Data Reception in Asynchronous Mode

(1) Non-FIFO selected

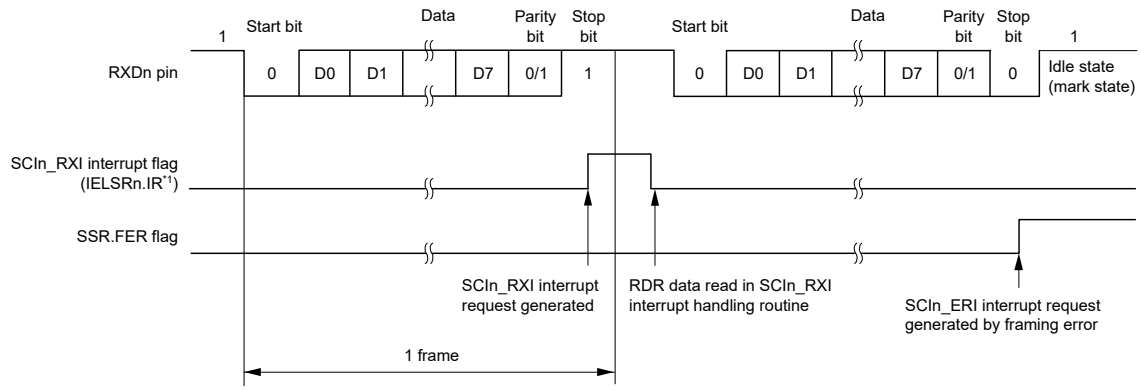
Figure 30.18 and Figure 30.19 show an example of the operation for serial data reception in asynchronous mode.

In serial data reception, the SCI operates as follows:

1. When the value of the SCR.RE bit becomes 1, the output signal on the CTSn_RTSn pin goes low.
2. The SCI monitors the communications line and when it detects a start bit, the SCI performs internal synchronization, stores receive data in RSR.
3. If the multi-processor communication function is enabled (SMR.MP = 1), see section 30.4.2. Multi-Processor Serial Data Reception. If the address match function (data compare match function) is enabled (DCCR.DCME = 1), the SCI cannot detect a parity or framing error as receive data are skipped (discarded) until the SCI detects a match between the receive data and comparison data (CDR.CMPD*1).
4. If the SCI detects an address match, the DCCR.DCME bit is automatically cleared, the DCCR.DCMF flag becomes 1, and an SCIn_AM interrupt*2 request is generated. To enable the generation of an SCIn_RXI interrupt request, set the SCR.RIE bit to 1. The compared receive data are not stored in the RDR register*3. The SSR.RDRF flag remains 0.

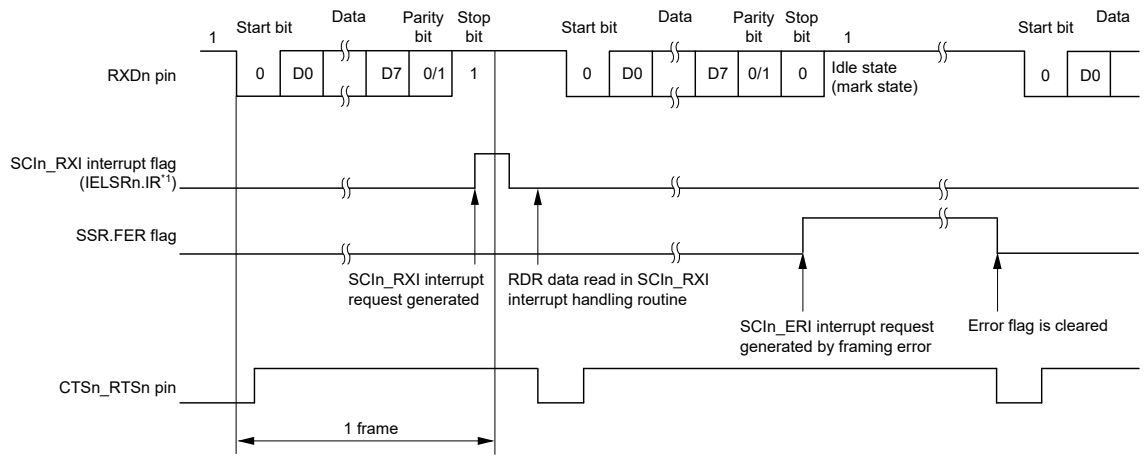
5. If the SCI detects a framing error in the receive data for which an address match is detected, the DCCR.DFER flag is set to 1, and if the SCI detects a parity error in that frame, the DCCR.DPER flag becomes 1. To enable the generation of an SCIn_ERI interrupt request, set the SCR.RIE bit to 1.
6. If a framing or a parity error is detected (the DCCR.DFER flag or DCCR.DPER flag is 1) in the SCIn_AM interrupt handling routine, set the DCCR.DFER and DCCR.DPER flags to 0 and set the DCCR.DCME bit to 1 to enable the address match function again. If neither a framing nor a parity error has been detected (the DCCR.DFER and DCCR.DPER flags are both 0), set the DCCR.DCMF flag to 0. See Figure 30.9.
7. If an overrun error occurs, the SSR.ORER flag is set to 1. If the SCR.RIE bit is 1, an SCIn_ERI interrupt request is generated. Receive data is not transferred to the RDR*3 register.
8. If a parity error is detected, the SSR.PER flag is set to 1 and receive data is transferred to the RDR*3 register. If the SCR.RIE bit is 1, an SCIn_ERI interrupt request is generated.
9. If a framing error is detected, the SSR.FER flag is set to 1 and receive data is transferred to the RDR*3 register. If the SCR.RIE bit is 1, an SCIn_ERI interrupt request is generated.
10. When reception finishes successfully, receive data is transferred to the RDR*3 register. If the SCR.RIE bit is 1, an SCIn_RXI interrupt request is generated. Continuous reception is enabled by reading the receive data transferred to the RDR register in the SCIn_RXI interrupt handling routine before reception of the next receive data is complete. Reading the received data that was transferred to the RDR register causes the CTSn_RTSn pin to output low.

Note 1. This scope of comparison is selectable as one of three lengths: CMPD[6:0] is for 7-bit length, CMPD[7:0] is for 8-bit length, and CMPD[8:0] is for 9-bit length.
Note 2. As no interrupt enable bit is assigned to the SCIn_AM interrupt, an interrupt request is generated by setting the DCCR.DCMF to 1.
Note 3. Only read data in the RDRHL register when 9-bit data length is selected.



Note 1. See section 13, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 30.18 Example of SCI operation for serial reception in asynchronous mode (1) when the RTS function is not used, and with 8-bit data, parity bit, and 1 stop bit



Note 1. See section 13, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 30.19 Example of SCI operation for serial reception in asynchronous mode (2) when RTS function is used, and with 8-bit data, parity bit, and 1 stop bit

Table 30.30 lists the states of the flags in the SSR register and receive data handling when a receive error is detected.

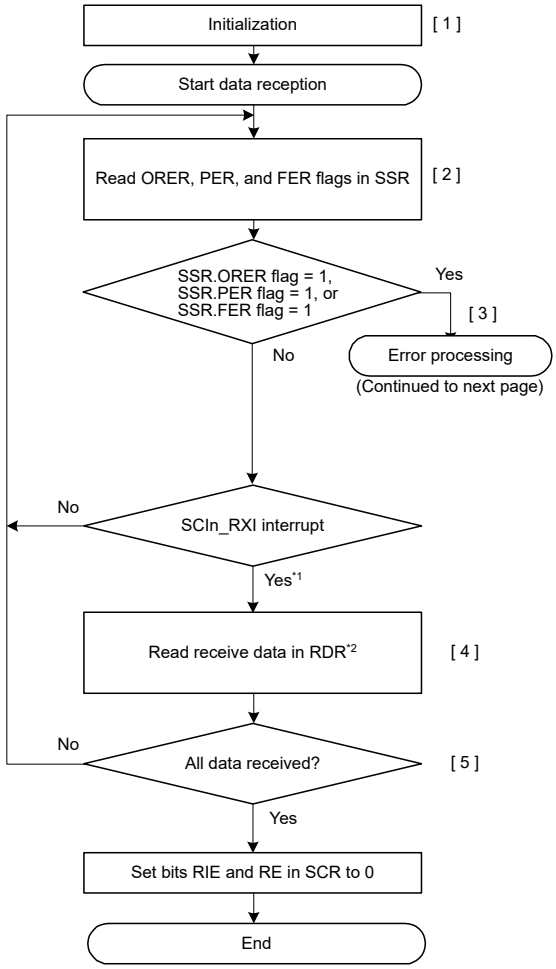
If a receive error is detected, an SCIn_ERI interrupt request is generated but an SCIn_RXI interrupt request is not generated. Data reception cannot be resumed while the receive error flag is 1. Accordingly, set the ORER, FER, and PER bits to 0 before resuming reception. In addition, be sure to read the RDR or RDRHL register during overrun error processing. When a reception is forced to terminate by setting the SCR.RE bit to 0 during operation, read the RDR or RDRHL register because received data that is not yet read might be left in the RDR or RDRHL.

Figure 30.20 and Figure 30.21 show example flows of serial data reception.

Table 30.30 Flags in SSR Status Register and receive data handling

Flags in the SSR Status Register			Receive data	Receive error type
ORER	FER	PER		
1	0	0	Lost	Overrun error
0	1	0	Transferred to RDR*1	Framing error
0	0	1	Transferred to RDR*1	Parity error
1	1	0	Lost	Overrun error + framing error
1	0	1	Lost	Overrun error + parity error
0	1	1	Transferred to RDR*1	Framing error + parity error
1	1	1	Lost	Overrun error + framing error + parity error

Note 1. Only read data in the RDRHL register when 9-bit data length is selected.



[1] SCI initialization:
Set data reception.

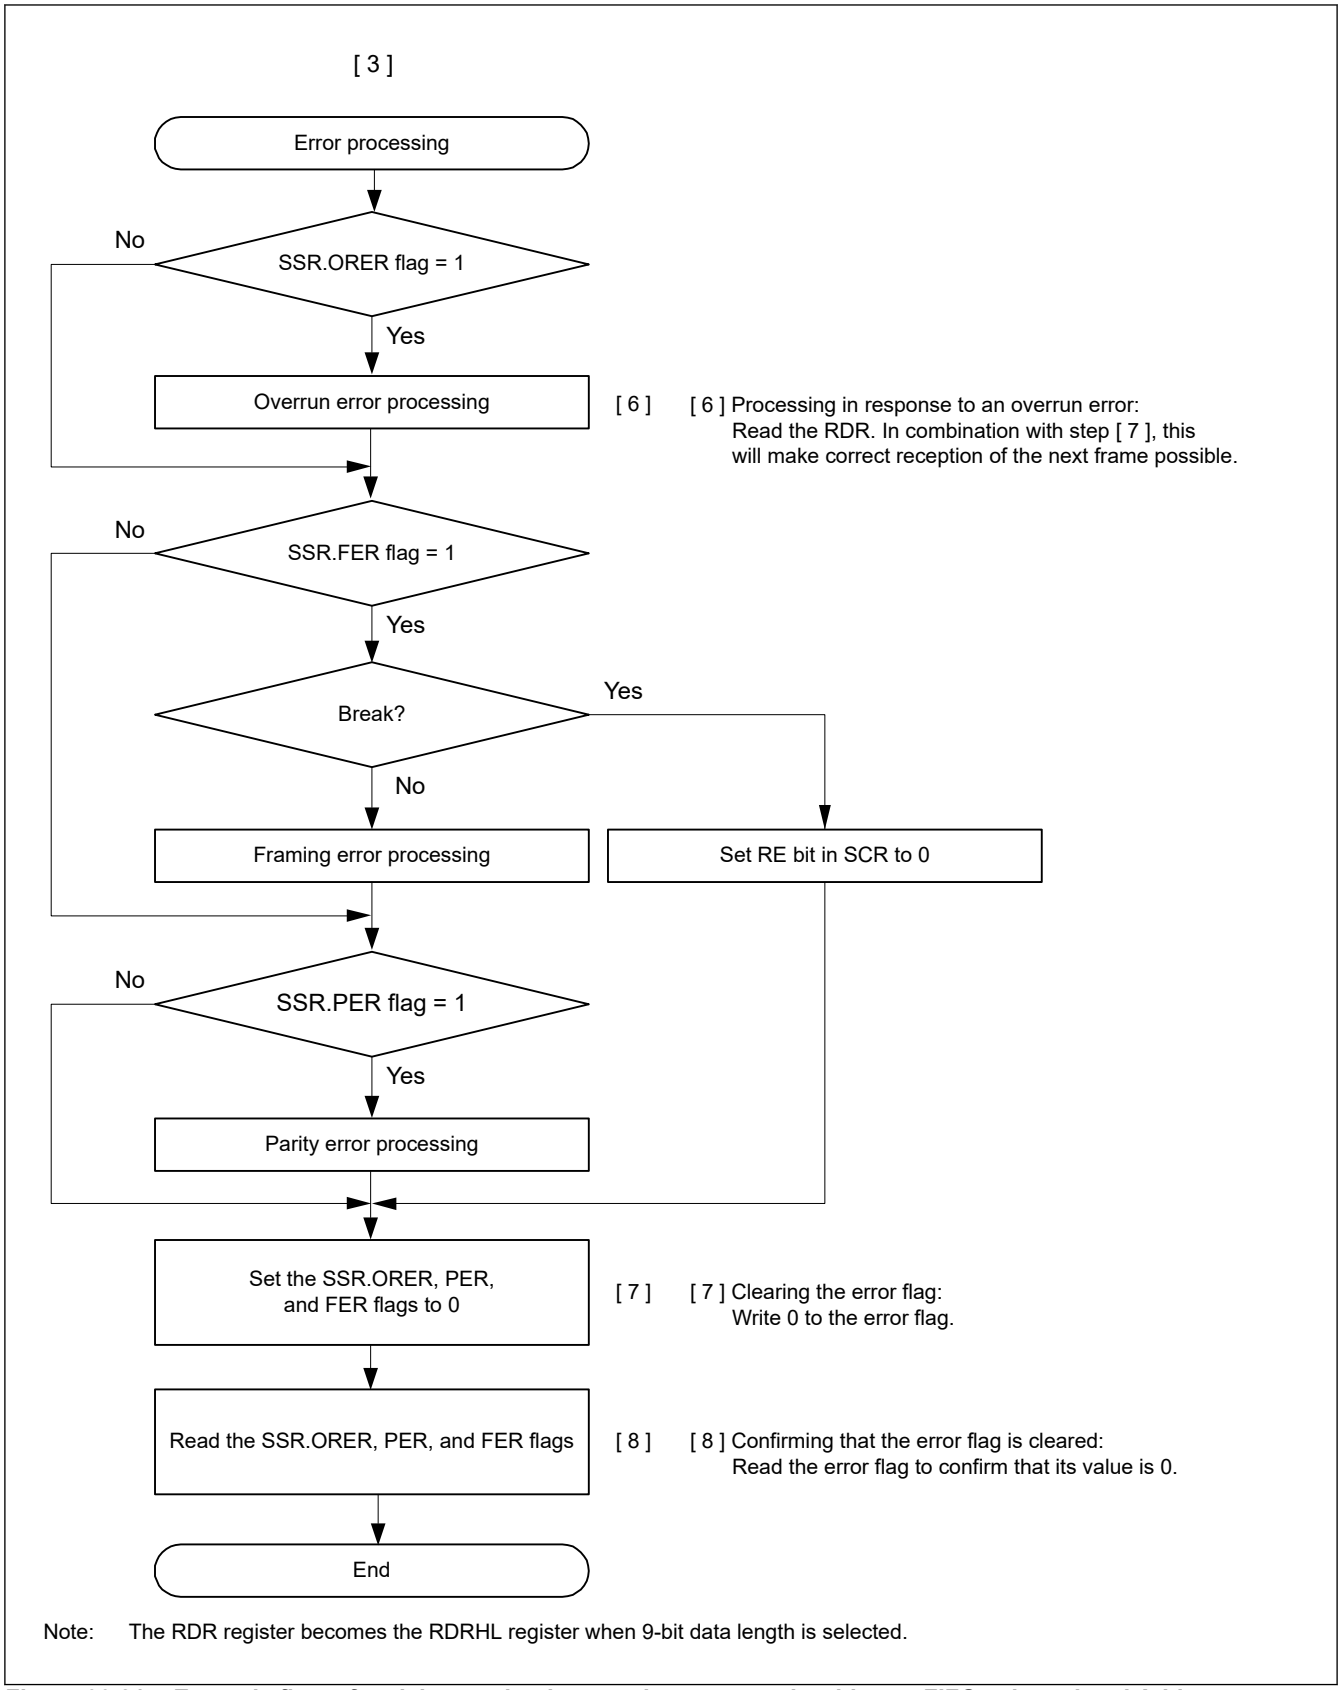
[2][3] Receive error processing and break detection:
If a receive error occurs, an SCIn_ERI interrupt is generated. The error type is identified by reading the ORER, PER, and FER flags in SSR. After performing the appropriate error processing, be sure to set the ORER, PER, and FER flags to 0. Reception cannot be resumed if any of these flags is set to 1. For a framing error, a break can be detected by reading the value of the input port associated with the RXDn pin.

[4] Read the receive data in RDR once inthe SCIn_RXI interrupt handling routine.

[5] To continue serial reception, before the stop bit of the current frame is received, read data from RDR in the SCIn_RXI interrupt processing routine. The RDR data can also be read by activating the DMAC or DTC.

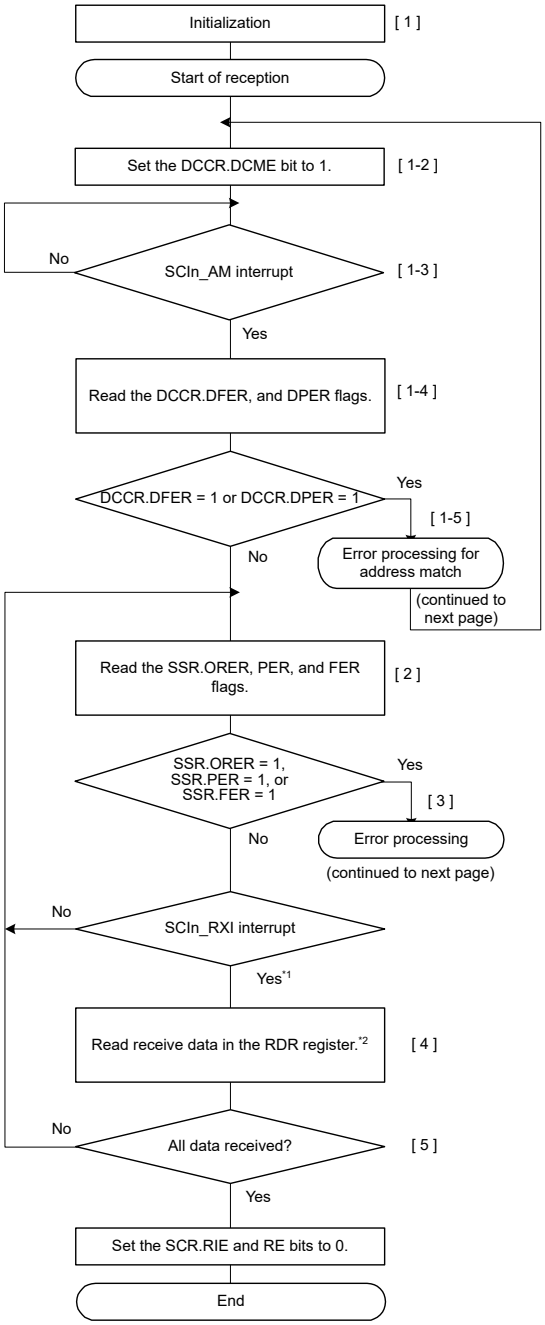
Note 1. Do not set RE to 0 before reading RDR.
Note 2. The RDR register becomes the RDRHL register when 9-bit data length is selected.

Figure 30.20 Example flow of serial reception in asynchronous mode with non-FIFO selected and Address Matching Disabled (1)



Note: The RDR register becomes the RDRHL register when 9-bit data length is selected.

Figure 30.21 Example flow of serial reception in asynchronous mode with non-FIFO selected and Address Matching Disabled (2)



[1] SCI initialization:
Set data reception.

[1-2] Address match cycle:
Set the DCCR.DCME bit to 1 to enable address matching.

[1-3] Comparing receive data and data for comparison (CDR.CMPD):
Compare receive data and data for comparison (CDR.CMPD).
The SCI cannot detect a parity or framing error as receive data are skipped (discarded) until the SCI detects a match between the receive data and data for comparison.
If the SCI detects an address match, the DCCR.DCME bit is cleared, the DCCR.DCMF flag becomes 1, and an SCIn_AM interrupt request is issued.

[1-4] [1-5] Reception error processing:
An error is identified by reading the DFER or DPER flag in DCCR in the SCIn_AM interrupt handling routine.
After appropriate handling of the error, set both the DFER and DPER flags to 0.
If either of these flags is set to 1, address matching cannot be resumed.

[2] [3] Reception error processing and break detection:
When a reception error occurs, the SCIn_ERI interrupt is generated.
The error is identified by reading the ORER, PER, and FER flags in the SSR.
After appropriate handling of the error, set all of the ORER, PER, and FER flags to 0. If any of these flags is set to 1, reception cannot be resumed.
If a framing error occurs, a break can be detected by reading the value of the input port bit corresponding to the RXDn pin.

[4] Read the receive data in the RDR register from within the SCIn_RXI interrupt handling routine.

[5] Procedure for continuing serial reception:
To continue serial reception, read the value of the RDR register in the SCIn_RXI interrupt handling routine before the stop bit is received.
The value of the RDR register can also be read by activating the DMAC or DTC.

Note 1. Be sure to set the RE bit to 0 before reading the RDR register.
Note 2. The RDRHL register is used instead of the RDR register when the 9-bit data length is selected.

Figure 30.22 Example Flowchart of Serial Reception in Asynchronous Mode (FIFO not Selected and Address Matching Enabled) (1)

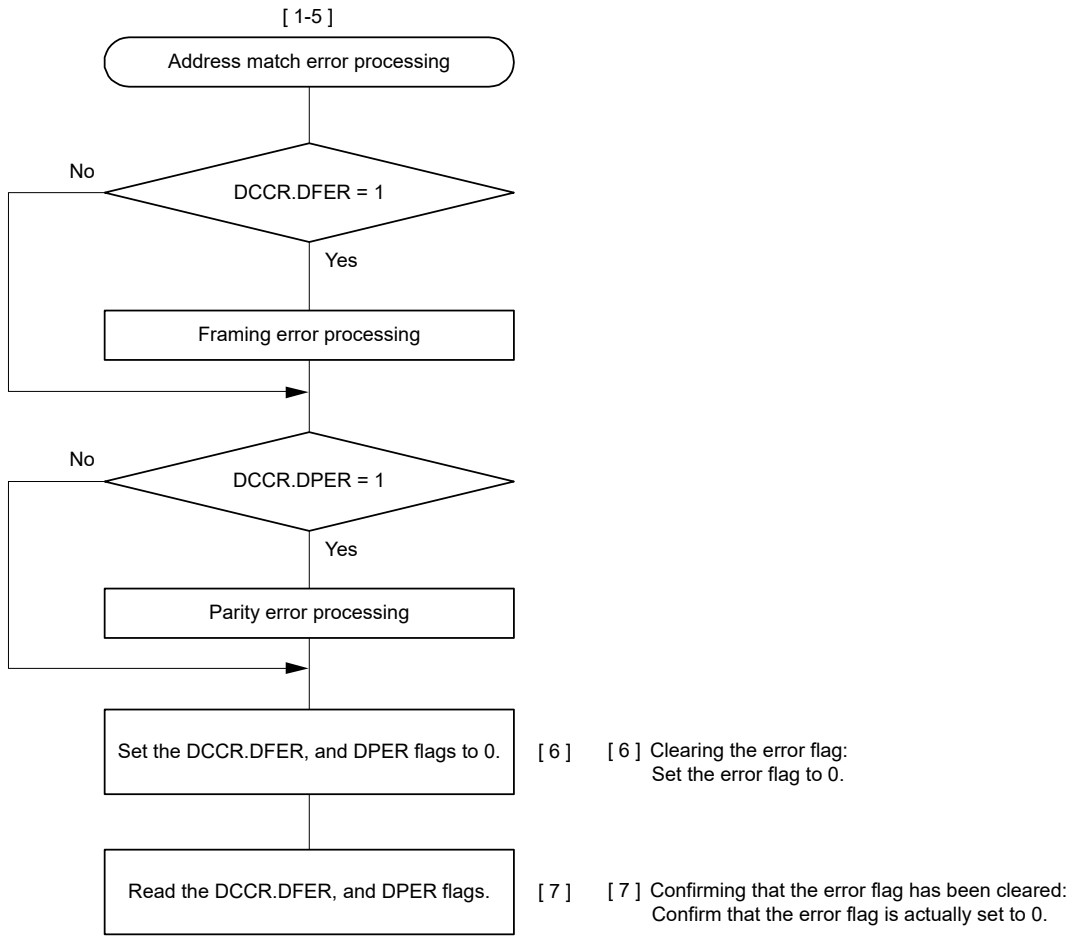


Figure 30.23 Example Flowchart of Serial Reception in Asynchronous Mode (FIFO not Selected and Address Matching Enabled) (2)

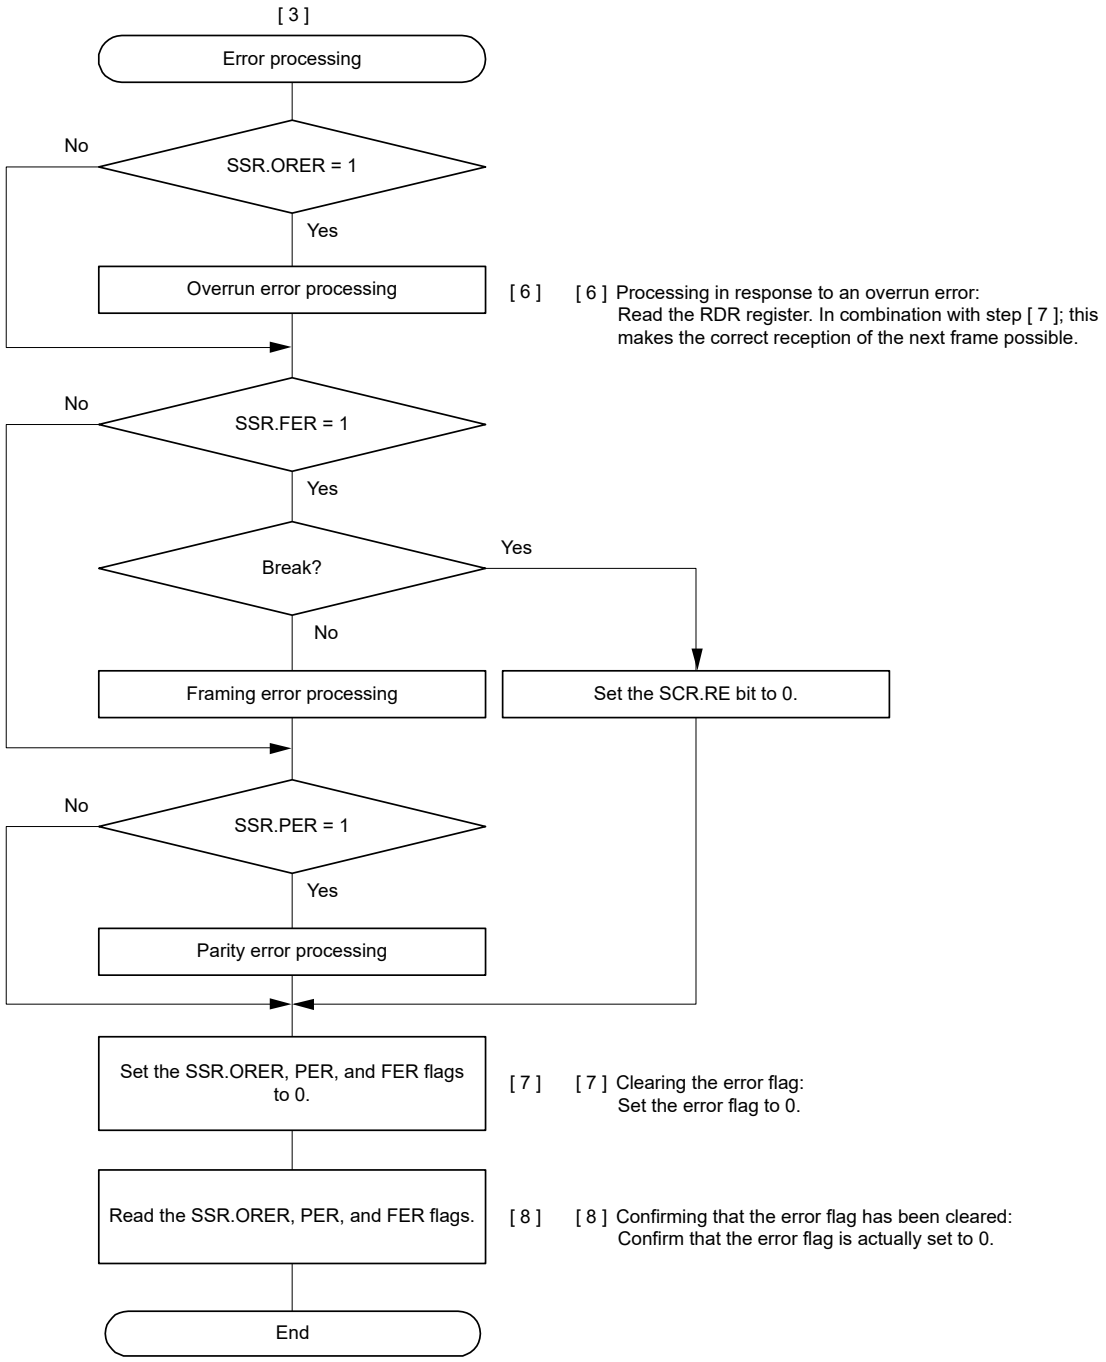


Note: The RDRHL register is used instead of the RDR register when the 9-bit data length is selected.

Figure 30.24 Example Flowchart of Serial Reception in Asynchronous Mode (FIFO not Selected and Address Matching Enabled) (3)

(2) FIFO selected

Figure 30.25 shows an example of a data format that is written to FRDRH register and FRDRL register in asynchronous mode.

In asynchronous mode, 0 is written to the MPB bit in the FRDRH register. Data that corresponds to the data length is written to FRDRH and FRDRL. Unused bits are written as 0. Read in order from FRDRH to FRDRL. If software reads FRDRL, the

SCI updates FER, PER, and receive data (RDAT[8:0]) in the FRDRL register with the next data. The flags RDF, ORER, and DR in the FRDRH register always reflect the associated flags in the SSR_FIFO register.

Data Length	Register Setting		Receive data in FRDRH, FRDRL															
			FRDRHL															
			FRDRH								FRDRL							
	SCMR.CHR1	SMR.CHR	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
7 bits	1	0	—	RDF	ORER	FER	PER	DR	0	0	0	7-bit receive data						
8 bits	1	1	—	RDF	ORER	FER	PER	DR	0	0	8-bit receive data							
9 bits	0	Don't care	—	RDF	ORER	FER	PER	DR	0	9-bit receive data								

Note: 0 is always read for MPB bit (FRDRH[1])
When data length is 7 bits, 0 is always read for FRDRH[0] and FRDRL[7]
When data length is 8 bits, 0 is always read for FRDRH[0]
FRDRH[7] bit is read as an indefinite value

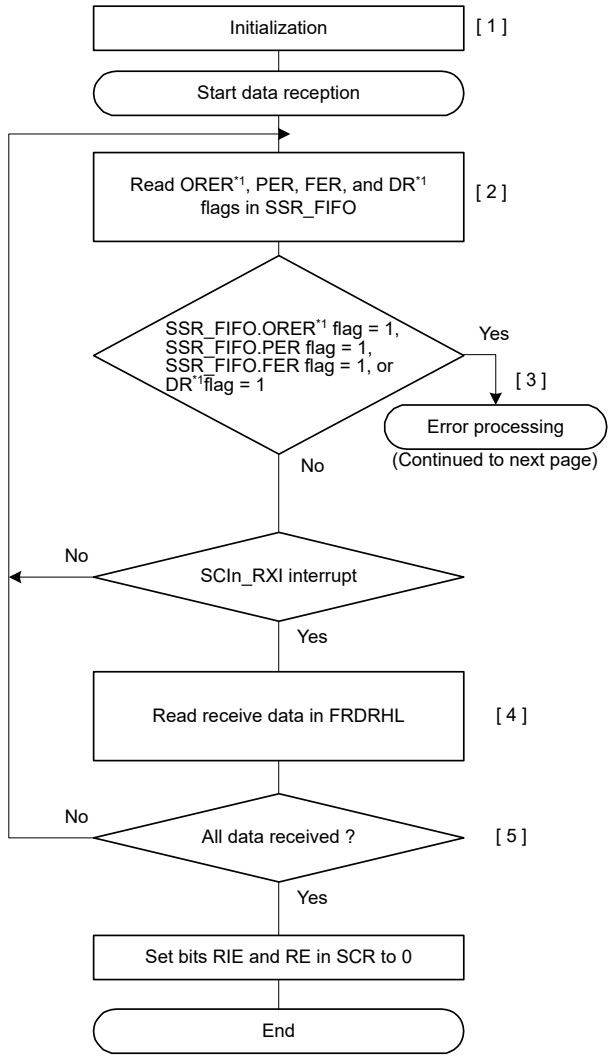
Figure 30.25 Data format stored in FRDRH and FRDRL with FIFO selected

In serial data reception, the SCI operates as follows:

1. When the value of the SCR.RE bit becomes 1, the output signal on the CTSn_RTSn pin goes low.
2. The SCI monitors the communications line and, when it detects a start bit, the SCI performs internal synchronization, stores receive data in the RSR register.
3. If the multi-processor communications function is enabled (SMR.MP = 1), see section 30.4.2. Multi-Processor Serial Data Reception. If the address match function (data compare match function) is enabled (DCCR.DCME = 1), the SCI cannot detect a parity or framing error as receive data are skipped (discarded) until the SCI detects a match between the receive data and the data for comparison (CDR.CMPD*1).
4. If the SCI detects an address match, the DCCR.DCME bit is automatically cleared, the DCCR.DCMF flag becomes 1, and an SCIn_AM interrupt*2 request is generated. To enable the generation of an SCIn_RXI interrupt request, set the SCR.RIE bit to 1. The compared receive data are not stored in the RDR register*3. The SSR.RDRF flag remains 0.
5. If the SCI detects a framing error in the receive data for which an address match was detected, the DCCR.DFER flag is set to 1, and if the SCI detects a parity error in that frame, the DCCR.DPER flag becomes 1. To enable the generation of an SCIn_ERI interrupt request, set the SCR.RIE bit to 1.
6. If a framing or a parity error is detected (the DCCR.DFER flag or DCCR.DPER flag is 1) in the SCIn_AM interrupt handling routine, set the DCCR.DFER and DCCR.DPER flags to 0 and set the DCCR.DCME bit to 1 to enable the address match function again. If neither a framing nor a parity error has been detected (the DCCR.DFER and DCCR.DPER flags are 0), set the DCCR.DCMF flag to 0. See Figure 30.9.
7. If an overrun error occurs during normal communications, the SSR_FIFO.ORER flag is set to 1. If the SCR.RIE bit in SCR is 1, an SCIn_ERI interrupt request is generated. Receive data is not transferred to the FRDRL*3 register.
8. If a parity error is detected, the PER flag and receive data are transferred to the FRDRL*3 register. If the SCR.RIE bit is set to 1, an SCIn_ERI interrupt request is generated.
9. If a framing error is detected, the FER flag and receive data are transferred to the FRDRL*3 register. If the SCR.RIE bit is set to 1, an SCIn_ERI interrupt request is generated.
10. After a framing error is detected and when SCI detects that the continuous receive data is zero for one frame, reception stops.
11. When the amount of data stored in the FRDRL register falls below the specified receive triggering number, and the next data is not received after 15 etus from the last stop bit in asynchronous mode, the SSR_FIFO.DR flag is set to 1. When the SCR.RIE bit is 1 and the FCR.DRES bit is 0, the SCI generates an SCIn_RXI interrupt request. When the FCR.DRES bit is 1, SCI generates an SCIn_ERI interrupt request.

12. When reception finishes successfully, receive data is transferred to the FRDRL[*3] register. The RDF bit is set to 1 when the amount of receive data written to FRDRHL is equal to or greater than the specified receive triggering number. If the SCR.RIE bit in SCR is 1, an SCIn_RXI interrupt request is generated. Continuous reception is enabled by reading the receive data transferred to the FRDRL[*4] register in the SCIn_RXI interrupt handling routine, before an overrun error occurs. If the received data that is transferred to FRDRL[*5] is less than the RTS trigger number, the CTSn_RTSn pin outputs low.

Note 1. One of three lengths is selected for the target for comparison: CMPD[6:0] is for 7-bit length, CMPD[7:0] is for 8-bit length, and CMPD[8:0] is for 9-bit length.
Note 2. As no interrupt enable bit is assigned to the SCIn_AM interrupt, an interrupt request is generated by setting the DCCR.DCMF to 1.
Note 3. Only read data in the FRDRH and FRDRL registers when 9-bit data length is selected.
Note 4. Read data in order from FRDRH to FRDRL when 9-bit data length is selected.
Note 5. The SCI only checks for update to the FRDRL register and not to the FRDRH register when 9-bit data length is selected.



[1] SCI initialization:
Set data reception.

[2] [3] Receive error processing and break detection:
If a receive error occurs, an SCIn_ERI interrupt is generated. A break can be detected by reading the SPTR.RXDMON flag. An error is identified by reading the ORER*1, PER, DR*1, and FER flags in SSR_FIFO. After performing the appropriate error processing, be sure to set the ORER*1 flag to 0. Reception cannot be resumed if ORER*1 flag is set to 1. The reception operation is continuous, even if the FER = 1 or PER = 1 or DR*1 = 1.

[4] Read the receive data in FRDRHL in the SCIn_RXI interrupt handling routine. The receive data stored in the FRDRHL register is read until the number of stored data is below the FCR.RTRG value. Confirm the number of the reception data in the FIFO by reading FDR.R.

[5] Serial reception continuation procedure:
To continue serial reception, before an overrun error occurs, read data from FRDRHL in the SCIn_RXI interrupt handling routine and clear RDF flag and DR flag to 0.
The FRDRHL data can also be read by activating the DMA or DTC. The RDF flag is cleared automatically in this case, so do not write to the RDF flag.

Note 1. Can be read in the FRDRHL.ORER and DR flags.

Figure 30.26 Example flow of serial reception in asynchronous mode with FIFO selected and Address Matching Enabled (1)

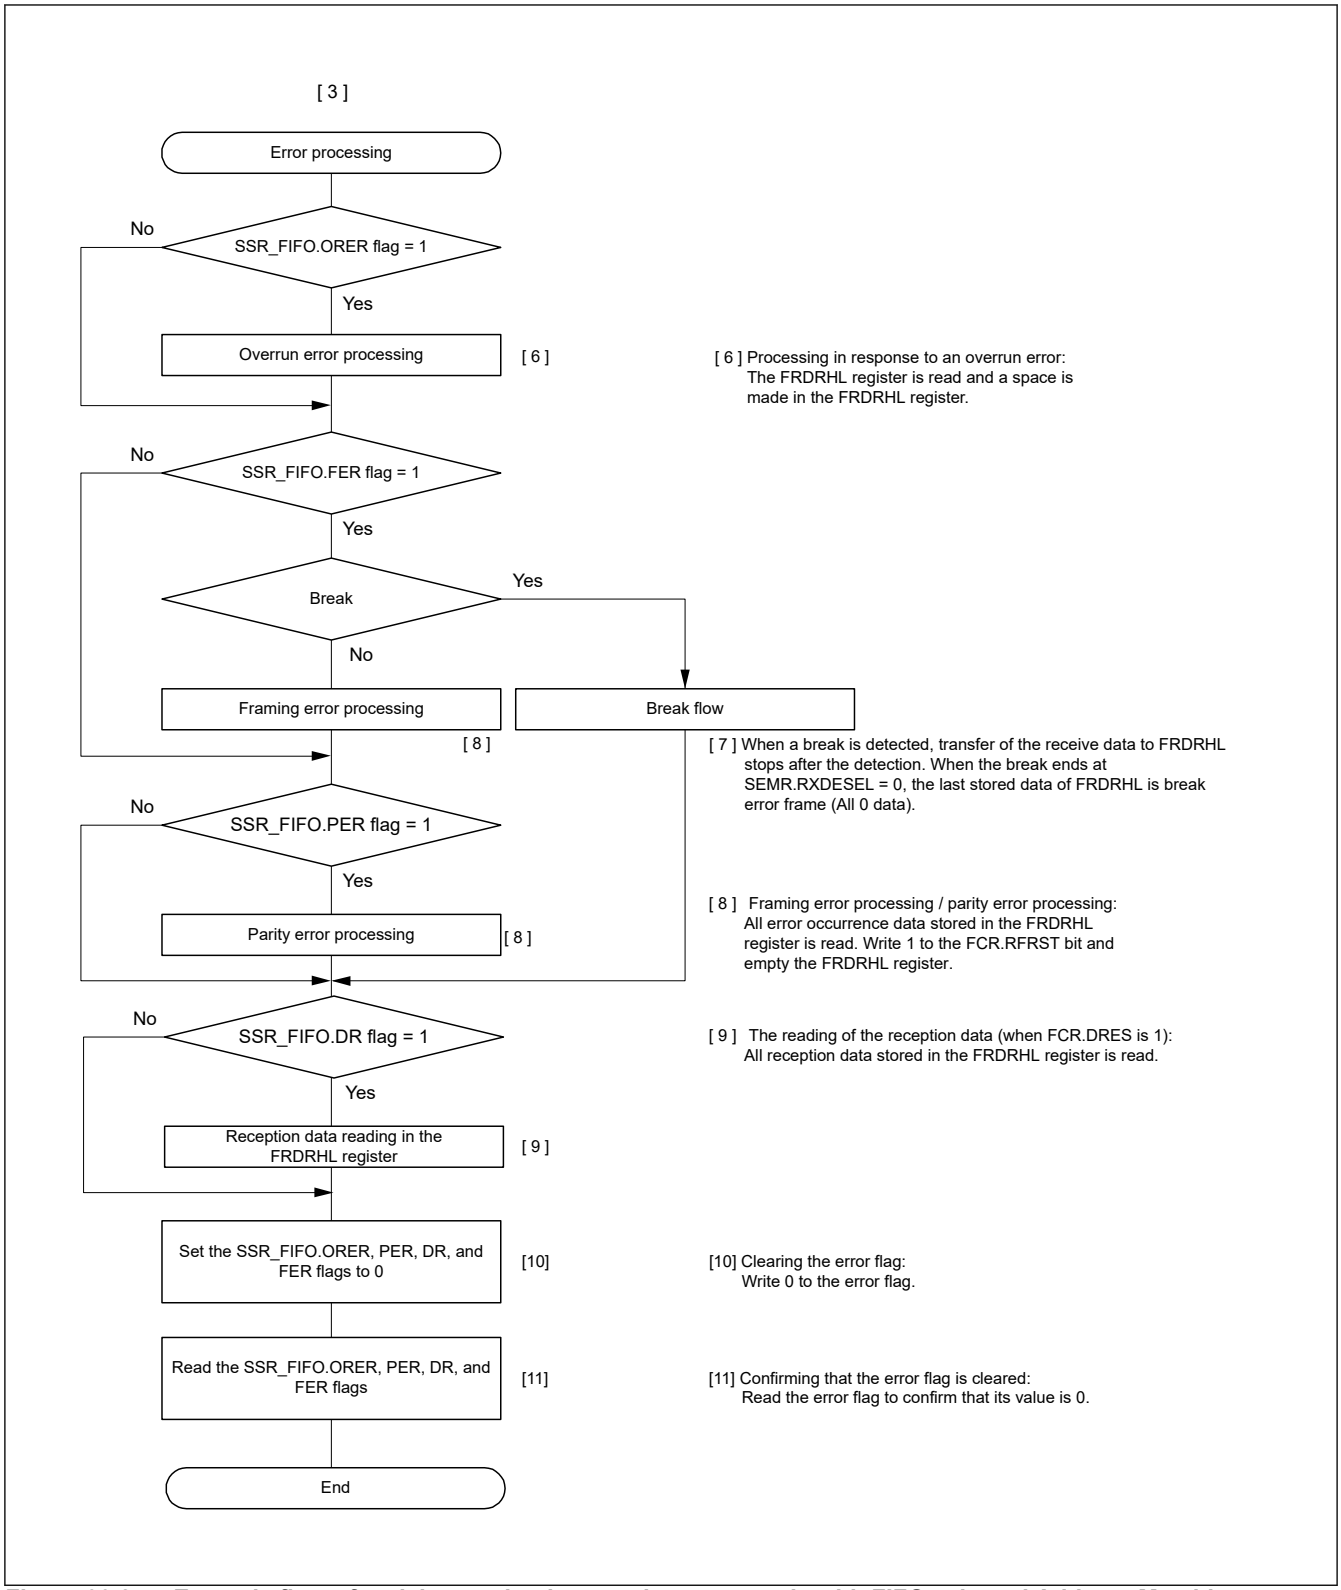


Figure 30.27 Example flow of serial reception in asynchronous mode with FIFO selected Address Matching Disabled (2)

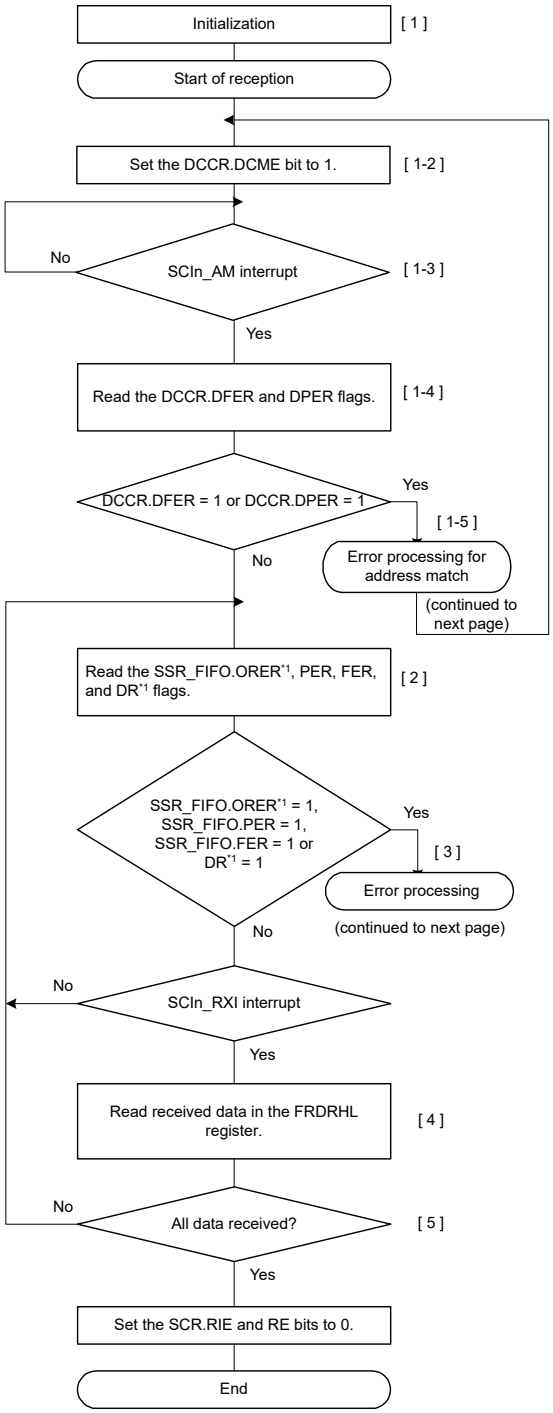

[1] SCI initialization:
Set data reception.

[1-2] Address match cycle:
Set the DCCR.DCME bit to 1 to enable address matching.

[1-3] Comparing received data and data for comparison (CDR.CMPD):
Compare receive data and comparison data.
The SCI cannot detect a parity or framing error as received data are skipped (discarded) until the SCI detects a match between the received data and data for comparison.
If the SCI detects an address match, the DCCR.DCME bit is cleared, the DCCR.DCMF flag becomes 1, and an SCIn_AM interrupt request is issued.

[1-4] [1-5] Reception error processing:
An error is identified by reading the DFER or DPER flag in DCCR from within the SCIn_AM interrupt handling routine.
After appropriate handling of the error, set both the DFER and DPER flags to 0.
If either of these flags is set to 1, address matching cannot be resumed.

[2] [3] Reception error processing and break detection:
When a reception error occurs, an SCIn_ERI interrupt is generated.
A break is identified by reading SPTR.RXDMON.
The error is identified by reading each among the SSR_FIFO.ORER*1, PER, FER, and DR*1 flags.
After appropriate handling of the error, set the ORER*1 flag to 0.
If the ORER*1 flag remains 1, reception cannot be resumed.
The reception operation is continuous, even if the FER = 1, PER = 1 or DR*1 = 1.

[4] Reading the received data in the FRDRHL register from within the SCIn_RXI interrupt handling routine:
The received data stored in the FRDRHL register are read until the amount of stored data is less than the value of the FCR.RTRG[3:0] bits.
Confirm the number of received data in the FIFO with the value of the FDR.R[4:0] bits.

[5] Serial reception continuation procedure:
To continue with serial reception, read data from the FRDRHL register from within the SCIn_RXI interrupt handling routine before an overrun error occurs, and set the RDF and DR flags to 0. The data in the FRDRHL register can also be read by activating the DMAC or DTC. In this case, do not write to the RDF flag because the flag is automatically cleared.

Note 1. The FRDRHL.ORER and DR flags can also be read.

Figure 30.28 Example Flowchart of Serial Reception in Asynchronous Mode (FIFO Selected and Address Matching Enabled) (1)

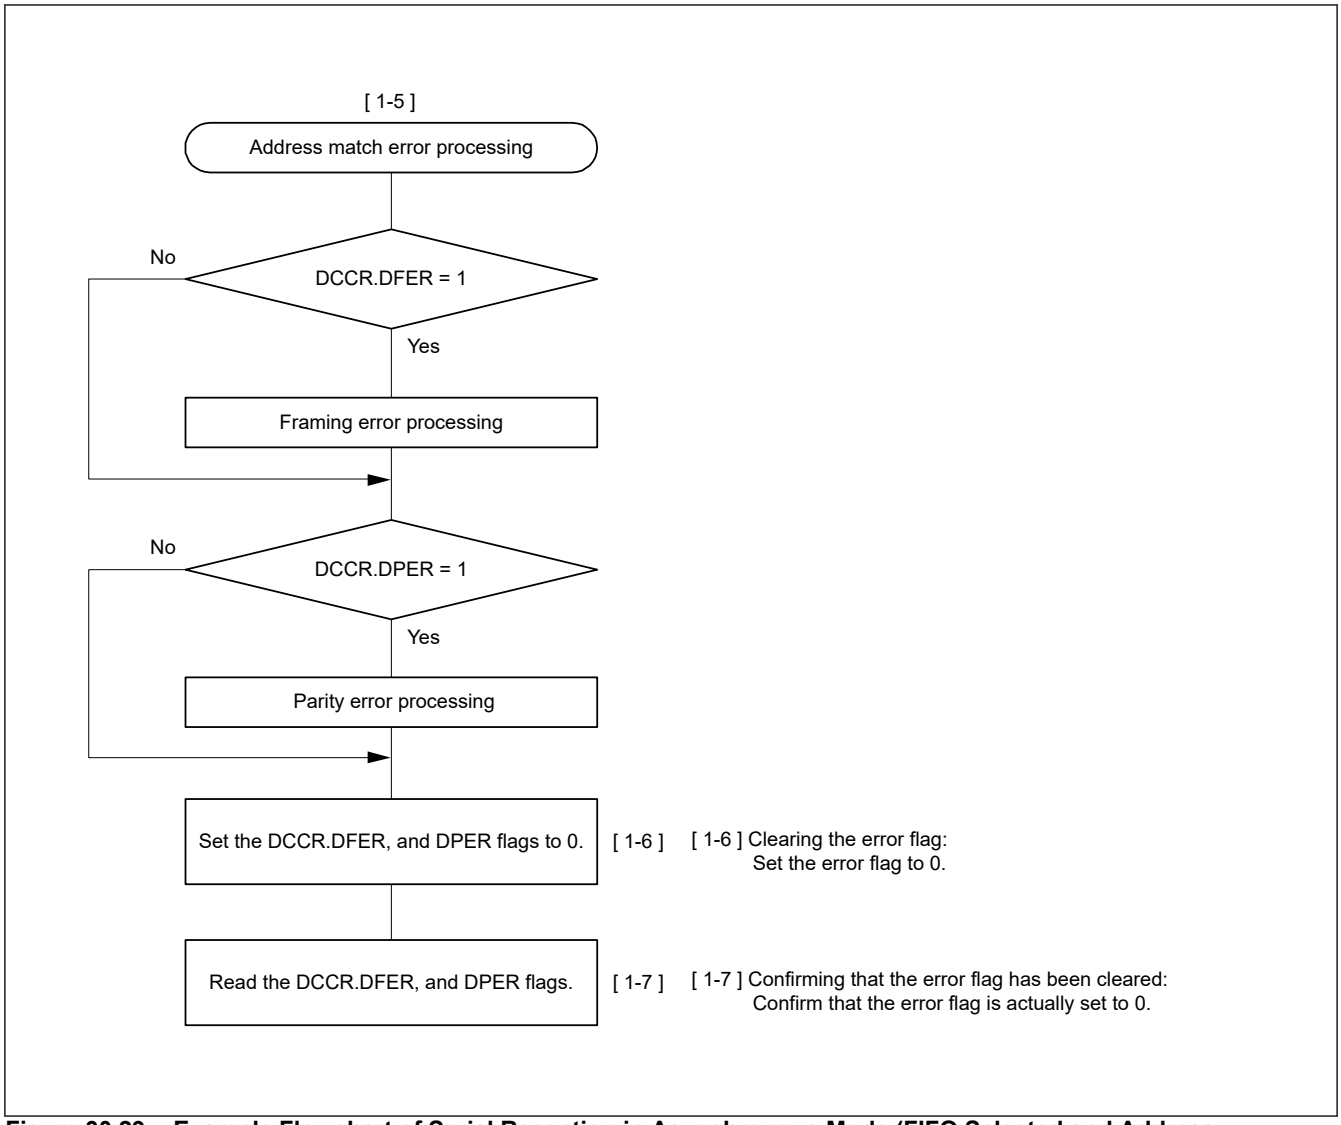

Figure 30.29 Example Flowchart of Serial Reception in Asynchronous Mode (FIFO Selected and Address Matching Enabled) (2)

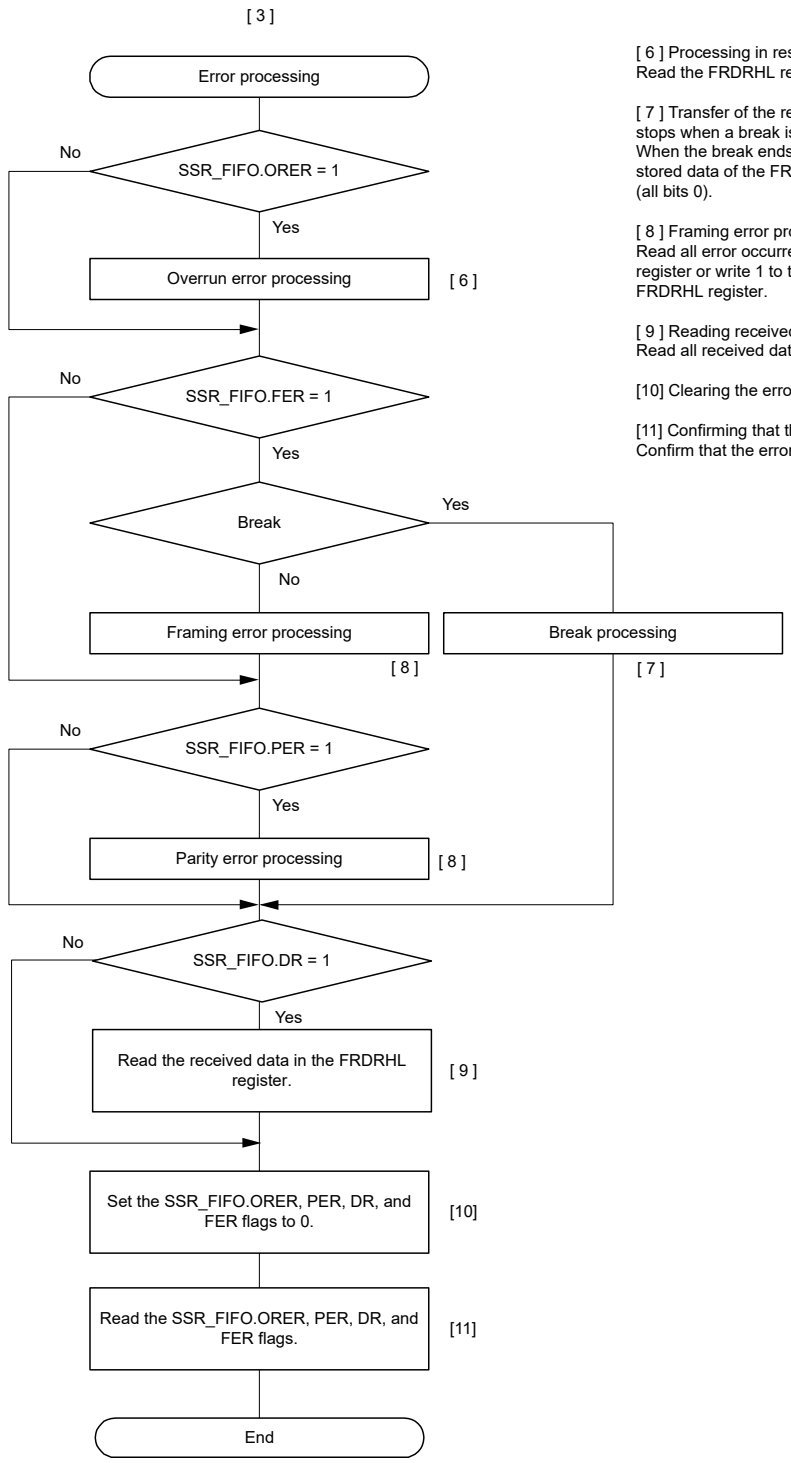

Figure 30.30 Example Flowchart of Serial Reception in Asynchronous Mode (FIFO Selected and Address Matching Enabled) (3)

30.3.10 The function of adjust receive sampling timing (Asynchronous Mode)

When there is the difference between the rising transfer time and the falling transfer time through a photo coupler, the receive sampling timing at middle of bit affects the reception margin. In this case, the receive sampling timing is able to adjust from the middle of bit to the optimum timing by using this function.

The receive sampling timing is adjusted from the middle of bit by following formula. The adjustable direction is set by ACTR.AJD. When adjusting backward (ACTR.AJD = 0), substitute AJD = +1 and substitute AJD = −1 when adjusting forward (ACTR.AJD = 1).

Adjusted sampling timing = the middle of bit + AJD × (base clock × the setting value of ACTR.AST[2:0])

The setting timing is limited by base clock cycles per 1 bit. For details, see Table 30.31.

An overview of reception operation of the communication through a photo coupler with this function is shown in Figure 30.31, Figure 30.32 and Figure 30.33, the explanation of operation with this function is shown in Figure 30.34.

Do not use this function when there is no difference between the rising transfer time and the falling transfer time, because there is a possibility of deteriorating the reception margin.

Table 30.31 The acceptable value of ACTR register (asynchronous mode using internal clock)

SEMR.ABCSE	SEMR.ABCS	The number of base clock cycles/1bit	The acceptable value of ACTR	
			ACTR.AJD	ACTR.AST
1	x	6	0	000b – 010b*1
			1	
0	1	8	0	000b – 011b*1
			1	
0	0	16	0	000b – 111b
			1	

Note: x: Don't care
Note 1. When the value of ACTR.AST exceeds the acceptable value, sampling is done at default timing. (Adjustment of sampling is not done.)

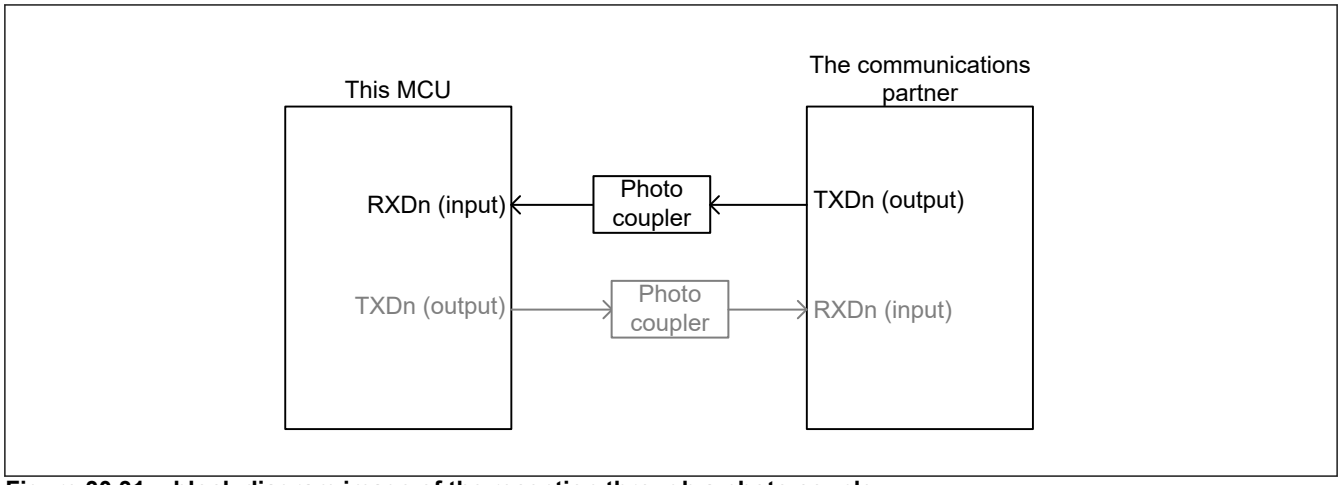

Figure 30.31 block diagram image of the reception through a photo couple

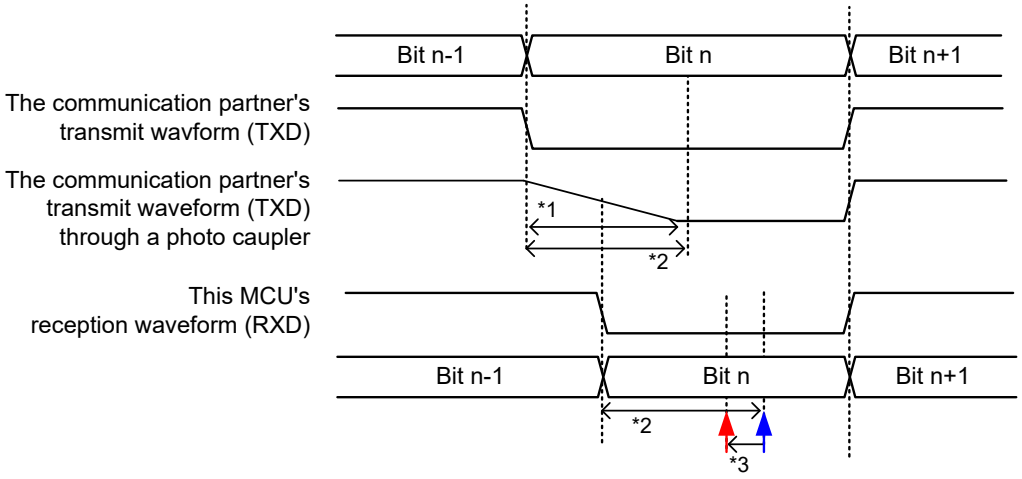
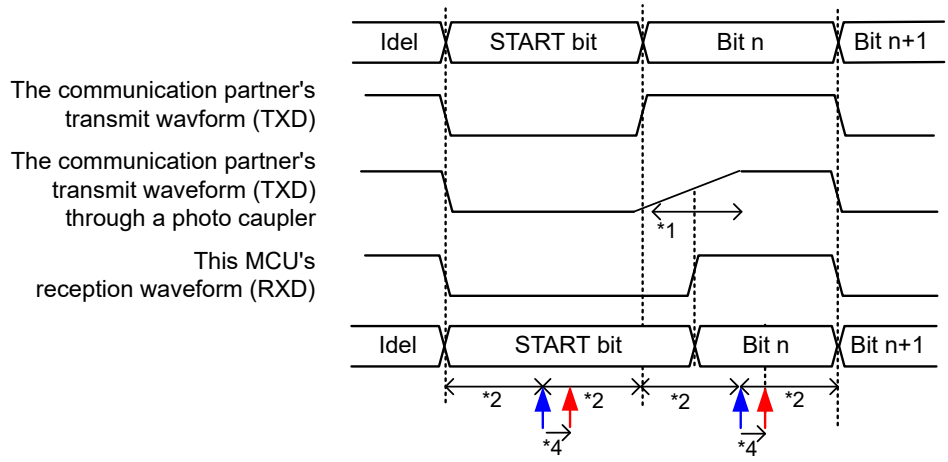
(a) In the case of the falling transfer time >> rising transfer time

The falling edge of reception waveform is made dull like following chart.
In this case, you can sampling at the middle of bit if you adjust the receive sampling timing to forward (AJD = 1).



(b) In the case of the falling transfer time << rising transfer time

The rising edge of reception waveform is made dull like following chart.
Thus, the reception margin of communications partner will be bad. In this case, you can improve the reception margin if you adjust the receive sampling timing to back.



The receive sampling timing when unadjusted (middle of bit)

The adjusted receive sampling timing

Note: This waveform shows the operation image of adjustment in reception sampling timing.
Note 1. The dull period by a photo coupler
Note 2. Bit center timing at set communication rate
Note 3. When ACTR.AJD is 1, the receive sampling timing is shifted to forward by the setting value of ACTR.AST[2:0].
Note 4. When ACTR.AJD is 0, the Receive sampling timing is shifted to backward by the setting value of ACTR.AST[2:0].

Figure 30.32 Overview of reception operation of the communication through a photo coupler

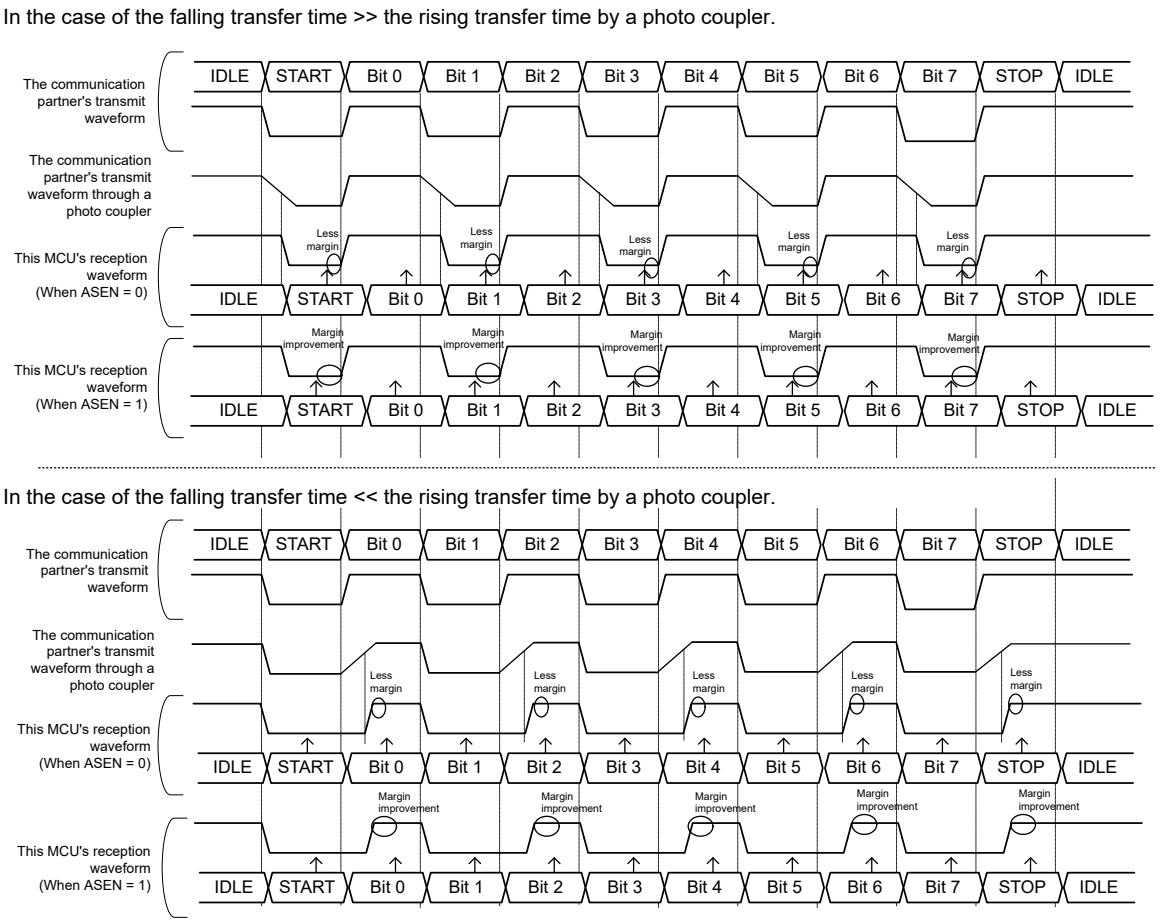


Figure 30.33 Example of improvement in reception margin by the reception sampling timing adjustment function

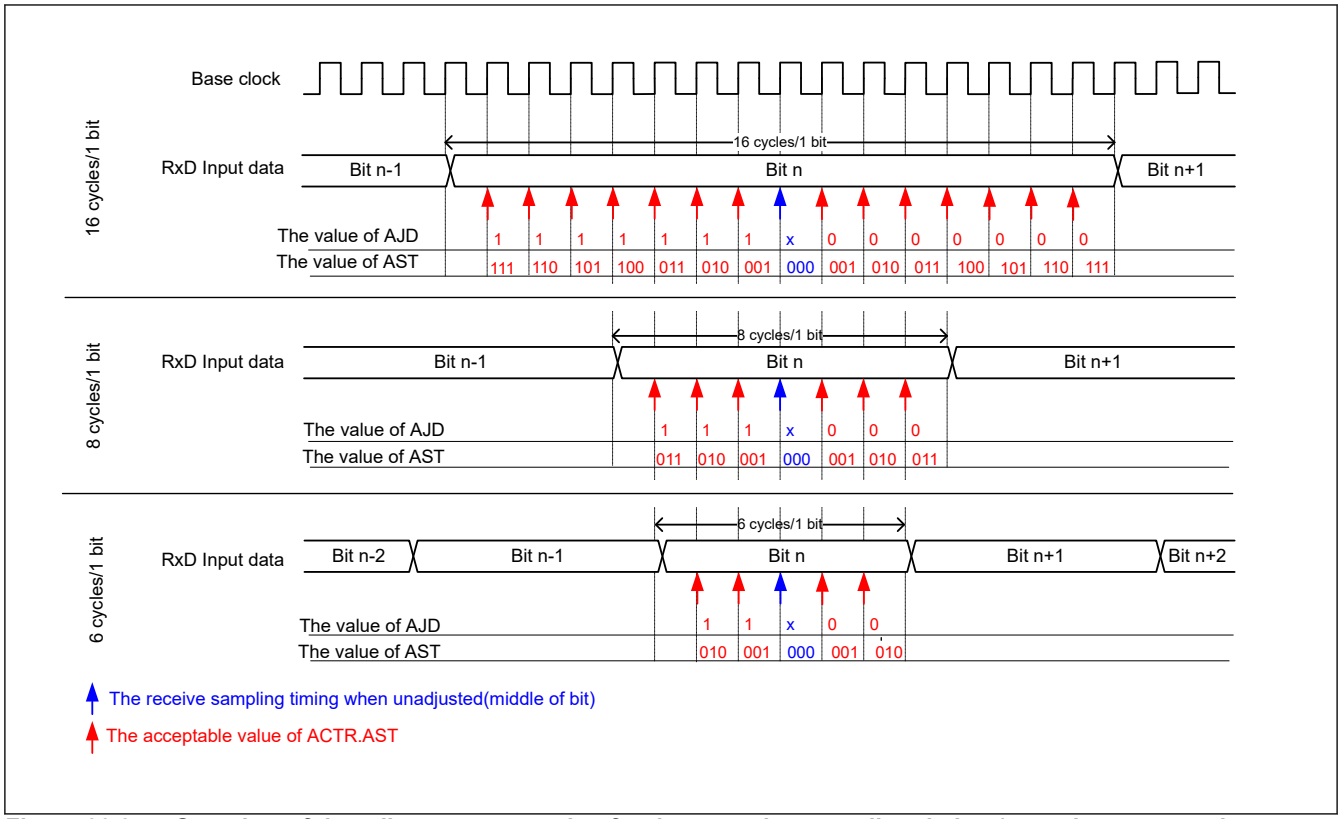

Figure 30.34 Overview of the adjustment operation for the reception sampling timing (asynchronous mode using internal clock)

30.3.11 The function of adjust transmit timing (Asynchronous Mode)

In communication via a photo coupler or the like, when either the rising or falling transition time of the TXDn output signal is long, then a communication partner receive dulled waveform. In this case, the reception margin may be affected.

In these cases, make a communication partner to be sampling at middle of bit using the function of adjust transmit timing.

When SPTR.ATEN is 1, this function can adjust the edge timing at the timing calculated by the following formula for the edge set with ACTR.AET.

The adjustment edge timing = the base clock × ACTR.ATT[2:0]

In addition, the upper limit of the adjustment edge timing is limited by setting the base clock cycles. For details, see Table 30.32.

A transmission movement image figure of the communication through a photo coupler with this function is shown in Figure 30.35, Figure 30.36 and Figure 30.37, the overview of operation with this function is shown in Figure 30.38 and Figure 30.39.

Do not use this function when there is not the difference between the rising transfer time and the falling transfer time, there is a possibility of deteriorating the reception margin of a communication partner.

Table 30.32 The acceptable value of ACTR.AET and ACTR.ATT (asynchronous mode using internal clock) (1 of 2)

ABCSE	ABCS	The number of base clock cycles/1bit	The acceptable value of ACTR	
			AET	ATT[2:0]
1	x	6	0	000b – 101b
			1	
0	1	8	0	000b – 111b
			1	

Table 30.32 The acceptable value of ACTR.AET and ACTR.ATT (asynchronous mode using internal clock) (2 of 2)

ABCSE	ABCS	The number of base clock cycles/1bit	The acceptable value of ACTR	
			AET	ATT[2:0]
0	0	16	0	000b – 111b
			1	

Note: x: Don't care
Note: When the value of ACTR.AET/ATT is out of the acceptable value, this SCI module doesn't adjust transmit timing.

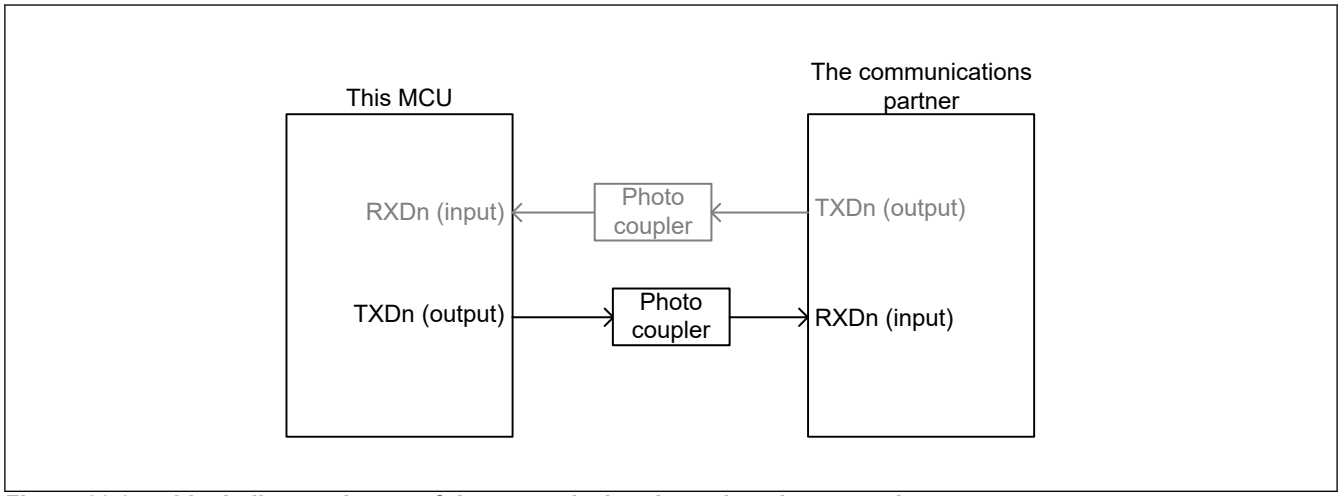

Figure 30.35 block diagram image of the transmission through a photo coupler

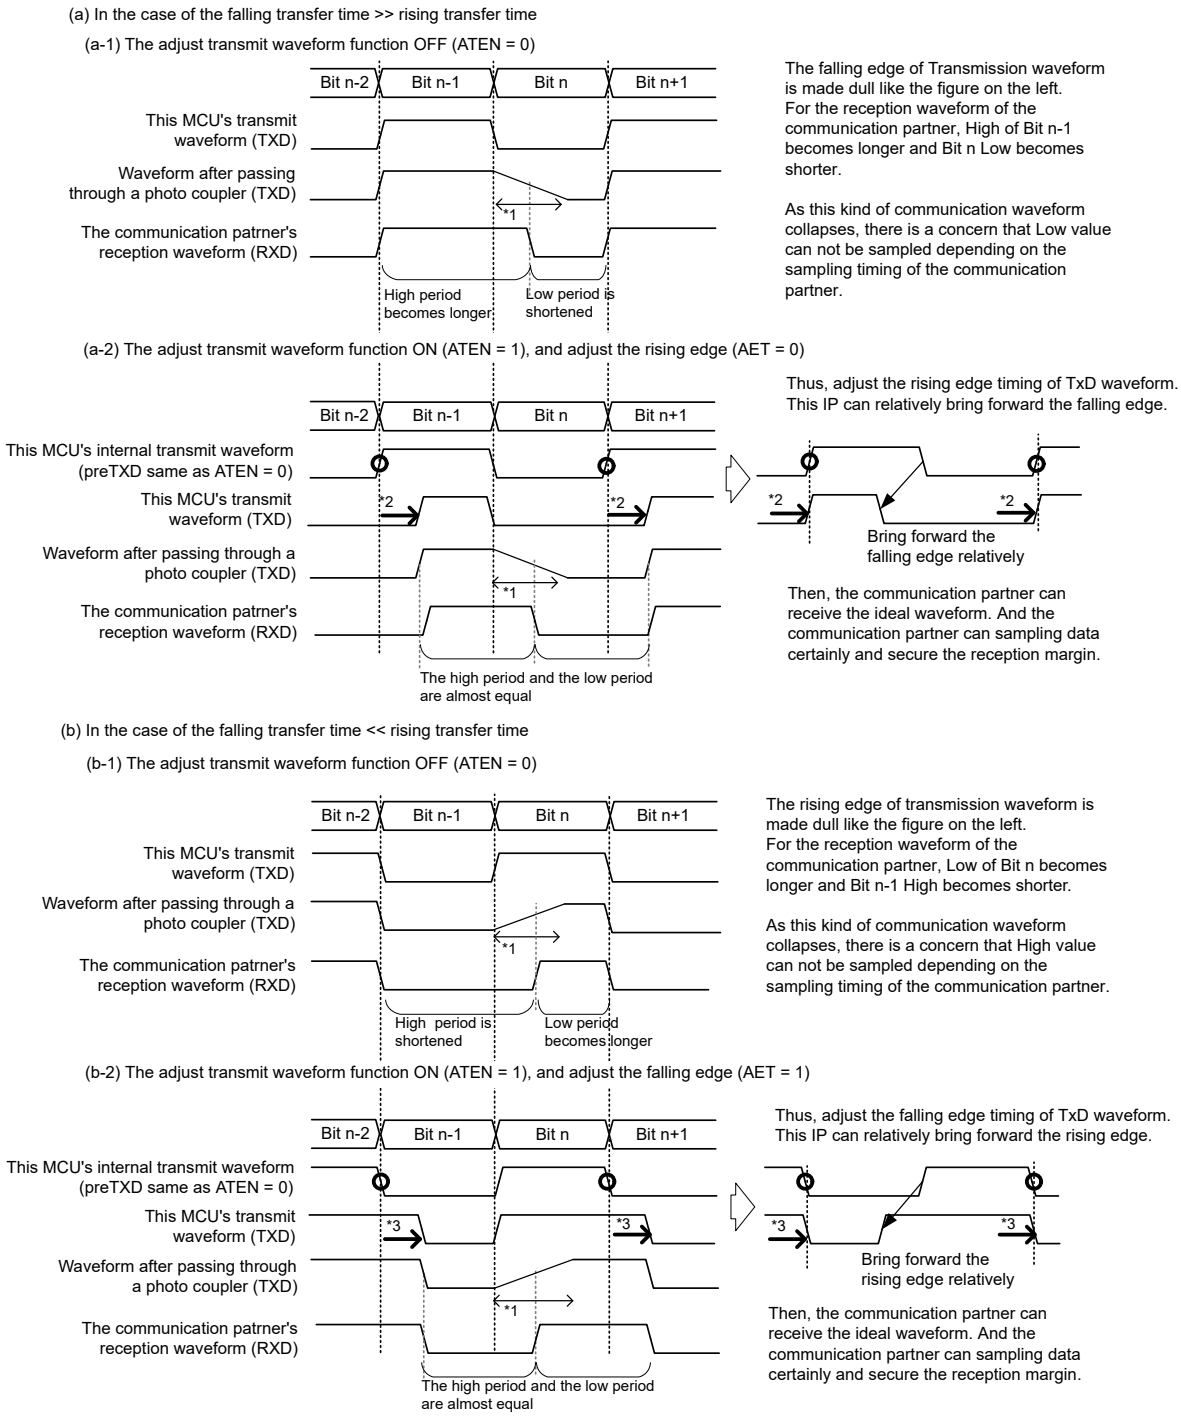

Note: This waveform shows the operation image of adjustment transmit waveform.
Note 1. The dull period by a photo coupler
Note 2. When ACTR.AET is 0, the rising edge of transmit waveform timing is shifted to back by the setting value of ACTR.ATT[2:0]. This IP transmit waveform bringing forward the falling edge relatively.
Note 3. When ACTR.AET is 1, the falling edge of transmit waveform timing is shifted to back by the setting value of ACTR.ATT[2:0]. This IP transmit waveform bringing forward the rising edge relatively.

Figure 30.36 The overview of transmission operation in the communication through a photo coupler

The explanation of transmit waveforms of the communication through a photo coupler using adjust transmit timing function

When using the transmission timing adjustment function, adjust the edge timing of the transmission waveform and correct the reception waveform of the communication partner

The following example is 8 bit long data.

Figure 30.39 The adjustment operation explanation for the transmit timing when AET is 1

30.4 Multi-Processor Communication Function

The multi-processor communication function enables the SCI to transmit and receive data between multiple processors by sharing an asynchronous serial communication line that has an added multi-processor bit. In multi-processor communication, a unique ID code is allocated to each receiving station. Serial communication cycles consist of an ID transmission cycle to specify the receiving station and a data transmission cycle to transmit data to the specified receiving station.

The multi-processor bit is used to distinguish between the ID transmission cycle and the data transmission cycle:

- When the multi-processor bit is set to 1, the transmission cycle is the ID transmission cycle
- When the multi-processor bit is set to 0, the transmission cycle is the data transmission cycle

Figure 30.40 shows an example of communication between processors using a multi-processor format. First, a transmitting station transmits communication data in which the multi-processor bit set to 1 is added to the ID code of the receiving station. Next, the transmitting station transmits communication data in which the multi-processor bit set to 0 is added to the transmit data. After receiving communication data with the multi-processor bit set to 1, the receiving station compares the received ID with the ID of the receiving station itself. If the two match, the receiving station receives communication data that is subsequently transmitted. If the received ID does not match with the ID of the receiving station, the receiving station skips the communication data until it receives data in which the multi-processor bit is set to 1.

(1) Non-FIFO selected

To support this function, the SCI provides the SCR.MPIE bit. When the MPIE bit is set to 1, the following operations are disabled until the reception of data in which the multi-processor bit is set to 1:

- Transfer of receive data from the RSR register to the RDR register (the RDRHL register when 9-bit data length is selected)
- Detection of a receive error
- Setting of the respective RDRF, ORER, and FER status flags in the SSR register

When the SCI receives a character in which the multi-processor bit is set to 1, the SSR.MPBT bit is set to 1 and the SCR.MPIE bit is automatically cleared, returning the SCI to normal reception operation. If the SCR.RIE bit is set to 1, an SCIn_RXI interrupt is generated.

When the multi-processor format is specified, the parity bit function is disabled. Apart from this, there is no difference from operation in normal asynchronous mode. The clock used for the multi-processor communication is the same as the clock used in normal asynchronous mode.

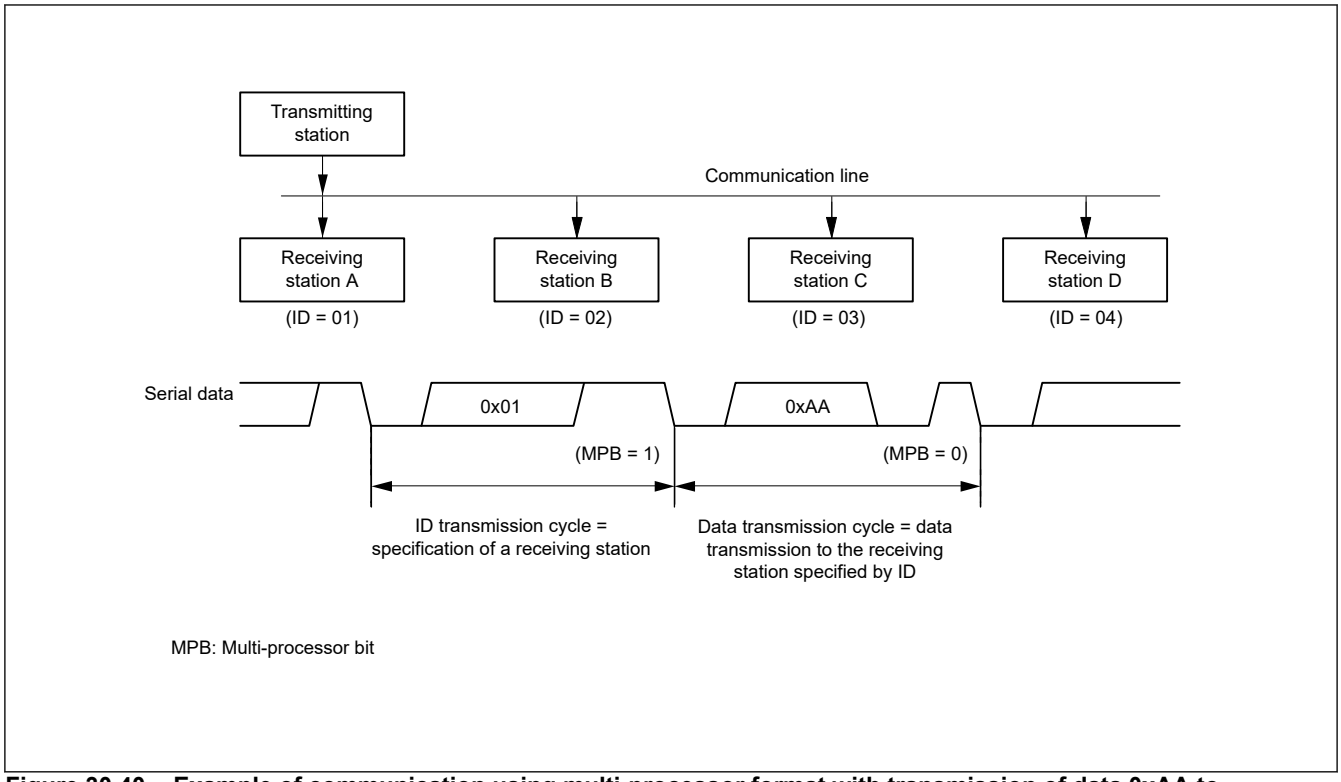

Figure 30.40 Example of communication using multi-processor format with transmission of data 0xAA to receiving station A

(2) FIFO selected

For data transmission, software must write data to FTDRHL.MPBT that corresponds to transmit data in FTDRHL.TDAT. For data reception, the multi-processor bit that is part of the receive data is written to FTDRHL.MPB and receive data is written to FRDRL.

When the MPIE bit is set to 1, the following operations are disabled until reception of data in which the multi-processor bit is set to 1:

- Transfer of receive data from the RSR register to the FRDRHL register
- Detection of a receive error
- Break
- Setting of the respective RDF, ORER, and FER status flags in the SSR_FIFO register

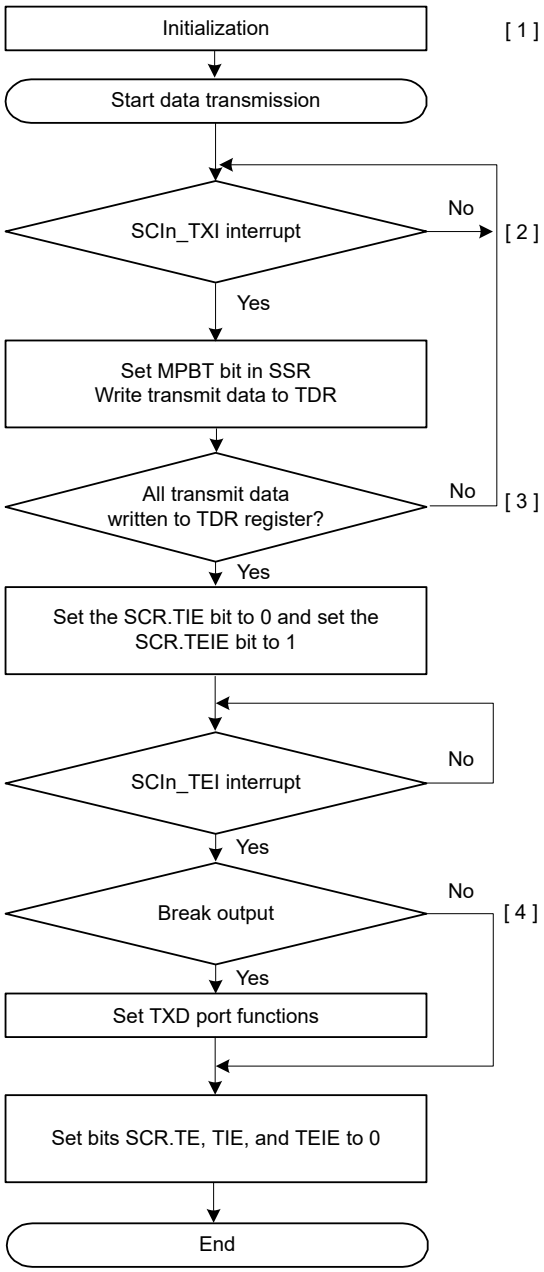
When the SCI receives an 8-bit character in which the multi-processor bit is set to 1, the FTDRHL.MPB bit is set to 1 and receive data is written to FRDRHL.RDAT. The SCR.MPIE bit is automatically cleared, returning the SCI to normal reception operation. If the SCR.RIE bit is set to 1, an SCIn_RXI interrupt is generated.

When the multi-processor format is specified, the parity bit function is disabled. Apart from this, there is no difference from operation in normal asynchronous mode with FIFO selected.

30.4.1 Multi-Processor Serial Data Transmission

(1) Non-FIFO selected

Figure 30.41 shows an example flow of multi-processor data transmission. In the ID transmission cycle, the ID must be transmitted with the SSR.MPBT bit set to 1. In the data transmission cycle, the data must be transmitted with the MPBT bit set to 0. The rest of the operations are the same as operations in asynchronous mode. Write the values in the order of the FTDRH register then the FTDRL register.



[1] SCI initialization:
Set data transmission.
After the SCR.TE bit is set to 1, 1 is output for a frame, and transmission is enabled.

[2] SCIn_TXI interrupt request:
When transmit data is transferred from TDR to TSR, a transmit data empty interrupt (SCIn_TXI) request is generated.
Set the MPBT bit in SSR to 0 or 1, and write transmit data to TDR once in the SCIn_TXI interrupt processing routine.

[3] Serial transmission continuation procedure:
To continue serial transmission, write transmit data to TDR once using an SCIn_TXI interrupt request.
Transmit data can also be written to TDR by activating the DMAC or DTC.
When SCIn_TEI interrupt requests are in use, set the SCR.TIE bit to 0 and the SCR.TEIE bit to 1 after the last of the data to be transmitted is written to the TDR.

[4] Break output at the end of serial transmission:
To output a break in serial transmission, after setting the output state (LOW level output) of TXD pin by SPTR.SPB2IO and SPTR.SPB2DT bits, set the SCR.TE bit to 0.

Figure 30.41 Example flow of multi-processor serial transmission with non-FIFO selected

(2) FIFO selected

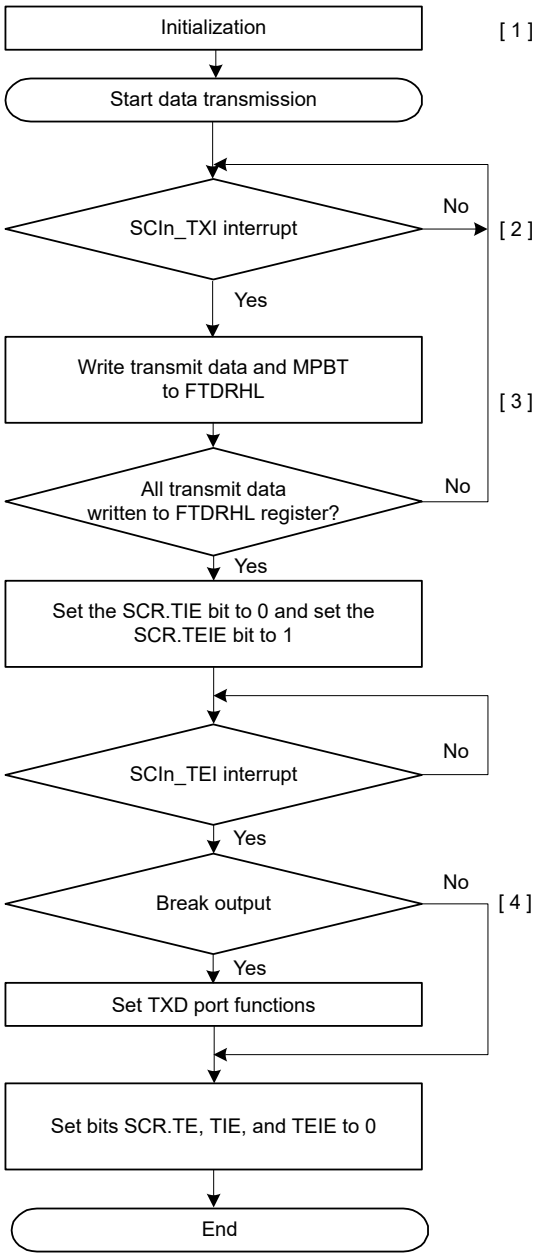
Figure 30.42 shows an example of data format that is written to FTDRH and FTDRL in multi-processor mode. The FTDRH.MPBT bit is set to 1. Data is set to FTDRH and FTDRL with the correct data length. Write 0 for unused bits. Write in order from FTDRH to FTDRL.

Data Length	Register Setting		Transmit data in FTDRH, FTDRL															
			FTDRHL															
			FTDRH								FTDRL							
	SCMR.CHR1	SMR.CHR	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
7 bits	1	0	—	—	—	—	—	—	MPBT	—	—	7-bit transmit data						
8 bits	1	1	—	—	—	—	—	—	MPBT	—	8-bit transmit data							
9 bits	0	Don't care	—	—	—	—	—	—	MPBT	9-bit transmit data								

Note: —: Invalid. The write value should be 0.

Figure 30.42 Data format written to FTDRH and FTDRL in multi-processor mode with FIFO selected

Figure 30.43 shows an example flow of multi-processor serial transmission with FIFO selected. In the ID transmission cycle, the ID must be transmitted with the FTDRH.MPBT bit set to 1. In the data transmission cycle, the data must be transmitted with the MPBT bit set to 0. The rest of the operations are the same as operations in asynchronous mode with FIFO selected.



[1] SCI initialization:
Set data transmission.
After the SCR.TE bit is set to 1, 1 is output for a frame, and transmission is enabled.

[2] Transmit data write to FTDRHL by an SCIn_TXI interrupt request:
When transmit data is transferred from FTDRHL to TSR, when the quantity of receive data written in FTDRHL is equal to or less than the specified transmit triggering number, a transmit data FIFO empty interrupt (SCIn_TXI) request is generated.

[3] Serial transmission continuation procedure:
To continue serial transmission, write transmit data and MPBT to FTDRHL once using an SCIn_TXI interrupt request.
Transmit data can also be written to FTDRHL by activating the DMAC or DTC.
When SCIn_TEI interrupt requests are in use, set the SCR.TIE bit to 0 and the SCR.TEIE bit to 1 after the last of the data to be transmitted is written to the FTDRHL.

[4] Break output at the end of serial transmission:
To output a break in serial transmission, after setting the output state (LOW level output) of TXD pin by SPTR.SPB2IO and SPTR.SPB2DT bits, set the SCR.TE bit to 0.

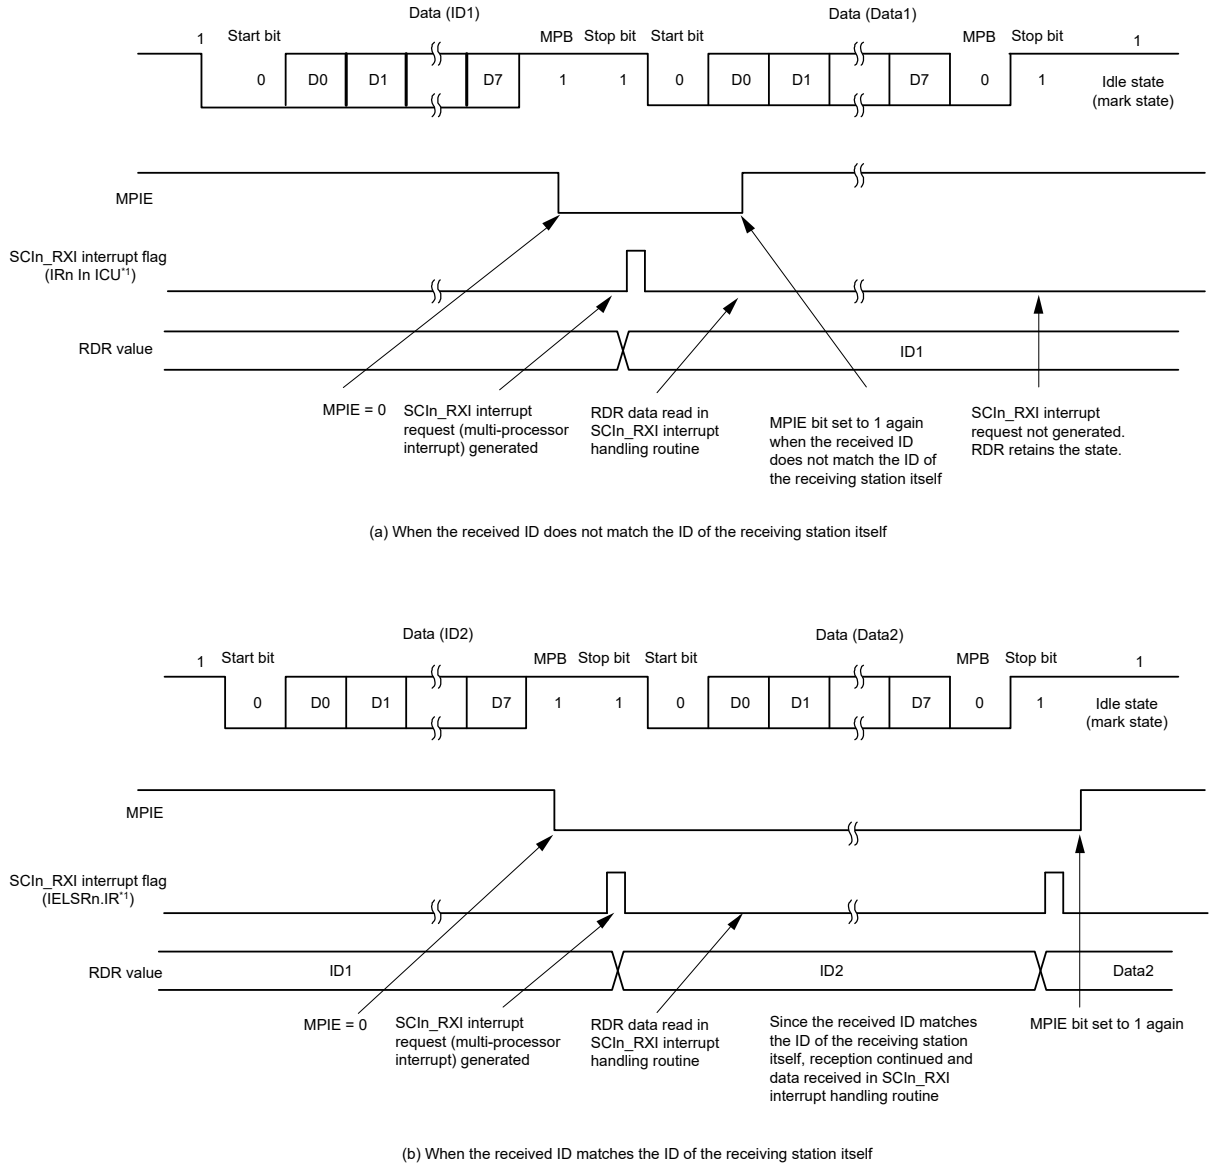
Figure 30.43 Example flow of serial transmission in multi-processor mode with FIFO selected

30.4.2 Multi-Processor Serial Data Reception

(1) Non-FIFO selected

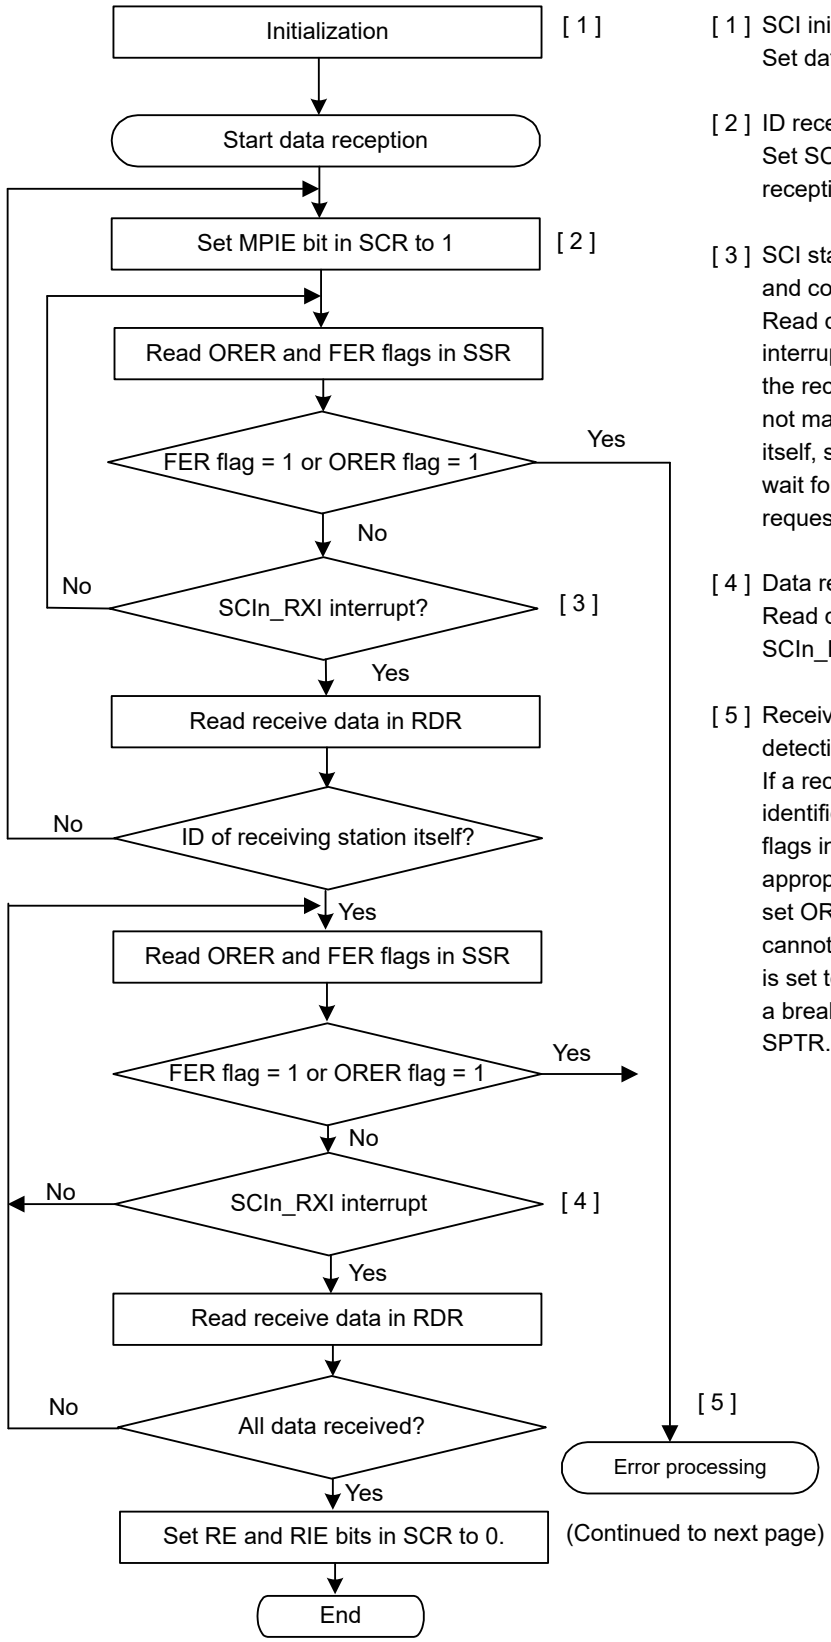
Figure 30.45 and Figure 30.46 are example flows of multi-processor serial reception. When the SCR.MPIE bit is set to 1, reading communication data is skipped until reception of communication data in which the multi-processor bit is set to 1. When communication data in which the multi-processor bit is set to 1 is received, the received data is transferred to the RDR register (the RDRHL register when 9-bit data length is selected), and the SCIn_RXI interrupt request is generated. The rest of the operations are the same as operations in asynchronous mode. Read the order from FRDRH to FRDRL.

Figure 30.44 shows an example operation for data reception.



Note 1. See section 13, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 30.44 Example of SCI reception with 8-bit data, multi-processor bit, and 1 stop bit



[1] SCI initialization:
Set data reception.

[2] ID reception cycle:
Set SCR.MPIE bit to 1 and wait for ID reception.

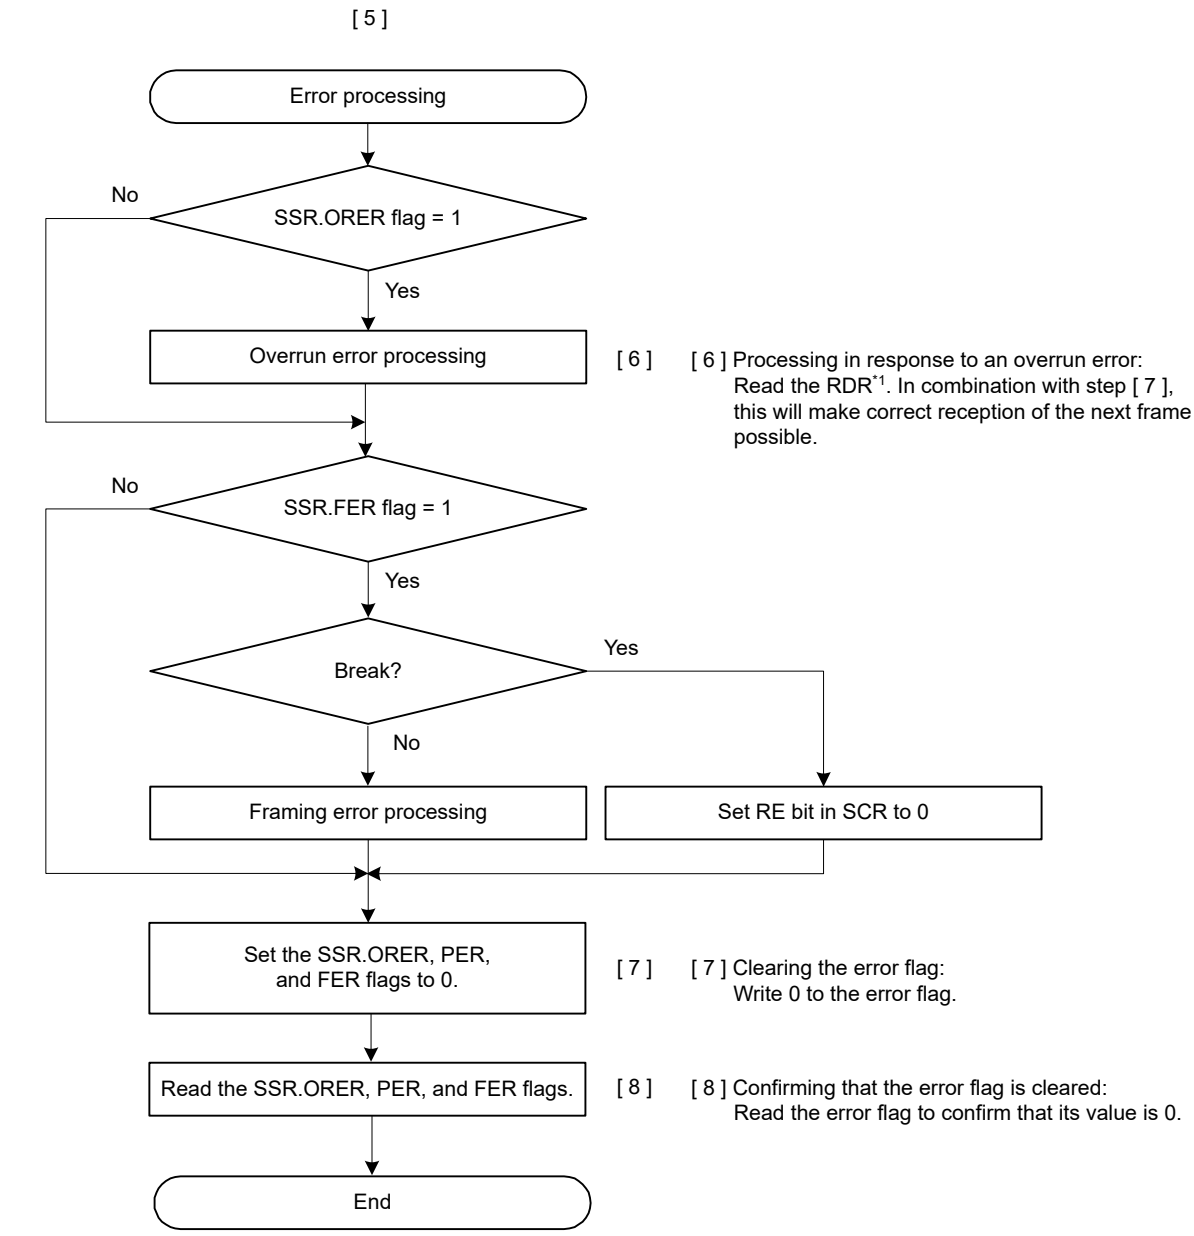
[3] SCI status confirmatIon and reception and comparison of ID:
Read data in RDR*1 at the first SCIn_RXI interrupt and compare it with the ID of the receiving statIon itself. If the ID does not match the ID of the receiving station itself, set the MPIE bit to 1 again, and wait for another SCIn_RXI interrupt request.

[4] Data reception at an SCIn_RXI interrupt:
Read data in RDR*1 once in the SCIn_RXI interrupt routine.

[5] Receive error processing and break detection:
If a receive error occurs, an error is identified by reading ORER and FER flags in SSR. After performing the appropriate error processing, be sure to set ORER and FER flags to 0. Reception cannot be resumed if any of these flags is set to 1. In the case of a framing error, a break can be detected by reading SPTR.RXDMON flag.

Note 1. The RDR register becomes the RDRHL register when 9-bit data length is selected.

Figure 30.45 Example flow of multi-processor serial reception with non-FIFO selected (1)



Note 1. The RDR register becomes the RDRHL register when 9-bit data length is selected.

Figure 30.46 Example flow of multi-processor serial reception with non-FIFO selected (2)

(2) FIFO selected

Figure 30.47 shows an example of a data format that is written to FRDRH and FRDRL in multi-processor mode.

In multi-processor mode, the MPB value that is a part of the receive data is written to the FRDRH.MPB bit. A value of 0 is written to the FRDRH.PER flag. Data is written to FRDRH and FRDRL with the correct data length. Unused bits are written with 0. Read in order from FRDRH to FRDRL. When software reads the FRDRL register, the SCI updates FER, MPB, and receive data (RDAT[8:0]) in FRDRL with the next data. The RDF, ORER and DR flags in the FRDRH register always reflect the associated flags in the SSR_FIFO register.

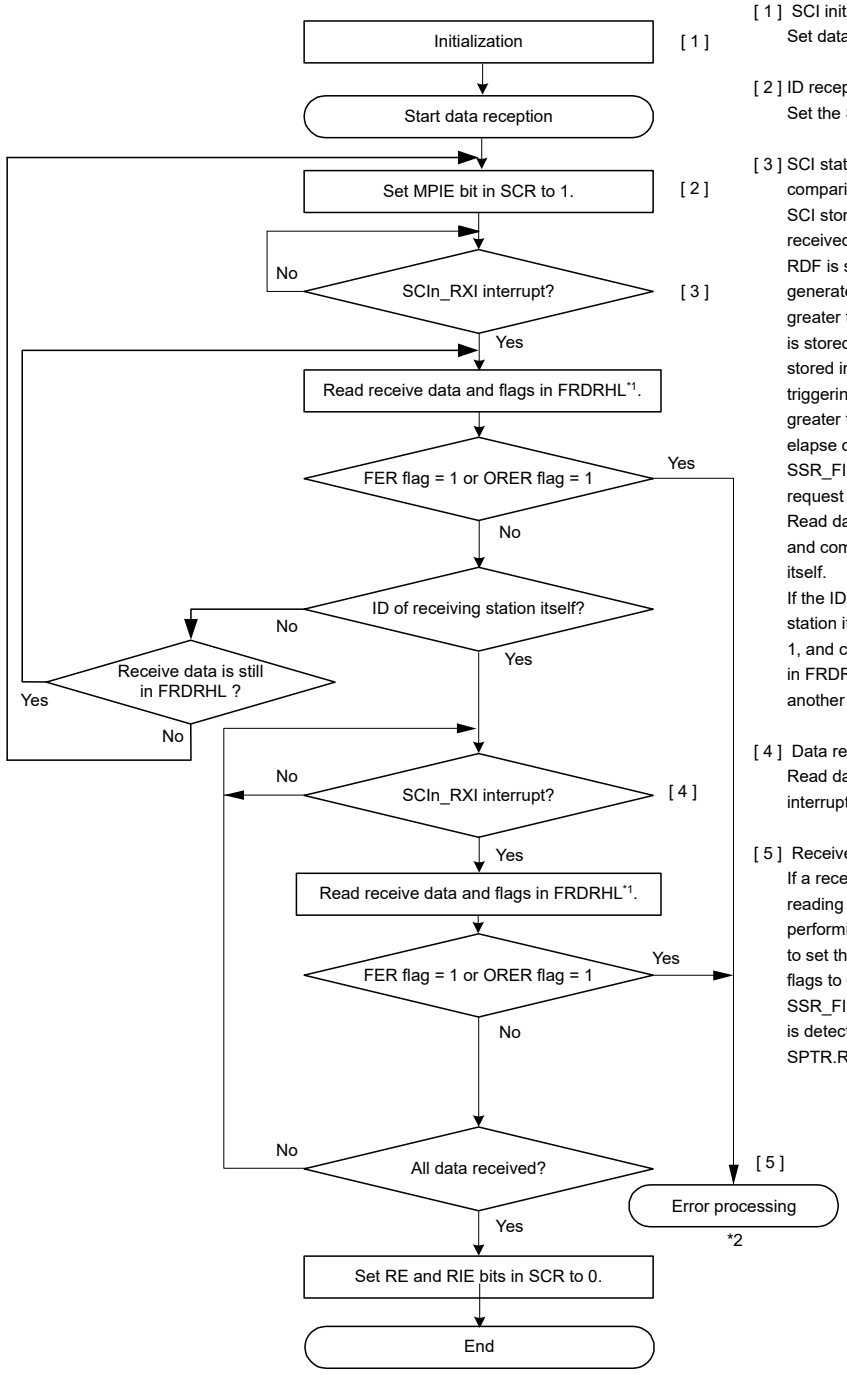
Data Length	Register Setting		Receive data in FRDRH, FRDRL															
			FRDRHL															
			FRDRH								FRDRL							
	SCMR.CHR1	SMR.CHR	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
7 bits	1	0	—	RDF	ORER	FER	0	DR	MPB	0	0	7-bit receive data						
8 bits	1	1	—	RDF	ORER	FER	0	DR	MPB	0	8-bit receive data							
9 bits	0	Don't care	—	RDF	ORER	FER	0	DR	MPB	9-bit receive data								

Note: When data length is 7 bits, 0 is always read for FRDRH[0] and FRDRL[7]
When data length is 8 bits, 0 is always read for FRDRH[0]
FRDRHL[15] bit is read as an indefinite value

Figure 30.47 Data format stored in FRDRH and FRDRL in multi-processor mode with FIFO selected

Figure 30.48 shows an example flow of multi-processor data reception with FIFO selected. When the SCR.MPIE is set to 1, reading communication data is skipped until reception of communication data in which the multi-processor bit is set to 1. When communication data in which the multi-processor bit is set to 1 is received, the received data, MPB and associated errors are transferred to the FRDRHL register. The SCR.MPIE bit is automatically cleared and normal reception continues.

If a framing error occurs and the SSR_FIFO.FER flag is set to 1, the SCI continues data reception. The rest of the operations are the same as operations in asynchronous mode with FIFO selected.



[1] SCI initialization:
Set data reception.

[2] ID reception cycle:
Set the SCR.MPIE bit to 1 and wait for ID reception.

[3] SCI status confirmation and reception and comparison of ID:
SCI stores first data (MPB = 1) and subsequent received data in FRDRHL.
RDF is set to 1 and an SCIn_RXI interrupt request is generated when a quantity of receive data equal to or greater than the specified receive triggering number is stored in FRDRHL. When the quantity of data stored in FRDRHL falls the specified receive triggering number and received data is equal to or greater than 1, and no next data is received after the elapse of 15 etus from the last stop bit, SSR_FIFO.DR is set to 1. An SCIn_RXI interrupt request is generated when FCR.DRES bit is 0.
Read data in FRDRHL at the first SCIn_RXI interrupt, and compare it with the ID of the receiving station itself.
If the ID does not match the ID of the receiving station itself, the SCI reads until the data with MPB = 1, and compares next ID. If it is no data with MPB = 1 in FRDRHL, set the MPIE bit to 1 again and wait for another SCIn_RXI interrupt request.

[4] Data reception at an SCIn_RXI interrupt:
Read data in FRDRHL once in the SCIn_RXI interrupt routine.

[5] Receive error processing and break detection:
If a receive error occurs, an error is identified by reading the ORER and FER flags in SSR_FIFO. After performing the appropriate error processing, be sure to set the SSR_FIFO.ORER and SSR_FIFO.FER flags to 0. Reception cannot be resumed if the SSR_FIFO.ORER flag is set to 1. When framing error is detected, a break can be detected by reading the SPTR.RXDMON flag.

Note 1. If FRDRH and FRDRL are used instead of FRDRHL, read in order from FRDRH to FRDRL.
Note 2. Same as Figure 30.46

Figure 30.48 Example flow of serial reception in multi-processor mode with FIFO selected

30.5 Operation in Manchester mode

In Manchester mode, the transmit or receive serial data is coded in Manchester encoding.

Figure 30.49 shows the conceptual image of Manchester encoding.

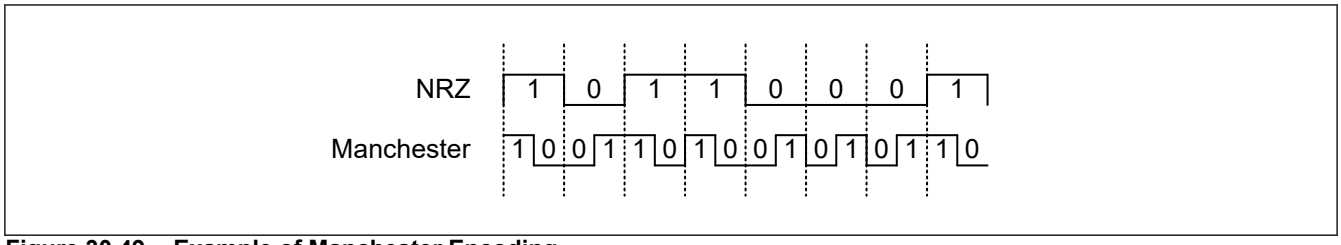


Figure 30.49 Example of Manchester Encoding

In Manchester mode, a preface and a start bit area are added to the transmit data in the register to configure a transmit frame. For transmission, data is encoded in Manchester encoding. When data is received, frames having the same format as transmitted frames are detected and Manchester decoding is performed.

For details on the frame format, see section 30.5.1. Frame Format.

30.5.1 Frame Format

Figure 30.50 shows the frame format in Manchester mode.

In the upper half of the figure, relevant setting registers are shown.

The preface area and the data area are encoded in Manchester encoding.

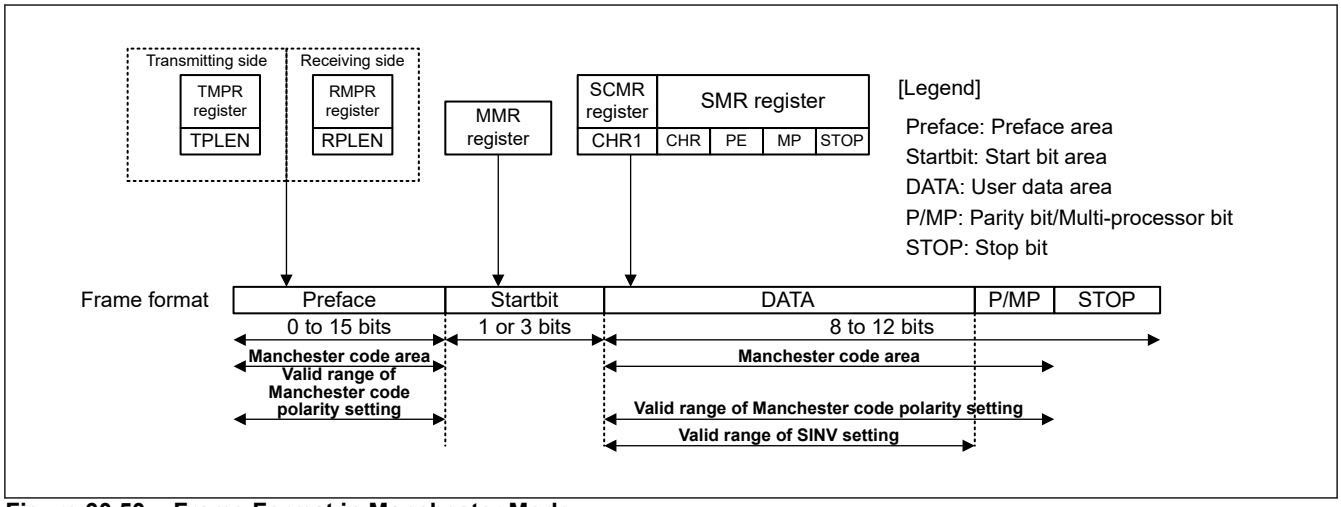

Figure 30.50 Frame Format in Manchester Mode

(1) Preface area

This is a fixed pattern area located at the beginning of each frame.

Different registers are used to set the preface area for transmission and reception. The preface length is determined by setting TMPR.TPLEN[3:0] for transmission. It is determined by setting RMPR.RPLEN[3:0] for reception.

If it is set to 0, the transmit preface is disabled and is not added.

If it is set to 1d to 15d, a preface whose length is determined by this setting is added.

(For example, if it is set to 1d, a 1-bit preface is added. If it is set to 15d, a 15-bit preface is added.)

The preface pattern is set with TMPR.TPPAT[1:0] for transmission and RMPR.RPPAT[1:0] for reception, and is selected from four types of patterns.

Figure 30.51 shows how the preface pattern is set. The preface area and the start bit area are added for each communication frame.

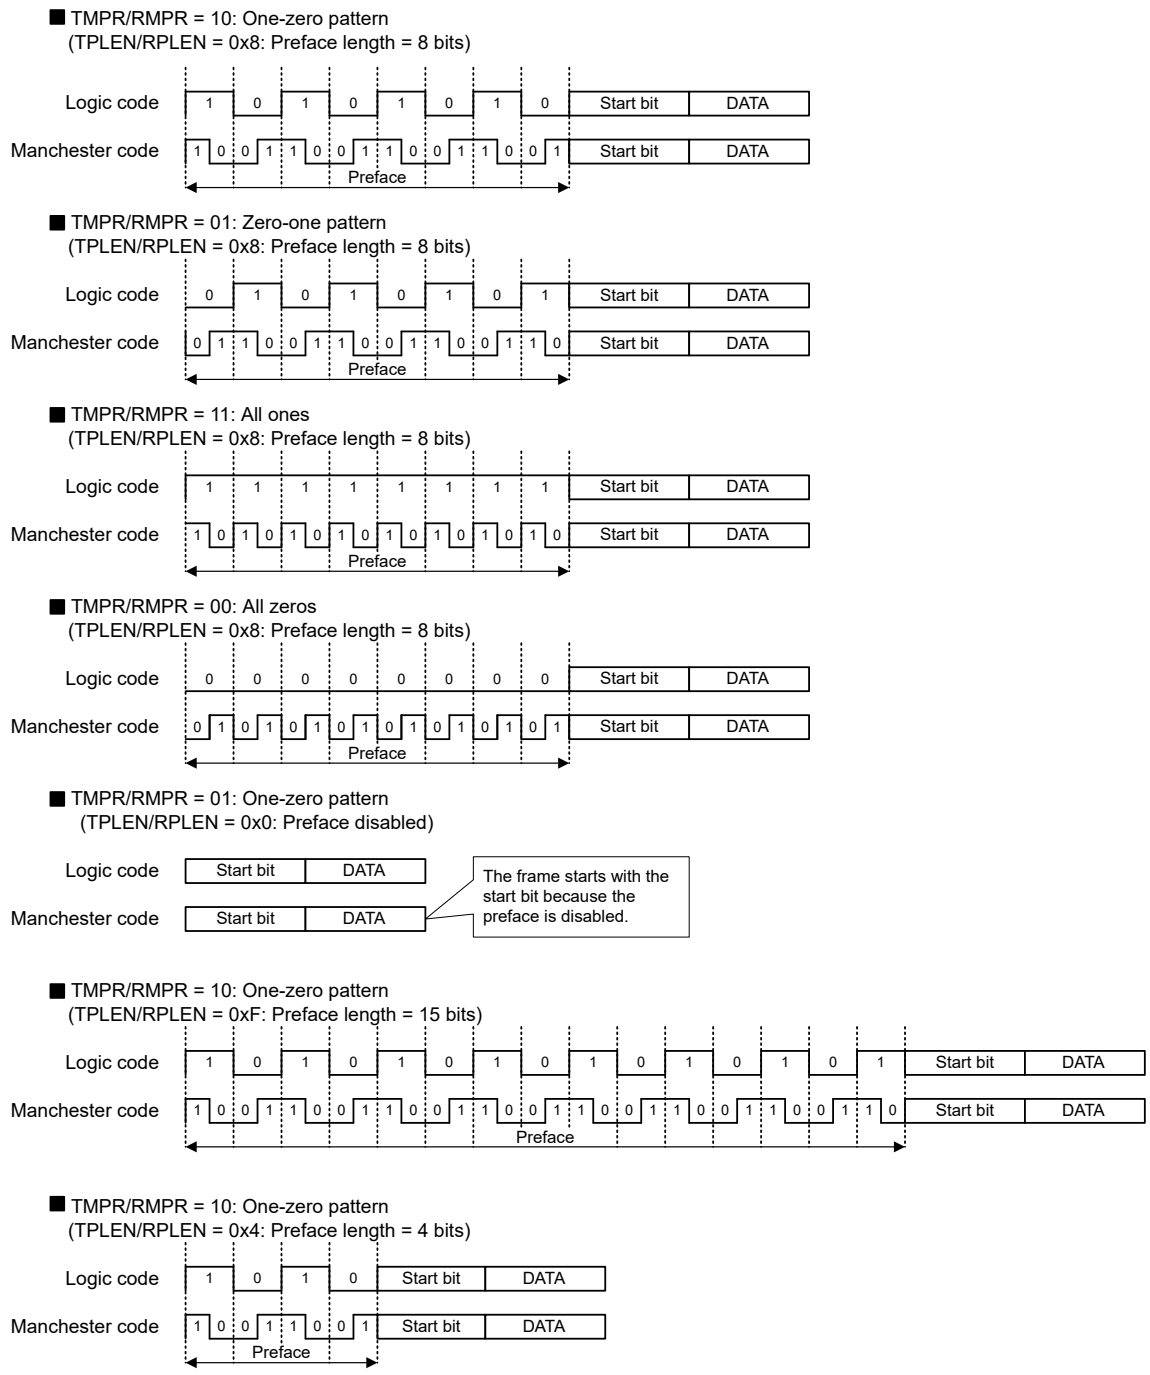

Figure 30.51 Preface Pattern Setting Example

(2) Start bit area

This is an area indicating the start of valid data in a frame. It is added after the preface area.

The start bit length is determined by MMR.SBSEL setting. When MMR.SBSEL = 0, the start bit length is 1 bit.

When MMR.SBSEL = 1, the start bit length is 3 bits.

When MMR.SBSEL = 1, the SYNC type can be selected from command SYNC and data SYNC.

Command SYNC means the three start bits are added as a one-to-zero transition.

Data SYNC means the three start bits are added as a zero-to-one transition.

The SYNC type is determined by the MMR.SYNSEL, MMR.SYNVAL and TDRH_MAN.TSYNC settings.

(When receiving, the received result is applied to RDRH_MAN.RSYNC.)

When MMR.SBSEL = 0, the start bit is added as a zero-to-one or one-to-zero transition.

The selection is determined by the MMR.SYNVAL setting.

The MMR.SYNSEL bit specifies the destination to be referred to when setting for transmission.

When the MMR.SYNSEL bit is set to 1, the MMR.SYNVAL setting is referred to. When the MMR.SYNSEL bit is set to 0, the TDRH_MAN.TSYNC setting is referred to.

Figure 30.52 shows the state of the start bit area according to the settings in the MMR.SYNSEL, MMR.SYNVAL and TDRH_MAN.TSYNC registers in the case of transmission. Figure 30.53 shows that in the case of reception.

The start bit(s) is not affected by the MMR.TMPOL or MMR.RMPOL setting.

*d.c.=don't care, Preface=preface area, START=start bit area, Data=user data area,
P=parity bit, MP=multi-processor bit, STOP=stop bit

Register setting				Output signal	Output start bit
MMR			TDRHL_MAN	Output TXDn waveform	
SBSEL	SYNSEL	SYNVAL	TSYNC		
0	d.c.	0	d.c.		1bit 0 to 1 transition
0	d.c.	1	d.c.		1bit 1->0transition
1	0	0	d.c.		3bit 0to1 transition (DATA SYNC)
1	0	1	d.c.		3bit 1to0 transition (COMMAND SYNC)
1	1	d.c.	0		3bit 0to1 transition (DATA SYNC)
1	1	d.c.	1		3bit 1to0 transition (COMMAND SYNC)

Figure 30.52 Settings Related to and Format of the Start Bit Area at Transmission

When the start bit area is 3 bits long, SYNVAL is not referenced.

d.c. = don't care, Preface = Preface area, START = Start bit area, Data = Data area
P = Parity bit, MP = Multi-processor bit, STOP = Stop bit

Register setting				Input signal	Start bit detection result*1	Register indication
MMR			TDRHL_MAN	RXDn input waveform		RDRHL_MAN.RSYNC
SBSEL	SYNSEL	SYNVAL	TSYNC			
0	d.c.	0	d.c.		Normal start bit (1 bit: 0-to-1 transition)	0
					Start bit error	0
					Start bit error	0
					Start bit error	0
0	d.c.	1	d.c.		Start bit error	0
					Normal start bit (1 bit: 1-to-0 transition)	0
					Start bit error	0
					Start bit error	0
1	d.c.	d.c.	d.c.		Start bit error	0
					Start bit error	0
					Data SYNC	0
					Command SYNC	1

Note 1. Data other than the start bit is assumed to be normal.

Figure 30.53 Settings Related to and Judgment of the Start Bit Area at Reception

(3) DATA

Since the format of the data area is the same as that of the asynchronous mode, see section 30.3.1. Serial Data Transfer Format.

As shown in Figure 30.49, Frame Format in Manchester Mode, the stop bit is not included in the Manchester encoding range.

30.5.2 Clock

As the transfer clock in Manchester mode, the clock generated by the on-chip baud rate generator is used by setting the SMR.CKS[1:0] bit.

Also it is possible to set the oversampling (transfer rate of one-bit period) by SEMR.ABCS bit.

When the SMER.ABCS bit is set to 0, oversampling x16 is selected with the one-bit period being 16 cycles of the base clock. When the SMER.ABCS bit is set to 1, oversampling x8 is selected with the one-bit period being 8 cycles of the base clock.

30.5.3 Initialization of the SCI in Manchester Mode

Before transferring data, write the initial value (0x00) to the SCR register and initialize the SCI following the example of flowchart shown in Figure 30.54.

Whenever the operating mode or transfer format is changed, the SCR register must be initialized before the change is made.

Note that setting the SCR.RE bit to 0 initializes none of the ORER, FER, PER, MER, and RDRF flags in the SSR_MANC register, the SYER, PFER and SBER flags in the MESR register, and the RDR, RDRHL_MAN registers.

Note also that switching the value of SCR.TE from 0 to 1 when SCR.TIE is 1 generates a SCIn_TXI interrupt request.

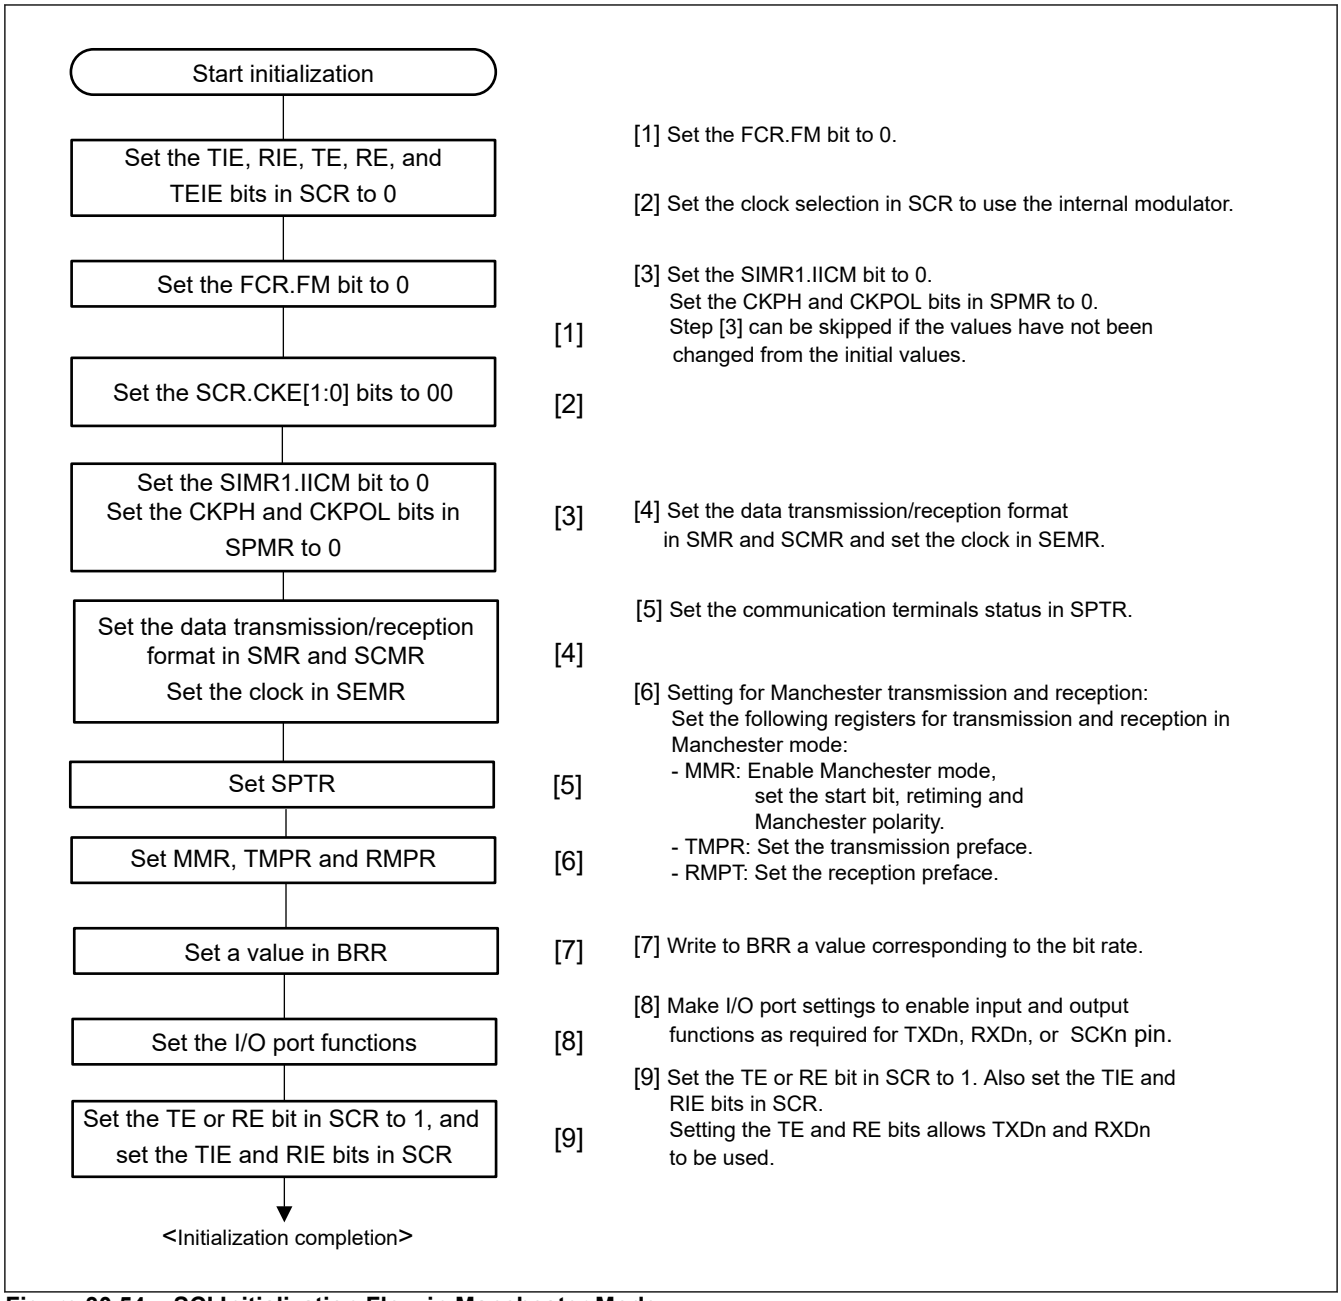

Figure 30.54 SCI Initialization Flow in Manchester Mode

30.5.4 Double-speed operation

When the ABCS bit in SEMR is set to 1 and eight pulses of the base clock for a 1-bit period is selected, the SCI operates on the bit rate twice that of when ABCS is set to 0.

When the BGDM bit in SEMR is set to 1, the cycle of the base clock is reduced to half and the SCI operates on the bit rate twice that of when ABCS is set to 0.

When the ABCS and the BGDM bits in SEMR are set to 1, the SCI operates on the bit rate four times that of when the ABCS and the BGDM bits in SEMR are set to 0.

30.5.5 CTS and RTS functions

The CTS function uses input on the CTSn_RTSn pin in transmission control. Setting the CTSE bit in SPMR to 1 enables the CTS function. The CTSn_RTSn pin can be set as a multiplexed pin which allows one pin to be used for either function, or as dedicated pins with each pin for a single function. Use the CTSPEN bit in SPMR for this setting.

When the CTS function is enabled, reception starts only when the CTSn_RTSn pin is at the low level.

Applying a high level to the CTSn_RTSn pin after transmission starts does not affect transmission of the current frame, which continues.

The RTS function uses output on the CTSn_RTSn pin to request transmission. When the SCI is ready to receive, it outputs a low level to the CTSn_RTSn pin, Conditions for output of the low level and high level are as follows:

[Conditions for low-level output]

When all conditions listed below are satisfied:

- The value of the RE bit in SCR is 1.
- The SCI is ready to receive.
- There is no received data yet to be read.
- All of the following flags are set to 0: SSR_MANC.ORER, FER, PER and MER flags, and MESR.SYER (when SYEREN = 1), PFER (when PFEREN = 1) and SBER flags (when SBEREN = 1).

[Conditions for high-level output]

- When the conditions for low output are not satisfied

30.5.6 Serial data transmission in Manchester mode

The SCI encodes data in Manchester encoding and sends the resultant data in Manchester mode.

When the polarity setting (MMR.TMPOL) set to 0, logic 0 is coded as a zero-to-one transition in Manchester code and logic 1 is coded as a one-to-zero transition in Manchester code.

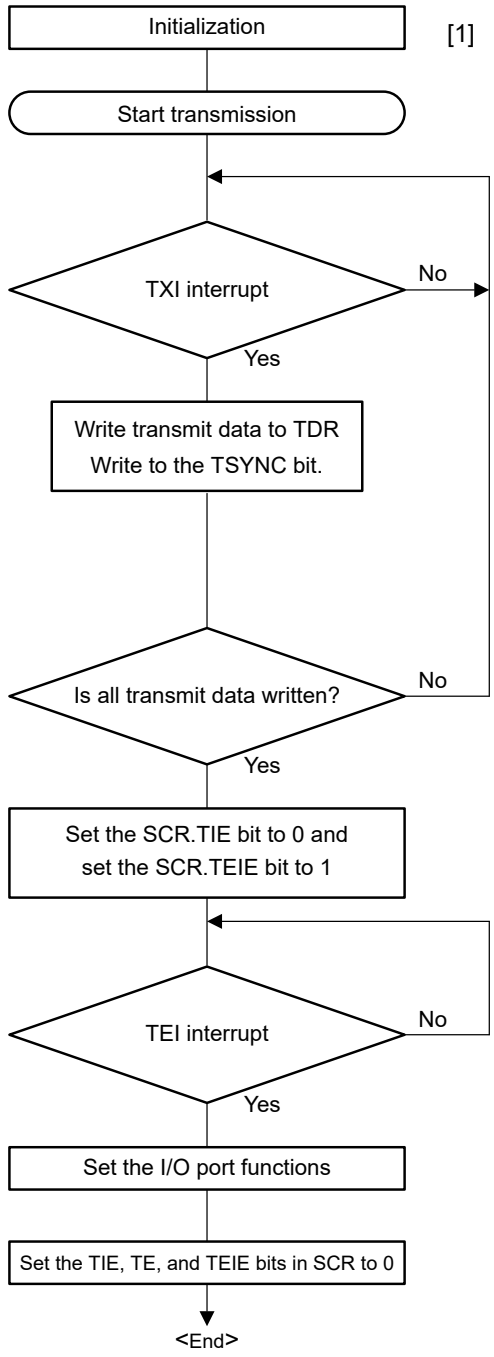
When the polarity setting (MMR.TMPOL) set to 1, logic 0 is coded as a one-to-zero transition in Manchester code and logic 1 is coded as a zero-to-one transition in Manchester code.

For this reason, a level transition occurs with the Manchester encoded data in the middle of individual logic data. (See Figure 30.49).

The transmitter constructs transmit frames in a specific format by adding a preface area to data and setting the start bit(s) according to the polarity setting and sends resultant serial data.

For details on the frame format, see section 30.5.1. Frame Format.

Figure 30.55 shows the flowchart in transmission. Figure 30.56, Figure 30.57, and Figure 30.58 show examples of the operation for serial transmission in Manchester mode.



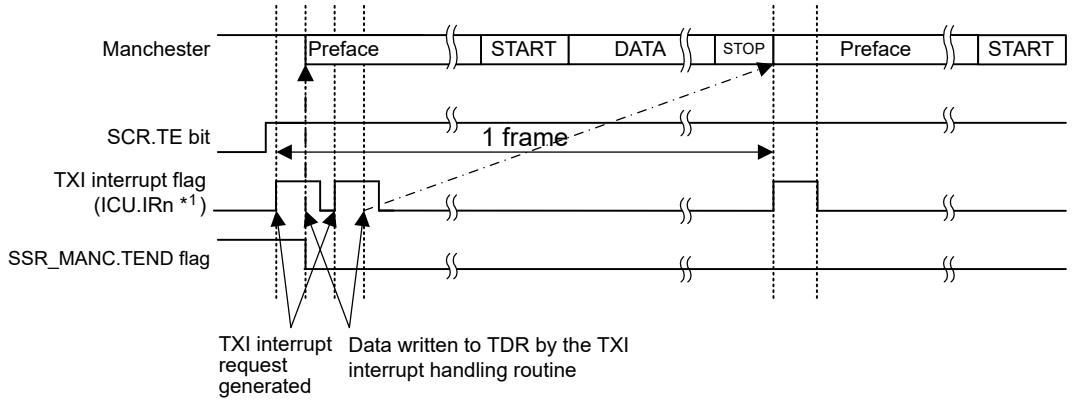
[1] SCI Initialization:
Set data transmission.
Setting the SCR.TE bit to 1 enables transmission.

[2] TXI interrupt:
When transmit data is transferred from TDR to TSR, a transmit data empty interrupt (TXI) request is generated.

[3] TDR setting:
Write the transmit data to TDR.
When TSYNC is used, also set TDRHL_MAN.TYSNC.

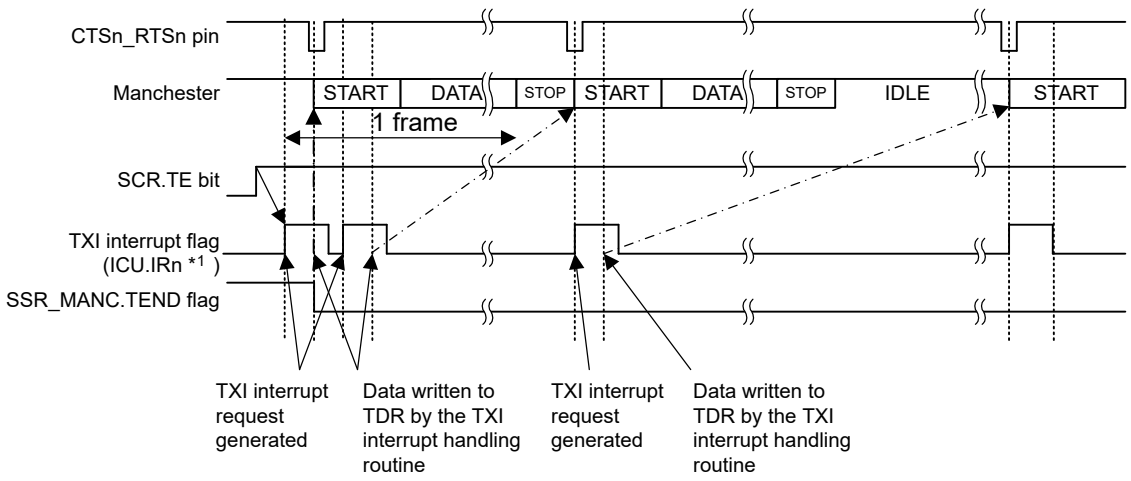
[4] Serial transmission continuation procedure:
To continue serial transmission, write the transmit data to TDR once by using an TXI interrupt.
The transmit data can also be written to TDR by activating the DMAC or DTC in the TXI interrupt request.
When TEI interrupt requests are used, set the SCR.TIE bit to 0 and the SCR.TEIE bit to 1 after the last of the data to be transmitted is written to TDR.

Figure 30.55 Example of Serial Transmission Flowchart in Manchester Mode



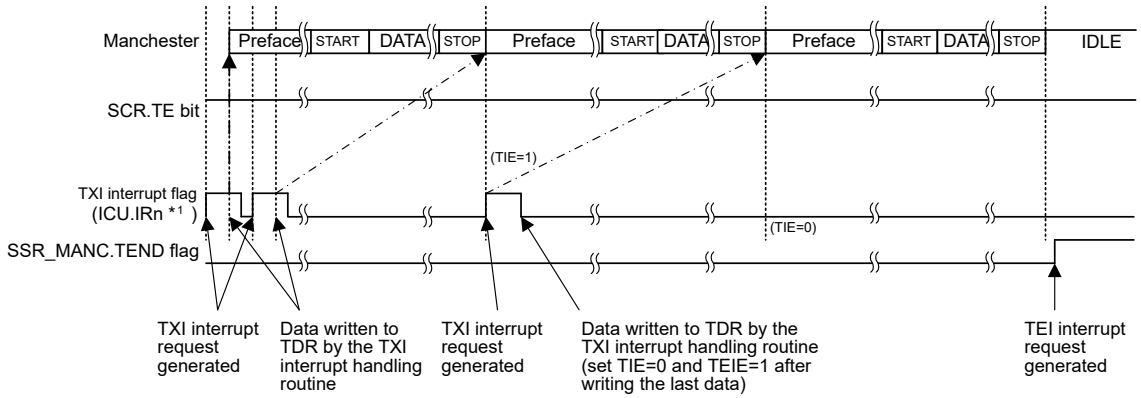
Note 1. For corresponding interrupt numbers, see section 13, Interrupt Controller Unit (ICU)

Figure 30.56 Example of Start-of-Transmission Operation for Serial Transmission in Manchester mode (with Preface but Without the CTS Function)



Note 1. For corresponding interrupt numbers, see section 13, Interrupt Controller Unit (ICU)

Figure 30.57 Example of Start-of-Transmission Operation for Serial Transmission in Manchester Mode (Without Preface but with the CTS Function)



Note 1. For corresponding interrupt numbers, see section 13, Interrupt Controller Unit (ICU)

Figure 30.58 Example of End-of-Transmission Operation for Serial Transmission in Manchester Mode (with Preface but Without the CTS Function)

30.5.7 Serial Data Reception in Manchester Mode

In Manchester mode, the SCI operates on a base clock with a frequency of 16 times*1 the bit rate. Reception starts by sampling the falling edges of received data at the base clock. As shown in Figure 30.59, reception starts at a falling edge of the received data and it continues if the received data keeps low for the duration of 1/4 bit. If the received data goes high within the duration of 1/4 bit, the SCI judges it as an error and waits for a falling edge again.

If a high level is expected in the first half of a bit in the received data, the SCI judges a low level that continues for one base clock cycle as an error and ignores the change to the low level.

Note 1. This is the case when SEMR.ABCS = 0. When SEMR.ABCS = 1, the SCI operates on a base clock with a frequency of 8 times the bit rate.

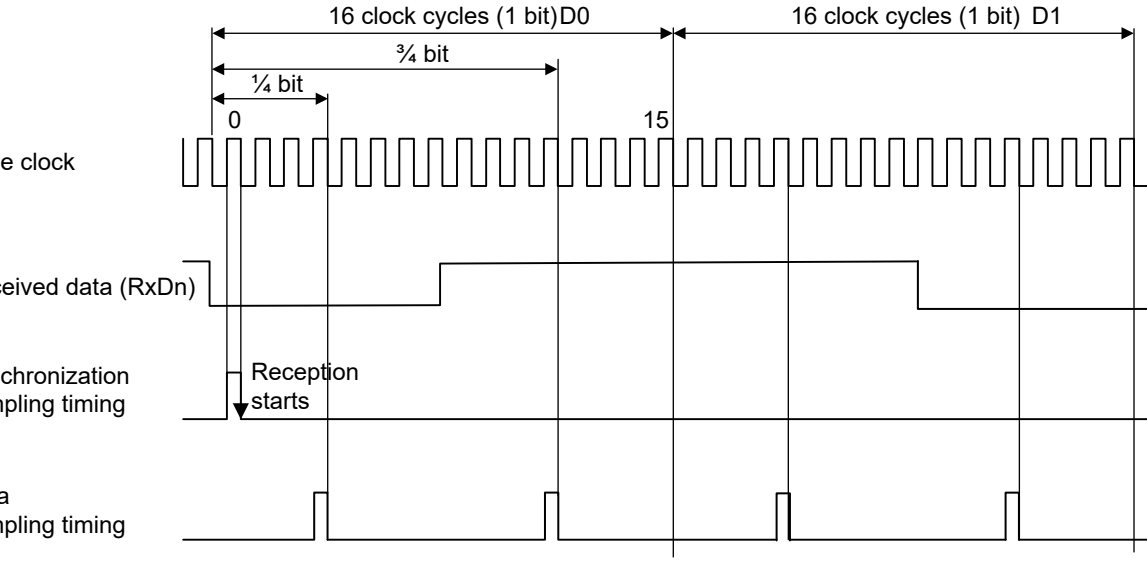


Figure 30.59 Data Reception Sampling Timing in Manchester Mode

In Manchester mode, data reception starts with detection of a preface and start bit area.

The SCI checks the input from the RXDn pin to see whether a preface is added based on the value of RMPR.RPLEN.

If the preface is disabled (RMPR.RPLEN = 0), it moves on to the detection of a start bit area without detecting a preface.

When a preface is enabled, it identifies a preface pattern setting according to the set value in RMPR.RPPAT, and compares it with the RXDn input for a pattern match to detect a preface pattern.

Upon detection of a preface pattern match, it judges it as a normal preface and moves on to the detection of a start bit area.

If detecting a preface pattern mismatch or a Manchester code error in the preface area, it judges it as a preface error and asserts a preface error (PFER).

For start bit detection, the SCI selects an expected value based on the register settings (MMR.SBSEL and SYNVAL), compares it with the RXDn input for a pattern match to detect a start bit area. Upon detection of a start bit pattern match, it judges it as a normal start bit area and moves on to the data processing.

Only when a preface and a start bit area are detected normally, it moves on to the next phase of data reception.

Upon detection of a start bit pattern mismatch, it asserts a start bit error flag (SBER).

In data processing, the SCI shifts the data by the expected received data length based on the register settings (SCMR.CHR1 and SMR.CHR) through the RSR register. If two sampling points in a bit of the received data are identical, the SCI judges this as a Manchester code error.

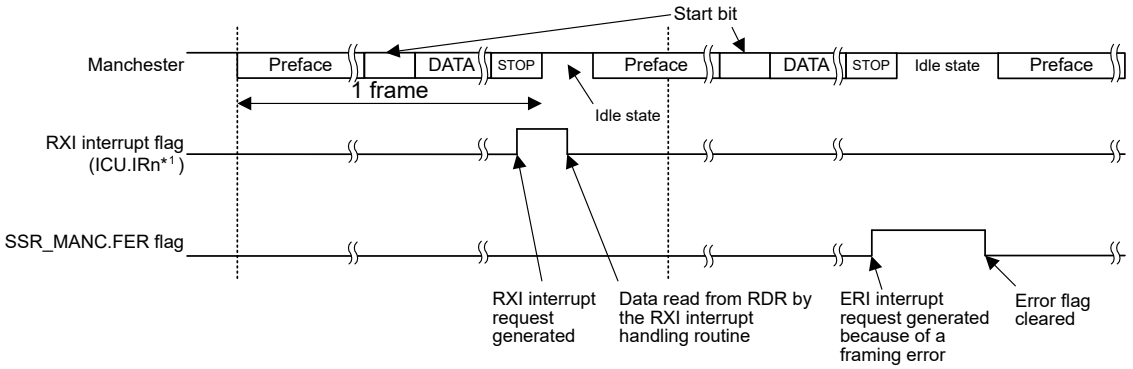
For details, see section 30.5.11. Errors in Manchester Mode (4).

When the parity function is disabled (SMR.PE = 0), the SCI moves on to the next phase of stop bit detection. When the parity function is enabled (SMR.PE = 1), the SCI performs parity checking. If detecting a parity error, it asserts a parity error flag (PER), and then moves on to stop bit detection.

In stop bit detection, the SCI checks the following in the stop bit area of the received frame:

It has two sampling points in a bit. If both points are at the high level, the bit is recognized as a normal stop bit and the data is stored in the RDR register. At least one low-level point is judged as an abnormal stop bit, causing a framing error flag (FER) to be set. Even when an error is detected, the received data is stored in the RDR register as abnormal data.

Figure 30.60 shows an example of the operation for serial data reception in Manchester mode.



Note 1. For corresponding interrupt numbers, see section 13, Interrupt Controller Unit (ICU).

Figure 30.60 Example of Operation for Serial Data Reception in Manchester mode (with a Preface)

For the state of each status flag in the SSR_MANC register and RXDn input processing when a receive error is detected, see section 30.5.11. Errors in Manchester Mode.

If a receive error is detected, an SCIn_ERI interrupt request is generated but an SCIn_RXI interrupt request is not generated.

Data reception cannot be resumed while the receive error flag is 1. Accordingly, set the ORER, FER, PER, MER, SYER*1, PFER*1, and SBER*1 flags to 0 before resuming reception. Also, be sure to read the RDR (or RDRHL_MAN) register during overrun error processing. When a reception is forcibly terminated by setting the SCR.RE bit to 0 during operation, read the RDR (or the RDRHL_MAN) register because received data which has not yet been read may be left in the RDR (or the RDRHL_MAN) register.

Figure 30.61 and Figure 30.62 show examples of serial data reception flowchart in Manchester mode.

Note 1. Effective when the corresponding bit is enabled.

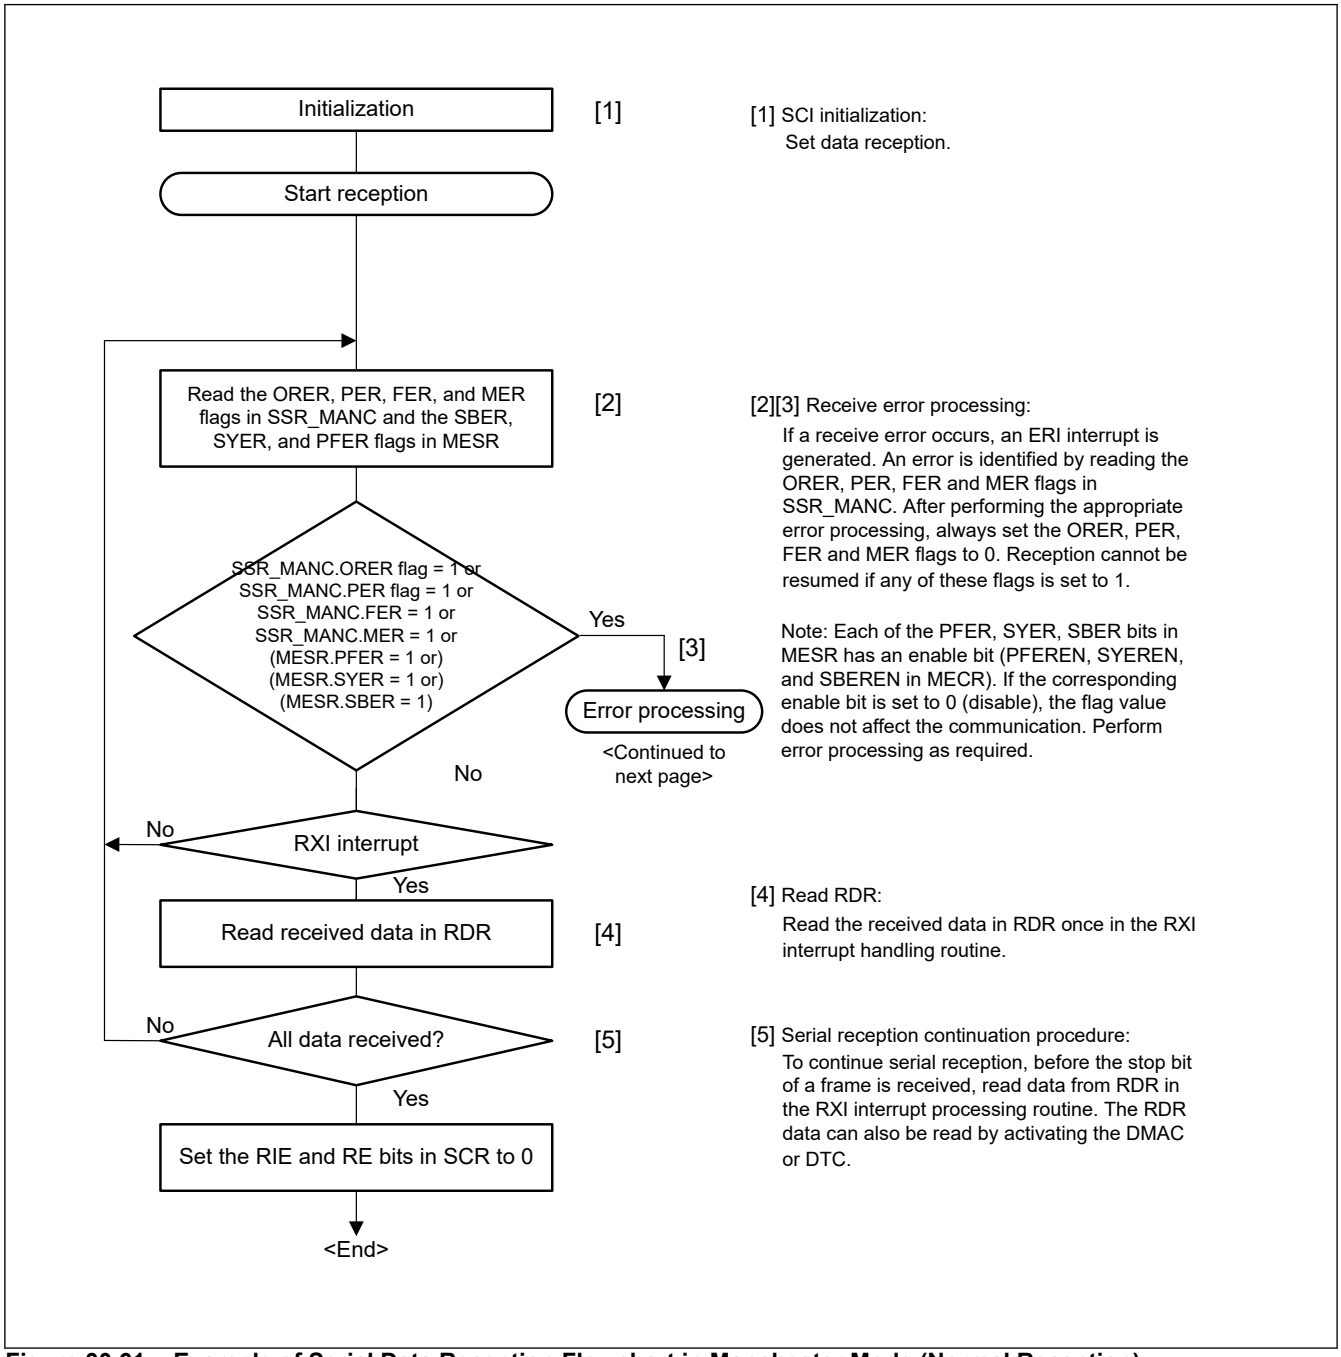


Figure 30.61 Example of Serial Data Reception Flowchart in Manchester Mode (Normal Reception)

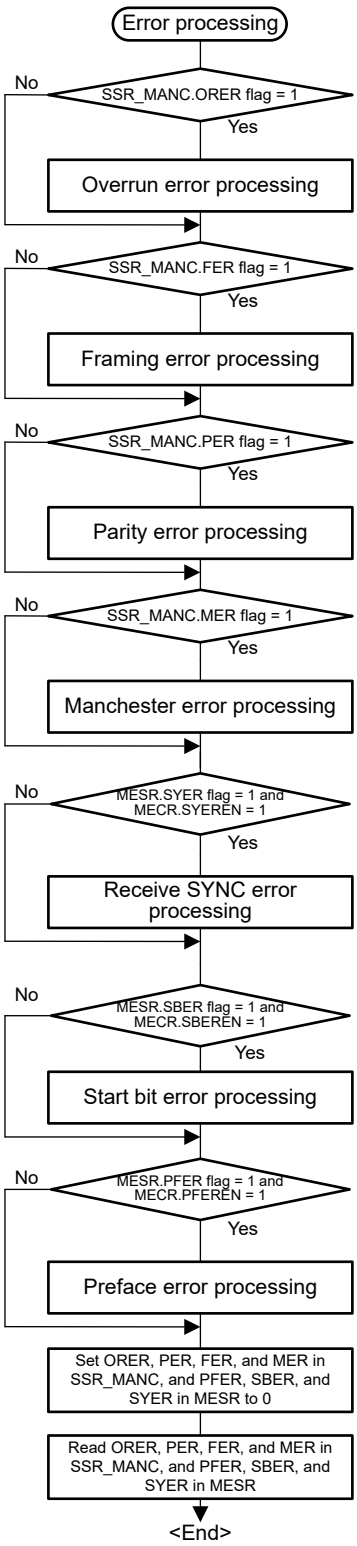

Figure 30.62 Example of Serial Reception Flowchart in Manchester Mode (Error Processing)

30.5.8 Operation When Multi-Processor Bit Is Used

See section 30.4. Multi-Processor Communication Function (1) for the operation in Manchester mode when using multi-processor mode because the operation is the same.

A preface and a start bit area are added to the frame format in Manchester mode. See Figure 30.62 for error processing in Manchester mode for the reception flowchart (Figure 30.46). See Table 30.35 for the operation status when detecting various errors.

30.5.9 Receive Retiming

This function corrects the timing for each central edge of the bit, taking advantage of the fact that each bit has an edge in the center in Manchester code.

The receive retiming function can be turned on or off by setting the ERTEN bit in the MMR register.

When the receive retiming function is turned off (MMR.ERTEN = 0), retiming is not performed, causing misalignment between the internal clock and the RXDn input to be accumulated and the receive margin to be reduced.

When the receive retiming function is turned on (MMR.ERTEN = 1), retiming is performed for the preface area, the start bit area*1, and the data area (excluding the stop bit).

Note 1. Retiming is not performed for the start bit area if the preface length is 0 and the start bit length is 3.

As an example, the receive retiming when oversampling x16 is selected is shown below.

When detecting an RXDn input edge two to four cycles before the expected receive cycle, the receive processing is shortened by one sampling CLK cycle.

When detecting a RXDn input edge two to three cycles after the expected receive cycle, the receive processing is extended by one sampling CLK cycle.

(Even if the clock is misaligned with the data by more than two cycles, one cycle is corrected for each bit.)

Figure 30.63 shows the conceptual image of receive retiming range.

When detecting an edge in the tolerance area in the figure, data is received as is without making correction.

When detecting an edge in the SyncJump area in the figure, data is corrected for reception.

When detecting an edge in the SyncError area in the figure, data is received as abnormal data with no correction made.

For a Manchester code error (data matches at the 1/4-phase and 3/4-phase sampling points), the SCI reports a code error.

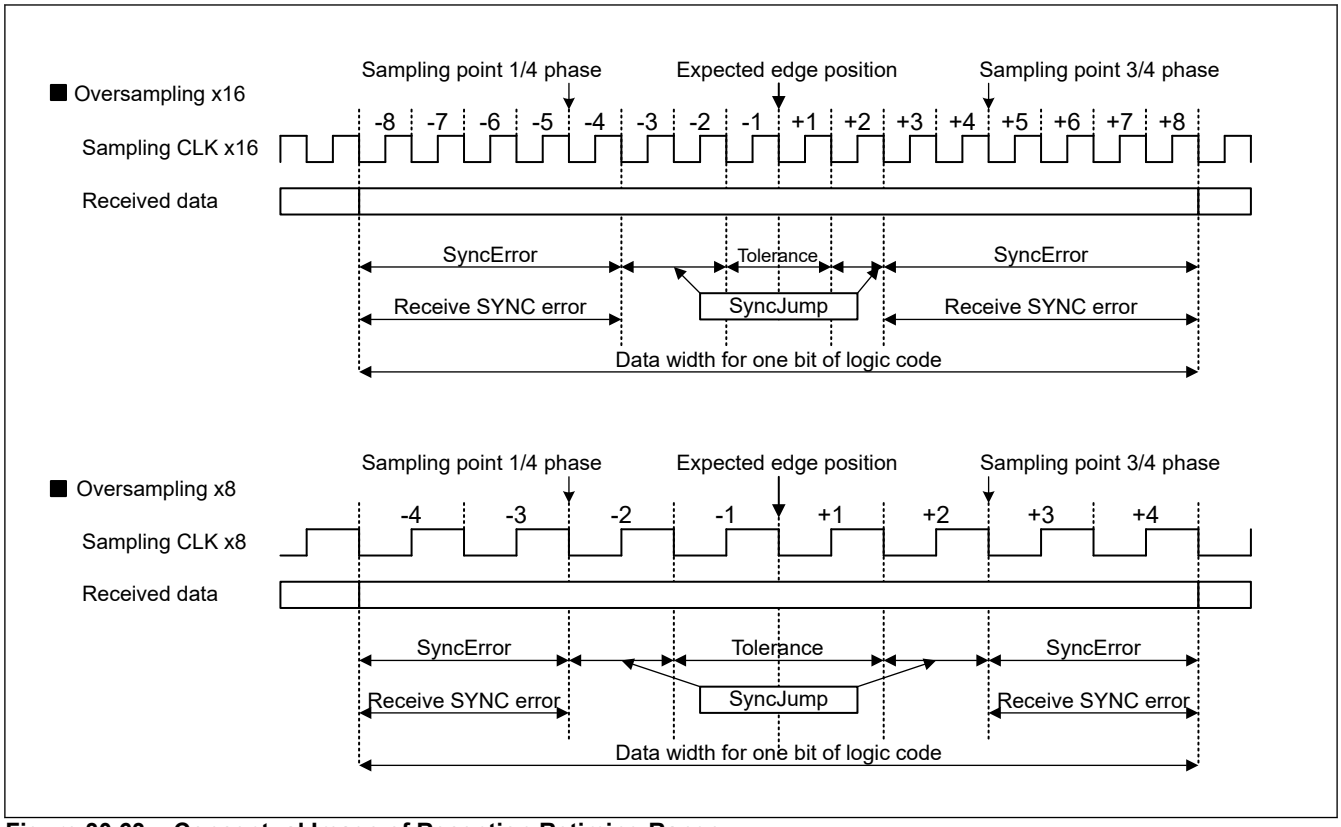

Figure 30.63 Conceptual Image of Reception Retiming Range

30.5.10 Polarity Setting for Manchester Code

The polarity of the Manchester code can be set with the Manchester Mode Register (MMR).

It can be set separately for transmission and reception. Use the MMR.TMPOL bit to set the polarity for transmission and the MMR.RMPOL bit to set the polarity for reception.

The Manchester code polarity setting is valid for the preface area, the data area, and the parity or multi-processor area.

When the initial settings (TMPOL/RMPOL = 0) are used for the polarity of Manchester code, logic 0 is encoded as a zero-to-one transition in Manchester code and logic 1 is encoded as a one-to-zero transition in Manchester code. If the settings are changed to TMPOL/RMPOL = 1, logic 0 is encoded as a one-to-zero transition in Manchester code and logic 1 is encoded as a zero-to-one transition in Manchester code. Figure 30.64 shows the conceptual image of the settings and operation.

Separately from the function above, the transmitted and received data in the data area can be inverted by the transmitted/received data inversion function (SCMR.SINV). Since the polarity of Manchester code (MMR.TMPOL/RMPOL) can be set separately from the transmitted/received data invert function (SCMR.SINV), if both are set to inversion (MMR.TMPOL/RMPOL = 1 and SCMR.SINV = 1), the transmitted and received data are set to initial state (inversion + inversion = normal).

The polarity of the start bit area can be set by a register different from the ones mentioned above.

Since a different register is used, the polarity of the start bit area is not affected by the polarity setting for Manchester code mentioned above.

For details on the setting for the start bit area, see section 30.5.1. Frame Format (2).

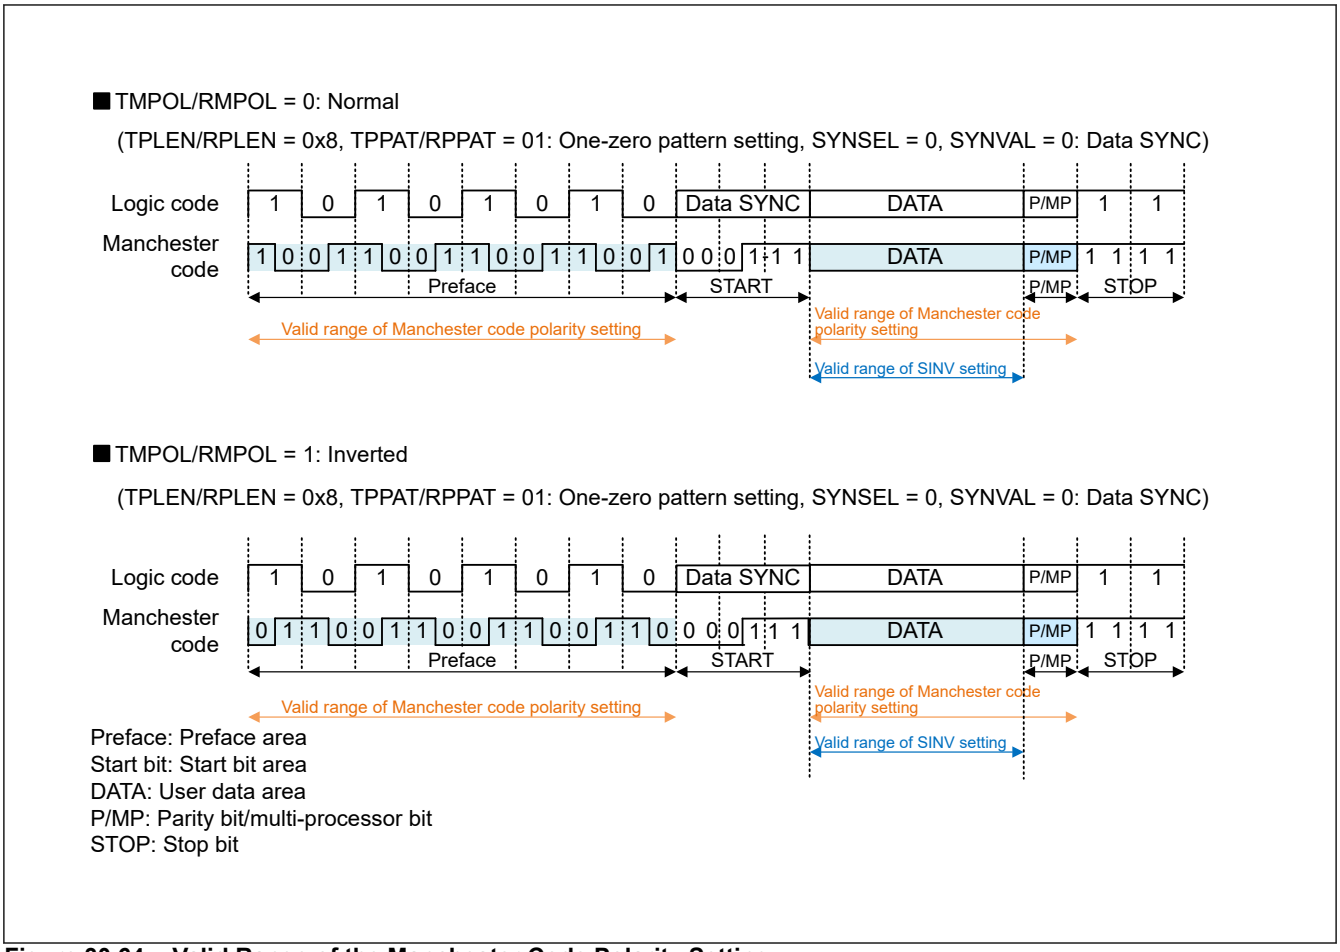

Figure 30.64 Valid Range of the Manchester Code Polarity Setting

30.5.11 Errors in Manchester Mode

There are the following errors in Manchester mode:

1. Parity error
2. Over run error
3. Framing error
4. Manchester error
5. Preface error
6. Start Bit error
7. Receive SYNC error

For errors (1) to (3), see section 30.3.9. Serial Data Reception in Asynchronous Mode (1) because they are the same as in asynchronous mode.

Each errors are judged in each area, but they are reflected on flags and operations at the timing of 3/4-bit sampling of the STOP bit area. If a preface error or start bit error is detected, subsequent data will not be received. Therefore, no other error detection is performed, and the error flag holds the previous information.

Table 30.33 lists the states of the serial status register when detecting errors and judgment about whether to store data in the RDR.

Table 30.34 lists the errors that can be detected in each area of a Manchester frame.

If a Preface error or Start bit error is detected, subsequent data will not be received. Therefore, no other error detection is performed, and the error flag holds the result of the previous frame reception. Also, if an error is detected in the previous frame, data will not be received, but errors in the pre-face area and start bit area will update that flag. Table 30.35 shows the flags and actions in this case.

(4) Manchester error

A Manchester error is generated when a Manchester code error is detected.

In Manchester code, there must be an edge (transition) in the center of the bit.

In the data area of a received frame (including the parity/multi-processor bit), the values of the 1/4-bit and 3/4-bit sampling points are checked in each received 1-bit data, and a Manchester code error is determined if these two values match.

If a Manchester code error is detected, the Manchester error flag (SSR_MANC.MER) is asserted.

If a Manchester error occurs, it is handled as an interrupt source and event source. If a Manchester error is detected, the next reception is not performed until the corresponding error flag is cleared.

(5) Preface error

A preface error is generated when the preface pattern does not match or a Manchester code error is detected in the preface area. If a preface error is detected, the preface error flag (SSR_MANC.PFER) is asserted.

It is possible to set whether to use this error flag as an interrupt source with the setting of the MECR register.

When MECR.PFEREN = 1, a preface error is handled as an interrupt source or event source. If a preface error is detected, the next reception is not performed until the corresponding error flag is cleared.

When MECR.PFEREN = 0, a preface error is not handled as an interrupt source or event source, and the next reception is not halted. However, a preface error is notified to MESR.PFER.

(6) Start bit error

A start bit error is generated when a mismatch is detected between the start bit area in the received frame and the preset start bit pattern. Upon detection of a start bit error, a start bit error flag (MESR.SBER) is asserted.

It is possible to set whether to use the start bit error as an interrupt source with the setting of the MECR register.

When MECR.SBEREN = 1, a start bit error is handled as an interrupt source or event source. If a start bit error is detected, the next reception is not performed until the corresponding error flag is cleared.

When MECR.SBEREN = 0, a start bit error is not handled as an interrupt source or event source, and the next reception is not halted. However, a start bit error is notified to MESR.SBER.

(7) Receive SYNC error

When the receive retiming function described in section 30.5.9. Receive Retiming is enabled, the receive retiming operation is performed.

If no edges are detected within the receive retiming range (SyncError area in Figure 30.63) when receive timing operation is being performed, a receive SYNC error is generated. Upon detection of a receive SYNC error, a receive SYNC error flag (MESR.SYER) is asserted. In areas not subject to retiming, receive SYNC errors are not detected.

The preface area[*1], the start bit area[*1,*2], and the data area (excluding the stop bit) for which receive retiming operation is performed are checked.

It is possible to set whether to use the receive SYNC error as an interrupt source with the setting of the MECR register.

When MECR.SYEREN = 1, a receive SYNC error is handled as an interrupt source or event source. If a receive SYNC error is detected, the next reception is not performed until the corresponding error flag is cleared.

When MECR.SYEREN = 0, a receive SYNC error is not handled as an interrupt source or event source, and the next reception is not halted. However, a receive SYNC error is notified to MESR.SYER.

Note 1. In the case of a frame that starts with a pattern that expects the first half of the bit to be High, it is excluded from retiming.

Note 2. In the start bit area, when there is no preface length and 3 bit start bit is set, it is not subject to retiming.

Also, the 1st bit and the 2nd bit in the start bit area when 3 bit start bit is set are not subject to retiming.

Table 30.33 Flags in the SSR_MANC Register and Receive Data Handling in Manchester Mode (1 of 2)

Flag in the SSR_MANC register				Flag in the MESR register			received data	Received error status (ERI interrupt / event generation)
ORER	FER	PER	MER	SBER[*1]	PFER[*1]	SYER		
0	0	0	0	0	0	0	transfer to RDR	No error

Table 30.33 Flags in the SSR_MANC Register and Receive Data Handling in Manchester Mode (2 of 2)

Flag in the SSR_MANC register				Flag in the MESR register			received data	Received error status (ERI interrupt / event generation)
ORER	FER	PER	MER	SBER[*1]	PFER[*1]	SYER		
0	1	0	0	0	0	0	transfer to RDR	Framin error
0	0	1	0	0	0	0	transfer to RDR	Parity error
0	1	1	0	0	0	0	transfer to RDR	Framing error + Parity error
0	0	0	1	0	0	0	transfer to RDR	Manchester error
0	1	0	1	0	0	0	transfer to RDR	Framing error + Manchester error
0	0	1	1	0	0	0	transfer to RDR	Parity error + Manchester error
0	1	1	1	0	0	0	transfer to RDR	Framing error + Parity error + Manchester error
1	0	0	0	0	0	0	Lost	Overrun error
1	1	0	0	0	0	0	Lost	Overrun error + Framing error
1	0	1	0	0	0	0	Lost	Overrun error + Parity error
1	1	1	0	0	0	0	Lost	Overrun error + Framing error + Parity error
1	0	0	1	0	0	0	Lost	Overrun error + Manchester error
1	1	0	1	0	0	0	Lost	Overrun error + Framing error + Manchester error
1	0	1	1	0	0	0	Lost	Overrun error + Parity error + Manchester error
1	1	1	1	0	0	0	Lost	Overrun error + Framing error + Parity error + Manchester error
0	Combination of above			0	0	0	transfer to RDR	Errors above + Receive SYNC error[*2]
1				0	0	0	Lost	Errors above + Receive SYNC error[*2]
hold	hold	hold	hold	0	1	0	Lost	Preface error[*3]
hold	hold	hold	hold	1	0	0	Lost	Start bit error[*3]
hold	hold	hold	hold	0	1	1	Lost	Preface error[*3] + Receive SYNC error[*2]
hold	hold	hold	hold	1	0	1	Lost	Start bit error[*3] + Receive SYNC error[*2]

Note 1. Start bit error and Preface error never become 1 at the same time.
Note 2. When MECR.SYEREN = 1, SCIn_ERI interrupt / event is generated by SYER factor.
Note 3. If MECR.PFEREN = 1 or MECR.SBEREN = 1, an SCIn_ERI interrupt / event is generated when the corresponding flag is set.

Table 30.34 Errors Detectable in Each Area

	Preface error (PFER)	Start Bit error (SBER)	Manchester error (MER)	Receive SYNC error (SYER)	Parity error (PER)	Framing error (FER)
Preface area	✓	—	—[*1]	✓[*2]	—	—
Start Bit area	—	✓	—	✓[*2]	—	—
Data area	—	—	✓	✓	—	—
Parity area	—	—	✓	✓	✓	—
Multi-processor area	—	—	✓	✓	—	—
Stop Bit area	—	—	—	—	—	✓

Note: ✓: Detected, —: Not detected
Note 1. When an Manchester code error occurs in the preface area, it is defined as a preface error.
Note 2. It may not be subject to Receive SYNC error detection. For details see the text section 30.5.11. Errors in Manchester Mode (7)

Table 30.35 Operation status due to presence / absence of error in previous frame and operation status list in multiprocessor mode (1 of 2)

Previous frame	Each area of the Frame					PFEREN	SBEREN	SYEREN	received data	Error flag	Interrupt request	Event signal

	No Error	No Error	No Error	No Error	No Error ORER	Don't Care	Don't Care	Don't Care	Lost	set ORER	output	output

Table 30.35 Operation status due to presence / absence of error in previous frame and operation status list in multiprocessor mode (2 of 2)

Previous frame	Each area of the Frame					PFEREN	SBEREN	SYEREN	received data	Error flag	Interrupt request	Event signal
	preface	start bit	data	parity	stop							
some error*3 *6	PFER No SYER*1	No Error	Don't Care	Don't Care	Don't Care	0	Don't Care	Don't Care	Lost	set PFER*1	output*4	not output*5
						1						
	No Error	SBER No SYER*1	Don't Care	Don't Care	Don't Care	Don't Care	0	Don't Care		set SBER*1		
							1					
	SYER No PFER	No Error	Don't Care	Don't Care	Don't Care	Don't Care	Don't Care	0		set SYER		
								1				
	No Error	SYER No SBER	Don't Care	Don't Care	Don't Care	Don't Care	Don't Care	0		set SYER		
								1				
	No Error	No Error	SYER		No Error	Don't Care	Don't Care	0		don't set any flags		
								1				
	No Error	No Error	MER		No Error	Don't Care	Don't Care	Don't Care				
	No Error	No Error	Don't Care	PER	No Error	Don't Care	Don't Care	Don't Care				
	No Error	No Error	Don't Care	Don't Care	FER	Don't Care	Don't Care	Don't Care				
	There is some error ORER					Don't Care	Don't Care	Don't Care				
	No Error	No Error	No Error	No Error	No Error ORER	Don't Care	Don't Care	Don't Care				

Note 1. If SYER is detected, the SYER flag is also set. Other operations are as shown in this table.
Note 2. Other detected error flags including ORER are also set.
Note 3. If all the error flags are cleared before the STOP bit is judged, the operation will be the same as the case where there is no error in the previous frame of this table.
Note 4. Since the SCIn_ERI interrupt request is level output, it remains active due to errors in the previous frame regardless of the presence or absence of error in the relevant frame.
Note 5. Since the error cause is continuously detected, the SCIn_ERI event is not newly output regardless of the presence or absence of errors in the relevant frame.
Note 6. For PFER, SBER, and SYER, when each enable bit is set to disable, it is treated as no error.

Table 30.36 Operation when MPIE = 1 in multi-processor mode (MPIE = 0)

MPB*1	Each area of the frame					PFEREN	SBEREN	SYEREN	received data	Error flag	Interrupt request	Event signal
	preface	start bit	data	parity	stop							
1	No Error	No Error	Don't Care	Don't Care	Don't Care	Don't Care	Don't Care	Don't Care	transfer to RDR	set some flags	output*2	output*2
	No PFER	No SBER	Don't Care	Don't Care	Don't Care	Don't Care	Don't Care	0				
	SYER*3	SYER*3						1	Lost	don't set any flags	not output	not output
	PFER	No Error	Don't Care	Don't Care	Don't Care	Don't Care	Don't Care	Don't Care				
	No Error	SBER	Don't Care	Don't Care	Don't Care	Don't Care	Don't Care					

Note 1. If the received MPB bit is 0, it is not received the frame, and the operation is the same as lost of the reception data of this table.
Note 2. If no error is detected, SCIn_RXI interrupt request or event is output, and if it is detected, SCIn_ERI interrupt request or event is output.

Note 3. When SYER is detected in the preface area or the start bit area, the behavior of handling as an error depending on the SYEREN bit changes.

30.6 Operation in Clock Synchronous Mode

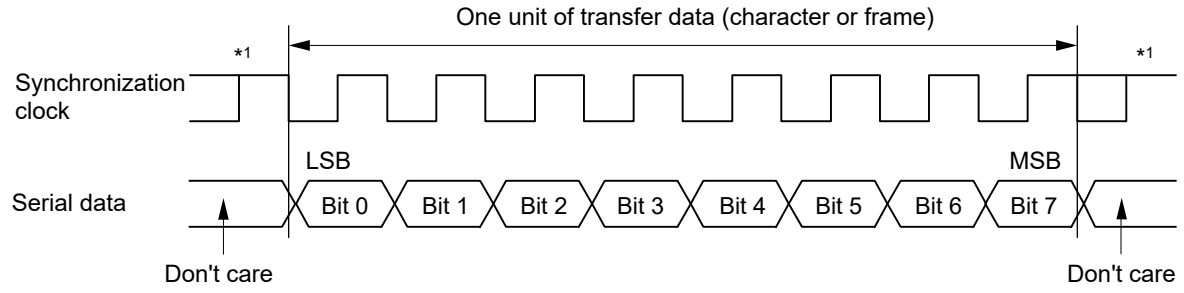
Figure 30.65 shows the data format for clock synchronous serial data communications.

In clock synchronous mode, data is transmitted or received in synchronization with clock pulses. For single-character data transfer, data consists of 8-bit. In clock synchronous mode, no parity bit can be added.

In data transmission, the SCI outputs data from one falling edge of the synchronization clock to the next falling edge. In data reception, the SCI receives data in synchronization with the rising edge of the synchronization clock. After 8-bit data is output, the transmission line holds the last bit as output state. When the SPMR.CKPH bit is 1 in slave mode, the transmission line holds the first bit output state.

Within the SCI, the transmitter and receiver are independent units, enabling full-duplex communications by using a shared clock. Both the transmitter and the receiver also have a double-buffered structure, so that the next transmit data can be written during transmission or the previous receive data can be read during reception, enabling continuous data transfer.

However, it is not possible to perform continuous transfer in the fastest bit rate setting (BRR[7:0] = 0x00 and SMR.CKS[1:0] = 00b). Therefore, when the FIFO is selected, this setting (BRR[7:0] = 0x00 and SMR.CKS[1:0] = 00b) is not available.



Note 1. Holds a high level except during continuous transfer.

Figure 30.65 Data format in clock synchronous serial communications with LSB-first order

30.6.1 Clock

Either an internal clock generated by the on-chip baud rate generator or an external synchronization clock input at the SCKn pin can be selected based on the SCR.CKE[1:0] setting.

When the SCI operates on an internal clock, the synchronization clock is output from the SCKn pin. Eight synchronization clock pulses are output in the transfer of one character. When no transfer is performed, the clock is held high. However, when only data reception is performed while the CTS function is disabled, the synchronization clock output starts when the SCR.RE bit set to 1. The synchronization clock stops when it goes high[*1] and an overrun error occurs or the SCR.RE bit is set to 0.

When only data reception is performed and the CTS function is enabled, the clock output does not start when the SCR.RE bit set to 1 and the CTSn_RTSn pin input is high. The synchronization clock output starts when the SCR.RE bit is set to 1 and the CTSn_RTSn pin input is low. Following that, when the CTSn_RTSn pin input is high on completion of the frame reception, the synchronization clock output stops when it goes high. If the CTSn_RTSn pin input continues to be low, the synchronization clock stops when it goes high[*1] and an overrun error occurs or the SCR.RE bit is set to 0.

Note 1. The signal is held high while (SPMR.CKPH = 0 and SPMR.CKPOL = 1) or (SPMR.CKPH = 1 and SPMR.CKPOL = 1). It is held low while (SPMR.CKPH = 0 and SPMR.CKPOL = 1) or (SPMR.CKPH = 1 and SPMR.CKPOL = 0).

30.6.2 CTS and RTS Functions

In the CTS function, the CTSn_RTSn pin input controls the start of data reception or transmission when the clock source is the internal clock. Setting the SPMR.CTSE bit to 1 enables the CTS function. When the CTS function is enabled, setting the CTSn_RTSn pin low causes data reception or transmission to start.

Setting the CTSn_RTSn pin high while the data transmission or reception is in progress does not affect transmission or reception of the current frame.

In the RTS function, the CTSn_RTSn pin output is used to request the start of data reception or transmission when the clock source is an external synchronizing clock. The CTSn_RTSn output goes low when serial communication is enabled. Conditions for output of the CTSn_RTSn low and high are shown as follows:

[Conditions for low output]

Satisfaction of all the following conditions:

Non-FIFO selected when all of the following conditions are satisfied

- The value of the SCR.RE bit or the SCR.TE bit is 1
- Neither transmission nor reception is in progress
- There is no received data available to be read when the SCR.RE bit is 1
- Transmit data is written when the SCR.TE bit is 1 and SCR.CKE[1] bit is 0
- Data is available for transmission in the TSR register when SCR.TE bit is 1 and SCR.CKE[1] bit is 1
- The SSR.ORER flag is 0

FIFO selected when all of the following conditions are satisfied

- The value of the SCR.RE bit or the SCR.TE bit is 1
- Neither transmission nor reception is in progress
- The amount of receive data written in FRDRHL is less than the setting value of FCRH.RSTRG[3:0] when SCR.RE = 1
- Data that has not been transmitted is available in FTDRHL when SCR.TE bit is 1 and SCR.CKE[1] bit is 0
- Data is available for transmission in the TSR register when SCR.TE bit is 1 and SCR.CKE[1] bit is 1
- The SSR_FIFO.ORER flag is 0

[Condition for high output]

- The conditions for low output are not satisfied

30.6.3 SCI Initialization in Clock Synchronous Mode

Before transmitting and receiving data, start by writing the initial value 0x00 to the SCR register, then continue through the SCI initialization procedure given in the sections describing non-FIFO and FIFO selection in section 30.6.2. CTS and RTS Functions. Anytime the operating mode or transfer format is to be changed, the SCR register must be initialized before the change can be made.

Note: Setting the SCR.RE bit to 0 initializes neither the ORER, FER, and PER flags in SSR/SSR_FIFO nor the RDR register. When the TE bit is set to 0, the TEND flag for the selected FIFO buffer is not initialized.

Note: In non-FIFO mode, switching the value of the SCR.TE bit from 1 to 0 or 0 to 1 when the SCR.TIE bit is 1 generates an SCIn_TXI interrupt request.

Table 30.37 Example flow of SCI initialization in clock synchronous mode with non-FIFO selected (1 of 2)

No.	Step Name	Description
1	Start initialization	
2	Set the SCR.TIE, RIE, TE, RE, and TEIE bits to 0	
3	Set the FCR.FM bit to 0	Set the FCR.FM bit to 0.
4	Set the SCR.CKE[1:0] bits	Set the clock selection in SCR.
5	Set the SIMR1.IICM bit to 0. Set the SPMR.CKPH and CKPOL bits.	Set the SIMR1.IICM bit to 0. Set the SPMR.CKPH and CKPOL bits. Step 5 can be skipped if the values have not been changed from the initial values.

Table 30.37 Example flow of SCI initialization in clock synchronous mode with non-FIFO selected (2 of 2)

No.	Step Name	Description
6	Set the data transmission/ reception format in SMR, SCMR, and SEMR	Set data transmission/reception format in SMR, SCMR, and SEMR.
7	Set a value in SPTR	Set the communication terminals status in SPTR.
8	Set a value in BRR	Write a value corresponding to the bit rate to BRR. This step is not necessary if an external clock is used.
9	Set a value in MDDR	Write the value obtained by correcting a bit rate error in MDDR. This step is not necessary if the BRME bit in SEMR is set to 0 or an external clock is used.
10	Set the I/O port functions	Make I/O port settings to enable input and output functions as required for TXDn, RXDn, and SCKn pins.
11	Set the SCR.TE or RE bit to 1, and set the SCR.TIE and RIE bits	Set the SCR.TE or RE bit to 1. Also set the SCR.TIE and RIE bits. Setting the TE and RE bits allows TXDn and RXDn pins to be used.
12	Initialization completion	

Note: In simultaneous transmit and receive operations, the TE and RE bits in SCR must both be set to 0 or set to 1 simultaneously

Table 30.38 Example flow of SCI initialization in clock synchronous mode with FIFO selected

No.	Step Name	Description
1	Start initialization	
2	Set the SCR.TIE, RIE, TE, RE, and TEIE bits to 0	
3	Set the FCR.FM, TFRST, and RFRST bits to 1. Set the FCR.TTRG[3:0], RTRG[3:0], and RSTRG[3:0] bits.	Set the FCR.FM, TFRST, and RFRST bits to 1 (FIFO mode enabled, transmit/receive FIFOs empty). Set the FCR.TTRG[3:0], RTRG[3:0], and RSTRG[3:0] bits.
4	Set the SCR.CKE[1:0] bits	Set the clock selection in SCR.
5	Set the SIMR1.IICM bit to 0. Set the SPMR.CKPH and CKPOL bits.	Set the SIMR1.IICM bit to 0. Set the SPMR.CKPH and CKPOL bits. Step 5 can be skipped if the values have not been changed from the initial values.
6	Set the data transmission/ reception format in SMR, SCMR, and SEMR	Set data transmission/reception format in SMR, SCMR, and SEMR.
7	Set a value in SPTR	Set the communication terminals status in SPTR.
8	Set a value in BRR	Write a value corresponding to the bit rate to BRR. This step is not necessary if an external clock is used.
9	Set a value in MDDR	Write the value obtained by correcting a bit rate error in MDDR. This step is not necessary if the BRME bit in SEMR is set to 0 or an external clock is used.
10	Set the FCR.TFRST and RFRST bits to 0	Set the FCR.TFRST and RFRST bits to 0.
11	Set the I/O port functions	Make I/O port settings to enable input and output functions as required for TXDn, RXDn, and SCKn pins.
12	Set the SCR.TE or RE bit to 1, and set the SCR.TIE and RIE bits	Set the SCR.TE or RE bit to 1. Also set the SCR.TIE and RIE bits. Setting the TE and RE bits allows TXDn and RXDn pins to be used.
13	Initialization completion	

Note: In simultaneous transmit and receive operations, the TE and RE bits in SCR must both be set to 0 or set to 1 simultaneously.

30.6.4 Serial Data Transmission in Clock Synchronous Mode

(1) Non-FIFO selected

Figure 30.66, Figure 30.67, and Figure 30.68 show examples of serial transmission in clock synchronous mode.

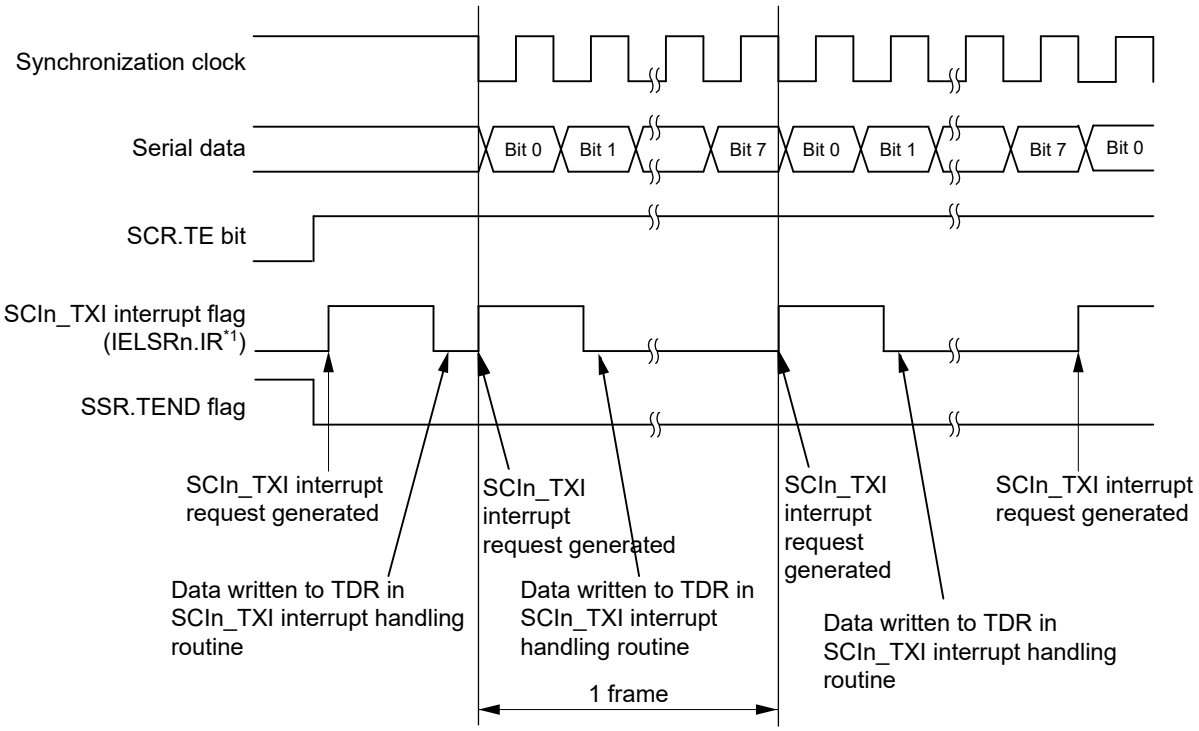
In serial data transmission, the SCI operates as follows:

1. The SCI transfers data from the TDR register to the TSR register when data is written to TDR in the SCIn_TXI interrupt handling routine. The SCIn_TXI interrupt request at the beginning of transmission is generated when the TE bit is set to 1 but only after the TIE bit in the SCR is also set to 1 or when these two bits are set to 1 simultaneously by a single instruction.
2. After transferring data from TDR to TSR, the SCI starts transmission. When the SCR.TIE bit is set to 1, an SCIn_TXI interrupt request is generated. Continuous transmission is enabled by writing the next transmit data to TDR in the SCIn_TXI interrupt handling routine before transmission of the current transmit data finishes. When SCIn_TEI interrupt requests are in use, set the SCR.TIE bit to 0 and the SCR.TEIE bit to 1 after the last of the data to be transmitted is written to the TDR register from the handling routine for SCIn_TXI requests.
3. 8-bit data is sent from the TXDn pin in synchronization with the output clock when the clock output mode is specified and in synchronization with the input clock when the use of an external clock is specified. Output of the clock signal is suspended until the input CTS signal is low when the SPMR.CTSE bit is 1.
4. The SCI checks for update to the TDR register on output of the last bit.
5. When the TDR register is updated, the next transmit data is transferred from TDR to TSR, and serial transmission of the next frame starts.
6. If TDR is not updated, the SSR.TEND flag is set to 1. The TXDn pin retains the output state of the last bit. If the SCR.TEIE bit is 1, an SCIn_TEI interrupt request is generated and the SCKn pin is held high.

Figure 30.66, Figure 30.67, and Figure 30.68 show examples of serial data transmission.

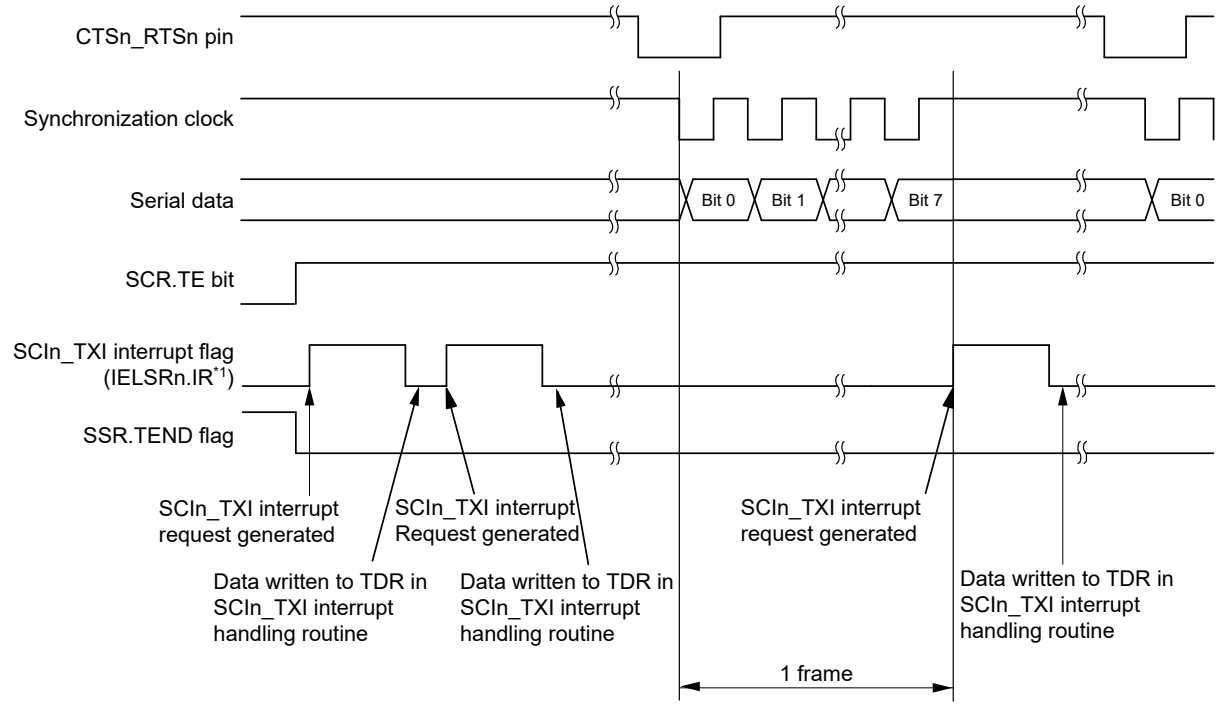
Transmission does not start while a receive error flag (ORER, FER, or PER in SSR) is set to 1. Always set the receive error flags to 0 before starting transmission.

Note: Setting the SCR.RE bit to 0 does not clear the receive error flags.



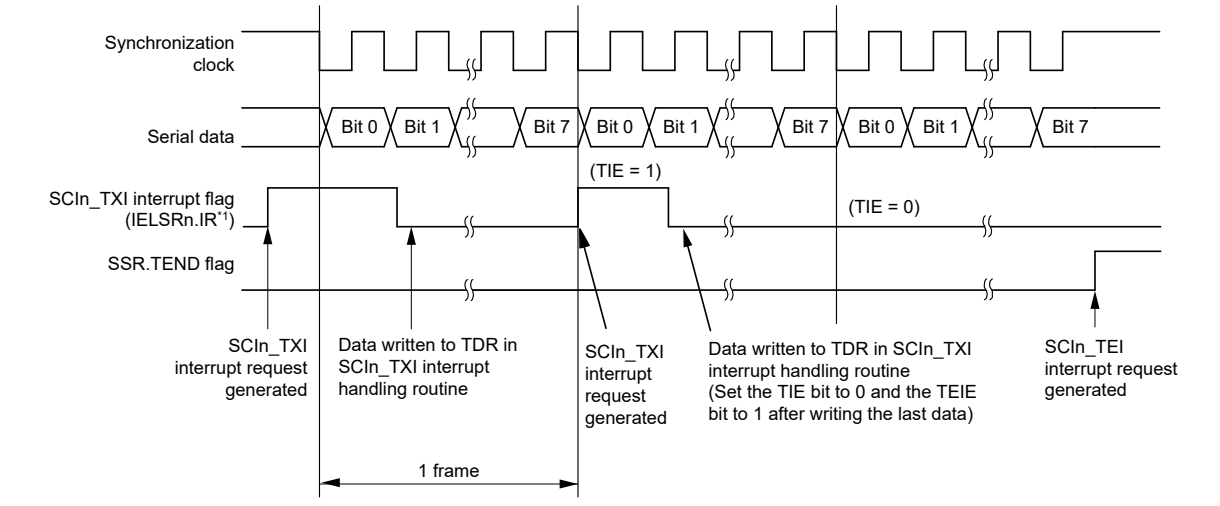
Note 1. See section 13, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 30.66 Example of serial data transmission in clock synchronous mode when the CTS function is not used at the beginning of transmission



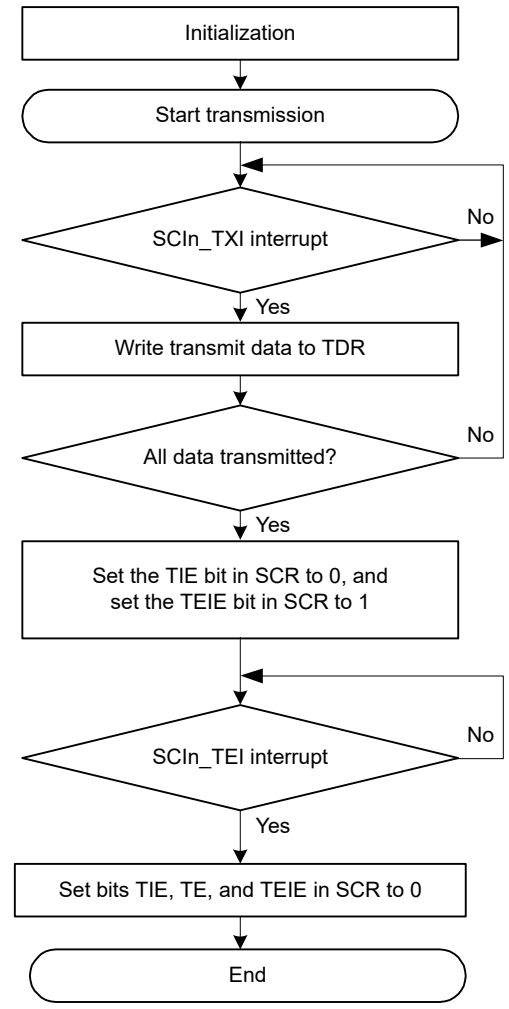
Note 1. See section 13, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 30.67 Example of serial data transmission in clock synchronous mode when the CTS function is used at the beginning of transmission



Note 1. See section 13, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 30.68 Example of serial data transmission in clock synchronous mode from the middle of transmission until transmission completion



[1] [1]SCI initialization:
Set data transmission.

[2] [2]Writing transmit data write to TDR by an SCIn_TXI interrupt request:
When transmit data is transferred from TDR to TSR, a transmit data empty interrupt (SCIn_TXI) request is generated.
Transmit data is written to TDR once from the handling routine for SCIn_TXI requests.

[3] [3]Serial transmission continuation procedure:
To continue serial transmission, write transmit data to TDR upon accepting a transmit data empty interrupt (SCIn_TXI) request. Transmit data can also be written to TDR by activating the DMAC or DTC by theSCIn_TXI interrup trequest.
When SCIn_TEI interrupt requests are in use, set the SCR.TIE bit to 0 and the SCR.TEIE bit to 1 after the last of the data to be transmitted is written to theTDR

Note: When the external clock is in use (the value of the SCR.CKE[1:0] bits is 10b or 11b), the rising edge on the SCKn pin for the last bit sets the SSR.TEND flag to 1. Setting the SCR.TE bit to 0 immediately after this might lead to insufficient received-data hold time on the receiver side.

Figure 30.69 Example flow of serial transmission in clock synchronous mode with non-FIFO selected

(2) FIFO selected

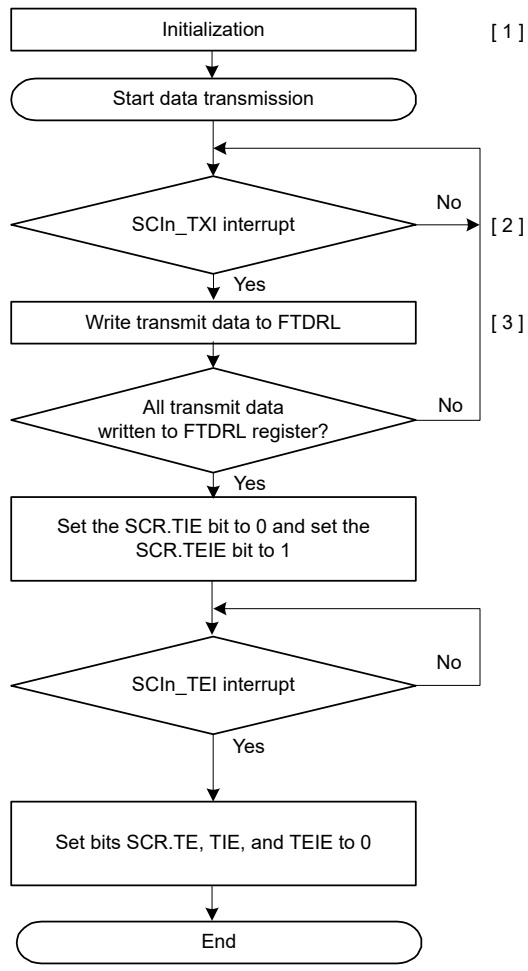
Figure 30.70 shows an example of serial transmission in clock synchronous mode with FIFO selected.

In serial data transmission, the SCI operates as follows:

1. The SCI transfers data from the FTDRL[*1] register to the TSR register when data is written to FTDRL[*1] in the SCIn_TXI interrupt handling routine. The amount of data that can be written to FTDRL is 16 minus FDR.T[4:0] bytes. The SCIn_TXI interrupt request at the beginning of transmission is generated when the SCR.TE bit is set to 1 but only after the SCR.TIE bit is also set to 1 or when these two bits are set to 1 simultaneously by a single instruction.
2. After transferring data from FTDRL to TSR, the SCI starts transmission. When the amount of transmit data written in FTDRL is equal to or less than the specified transmit triggering number, the SSR_FIFO.TDFE is set to 1. When the SCR.TIE bit is set to 1, an SCIn_TXI interrupt request is generated. Continuous transmission is enabled by writing the next transmit data to FTDRL in the SCIn_TXI interrupt handling routine before transmission of the current transmit data has finished. When SCIn_TEI interrupt requests are in use, set the SCR.TIE bit to 0 and the SCR.TEIE bit to 1 after the last of the data to be transmitted is written to the FTDRL from the handling routine for SCIn_TXI requests.
3. 8-bit data is sent from the TXDn pin in synchronization with the output clock when the clock output mode is specified and in synchronization with the input clock when the use of an external clock is specified. Output of the clock signal is suspended until the input CTS signal is low when the SPMR.CTSE bit is 1.
4. The SCI checks whether non-transmitted data remains in FTDRL on output of the stop bit.

5. When FTDRL is updated, the next transmit data is transferred from FTDRL to TSR and serial transmission of the next frame starts.
6. If FTDRL is not updated, the SSR_FIFO.TEND flag is set to 1. The TXDn pin retains the output state of the last bit. If the SCR.TEIE bit is 1, an SCIn_TEI interrupt request is generated and the SCKn pin is held high.

Note 1. In clock synchronous mode, FTDRH is not used.



[1]SCI initialization:
Set data transmission.
After the TE bit in SCR is set to 1, 1 is output for a frame, and transmission is enabled.

[2]Transmit data write to FTDRL by an SCIn_TXI interrupt request:
For transmission data from FTDRL to TSR, when the amount of transmit data written in FTDRL is equal to or less than the specified transmit triggering number, a transmit data FIFO empty interrupt (SCIn_TXI) request is generated. Write transmit data to FTDRL once in the SCIn_TXI interrupt handling routine.

[3]Serial transmission continuation procedure:
To continue serial transmission, write the next transmit data to FTDRL in this SCIn_TXI interrupt handling routine and clear the SSR_FIFO.TDFE flag to 0 before transmission of the current transmit data finishes.
Transmit data can also be written to FTDRL by activating the DMAC or DTC. The TDFE flag is cleared automatically in this case. Do not write to the TDFE flag.
When SCIn_TEI interrupt requests are in use, set the SCR.TIE bit to 0 and the SCR.TEIE bit to 1 after the last of the data to be transmitted is written to the FTDRL.

Note: When the external clock is in use (the value of the SCR.CKE[1:0] bits is 10b or 11b), the rising edge on the SCKn pin for the last bit sets the SSR_FIFO.TEND flag to 1. Setting the SCR.TE bit to 0 immediately after this might lead to insufficient received-data hold time on the receiver side.

Figure 30.70 Example flow of serial transmission in clock synchronous mode with FIFO selected

30.6.5 Serial Data Reception in Clock Synchronous Mode

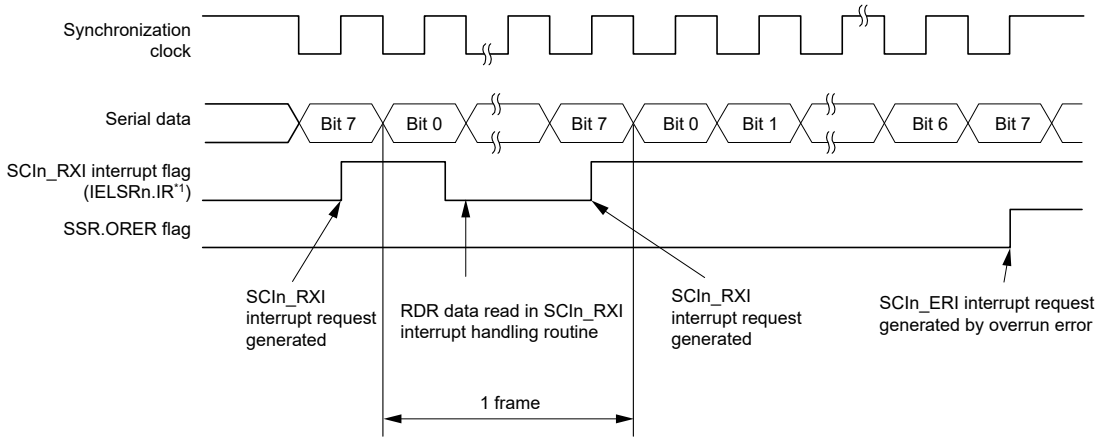
(1) Non-FIFO selected

Figure 30.71 and Figure 30.72 show examples of SCI operation for serial reception in clock synchronous mode.

In serial data reception, the SCI operates as follows:

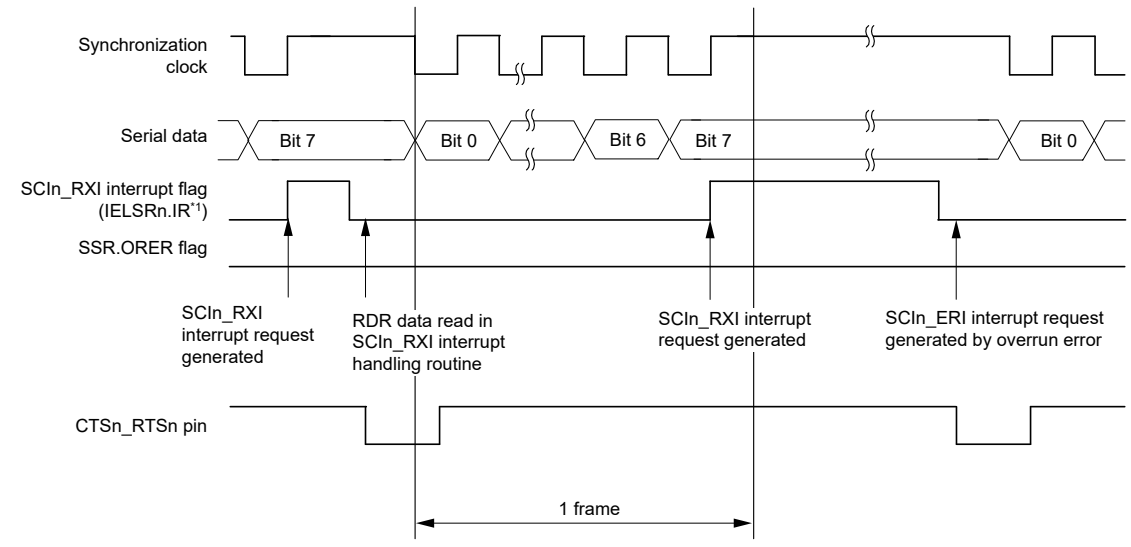
1. When the value of the SCR.RE bit becomes 1, the CTSn_RTSn pin goes low.
2. The SCI performs internal initialization and starts receiving data in synchronization with a synchronization clock input or output, and stores the receive data in the RSR register.
3. If an overrun error occurs, the SSR.ORER flag is set to 1. If the SCR.RIE bit is 1, an SCIn_ERI interrupt request is generated. Receive data is not transferred to the RDR register.

4. When reception completes successfully, receive data is transferred to the RDR register. If the SCR.RIE bit is 1, an SCIn_RXI interrupt request is generated. Continuous reception is enabled by reading the received data transferred to the RDR register in the SCIn_RXI interrupt handling routine before reception of the next receive data completes. Reading the received data that is transferred to RDR causes the CTSn_RTSn pin to output low.



Note 1. See section 13, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 30.71 Example operation for serial reception in clock synchronous mode (1) when the RTS function is not used



Note 1. See section 13, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 30.72 Example operation for serial reception in clock synchronous mode (2) when RTS function is used

Data transfer cannot resume while the receive error flag is 1. Therefore, clear the ORER, FER, and PER flags in the SSR register to 0 before resuming data reception. Additionally, always read the RDR register during overrun error processing. When a data reception is forced to terminate by a 0 write to the SCR.RE bit during operation, read the RDR register because received data that is not yet read might be left in the RDR register.

Figure 30.73 shows an example flow of serial data reception.

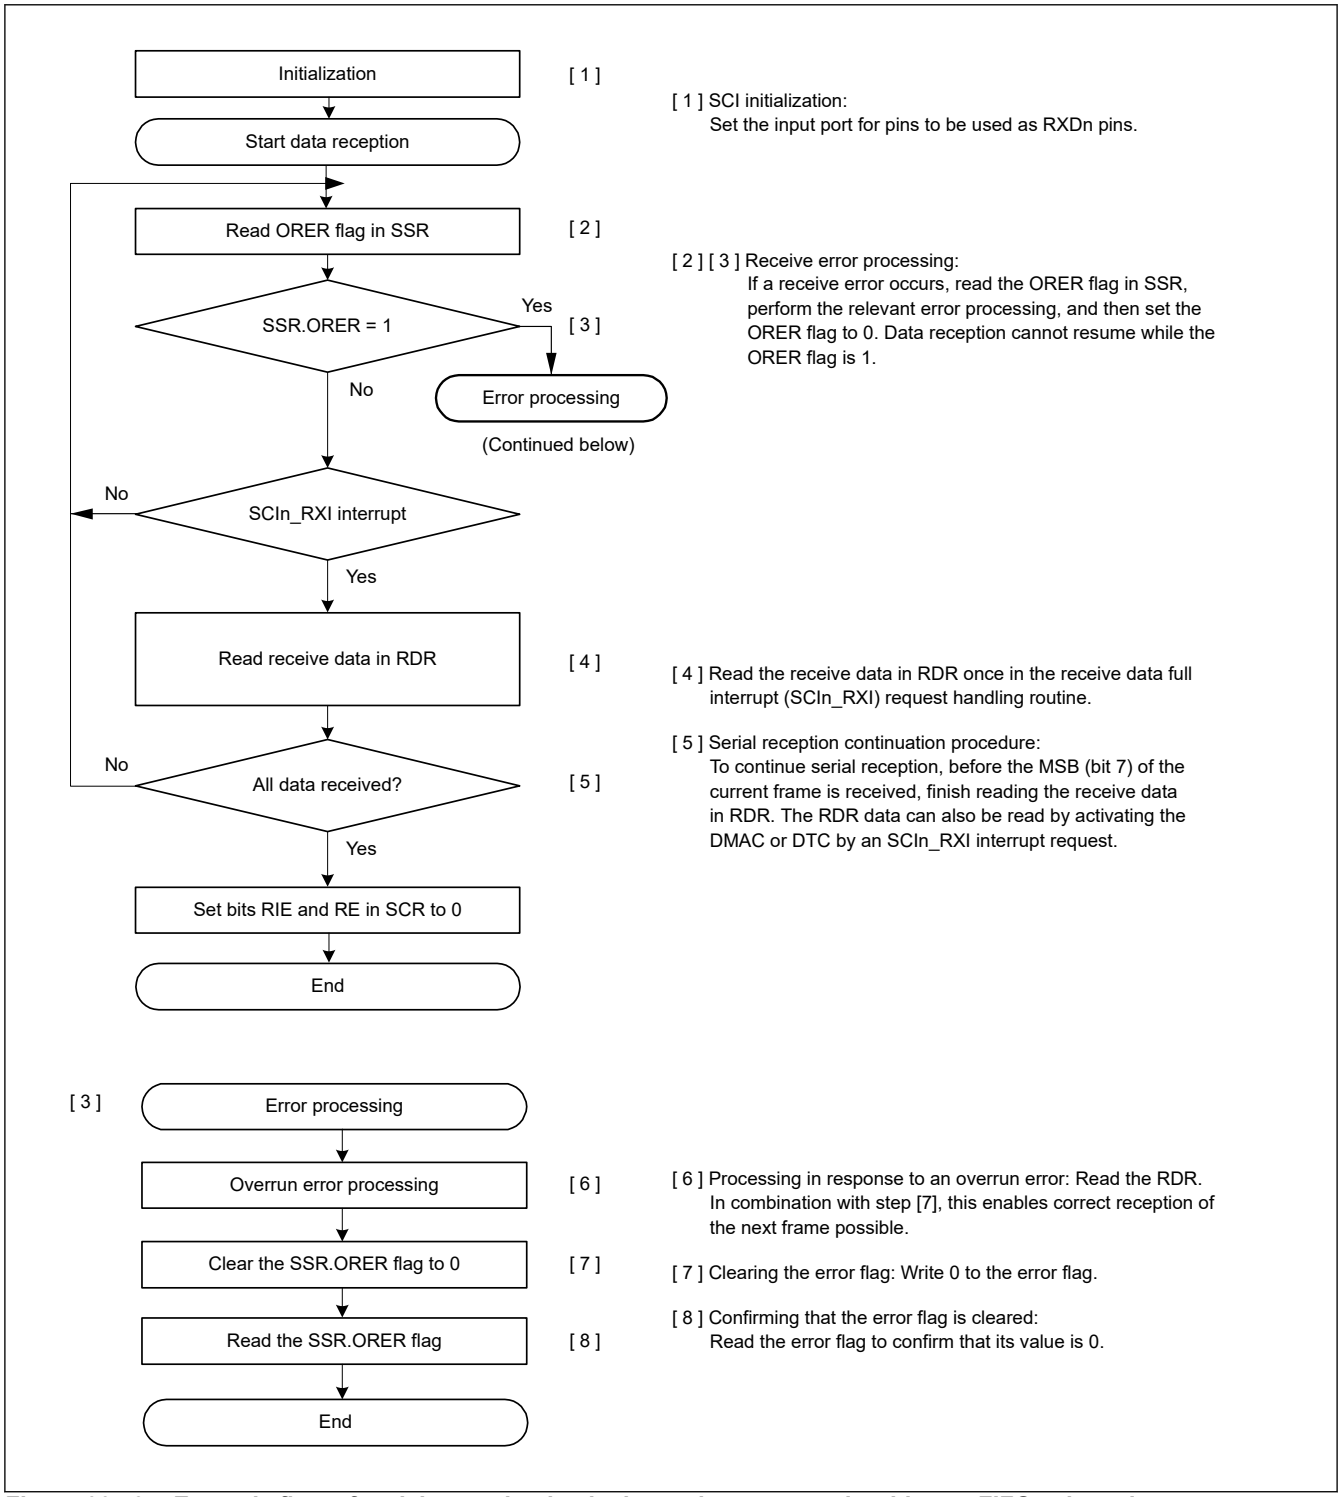


Figure 30.73 Example flow of serial reception in clock synchronous mode with non-FIFO selected

(2) FIFO selected

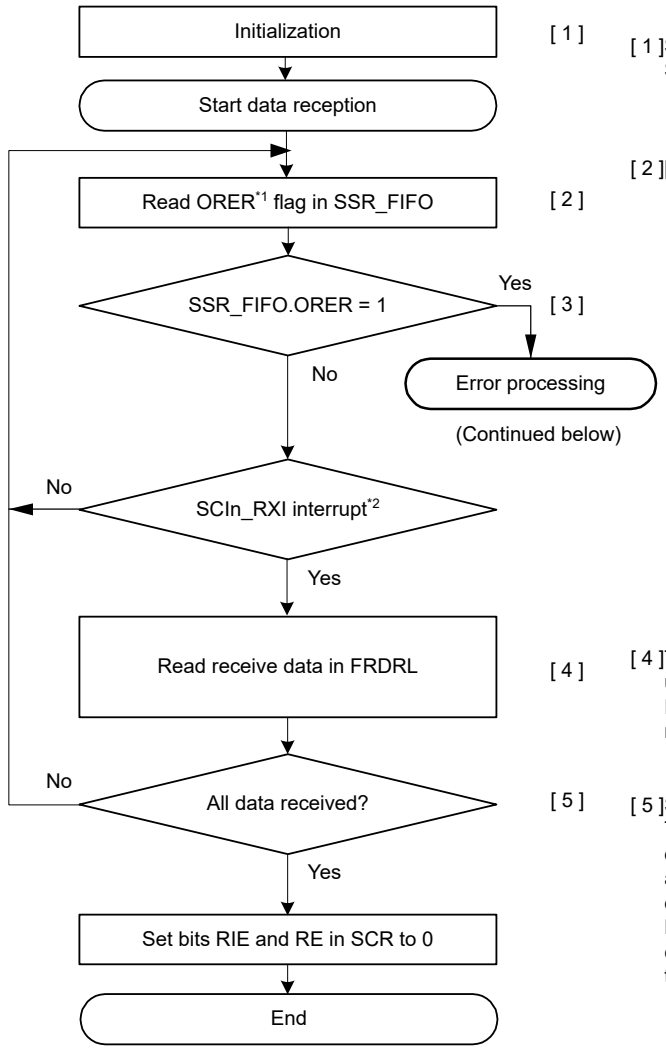
Figure 30.74 shows an example of serial reception in clock synchronous mode with FIFO selected.

In serial data reception, the SCI operates as follows:

1. When the value of the SCR.RE bit becomes 1, the CTSn_RTSn pin goes low.
2. The SCI performs internal initialization and starts receiving data in synchronization with a synchronization clock input or output, and stores the receive data in the RSR register.

3. If an overrun error occurs, the SSR_FIFO.ORER flag is set to 1. If the SCR.RIE bit is 1, an SCIn_ERI interrupt request is generated. Received data is not transferred to the FRDRL[*1] register.
4. When data reception completes successfully, the receive data is transferred to the FRDRL[*1] register. The RDF flag is set to 1 when the amount of the receive data stored in FRDRL is equal to or greater than the specified receive triggering number. If the SCR.RIE bit is 1, an SCIn_RXI interrupt request is generated. Continuous data reception is enabled by reading the receive data transferred to FRDRL[*2] in the SCIn_RXI interrupt handling routine before an overrun error occurs. If the amount of received data that is transferred to FRDRL is less than the specified receive triggering number, the CTSn_RTSn pin goes low.

Note 1. In clock synchronous mode, FRDRH is not used.
Note 2. Read data in order from FRDRH to FRDRL when RDF and ORER are read with receive data.

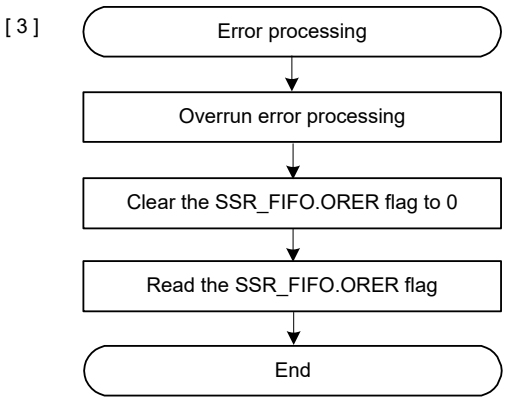


[1]SCI initialization:
Set the input port for pins to be used as RXDn pins.

[2][3]Receive error processing:
If a receive error occurs, read the ORER flag in SSR_FIFO, perform the relevant error processing, then set the SSR_FIFO.ORER flag to 0. Data reception cannot resume while the ORER flag is 1.

[4]The receive data stored in FRDRL register is read until the amount of stored data is less than the FCR.RTRG[3:0] value. Software can check readable data in FDR.R[4:0].

[5]Serial reception continuation procedure:
To continue serial reception, before overrun error occurs, finish reading the receive data in FRDRL and clear the SSR_FIFO.RDF flag to 0.The FRDRL data can also be read by activating the DMAC or DTC by an SCIn_RXI interrupt request. The RDF flag is cleared automatically in this case. Do not write to the RDF flag.



[6]Processing in response to an overrun error:
Read the FRDRL. In combination with step [7], this enables correct reception of the next frame possible.

[7]Clearing the error flag:
Write 0 to the error flag.

[8]Confirming that the error flag is cleared:
Read the error flag to confirm that its value is 0.

Note 1. It can also be read from FRDRH.ORER. However, to clear the ORER flag, write 0 to the associated bit in the SSR_FIFO register.
Note 2. It should be all receive data and is an integer times the FIFO triggering number.

Figure 30.74 Example flow of serial reception in clock synchronous mode with FIFO selected

30.6.6 Simultaneous Serial Data Transmission and Reception in Clock Synchronous Mode

(1) Non-FIFO selected

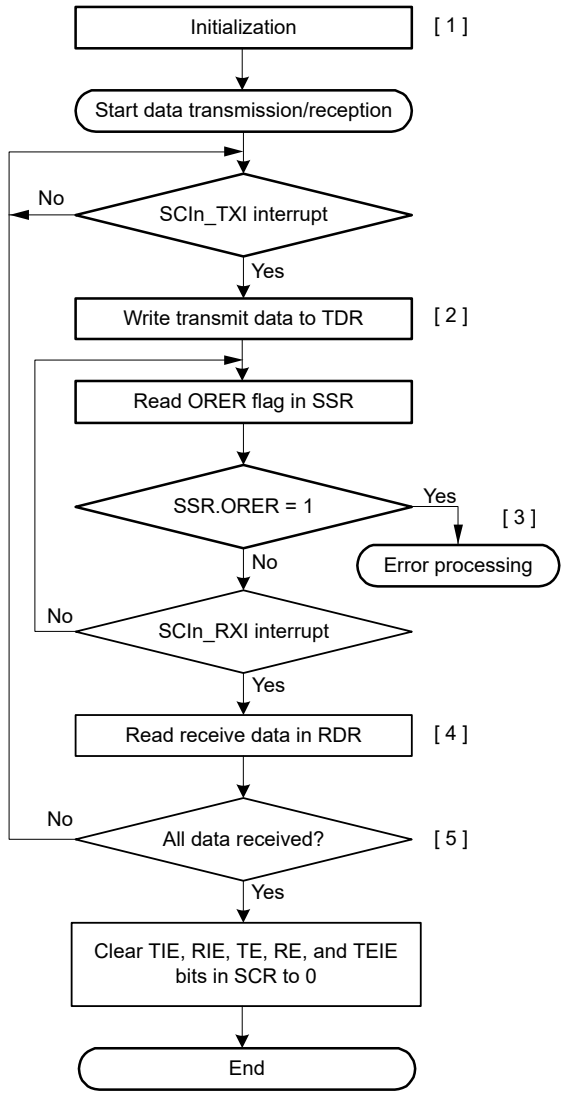
Figure 30.75 shows an example flow of simultaneous serial transmit and receive operations in clock synchronous mode. After initializing the SCI, use the following procedure for simultaneous serial data transmit and receive operations.

To switch from transmit mode to simultaneous transmit and receive mode:

1. Check that the SCI completes the data transmission by verifying that the SSR.TEND flag is set to 1.
2. Initialize the SCR register, and then set the TIE, RIE, TE, and RE bits in the SCR register to 1 simultaneously by a single instruction.

To switch from receive mode to simultaneous transmit and receive mode:

1. Check that the SCI completes the data reception.
2. Set the RIE and RE bits to 0, and then check that the receive error flag ORER in the SSR register is 0.
3. Set the TIE, RIE, TE, and RE bits in the SCR register to 1 simultaneously by a single instruction.



[1] SCI initialization:
The TXDn pin can act as the output pin for transmitted data and the RXDn pin can act as the input pin for received data at the same time.

[2] Transmit data write:
Write transmit data to TDR once in the SCIn_TXI interrupt request handling routine.

[3] Receive error processing:
If a receive error occurs, read the ORER flag in SSR, perform the relevant error processing, then set the ORER flag to 0. Data reception cannot resume while the ORER flag is 1.

[4] Reading receive data:
Read the receive data in RDR once in the SCIn_RXI interrupt request handling routine.

[5] Serial transmission/reception continuation procedure:
To continue serial transmission and reception, before the MSB bit 7 of the current frame is received, finish reading the receive data in RDR by the SCIn_RXI interrupt. Also, before the MSB bit 7 of the current frame is transmitted, write data to TDR by the SCIn_TXI interrupt.
Transmit data can also be written to TDR by activating the DMAC or DTC by a transmit data empty interrupt (SCIn_TXI) request. Similarly, the RDR data can also be read by activating the DMAC or DTC by a receive data full interrupt (SCIn_RXI) request.

Note: When switching from transmit or receive operation to simultaneous transmit and receive operations, first set the TIE, RIE, TE, RE, and TEIE bits in SCR to 0, then set TIE, RIE, TE, and RE bits to 1 simultaneously.

Figure 30.75 Example flow of simultaneous serial transmission and reception in clock synchronous mode with non-FIFO selected

(2) FIFO selected

Figure 30.76 shows an example flow of simultaneous serial transmit and receive operations in clock synchronous mode with FIFO selected.

After initializing the SCI, use the following procedure for simultaneous serial data transmit and receive operations.

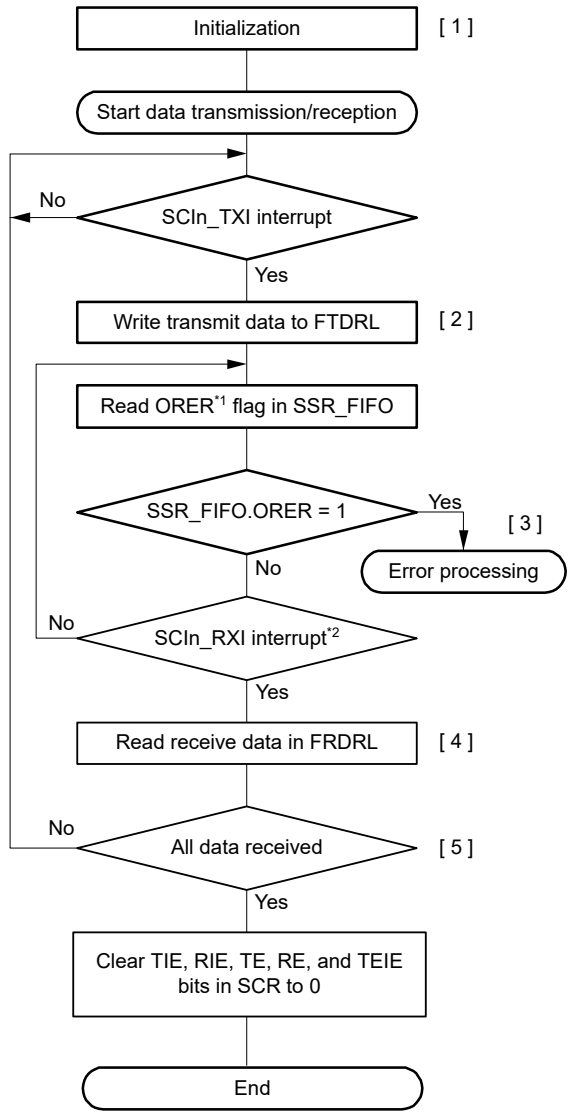
To switch from transmit mode to simultaneous transmit and receive mode:

1. Check that the SCI completes the transmission by verifying that the SSR_FIFO.TEND flag is set to 1.
2. Initialize the SCR register, then set the TIE, RIE, TE, and RE bits in the SCR register to 1 simultaneously by a single instruction.

To switch from receive mode to simultaneous transmit and receive mode:

1. Check that the SCI completes the reception.

2. Set the RIE and RE bits to 0.
3. Check that the receive error flags ORER in the SSR_FIFO register are 0, and then set the TIE, RIE, TE, and RE bits in the SCR register to 1 simultaneously by a single instruction.



[1] SCI initialization:
The TXDn pin can act as the output pin for transmitted data and the RXDn pin can act as the input pin for received data at the same time.

[2] Transmit data write:
Write transmit data to FTDRL in the SCIn_TXI interrupt request handling routine. The number of transmission data that can be written is 16 bits, which is the number of stored transmit data in the FIFO.

[3] Receive error processing:
If a receive error occurs, read the ORER flag in SSR_FIFO, performthe relevant error processing, and then set the ORER flag to 0. Data reception cannot resume while the ORER flag is 1.

[4] Reading receive data:
The reception data stored in FRDRL register is read until the number of stored data is less than the FCR.RTRG value. Software can check readable data in FDR.R[4:0].

[5] Serial transmission/reception continuation procedure:
To continue serial reception, before overrun error occurs, finish reading the receive data in FRDRL and clear the SSR_FIFO.RDF flag to 0. To continue serial transmission, before transmission of the current transmit data is finished, write the next transmit data to FTDRL in the SCIn_TXI interrupthandling routine and clear the SSR_FIFO.TDFE flag to 0.
Transmit data can also be written to FTDRL by activating the DMAC or DTC by a transmit FIFO data empty interrupt (SCIn_TXI) request. Similarly, the FRDRL data can also be read by activating the DMAC or DTC by a receive FIFO data full interrupt (SCIn_RXI) request. The RDF and TDFE flags are cleared automatically in this case. Do not write to the RDF and TDFE flags.

Note 1. It can also be read from FRDRH.ORER. To clear the ORER flag, write 0 to the associated bit in the SSR_FIFO register.
Note 2. It should be all receive data with amount an integer times FIFO triggering number.

Figure 30.76 Example flow of simultaneous serial transmission and reception in clock synchronous mode with FIFO selected

30.7 Operation in Smart Card Interface Mode

The SCI supports smart card (IC card) interfaces conforming to ISO/IEC 7816-3 (standard for Identification Cards), as an extended function of the SCI.

Smart card interface mode can be selected using the appropriate register.

30.7.1 Example Connection

Figure 30.77 shows an example connection between a smart card (IC card) and the MCU. As shown in Figure 30.77, because the MCU communicates with an IC card using a single transmission line, interconnect the TXDn and RXDn pins and pull up the data transmission line to VCC using a resistor.

Setting the SCR_SMCI.TE and SCR_SMCI.RE bits to 1 with an IC card disconnected enables closed-loop transmission or reception, allowing self-diagnosis. To supply an IC card with the clock pulses generated by the SCI, input the SCKn pin output to the CLK pin of an IC card.

An output port of the MCU can be used to output a reset signal.

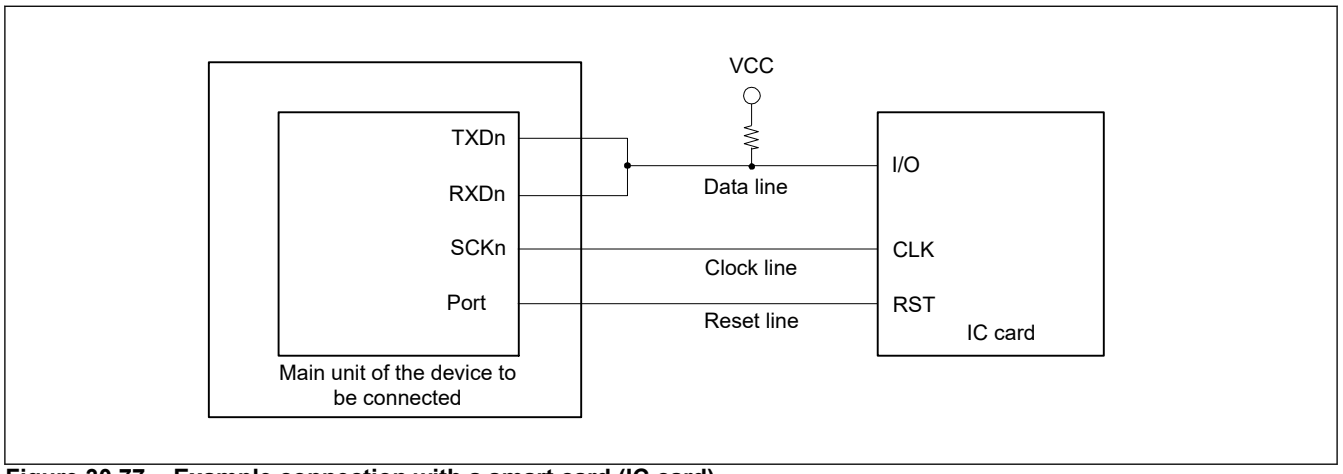


Figure 30.77 Example connection with a smart card (IC card)

30.7.2 Data Format (Except in Block Transfer Mode)

Figure 30.78 shows the data transfer formats in smart card interface mode:

- One frame consists of 8-bit data and a parity bit in asynchronous mode.
- During transmission, at least 2 etus (elementary time unit – the time required for transferring 1 bit) is set as a guard time from the end of the parity bit until the start of the next frame.
- If a parity error is detected during reception, a low error signal is output for 1 etu after 10.5 etus elapse from the start bit.
- If an error signal is sampled during transmission, the same data is automatically retransmitted after at least 2 etus.

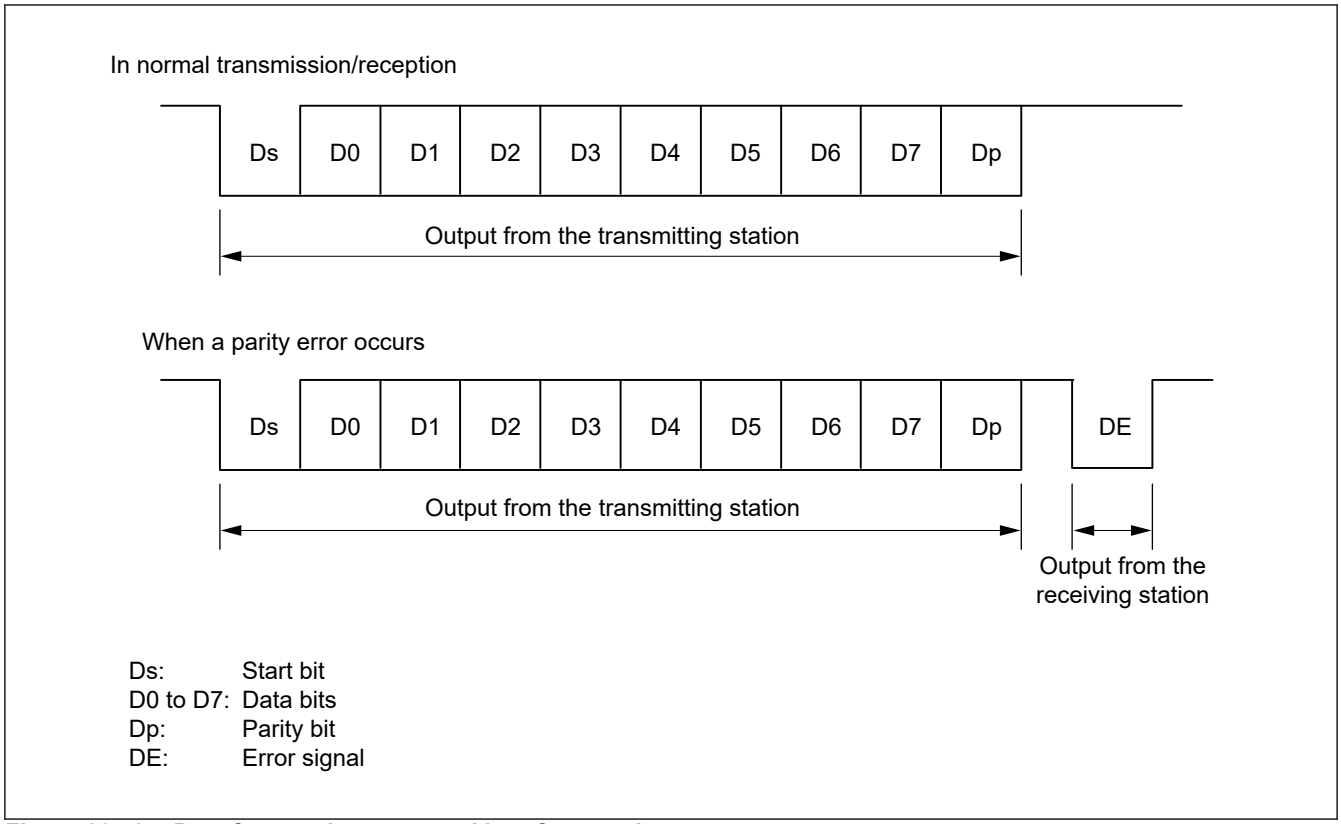

Figure 30.78 Data formats in smart card interface mode

For communications with IC cards of the direct convention type and inverse convention type, follow the procedures in this section.

(1) Direct Convention Type

For the direct convention type, logic levels 1 and 0 indicate the Z and A states, respectively, and data is transferred with LSB-first for the start character, as shown in Figure 30.79. Therefore, data in the start character in the figure is 0x3B.

When using the direct convention type, write 0 to both the SCMR.SDIR and SCMR.SINV bits. Write 0 to the SMR_SMCI.PM bit to use even parity, which is prescribed by the smart card standard.

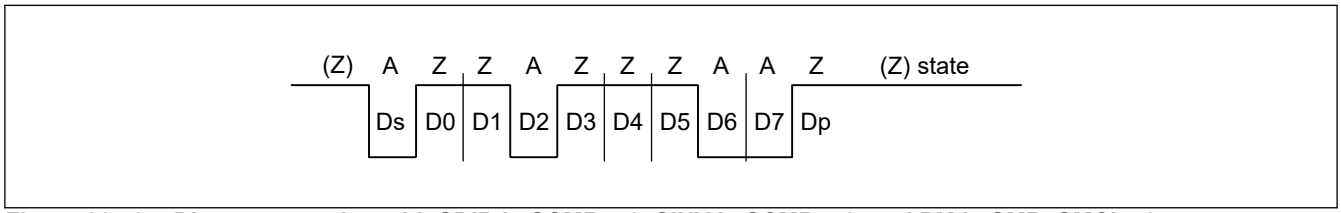

Figure 30.79 Direct convention with SDIR in SCMR = 0, SINV in SCMR = 0, and PM in SMR_SMCI = 0

(2) Inverse Convention Type

For the inverse convention type, logic levels 1 and 0 indicate the A and Z states, respectively, and data is transferred with MSB-first for the start character, as shown in Figure 30.80. Therefore, data in the start character in the figure is 0x3F.

When using the inverse convention type, write 1 to both the SCMR.SDIR and SCMR.SINV bits. The parity bit is logic level 0 to produce even parity, which is prescribed by the smart card standard, and corresponds to the Z state. Because the SINV bit of the MCU only inverts data bits D7 to D0, write 1 to the PM bit in SMR_SMCI to invert the parity bit for both transmission and reception.

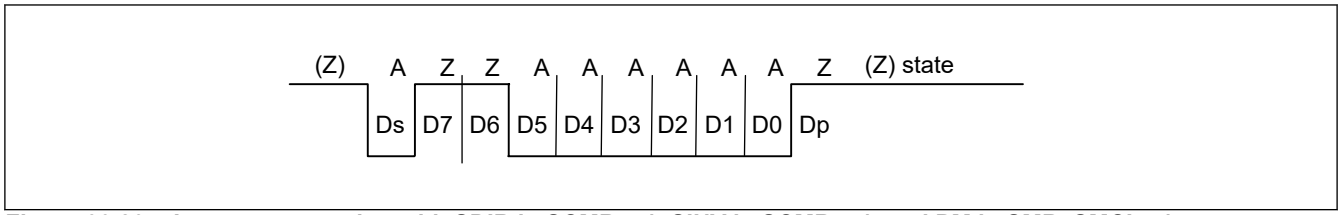

Figure 30.80 Inverse convention with SDIR in SCMR = 1, SINV in SCMR = 1, and PM in SMR_SMCI = 1

30.7.3 Block Transfer Mode

Block transfer mode differs from normal smart card interface mode as follows:

- Even if a parity error is detected during reception, no error signal is output. Because the PER flag in SSR_SMCI is set by error detection, clear the PER flag before receiving the parity bit of the next frame.
- During transmission, at least 1 etu is set as a guard time from the end of the parity bit until the start of the next frame
- Because the same data is not retransmitted, the TEND flag in SSR_SMCI is set to 11.5 etus after transmission starts
- In block transfer mode, the ERS flag in SSR_SMCI indicates the error signal status as in normal smart card interface mode, but the flag is read as 0 because no error signal is transferred

30.7.4 Receive Data Sampling Timing and Reception Margin

Only the internal clock generated by the on-chip baud rate generator can be used as a transfer clock in smart card interface mode.

In this mode, the SCI can operate on a base clock with a frequency of 32, 64, 372, 256, 93, 128, 186, or 512 times the bit rate set up in the SCMR.BCP2 and the SMR_SMCI.BCP[1:0] bits. The frequency is always 16 times the bit rate in normal asynchronous mode.

For data reception, the falling edge of the start bit is sampled with the base clock to perform internal synchronization.

Receive data is sampled on the 16th, 32nd, 186th, 128th, 46th, 64th, 93rd, and 256th rising edges of the base clock so that it can be latched at the middle of each bit as shown in Figure 30.81. The reception margin is determined by the following formula:

$$M = \left|\left(0.5 - \frac{1}{2N}\right) - (L - 0.5)F - \frac{|D - 0.5|}{N}(1 + F)\right| \times 100\ [\%]$$

M: Reception margin (%)

N: Ratio of bit rate to clock ($N = 32, 64, 372, 256$)

D: Duty cycle of clock ($D = 0$ to 1.0)

L: Frame length ($L = 10$)

F: Absolute value of clock frequency deviation

Assuming values of F = 0, D = 0.5, and N = 372 in the specified formula, the reception margin is determined using the following formula:

$$M = \{0.5 - 1/(2 \times 372)\} \times 100\ [\%] = 49.866\ \%$$

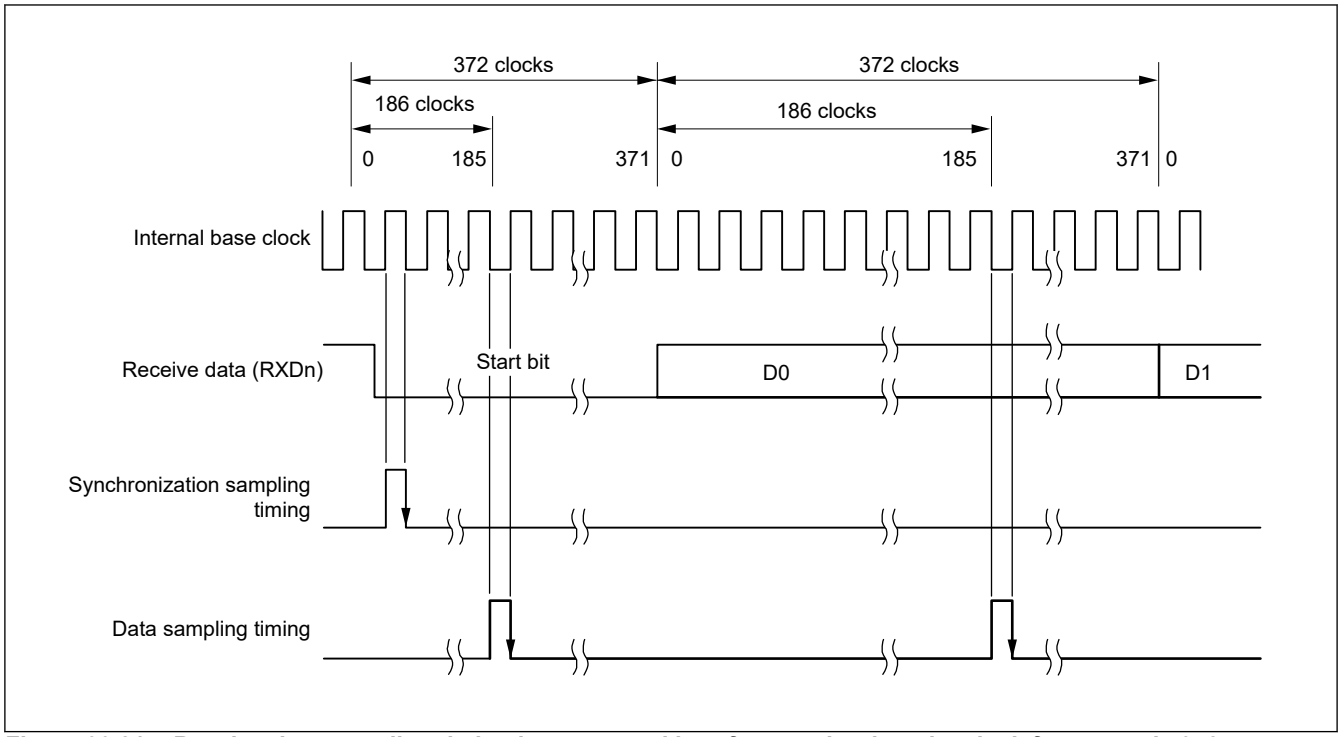

Figure 30.81 Receive data sampling timing in smart card interface mode when the clock frequency is 372 times the bit rate

30.7.5 SCI Initialization (Smart Card Interface Mode)

Before transmitting and receiving data, write the initial value 0x00 in the SCR_SMCI register and initialize the SCI following the example flow shown in Table 30.39.

Always set the initial value in the TIE, RIE, TE, RE, TEIE bits in the SCR_SMCI register before switching from transmission to reception mode or from reception to transmission mode. When SCR_SMCI.RE is set to 0, the RDR register is not initialized.

To change from reception mode to transmission mode, first check that reception has completed, then initialize the SCI. At the end of initialization, set SCR_SMCI.TE = 1 and SCR_SMCI.RE = 0. Reception completion can be verified by reading the SCIn_RXI request, ORER, or PER flag in SSR_SMCI.

To change transmission mode to reception mode, first check that transmission has completed, then initialize the SCI. At the end of initialization, set SCR_SMCI.TE = 0 and SCR_SMCI.RE = 1. Transmission completion can be verified by reading the TEND flag in SSR_SMCI.

Table 30.39 Example flow of SCI initialization in smart card interface mode (1 of 2)

No.	Step Name	Description
1	Start initialization	
2	Set SCR_SMCI.TIE, RIE, TE, RE, TEIE, and CKE[1:0] to 0	Stop the communication and initialize SKE[1:0].
3	Set SIMR1.IICM bit to 0. Set SCMR.SMIF to 1.	Set to smart card interface mode.
4	Set SSR_SMCI.ORER, ERS, PER to 0	Write to SSR_SMCI after reading SSR_SMCI.
5	Set SPMR.CKPH, CKPOL	Set the transmission or reception format in SPMR.
6	Set SMR_SMCI.GM, BLK, PM, BCP[1:0], CKS[1:0], and set SMR_SMCI.PE to 1	Set the operation mode and the transmission or reception format in SMR_SMCI.
7	Set SCMR.BCP2, SDIR, SINV	Set the transmission or reception format in SCMR.
8	Set SPTR to the initial value.	Set the Initial value to SPTR.

Table 30.39 Example flow of SCI initialization in smart card interface mode (2 of 2)

No.	Step Name	Description
9	Set SEMR.BRME and SEMR.RXDESEL to 0	Set SEMR.BRME and SEMR.RXDESEL to 0.
10	Set a value in BRR	Write the value for the bit rate in BRR.
11	Set the I/O port functions	Set the I/O port functions for TXDn, RXDn, and SCKn.
12	Set a value in SCR_SMCI.CKE[1:0]	Set the SCR_SMCI.CKE[1:0]. Even though the function depends on SMR_SMCI.GM, when the CKE[0] bit is set to 1, the clock is output from the SCKn pin.
13	Set SCR_SMCI.TE or RE to 1, and set SCR_SMCI.TIE, RIE	Set the TE or RE bit in SCR_SMCI to 1, then set the TIE and RIE bits in SCR_SMCI. Do not simultaneously set the TE and RE bits to 1 if self-diagnosis is not used.
14	Initialization completed	

30.7.6 Serial Data Transmission (Except in Block Transfer Mode)

Serial data transmission in smart card interface mode (except in block transfer mode) is different from that in non-smart card interface mode, in that an error signal is sampled and data can be re-transmitted in smart card mode. Figure 30.82 shows the data re-transfer operation during transmission.

1. When an error signal from the receiver end is sampled after 1-frame data is transmitted, the SSR_SMCI.ERS flag is set to 1. If the SCR_SMCI.RIE bit is 1, an SCIn_ERI interrupt request is generated. Clear the ERS flag to 0 before the next parity bit is sampled.
2. For a frame in which an error signal is received, the SSR_SMCI.TEND flag is not set. Data is re-transferred from TDR to TSR, allowing automatic data retransmission.
3. If no error signal is returned from the receiver, the ERS flag is not set to 1.
4. In this case, the SCI determines that transmission of 1-frame data, including the re-transfer, is complete, and the TEND flag is set. If the SCR_SMCI.TIE bit is 1, an SCIn_TXI interrupt request is generated. Write transmit data to the TDR to start transmission of the next data.

Figure 30.84 shows an example flow of serial transmission. All the processing steps are automatically performed using an SCIn_TXI interrupt request to activate the DTC or DMAC.

When the SSR_SMCI.TEND flag is set to 1 in transmission and when the SCR_SMCI.TIE bit is 1, an SCIn_TXI interrupt request is generated.

The DTC or DMAC is activated by an SCIn_TXI interrupt request if the SCIn_TXI interrupt request is previously specified as a source of DTC or DMAC activation, allowing the transfer of transmit data. The TEND flag is automatically set to 0 when the DTC or DMAC transfers the data.

If an error occurs, the SCI automatically retransmits the same data. During this retransmission, the TEND flag is kept at 0 and the DTC or DMAC is not activated. Therefore, the SCI and DTC or DMAC automatically transmit the specified number of bytes, including retransmission when an error occurs. Because the ERS flag is not automatically cleared, set the RIE bit to 1 before enabling an SCIn_ERI interrupt request to be generated if an error occurs, and clear the ERS flag to 0.

When transmitting or receiving data using the DTC or DMAC, always enable the DTC or DMAC before making the SCI settings.

For DTC or DMAC settings, see section 17, Data Transfer Controller (DTC), section 16, DMA Controller (DMAC).

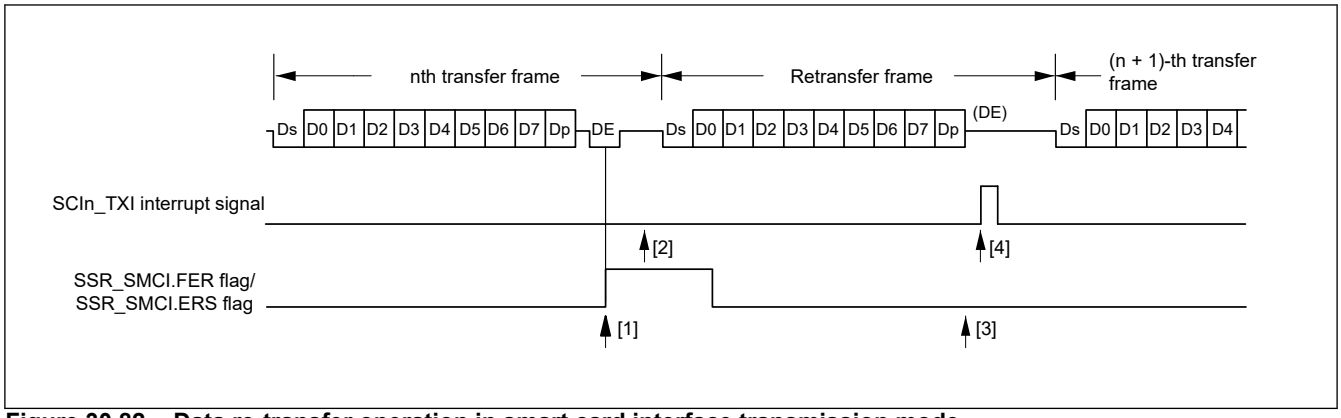

Figure 30.82 Data re-transfer operation in smart card interface transmission mode

The SSR_SMCI.TEND flag is set at different timings depending on the SMR_SMCI.GM bit setting. Figure 30.83 shows the TEND flag generation timing.

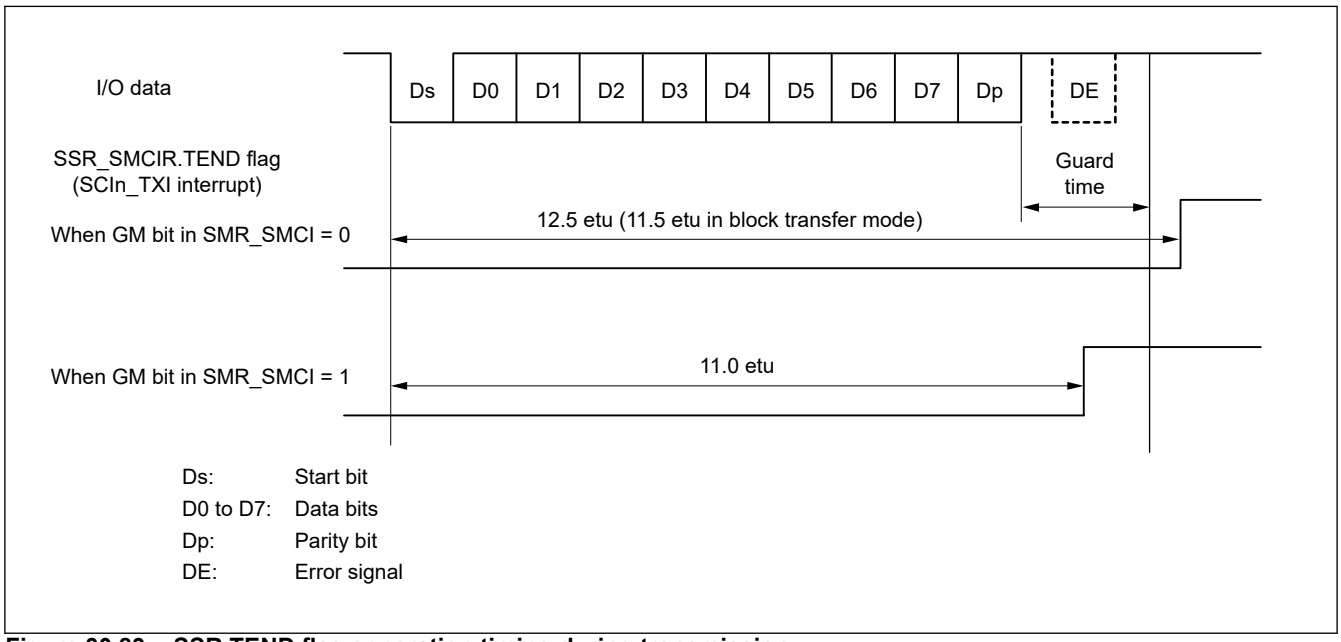

Figure 30.83 SSR.TEND flag generation timing during transmission

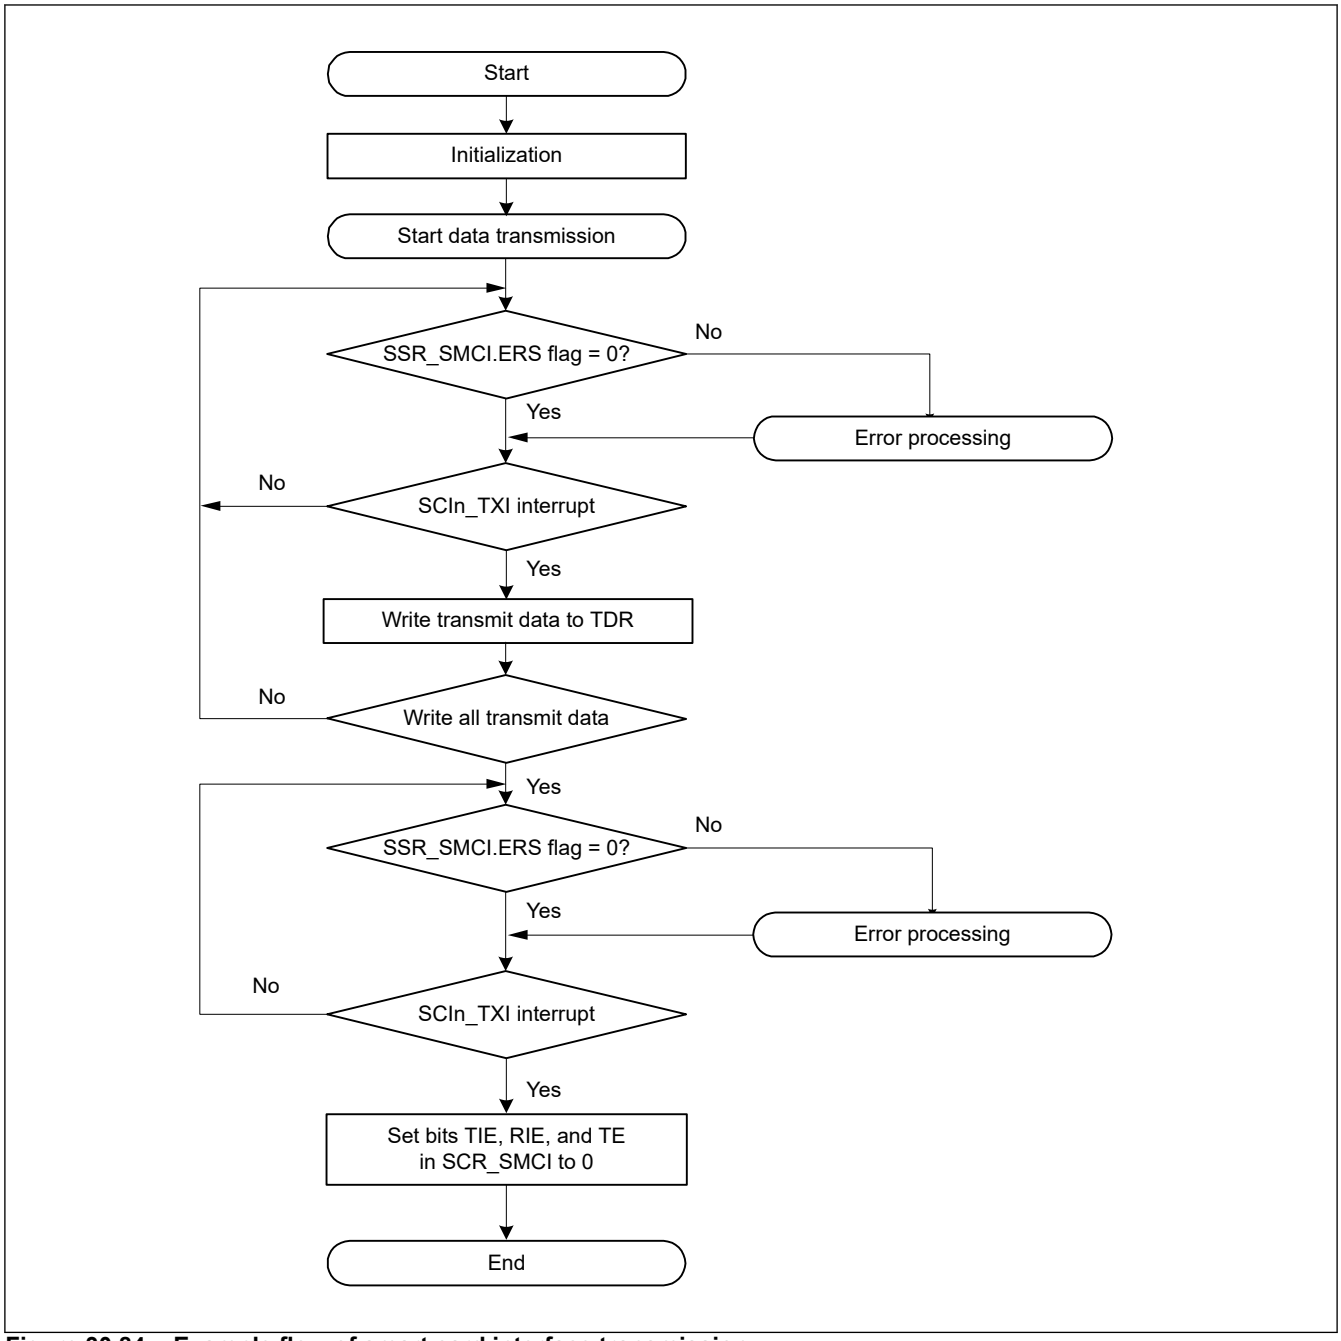

Figure 30.84 Example flow of smart card interface transmission

30.7.7 Serial Data Reception (Except in Block Transfer Mode)

Serial data reception in smart card interface mode is similar to that in non-smart card interface mode. Figure 30.85 shows the data re-transfer operation in reception mode.

1. If a parity error is detected in the receive data, the SSR_SMCI.PER flag is set to 1. When the SCR_SMCI.RIE bit is 1, an SCIn_ERI interrupt request is generated. Clear the PER flag to 0 before the next parity bit is sampled.
2. For a frame in which a parity error is detected, no SCIn_RXI interrupt is generated.
3. When no parity error is detected, the SCR_SMCI.PER flag is not set to 1.
4. In this case, data is determined to be received successfully. When the SCR_SMCI.RIE bit is 1, an SCIn_RXI interrupt request is generated.

Figure 30.86 shows an example flow of serial data reception. All the processing steps are automatically performed using an SCIn_RXI interrupt request to activate the DTC or DMAC.

In reception, setting the RIE bit to 1 allows an SCIn_RXI interrupt request to be generated. The DTC or DMAC is activated by an SCIn_RXI interrupt request if the SCIn_RXI interrupt request is previously specified as a source of DTC or DMAC activation, allowing the transfer of receive data.

If an error occurs during reception and either the ORER or PER flag in SSR_SMCI is set to 1, a receive error interrupt (SCIn_ERI) request is generated. Clear the error flag after the error occurrence. If an error occurs, the DTC or DMAC is not activated and receive data is skipped. Therefore, the number of bytes of receive data specified in the DTC or DMAC is transferred.

If a parity error occurs and the PER flag is set to 1 during reception, the receive data is transferred to RDR, allowing the data to be read.

When a reception is forced to terminate by setting SCR_SMCI.RE to 0 during operation, read the RDR register because the received data that is not yet read might be left in the RDR.

Note: For operations in block transfer mode, see section 30.3.9. Serial Data Reception in Asynchronous Mode.

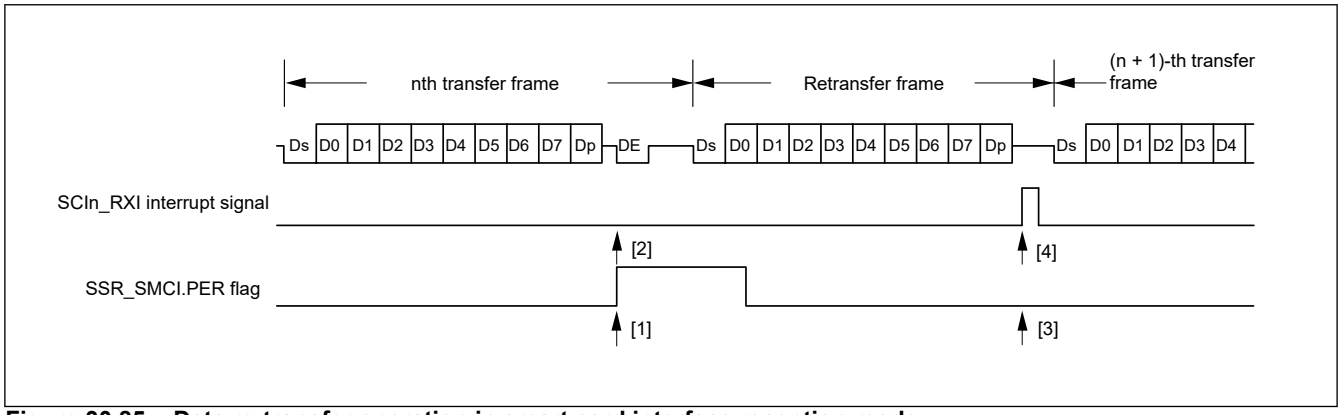

Figure 30.85 Data re-transfer operation in smart card interface reception mode

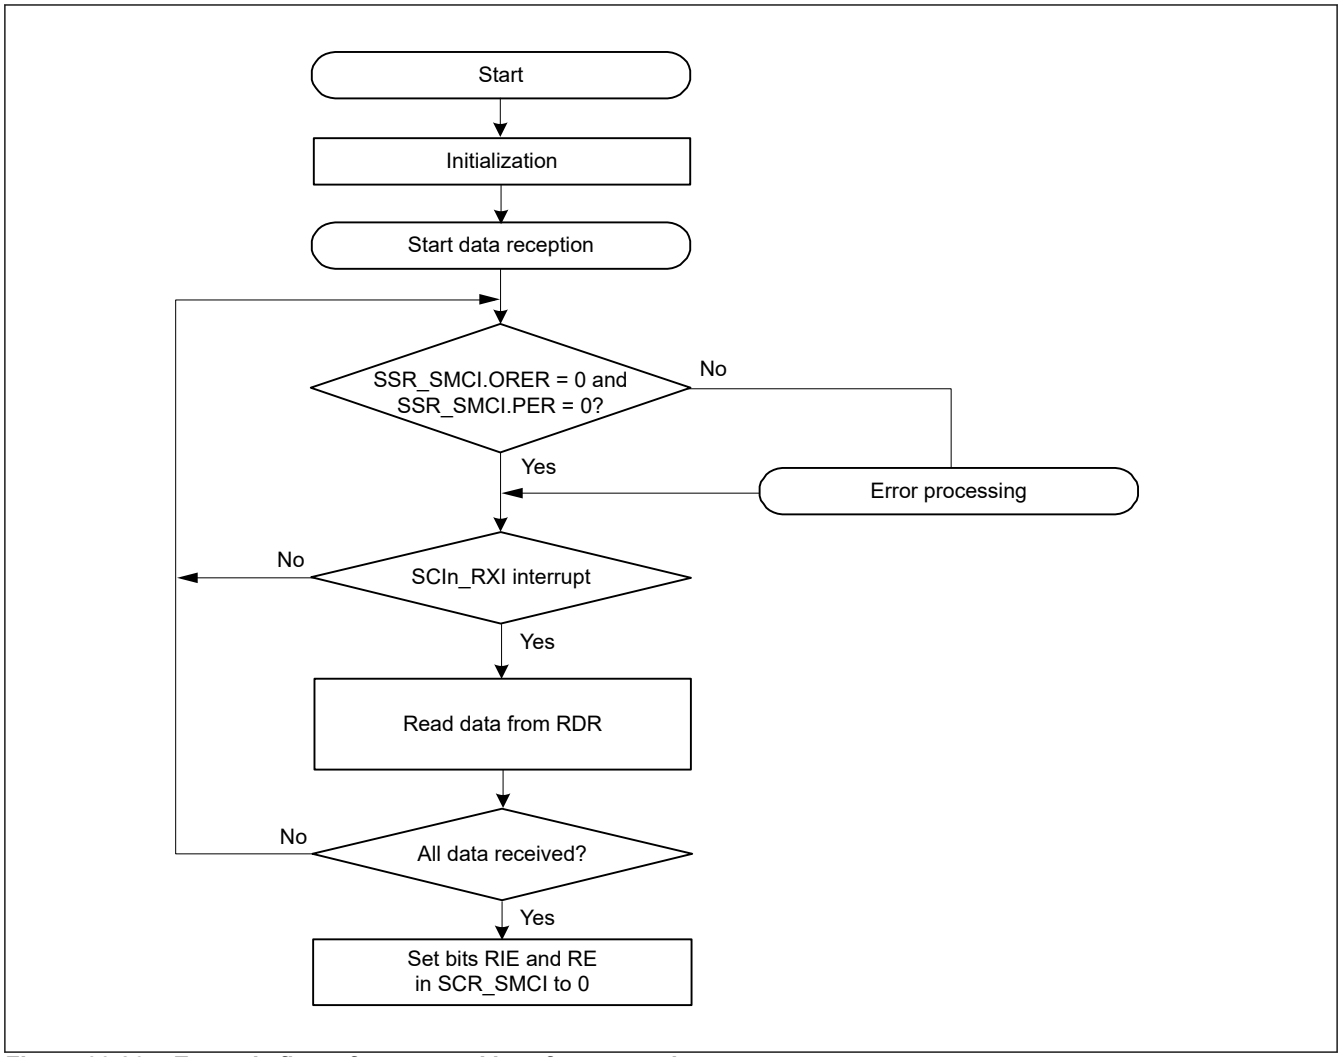

Figure 30.86 Example flow of smart card interface reception

30.7.8 Clock Output Control

When the GM bit in SMR_SMCI is set to 1, the clock output can be controlled by the CKE[1:0] bits in SCR_SMCI. For details on the CKE[1:0] bits, see section 30.2.14. SCR_SMCI : Serial Control Register for Smart Card Interface Mode (SCMR.SMIF = 1). When setting the clock output, the base clock described in section 30.7.4. Receive Data Sampling Timing and Reception Margin is applied.

Figure 30.87 shows an example timing for the clock output control when the CKE[1] bit in SCR_SMCI is set to 0 and the CKE[0] bit in SCR_SMCI is controlled.

When the GM bit in SMR_SMCI is 0, output control by the CKE[0] bit in SCR_SMCI is immediately reflected on the SCKn pin, so there is a possibility that pulses with an unintended width may be output from the SCKn pin.

When the GM bit in SMR_SMCI is 1, the clock with the same pulse width as the base clock is output even if the CKE[0] bit in SCR_SMCI is changed.

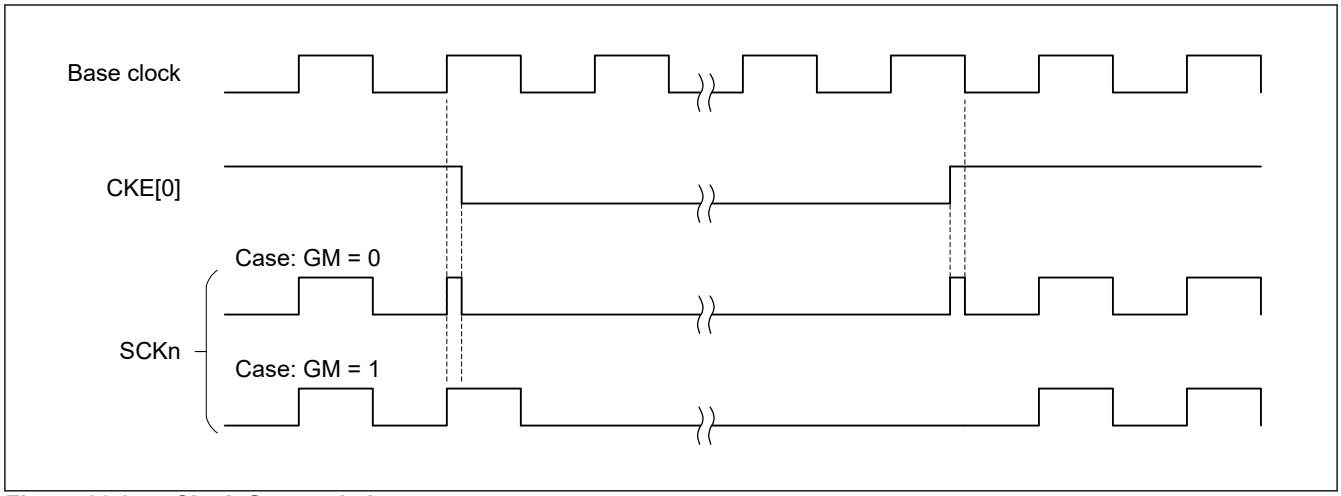

Figure 30.87 Clock Output timing

30.8 Operation in Simple IIC Mode

Simple IIC mode format is composed of 8 data bits and an acknowledge bit. By continuing into a slave-address frame after a start condition or restart condition, a master device can specify a slave device as the partner for communications. The currently specified slave device remains valid until a new slave device is specified or a stop condition is satisfied. The 8 data bits in all frames are transmitted in order from the MSB.

The I^2C bus format and timing of the I^2C bus are shown in Figure 30.88 and Figure 30.89.

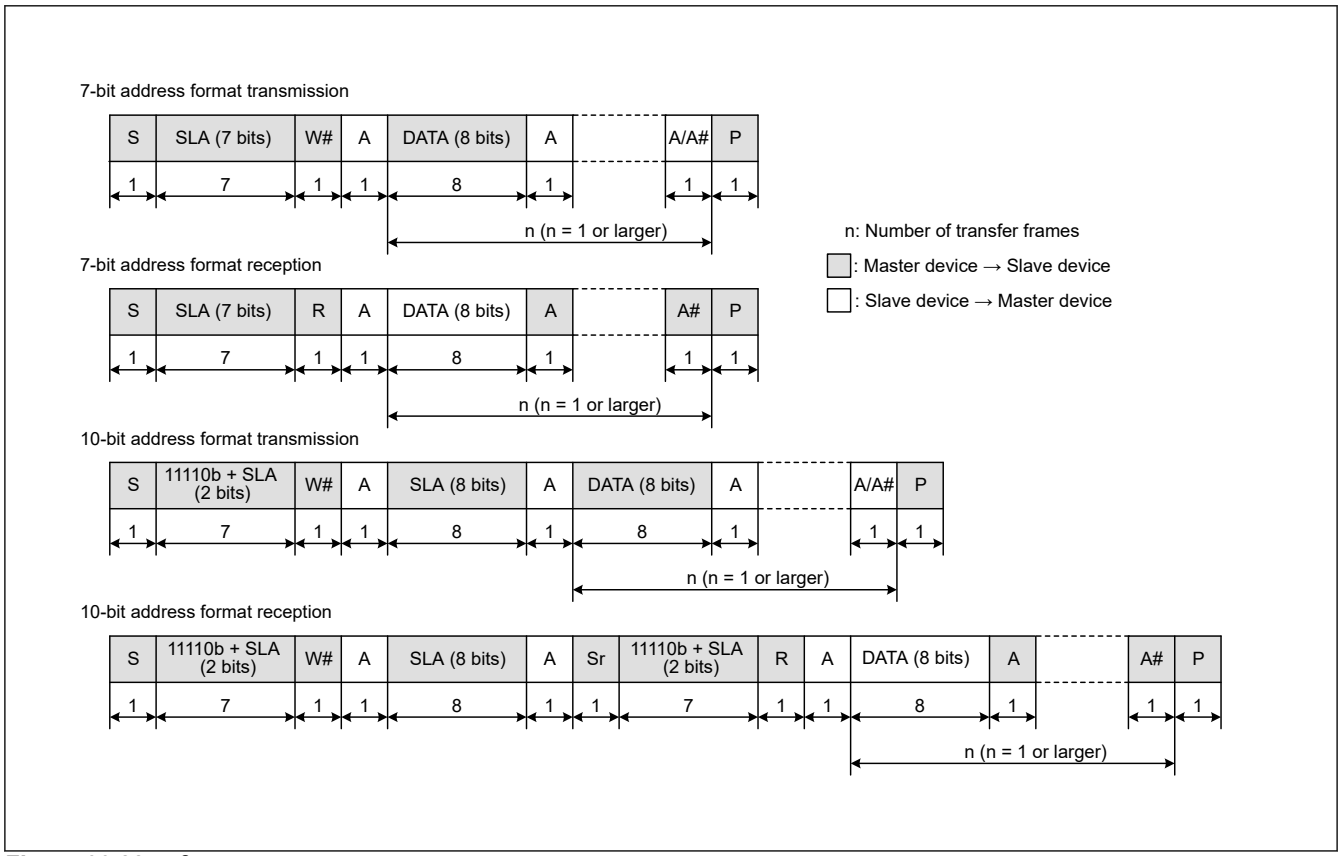

Figure 30.88 I^2C bus format

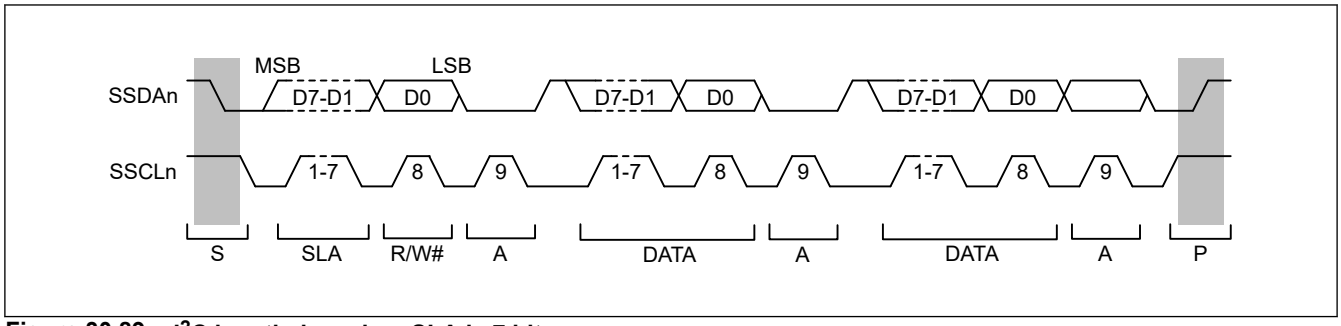

Figure 30.89 I²C bus timing when SLA is 7 bits

- S: Indicates a start condition, when the master device changes the level on the SDAn line from high to low while the SCLn line is high
- SLA: Indicates a slave address, by which the master device selects a slave device
- R/W#: Indicates the direction of transfer (reception or transmission). The value 1 indicates transfer from the slave device to the master device and 0 indicates transfer from the master device to the slave device.
- A/A#: Indicates an acknowledge bit. This is returned by the slave device for master transmission and by the master device for master reception. Return low indicates ACK and return high indicates NACK.
- Sr: Indicates a restart condition, when the master device changes the level on the SDAn line from high to low while the SCLn line is high and after the setup time elapses
- DATA: Indicates the data being received or transmitted
- P: Indicates a stop condition, when the master device changes the level on the SDAn line from low to high while the SCLn line is high

30.8.1 Generation of Start, Restart, and Stop Conditions

Writing 1 to the SIMR3.IICSTAREQ bit causes the generation of a start condition. The generation of a start condition proceeds through the following operations:

- The level on the SDAn line falls (from the high level to the low level) and the SCLn line is kept in the released state
- The hold time for the start condition is set as half of a bit period at the bit rate determined by the BRR setting
- The level on the SCLn line falls (from the high level to the low level), the IICSTAREQ bit in SIMR3 is set to 0, and a start-condition generated interrupt is output

Writing 1 to the IICRSTAREQ bit in SIMR3 causes the generation of a restart condition. The generation of a restart condition proceeds through the following operations:

- The SDAn line is released and the SCLn line is kept at the low level
- The period at low level for the SCLn line is set as half of a bit period at the bit rate determined by the BRR setting
- The SCLn line is released (transition from the low to the high level)
- When a high level is detected on the SCLn line, the setup time for the restart condition is set as half of a bit period at the bit rate determined by the BRR setting
- The level on the SDAn line falls (from the high level to the low level)
- The hold time for the restart condition is set as half of a bit period at the bit rate determined by the BRR setting
- The level on the SCLn line falls (from the high level to the low level), the SIMR3.IICRSTAREQ bit is set to 0, and a restart-condition generated interrupt is output

Writing 1 to the SIMR3.IICSTPREQ bit causes the generation of a stop condition. The generation of a stop condition proceeds through the following operations:

- The level on the SDAn line falls (from the high level to the low level) and the SCLn line is kept at the low level
- The period at low level for the SCLn line is set as half of a bit period at the bit rate determined by the BRR setting
- The SCLn line is released (transition from the low to the high level)

- When a high level is detected on the SCLn line, the setup time for the stop condition is set as half of a bit period at the bit rate determined by the BRR setting
- The SDAn line is released (transition from the low to the high level), the SIMR3.IICSTPREQ bit is set to 0, and a stop-condition generated interrupt is output

Figure 30.90 shows the timing of operations in the generation of start, restart, and stop conditions.

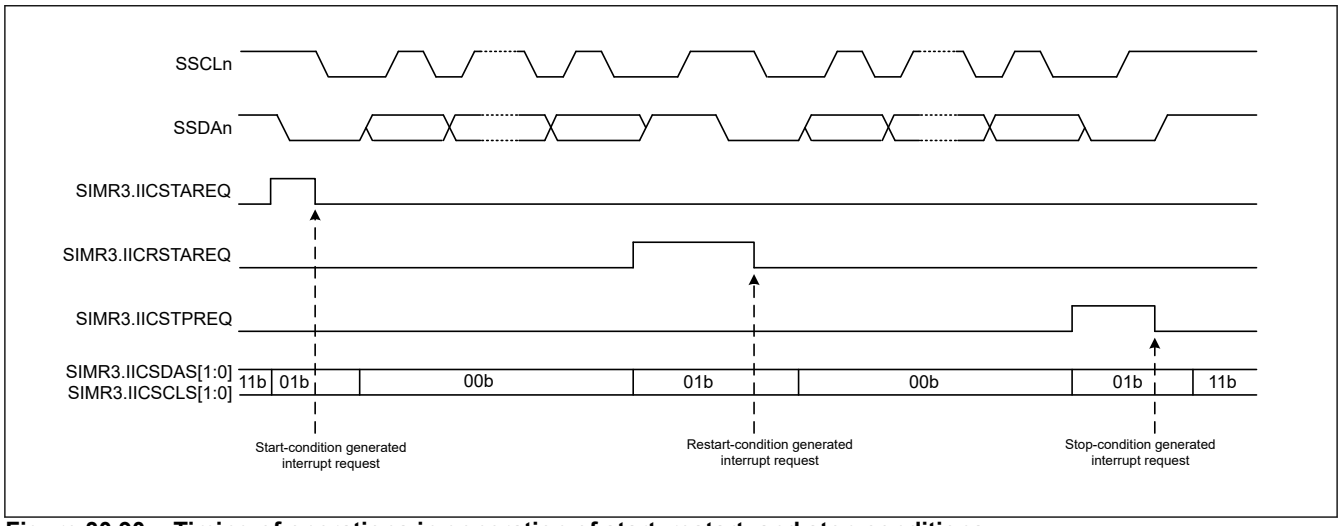

Figure 30.90 Timing of operations in generation of start, restart, and stop conditions

30.8.2 Clock Synchronization

The SCLn line can be driven low if a wait is inserted by a slave device at the other side of the transfer. Setting the SIMR2.IICCSC bit to 1 applies control to obtain synchronization when a difference arises between the levels of the internal SCLn clock signal and the level being input on the SCLn pin.

When the SIMR2.IICCSC bit is set to 1, the level of the internal SCLn clock signal changes from low to high. Counting to determine the period at a high level stops while the low level is being input on the SCLn pin. Counting to determine the period at a high level starts after the transition of the input on the SCLn pin to the high level.

The interval from this time until counting to determine the period at high level starts on the transition of the SCLn pin to the high level, is the total of the delay of SCLn output, delay for noise filtering of the input on the SCLn pin (2 or 3 cycles of sampling clock for the noise filter), and delay for internal processing (1 or 2 cycles of PCLK). The period at high level of the internal SCLn clock is extended even when other devices do not place the low level on the SCLn line.

If the SIMR2.IICCSC bit is 1, synchronization is obtained for the transmission and reception of data by taking the logical AND of the input on the SCLn pin and the internal SCLn clock. If the SIMR2.IICCSC bit is 0, synchronization with the internal SCLn clock is obtained for the transmission and reception of data.

If a slave device inserts a wait period into the interval until the transition of the internal SCLn clock signal from the low to the high level after a request for the generation of a start, restart, or stop condition is issued, the time until generation is prolonged by that period.

If a slave device inserts a wait period after the transition of the internal SCLn clock signal from the low to the high level, although the generation-completed interrupt is issued without stopping the waiting period, generation of the condition itself is not guaranteed.

Figure 30.91 shows an example operation for synchronizing the clocks.

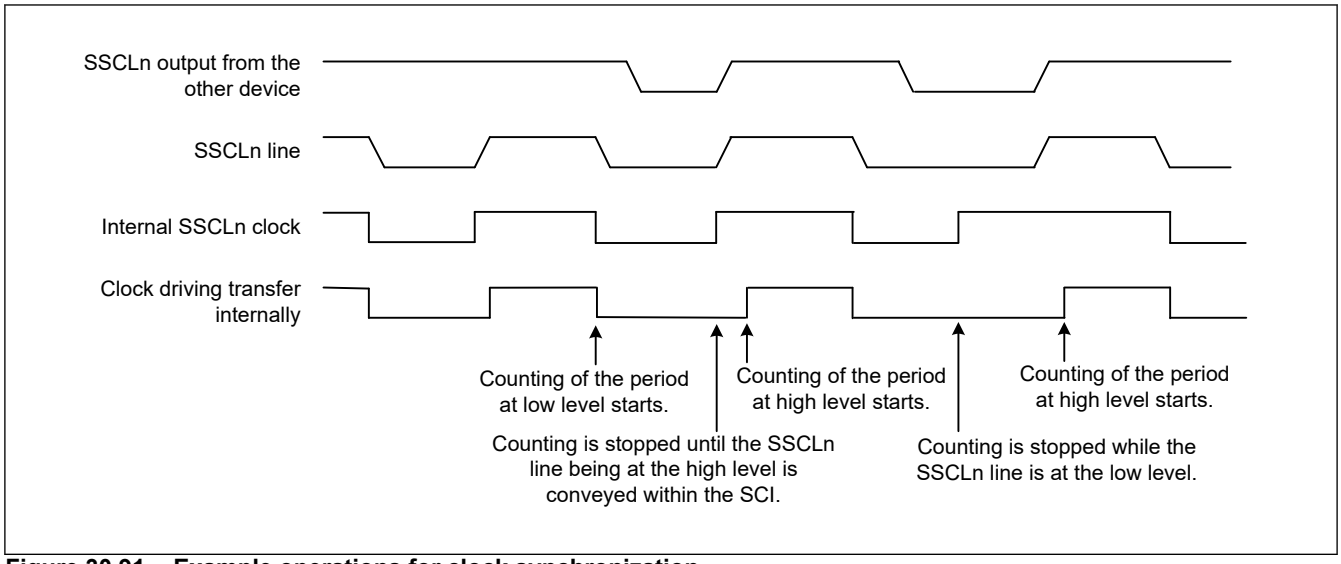

Figure 30.91 Example operations for clock synchronization

30.8.3 SDAn Output Delay

The SIMR1.IICDL[4:0] bits can be used to set a delay for output on the SDAn pin relative to falling edges of output on the SCLn pin. Delay settings from 0 to 31 are selectable, representing periods of the corresponding numbers of cycles of the clock signal from the on-chip baud rate generator (derived by frequency-dividing the base clock, PCLK, by the divisor selected in the SMR.CKS[1:0] bits). A delay for output on the SDAn pin applies to the start condition/restart condition/stop condition signal, 8-bit transmit data, and acknowledge bit.

If the SDAn output delay is shorter than the time for the level on the SCLn pin to fall, the change of the output on the SDAn pin starts while the output level on the SCLn pin is falling, creating a possibility of erroneous operation for slave devices. Ensure that settings for the delay of output on the SDAn pin specify times greater than the time output on the SCLn pin takes to fall (300 ns for IIC in normal mode and fast mode).

Figure 30.92 shows the timing of delays in SDAn output.

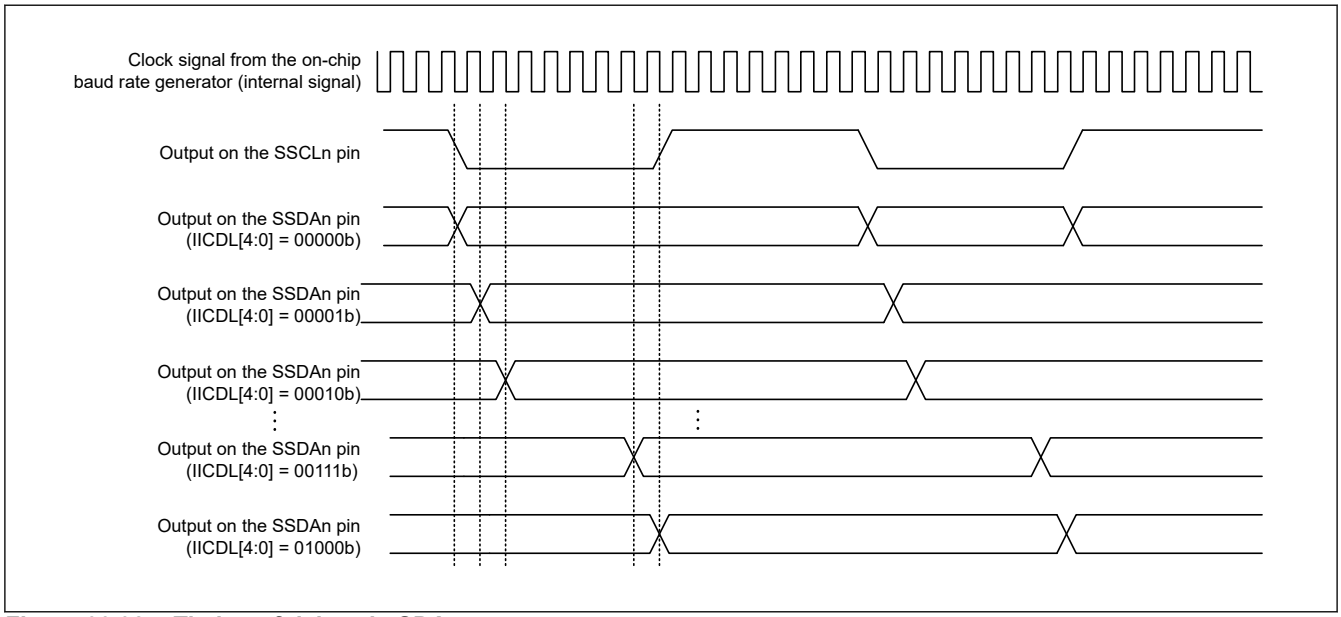

Figure 30.92 Timing of delays in SDAn output

30.8.4 SCI Initialization in Simple IIC Mode

Before transferring data, write the initial value 0x00 to SCR and initialize the interface following the example shown in Table 30.40.

Before making any changes to the operating mode or transfer format, be sure to set SCR to its initial value. In simple IIC mode, the open-drain setting for the communication ports should be made on the port side.

Table 30.40 Example flow of SCI initialization in simple IIC mode

No.	Step Name	Description
1	Start of initialization	
2	Set the TIE, RIE, TE, RE, TEIE and CKE[1:0] bits in SCR to 0	
3	Set the I/O port functions	Set the I/O port to allow use (on N-channel open-drain output pins) of the SSCLn and SSDAn pin functions.
4	Set the IICSDAS[1:0] and IICSCLS[1:0] bits in SIMR3 to 11b	Place the SSCLn and SSDAn pins in the high-impedance state until a start condition is to be generated.
5	Set up the transfer or reception format in SMR and SCMR	Set the format for transmission and reception in SMR and SCMR. In SMR, set the CKS[1:0] bits to the target value and set the other bits to 0. In SCMR, set the SDIR bit to 1 and the SINV and SMIF bits to 0.
6	Set the initial value to SPTR.	Set the Initial value to SPTR.
7	Set the value in BRR	Write the value for the targeted bit rate to BRR.
8	Set a value in MDDR	Write the value obtained by correcting a bit rate error in MDDR. This step is not required if the BRME bit in SEMR is set to 0.
9	Set the values in SEMR, SNFR, SIMR1, SIMR2, and SPMR	Set the values in SEMR, SNFR, SIMR1, SIMR2, and SPMR. Set the NFEN and BRME bits in SEMR. In SNFR, set the NFCS[2:0] bits. In SIMR1, set the IICM bit to 1 and the IICDL[4:0] bits as required. In SIMR2, set the IICACKT and IICCSC bits to 1 and the IICINTM bits as required. In SPMR, set all the bits to 0.
10	Set the SCR.RE and TE bit to 1 and set the SCR.TIE, RIE and TEIE bits	Set the RE and TE bits in the SCR to 1. Then, set the SCR.TIE, RIE, and TEIE bits (for transmission and when the SIMR2.IICINTM bit is 1, set the RIE bit to 0). Setting the TE and RE bits to 1 enables the SSCLn and SSDAn pin functions.
11	Start of transmission or reception	

30.8.5 Operation in Master Transmission in Simple IIC Mode

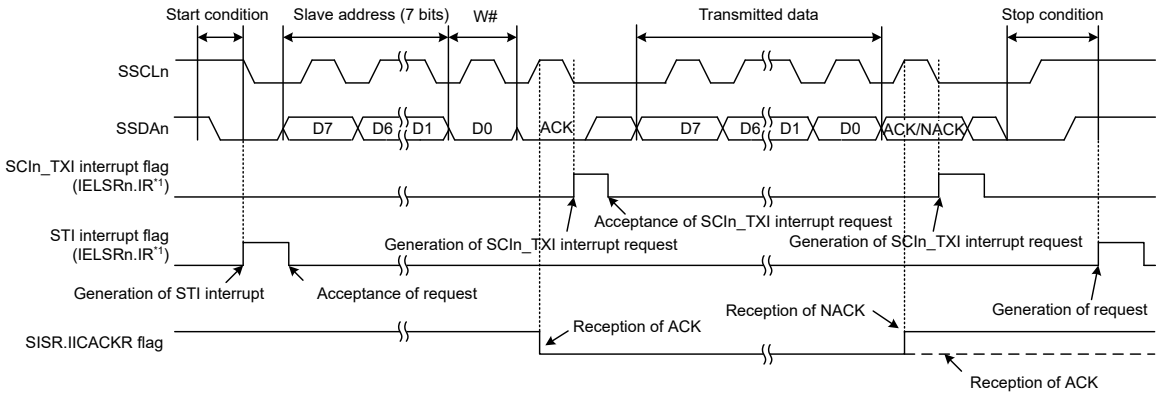
Figure 30.93 and Figure 30.94 show examples of master transmission and Figure 30.95 shows an example flow of data transmission.

Figure 30.93 shows the operation example when SIMR2.IICINTM bit is 1 (use reception and transmission interrupts) and the value of the SCR.RIE bit is assumed to be 0 (SCIn_RXI and SCIn_ERI interrupt requests are disabled).

See Table 30.45 for more information on the STI interrupt.

Figure 30.95 shows a flow chart in the case of SIMR2.IICINTM is 1 and address transmission by CPU and data transmission by DTC or DMAC. When 10-bit slave addresses are in use, steps [3] and [4] are repeated twice.

In simple IIC mode, the transmit data empty interrupt (SCIn_TXI) is generated when communication of one frame is complete, unlike the SCIn_TXI interrupt request generation timing during clock synchronous transmission.



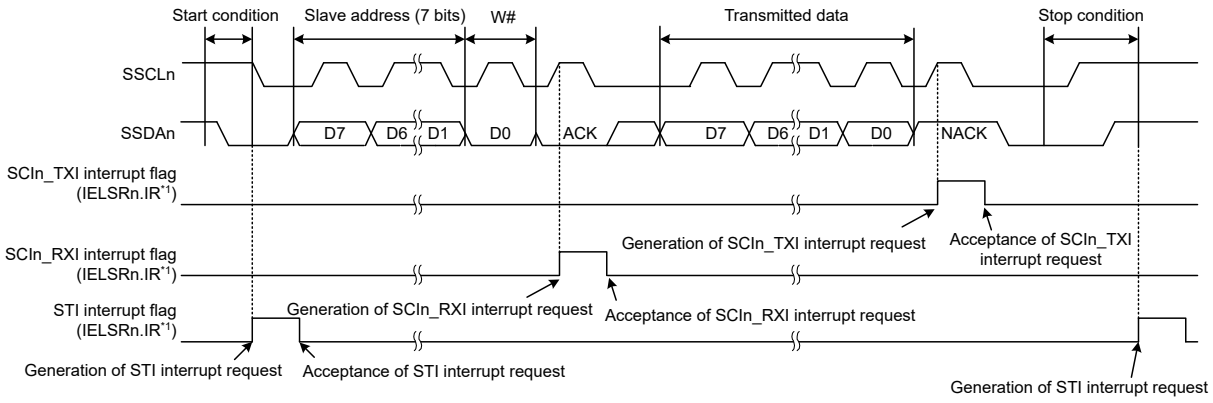
Note 1. See section 13, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 30.93 Example 1 of operations for master transmission in simple IIC mode with 7-bit slave addresses, transmission interrupts, and reception interrupts

When the SIMR2.IICINTM bit is set to 0 (use ACK/NACK interrupts) during master transmission, the DTC or DMAC is activated by the ACK interrupt as the trigger and required number of data bytes are transmitted. When the NACK is received, error processing such as transmission stop and retransmission is performed using the NACK interrupt as the trigger.

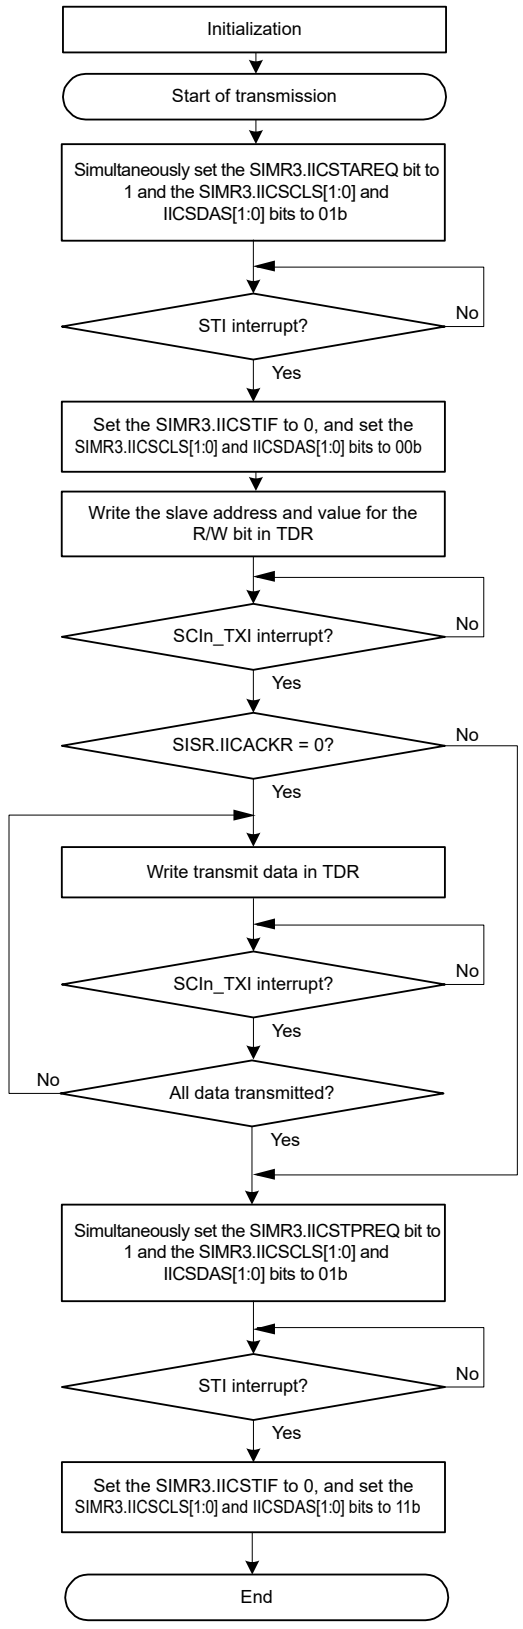
To restart communication for some reason after writing data in the TDR register, use the following procedure:

1. Set the TE and RE bits in the SCR register to 0 to stop communication.
2. Set 0xF0 in the SIMR3 register, release the I^2C bus, and clear the generation of a condition.
3. If the RDRF flag in the SSR register is set to 1, clear it.
4. Set the TE and RE bits in the SCR register to 1 and start the next communication.



Note 1. See section 13, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 30.94 Example 2 of operations for master transmission in simple IIC mode with 7-bit slave addresses, ACK interrupts, and NACK interrupts



[1] [1] Initialization in simple IIC mode:
For transmission, set the SCR.RIE to 0 to disable the SCIn_RXI and ERI interrupts.

[2] [2] Generate a start condition.

[3] [3] Writing to TDR:
Write the slave address and value for the R/W bit to TDR.

[4] [4] Confirming ACK response from the slave device:
Check the SISR.IICACKR bit. If SISR.IICACKR is 0, it indicates that the slave device responded with ACK and operations proceed. If SISR.IICACKR is 1, it indicates that there was no response from the slave device so the next transition is to generate a stop condition.

If 10-bit slave addresses are in use, processing of [3] and [4] is repeated twice.

[5] [5] Continuing with serial transmission:
When transmission is to continue, write additional transmit data to TDR. Except for the first data to be transmitted, a SCIn_TXI interrupt request can activate the DMAC or DTC to handle writing of data to TDR. But it cannot be confirmed status of ACK or NACK.

[6] [6] Generate a stop condition.

Note: In simple IIC mode, the SCIn_TXI interrupt is generated when communication completes.

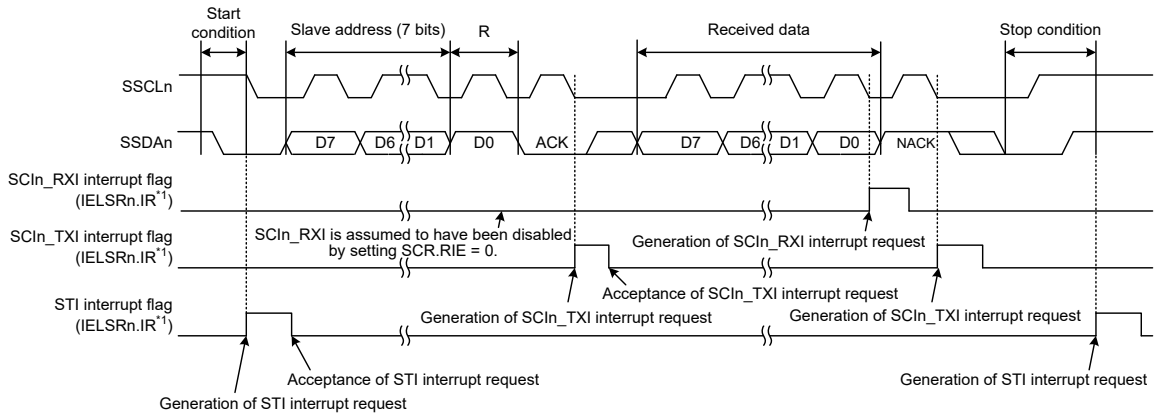
Figure 30.95 Example flow of master transmission in simple IIC mode with transmission interrupts and reception interrupts

30.8.6 Master Reception in Simple IIC Mode

Figure 30.96 shows an example operation in simple IIC mode master reception and Figure 30.97 shows an example flow of master reception.

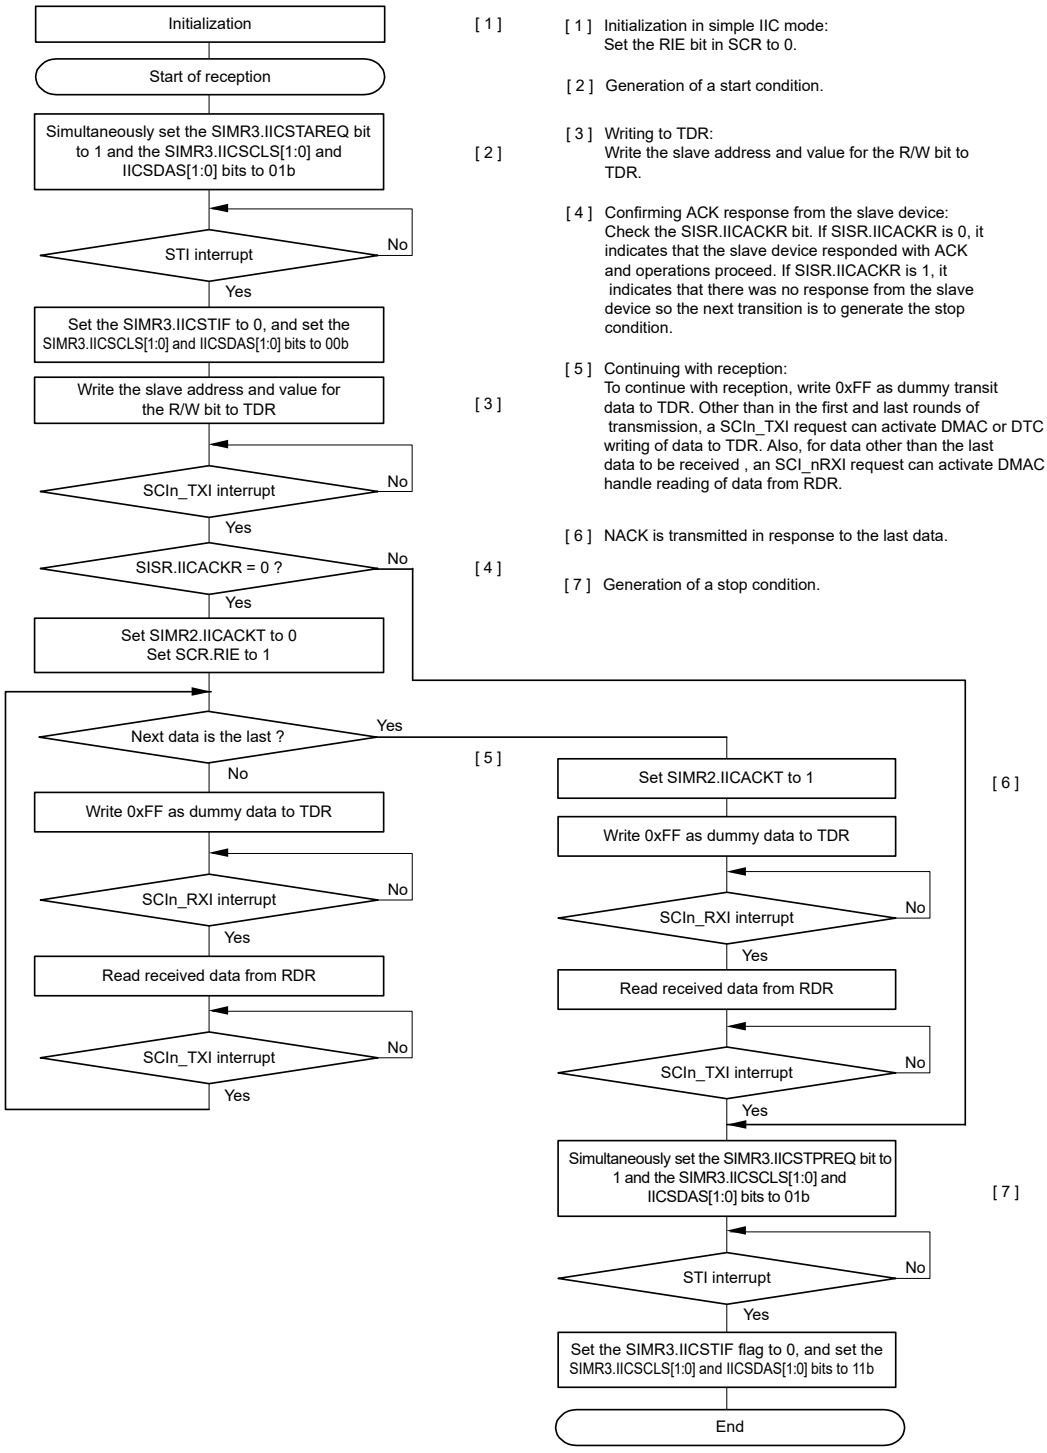
The value of the SIMR2.IICINTM bit is assumed to be 1 (use reception and transmission interrupts).

In simple IIC mode, the transmit data empty interrupt (SCIn_TXI) is generated when communication of one frame is complete, unlike the SCIn_TXI interrupt request generation timing during clock synchronous transmission.



Note 1. See section 13, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 30.96 Example operations for master reception in simple IIC mode with 7-bit slave addresses, transmission interrupts, and reception interrupts



Note: In simple IIC mode, the SCIn_TXI interrupt request is generated when communication is complete.

Figure 30.97 Example flow of master reception in simple IIC mode with transmission interrupts and reception interrupts

30.9 Operation in Simple SPI Mode

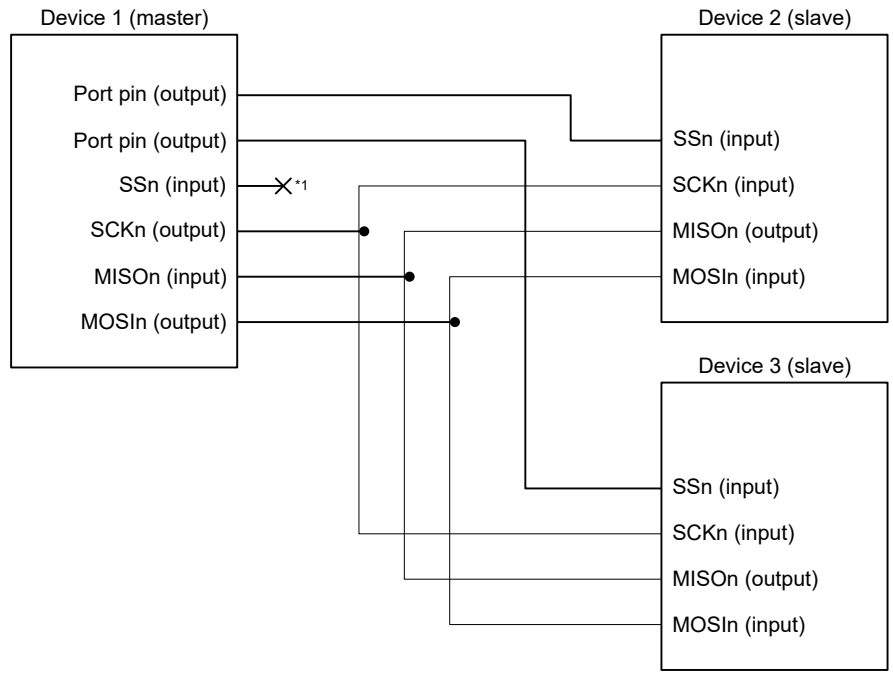
As an extended function, the SCI supports a simple SPI mode that handles transfer among one or multiple master devices and multiple slave devices.

Using the settings for clock synchronous mode (SCMR.SMIF = 0, SIMR1.IICM = 0, SMR.CM = 1) and setting the SPMR.SSE bit to 1 place the SCI in simple SPI mode. However, the SSn pin function on the master side is not required for connection of the device used as the master in simple SPI mode when the configuration only has a single master. Therefore, set the SPMR.SSE bit to 0 in such cases.

Figure 30.98 shows an example of connections for simple SPI mode. Control a general port pin to produce the SSn output signal from the master.

In simple SPI mode, data is transferred in synchronization with clock pulses in the same way as in clock synchronous mode. One character of data for transfer consists of 8 bits of data, and parity bits cannot be appended. The data can be inverted by setting the SCMR.SINV bit to 1.

Because the receiver and transmitter are independent of each other within the SCI module, full-duplex communications are possible, with a shared clock signal. Additionally, because both the transmitter and receiver have a buffered structure, writing the next transmit data while transmission is in progress and reading previously received data while reception is in progress are both possible. This enables continuous transfer.



Note 1. The SSn pin input is not required in a single-master system (the interface is used with the setting SPMR.SSE = 0).

Figure 30.98 Example connections using simple SPI mode in single master mode with SPMR.SSE bit = 0

30.9.1 States of Pins in Master and Slave Modes

The direction (input or output) of pins for the simple SPI mode interface differs according to whether the device is a master (SCR.CKE[1:0] = 00b or 01b and SPMR.MSS = 0) or slave (SCR.CKE[1:0] = 10b or 11b and SPMR.MSS = 1).

Table 30.41 lists the relationship between the pin states, mode, and level on the SSn pin.

Table 30.41 States of pins by mode and input level on SSn pin (1 of 2)

Mode	Input on SSn pin	State of MOSIn pin	State of MISOn pin	State of SCKn pin
Master mode*1	High level (transfer can proceed)	Output for data transmission*2	Input for received data	Clock output*3
	Low level (transfer cannot proceed)	High-impedance	Input for received data (but disabled)	High-impedance

Table 30.41 States of pins by mode and input level on SSn pin (2 of 2)

Mode	Input on SSn pin	State of MOSIn pin	State of MISOn pin	State of SCKn pin
Slave mode	High level (transfer cannot proceed)	Input for received data (but disabled)	High-impedance	Clock input (but disabled)
	Low level (transfer can proceed)	Input for received data	Output for data transmission	Clock input

Note 1. When there is only a single master (SPMR.SSE = 0), transfer is possible regardless of the input level on the SSn pin. This is equivalent to input of a high level on the SSn pin.
Note 2. The MOSIn pin output is in the high-impedance state when serial transmission is disabled (SCR.TE bit = 0).
Note 3. The SCKn pin output is in the high-impedance state when serial transmission is disabled (SCR.TE = 0 and SCR.RE = 0) in a multi-master configuration (SPMR.SSE = 1).

30.9.2 SS Function in Master Mode

Setting the CKE[1:0] bits in the SCR to 00b or 01b and the MSS bit in the SPMR to 0 selects master mode operation. The SSn pin is not used in single-master configurations (SPMR.SSE = 0), so transmission or reception can proceed regardless of the value of the SSn pin.

When the level on the SSn pin is high in a multi-master configuration (SPMR.SSE = 1), a master device outputs clock signals from the SCKn pin before starting transmission or reception to indicate that there are no other masters or another master is performing reception or transmission.

When the level on the SSn pin is low in a multi-master configuration (SPMR.SSE = 1), there are other masters, and a transmission or reception is in progress. The MOSIn output and SCKn pins are placed in the high-impedance state and starting transmission or reception is not possible. In addition, the value of the SPMR.MFF bit is 1, indicating a mode fault error. In a multi-master configuration, start error processing by reading SPMR.MFF flag. If a mode fault error occurs while transmission or reception is in progress, transmission or reception does not stop, but the MOSIn and SCKn outputs are in the high-impedance state after completion of the transfer.

Use a general port pin to produce the SS output signal from the master.

30.9.3 SS Function in Slave Mode

Setting the SCR.CKE[1:0] bits to 10b or 11b and the SPMR.MSS bit to 1 selects slave operation. When the SSn pin is high, the MISOn output pin is in the high-impedance state and clock input through the SCKn pin is ignored. When the SSn pin is low, clock input through the SCKn pin is valid and transmission or reception can proceed.

If the input on the SSn pin changes from low to high during transmission or reception, the MISOn output pin is placed in the high-impedance state. Meanwhile, the internal processing for transmission or reception continues at the rate of the clock input through the SCKn pin until processing for the character being transmitted or received is complete, after which it stops, and the appropriate interrupt (SCIn_TXI, SCIn_RXI, or SCIn_TEI) is generated.

30.9.4 Relationship between Clock and Transmit/Receive Data

The CKPOL and CKPH bits in the SPMR register can be used to set up the clock for use in transmission and reception in four different ways. The relation between the clock signal and the transmission and reception of data is shown in Figure 30.99. The relation is the same for both master and slave operation. This is the same as when the level on the SSn pin is high.

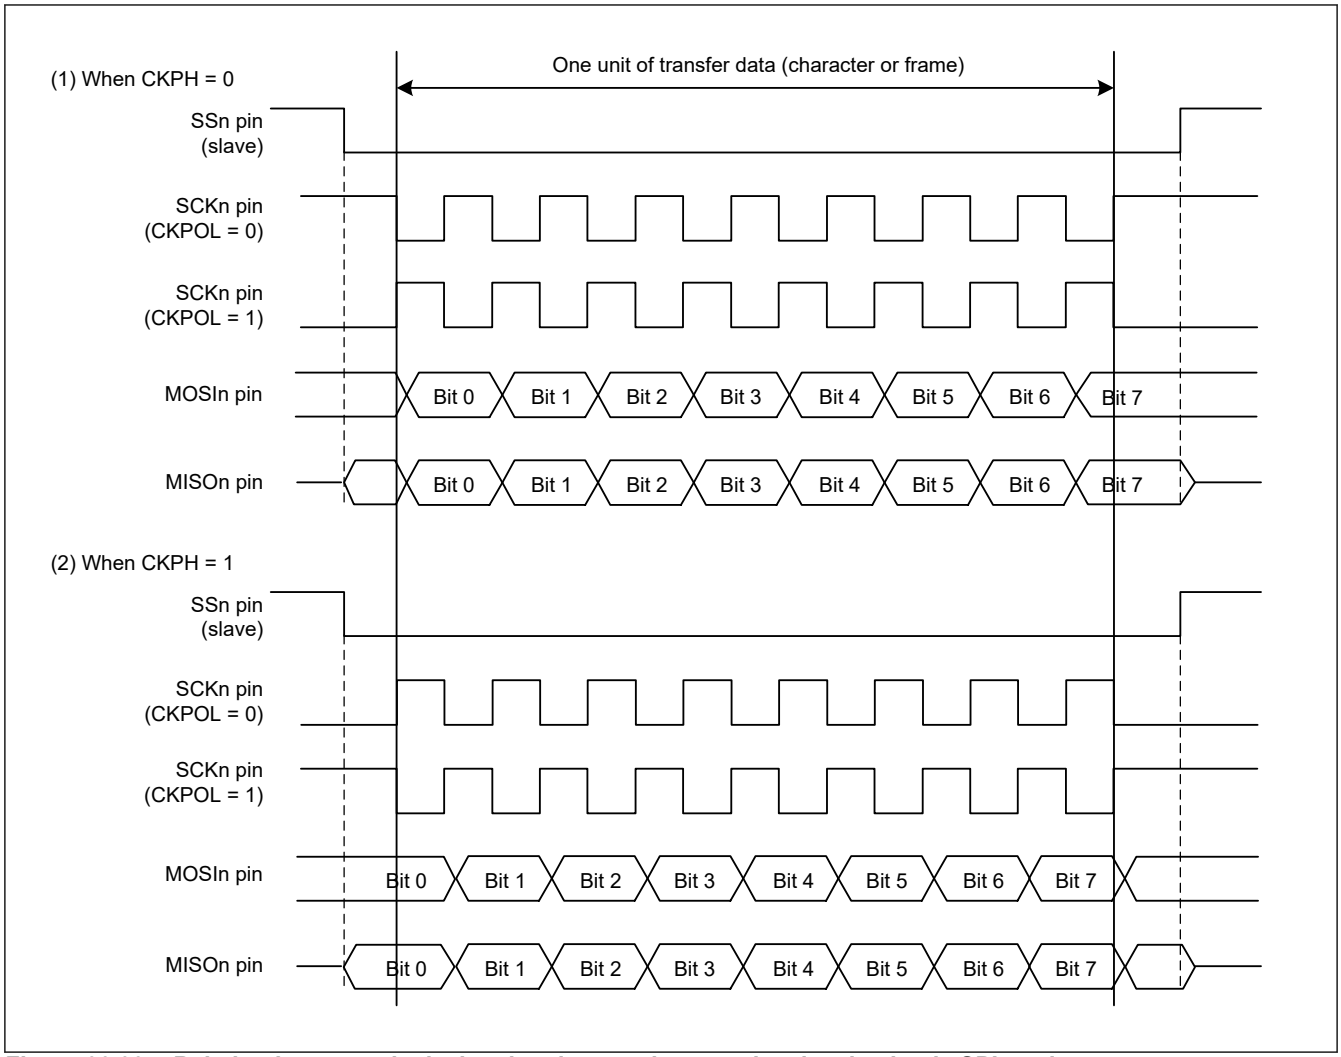


Figure 30.99 Relation between clock signal and transmit or receive data in simple SPI mode

30.9.5 SCI Initialization in Simple SPI Mode

Initialization in simple SPI mode is the same as in clock synchronous mode. See section 30.6.3. SCI Initialization in Clock Synchronous Mode for an example initialization flow. The CKPOL and CKPH bits in the SPMR register must be set to ensure that the clock signal is suitable for both master and slave devices.

Always initialize the SCR register before making any changes to the operating mode or transfer format.

Note: Only the RE bit is set to 0. The SSR.ORER, FER, PER, and RDR flags are not initialized.

Changing the value of the TE bit from 1 to 0 or from 0 to 1 when the TIE bit in the SCR register is 1 at the same time, leads to the generation of a transmit data empty interrupt (SCIn_TXI).

30.9.6 Transmission and Reception of Serial Data in Simple SPI Mode

In master operation, ensure that the SSn pin of the slave device on the other side of the transfer is at the low level before starting the transfer and at the high level on completion of the transfer. Otherwise, the procedures are the same as in clock synchronous mode.

30.10 Bit Rate Modulation Function

Using the bit rate modulation function, the bit rate can be evenly corrected using the number specified in the MDDR register among 256 clock cycles of internal clocks which is selected by the CKS[1:0] bits in SMR/SMR_SMCI.

Figure 30.100 shows an example where the PCLK is selected in the CKS[1:0] bits in SMR/SMR_SMCI, the BRR bit is set to 0, and the MDDR is set to 160 in asynchronous mode. In this example, the cycle of the base clock is evenly corrected (256/160) and the bit rate is also corrected (160/256).

Note: Enabling an internal clock causes bias, and expansion and contraction are generated in the pulse width of the internal base clock.

Do not use this function in clock synchronous mode and in the highest speed settings in simple SPI mode (SMR.CKS[1:0] = 00b, SCR.CKE[1] = 0, and BRR = 0).

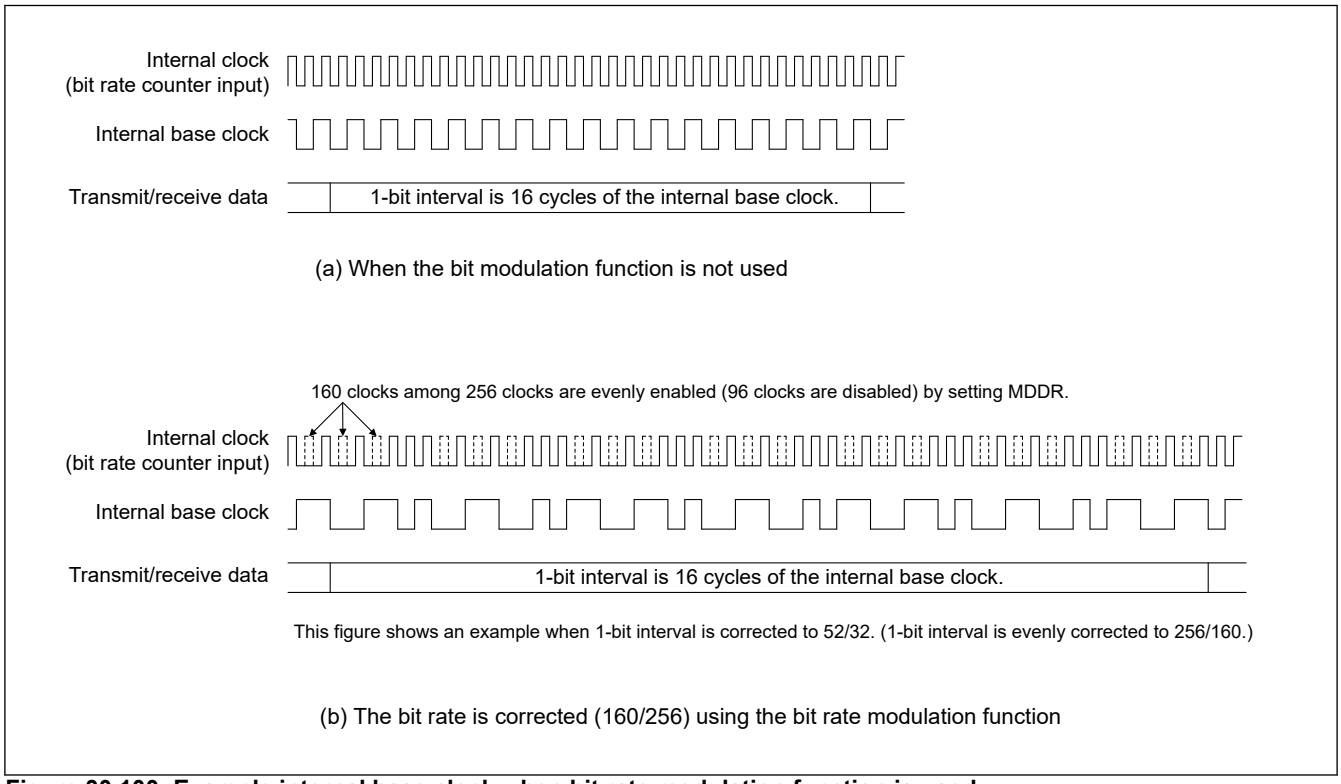

Figure 30.100 Example internal base clock when bit rate modulation function is used

30.11 Extended Serial Mode Control Section: Description of Operation

30.11.1 Serial Transfer Protocol

In conjunction with the SCIg module, the extended serial mode control section of the SCIh module can realize the serial transfer protocol composed of Start Frames and Information Frames that is shown in Figure 30.101.

A Start Frame is composed of a Break Field, Control Field 0, and Control Field 1. An Information Frame is composed of a number of Data Fields, a CRC16 Upper Field, and a CRC16 Lower Field.

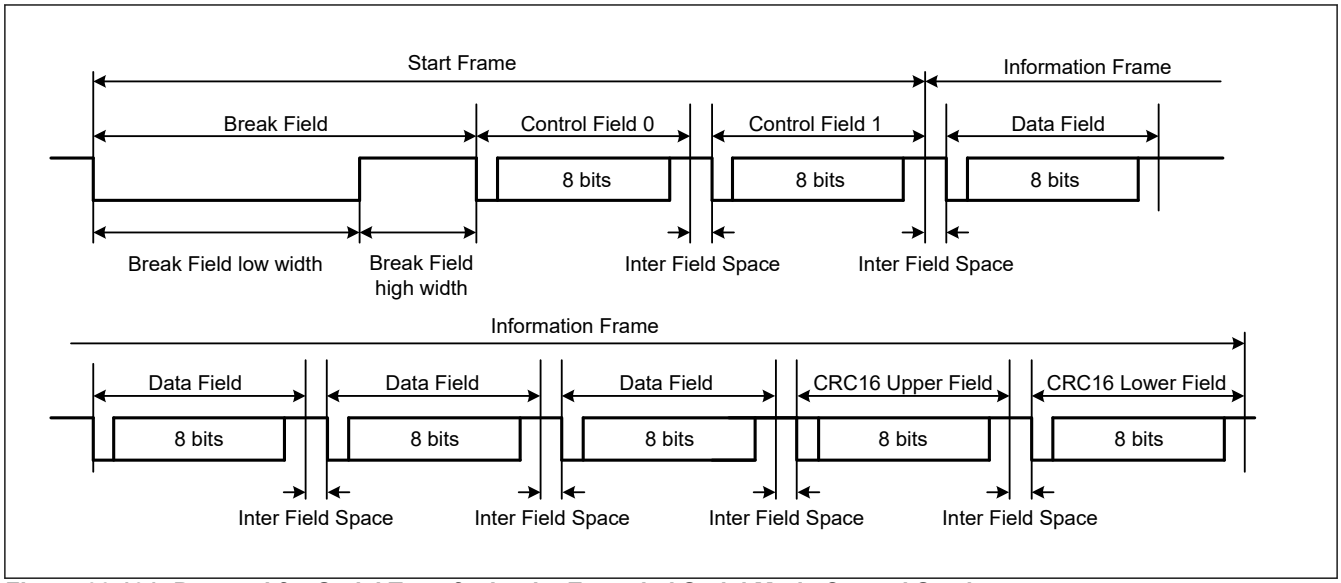

Figure 30.101 Protocol for Serial Transfer by the Extended Serial Mode Control Section

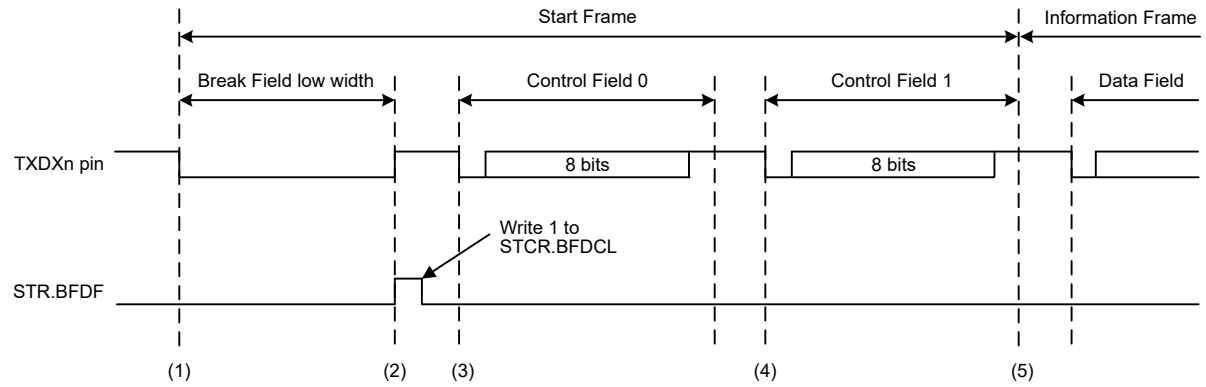
30.11.2 Transmitting a Start Frame

Figure 30.102 shows an example of operations to transmit a Start Frame, which is composed of the Break Field low width, Control Field 0, and Control Field 1. Figure 30.103 and Figure 30.104 are flowcharts for the transmission of a Start Frame.

Operations when the extended serial mode control section is to be used to transmit a Start Frame are as listed below. Be sure to use the SCIn (n = 1, 2) in asynchronous mode.

1. With Break Field low width output mode as the operating mode for the timer, writing 1 to the TCR.TCST bit starts counting by the timer, and the low level will be output from the TXDXn (n = 1, 2) pin over the period corresponding to registers TCNT and TPRE settings.
2. The output on the TXDXn pin is inverted when the timer counter underflows, and the STR.BFDF flag is set to 1. An SCIX0 interrupt is also generated if the value of the ICR.BFDIE bit is 1.
3. Write 0 to the TCR.TCST bit to stop counting by the timer, and send the data for Control Field 0 by using SCIn. After the Break Field low width output, stop counting before the next underflow occurs.
4. When the data for Control Field 0 have been transmitted, send the data for Control Field 1.
5. When the data for Control Field 1 have been transmitted, send an Information Frame.

Omit the Break Field and Control Field 0 to suit the structure of the Start Frame.



The above diagram assumes the following:

ESMER: ESME = 1
PCR: TXDXPS = 0
ICR: BFDIE = 1
TMR: TOMS[1:0] = 10b

Note: n = 1, 2

Figure 30.102 Example of Operations When Transmitting a Start Frame

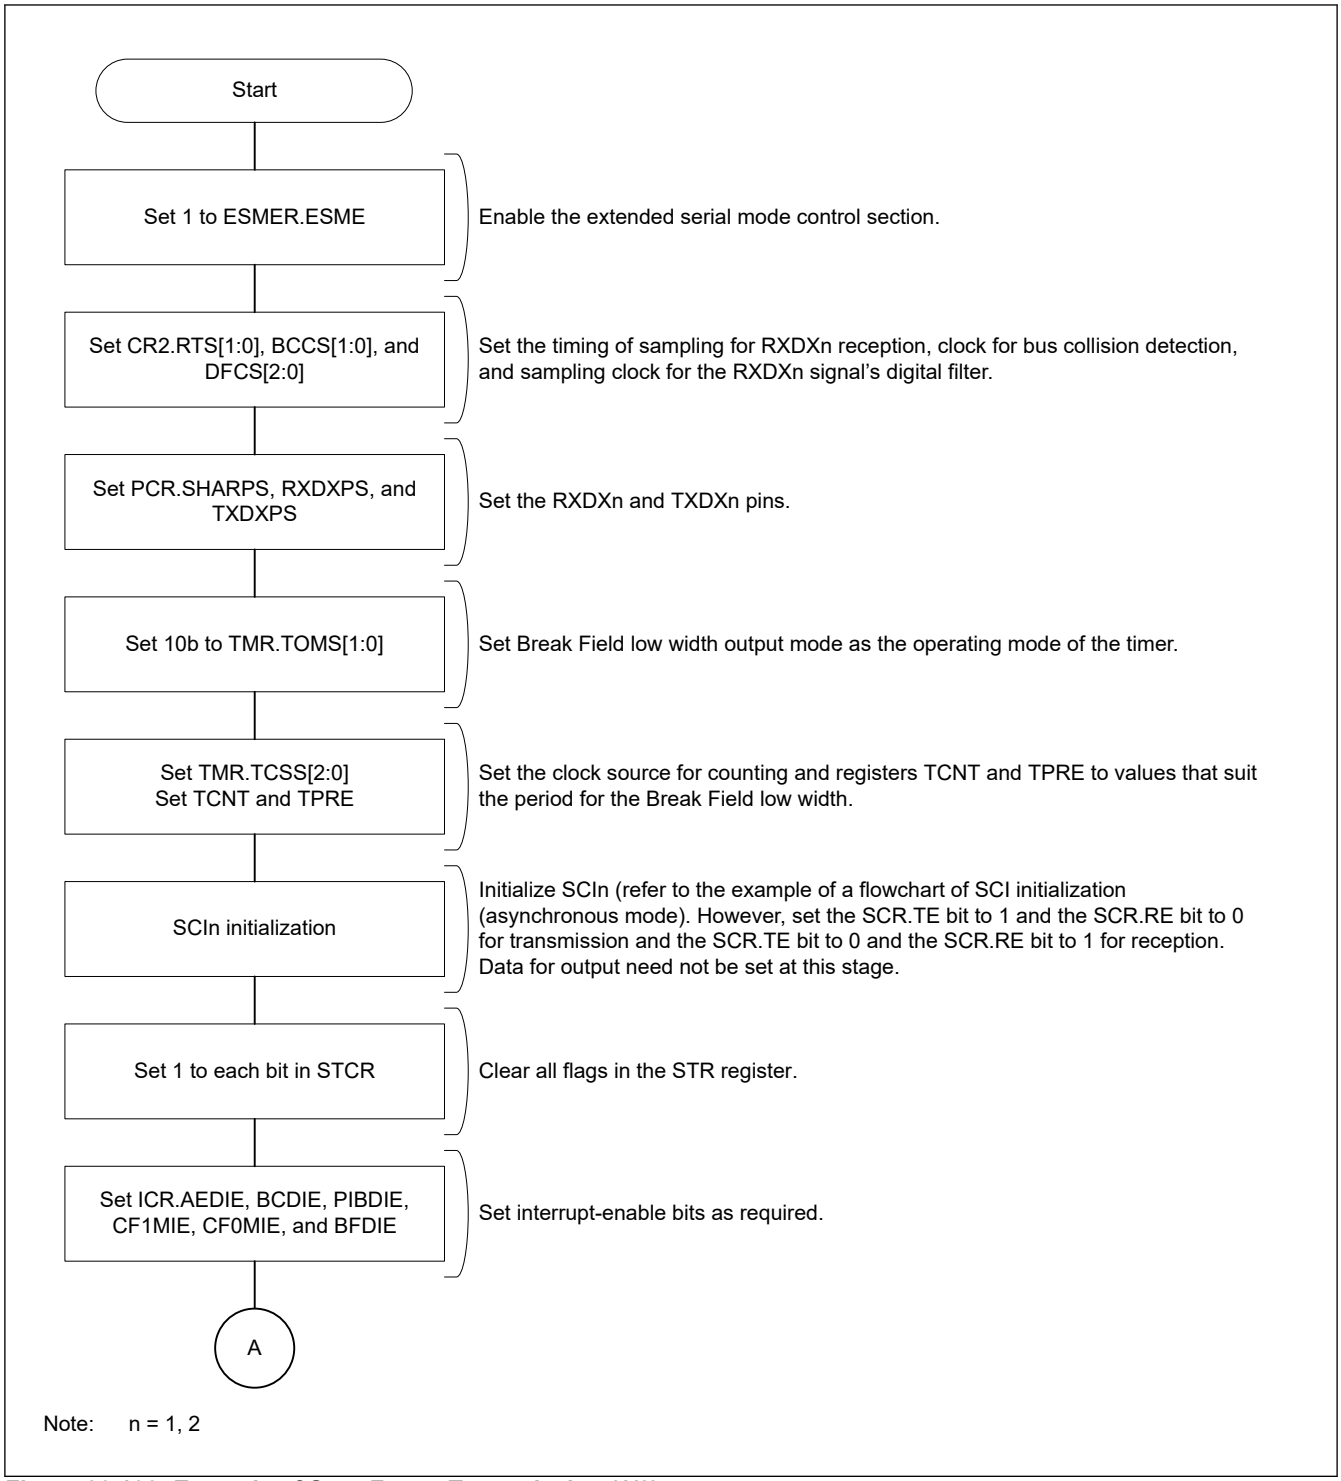


Figure 30.103 Example of Start Frame Transmission (1/2)

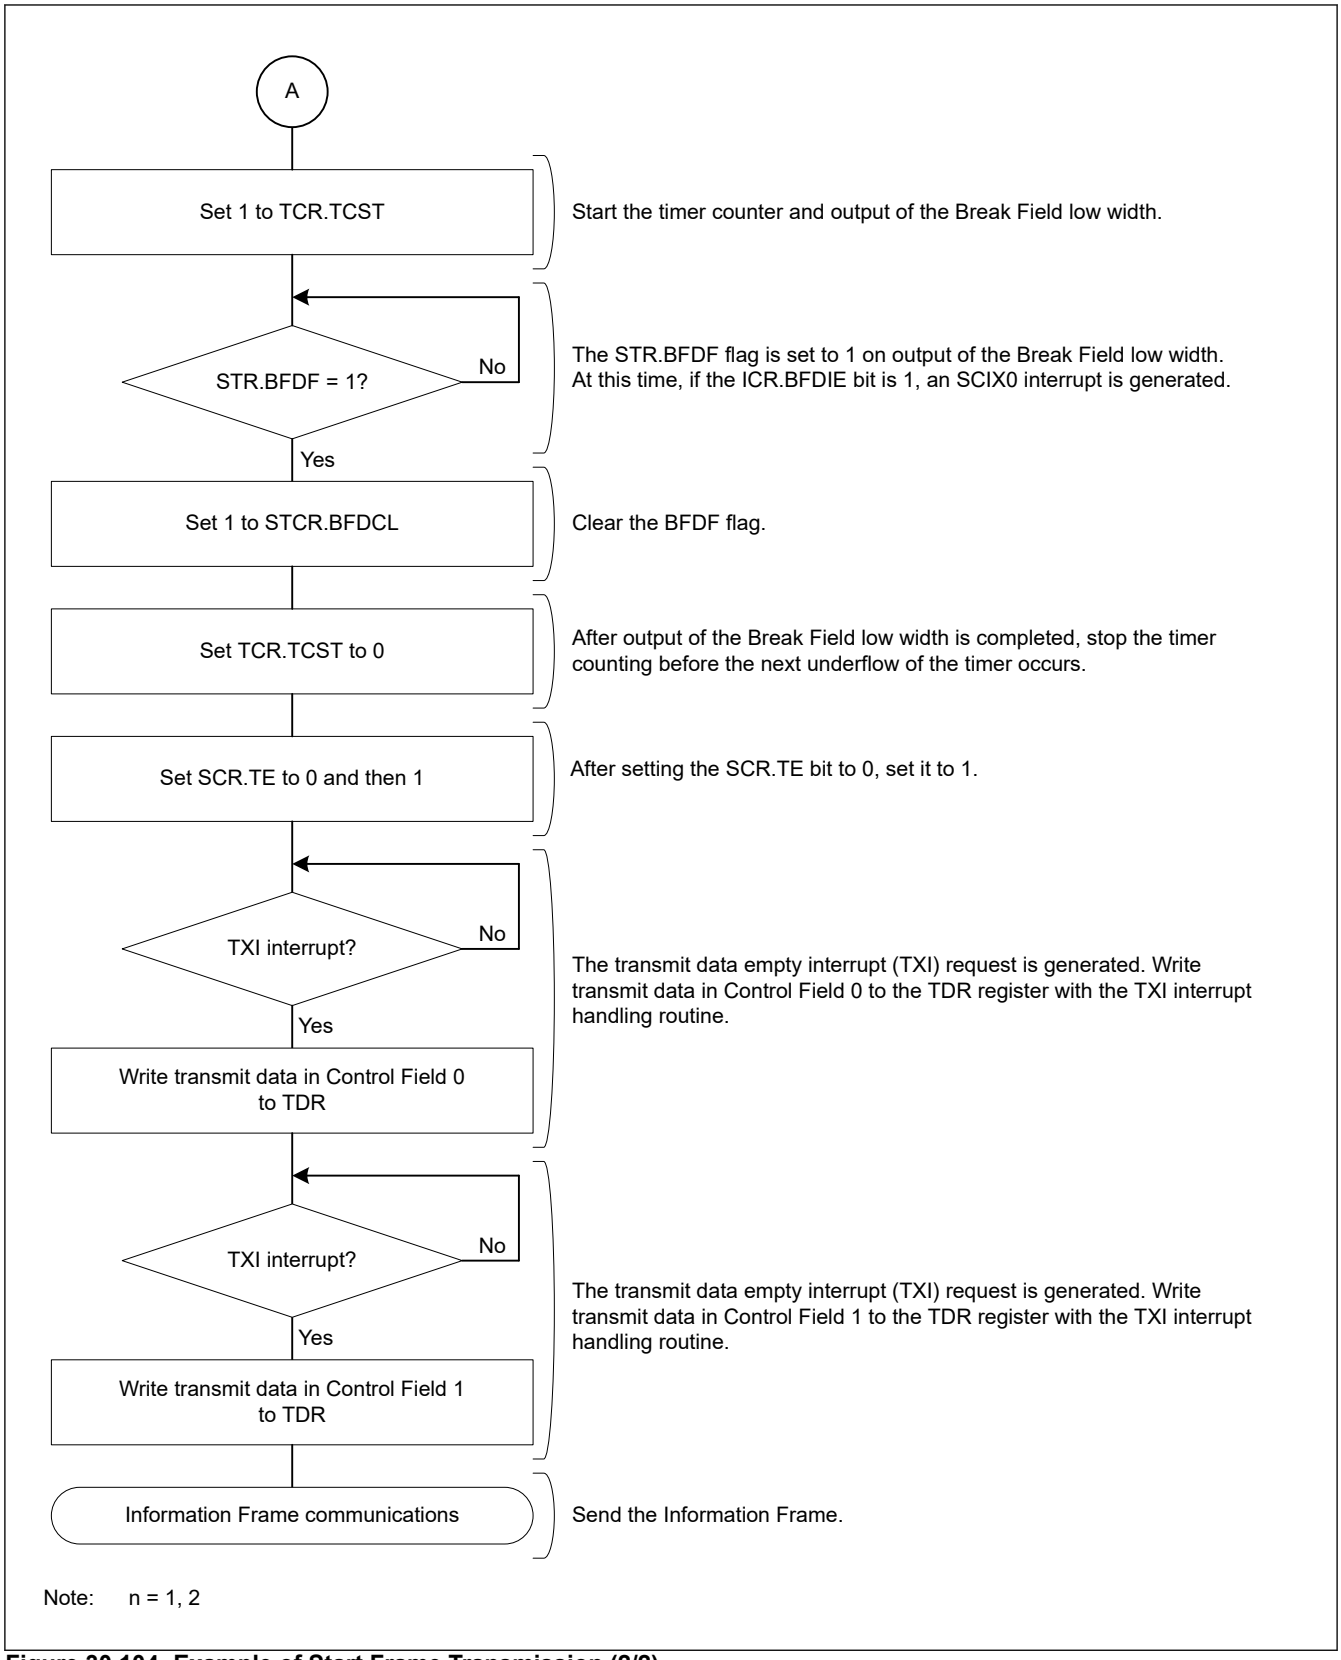

Figure 30.104 Example of Start Frame Transmission (2/2)

30.11.3 Receiving a Start Frame

The extended serial mode control section is capable of receiving Start Frames with the structures listed in Figure 30.105.

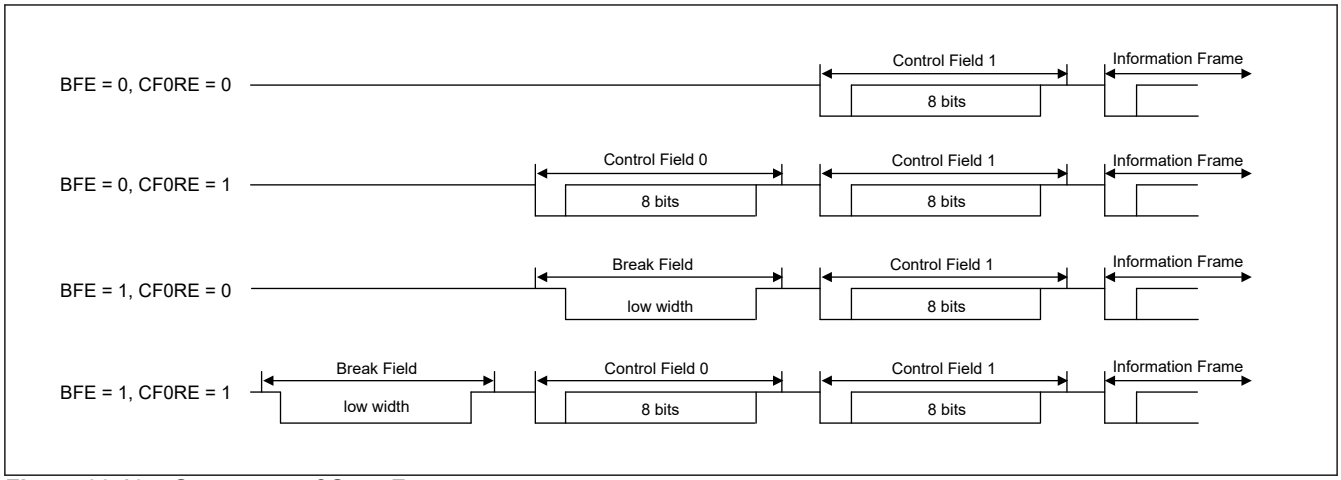

Figure 30.105 Structures of Start Frames

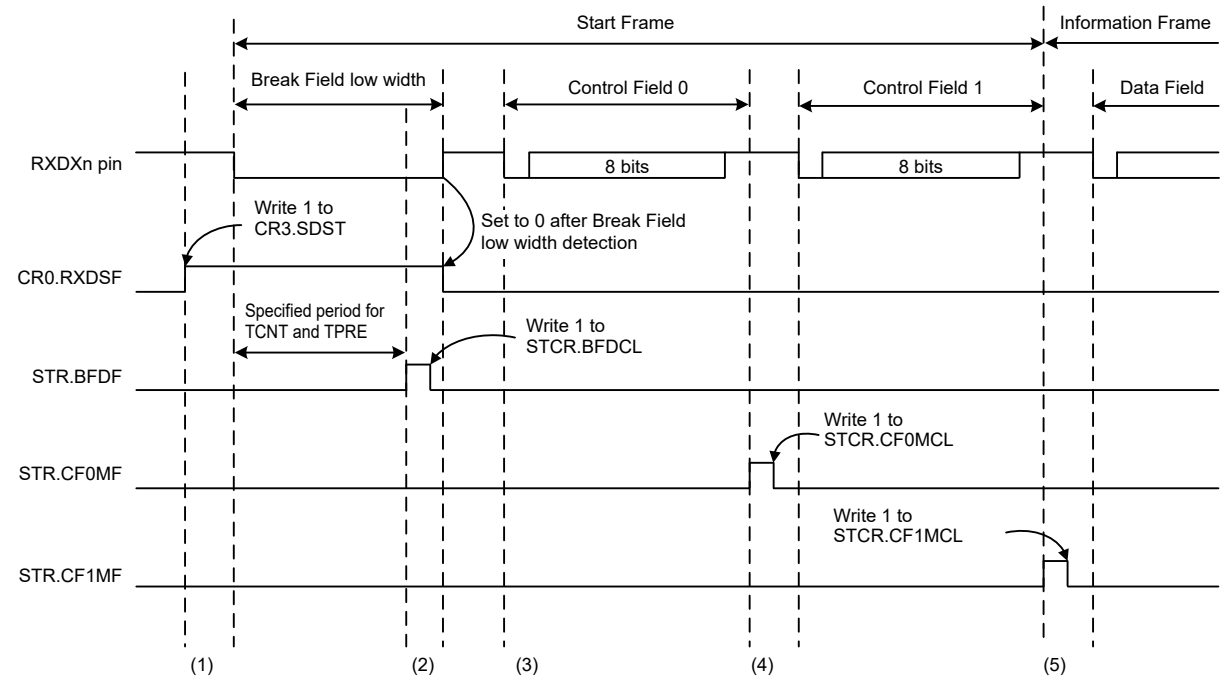
Figure 30.106 shows an example of operations to receive a Start Frame, which is composed of the Break Field low width, Control Field 0, and Control Field 1. Figure 30.107 and Figure 30.108 are flowcharts for the reception of a Start Frame, and Figure 30.109 is a state transition diagram for the extended serial mode control section.

Operations when the extended serial mode control section is to be used to receive a Start Frame are as listed below. Be sure to use the SCIn (n = 1, 2) in asynchronous mode.

1. With Break Field low width detection mode as the operating mode for the timer, writing 1 to the CR3.SDST bit enables detection of the Break Field low width. RXDXn input to the SCIn is disabled at this time.
2. Low-level input on the RXDXn pin continuing over a period longer than that corresponding to the settings of registers TCNT and TPRE is detected as the Break Field low width. At this time, the STR.BFDF flag is set to 1. An SCIX0 interrupt is also generated if the value of the ICR.BFDIE bit is 1.
3. When the input from the RXDXn pin goes high after the Break Field low width, the CR0.RXDSF flag becomes 0 and reception of Control Field 0 by the SCIn starts.
4. If the data received in Control Field 0 match the data set in the CF0DR register, the STR.CF0MF flag is set to 1. An SCIX1 interrupt is also generated if the value of the ICR.CF0MIE bit is 1. Reception of Control Field 1 by the SCIn starts after that. If the data received in Control Field 0 do not match the data set in the CF0DR register, a transition to the state prior to Break Field low width detection proceeds.
5. If the data received in Control Field 1 match the data set in registers PCF1DR and SCF1DR, the STR.CF1MF flag is set to 1. An SCIX1 interrupt is also generated if the value of the ICR.CF1MIE bit is 1. Transfer of the Information Frame by the SCIn starts after that. If the data received in Control Field 1 do not match the data set in either or both of registers PCF1DR and SCF1DR, a transition to the state prior to Break Field low width detection proceeds.

Omit the Break Field and Control Field 0 to suit the structure of the Start Frame.



The above diagram assumes the following:

ESMER: ESME = 1

CR1: BFE = 1, CF0RE = 1, CF1DS[1:0] = 10b

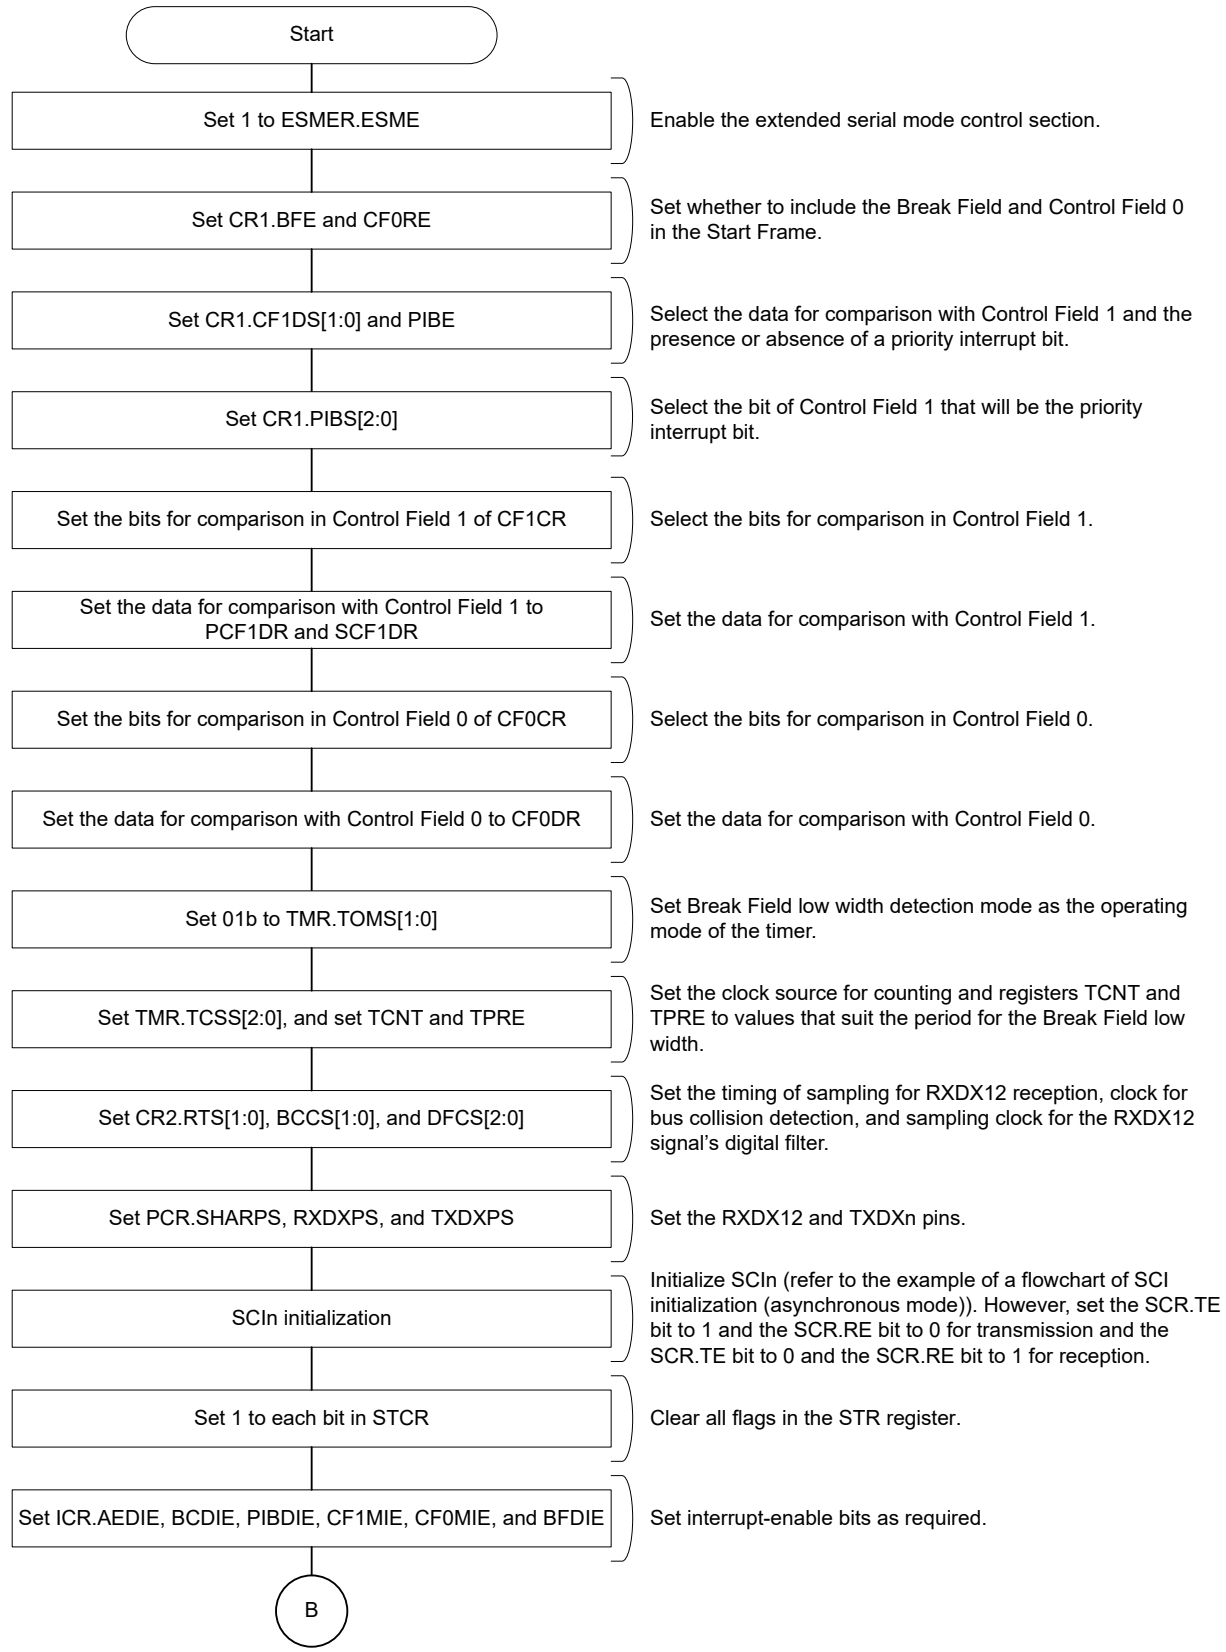
PCR: RXDXPS = 0

ICR: BFDIE = 1, CF0MIE = 1, CF1MIE = 1

TMR: TOMS[1:0] = 01b

Note: n = 1, 2

Figure 30.106 Example of Operations at the Time of Start Frame Reception



Note: n = 1, 2

Figure 30.107 Sample Flowchart for Reception of a Start Frame (1)

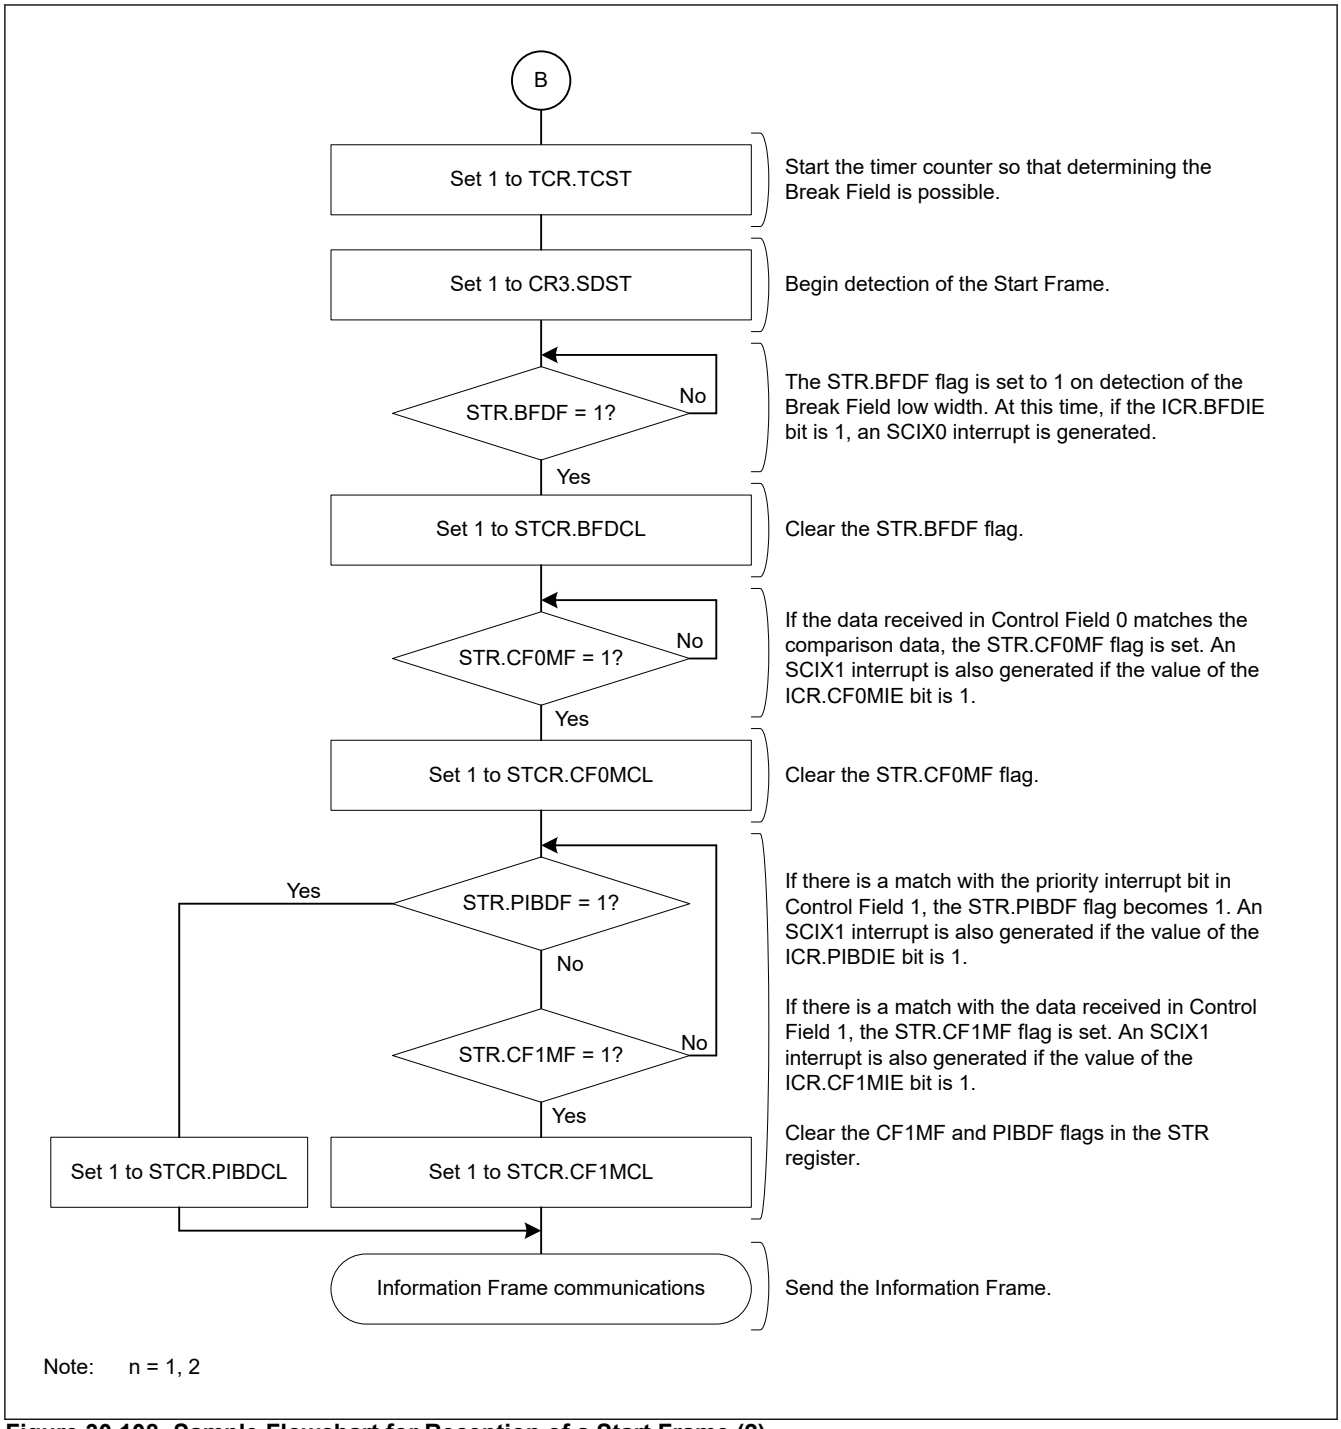


Figure 30.108 Sample Flowchart for Reception of a Start Frame (2)

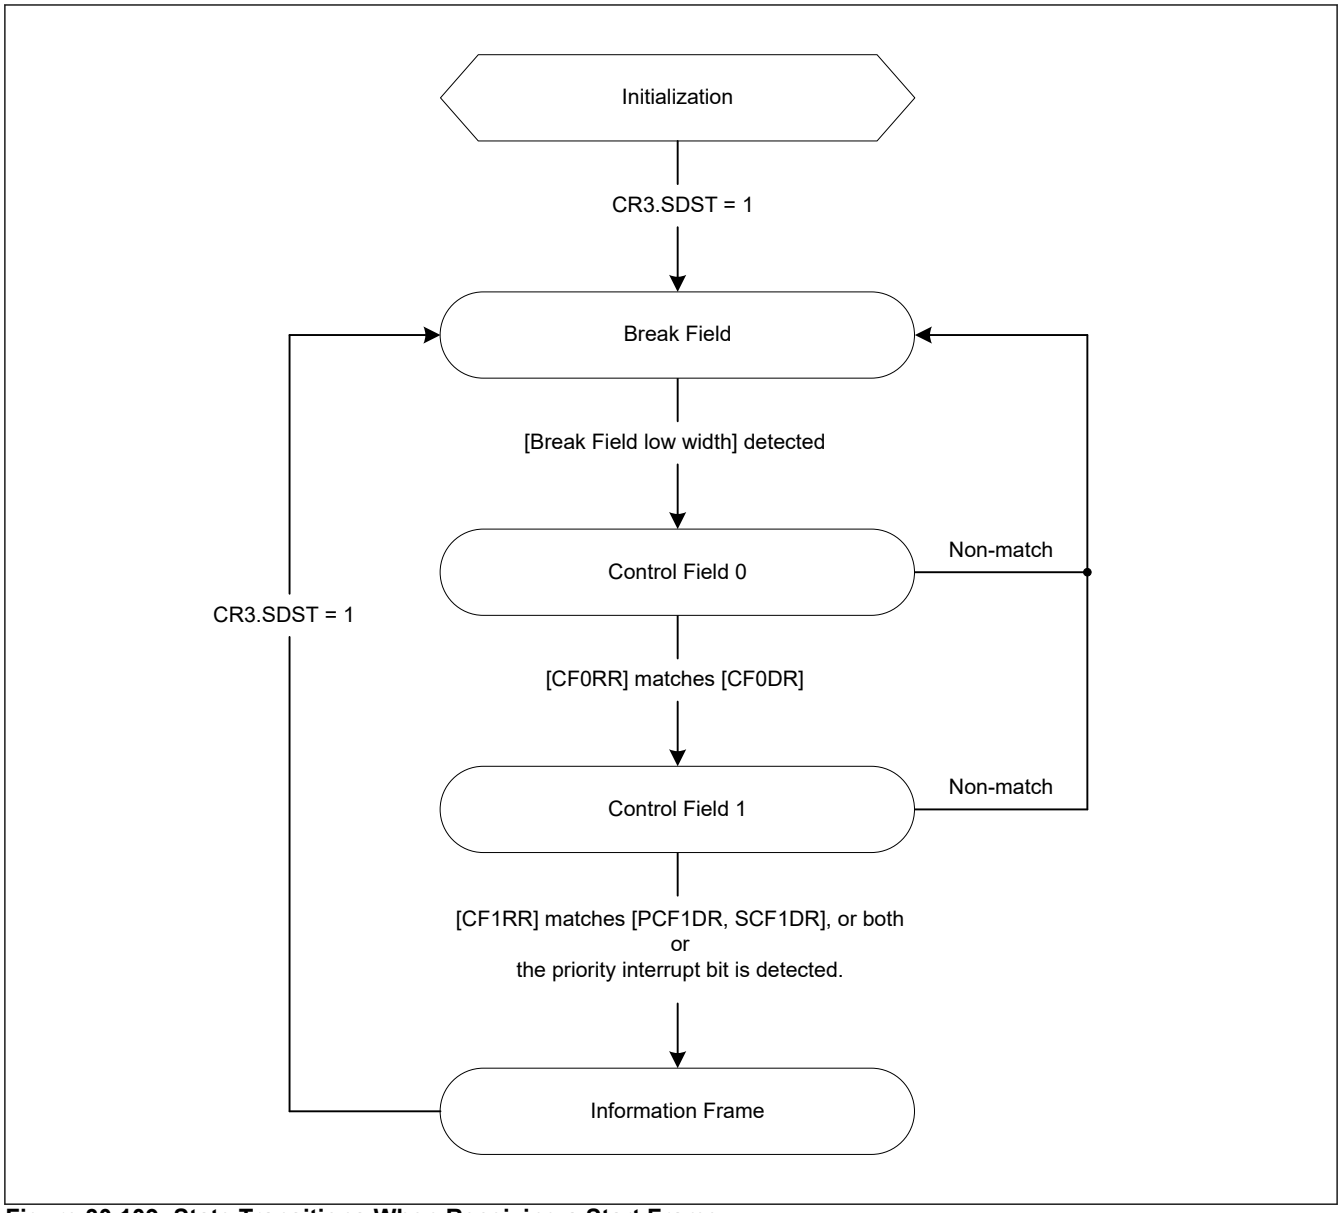

Figure 30.109 State Transitions When Receiving a Start Frame

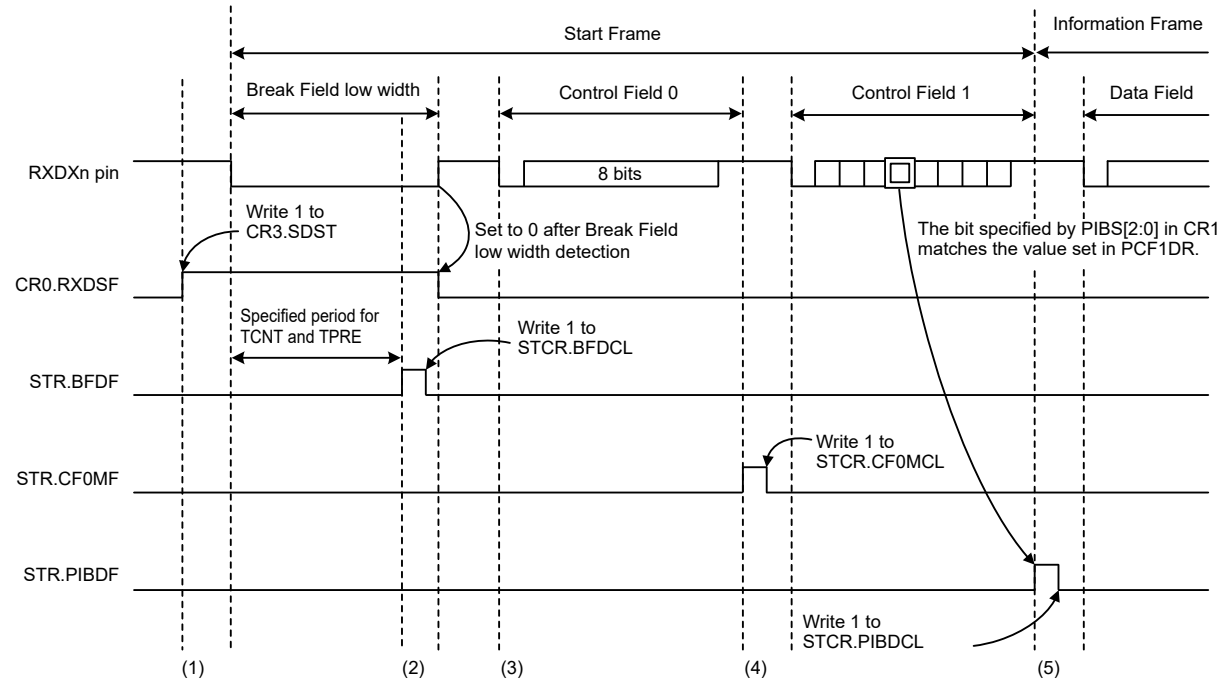
30.11.3.1 Priority Interrupt Bit

Figure 30.110 shows an example of operation in Start Frame reception where a priority interrupt bit is in use. Setting the CR1.PIBE bit to 1 enables the use of a priority interrupt bit.

Operations of the extended serial mode control section in start Frame reception where a priority interrupt bit is in use are as described below.

Steps (1) to (4) are the same as in Figure 30.106, for Start Frame reception.

(5) If the value of the bit selected by the CR1.PIBS[2:0] bits matches the corresponding bit in the PCF1DR register, the STR.PIBDF flag is set to 1. An SCIX1 interrupt is also generated if the value of the ICR.PIBDIE bit is 1. Transfer of the Information Frame by the SCIn (n = 1, 2) starts after that. If the data received in Control Field 1 do not match the data set in either or both of registers PCF1DR and SCF1DR and the priority interrupt bit is not detected, a transition to the state prior to Break Field low width detection proceeds.



The above diagram assumes the following:

ESMER: ESME = 1

CR1: BFE = 1, PIBE = 1, CF0RE = 0, CF1DS[1:0] = 10b, PIBS[2:0] = 011b

PCR: RXDXPS = 0

ICR: BFDIE = 1, CF0MIE = 1, PIBDIE = 1

TMR: TOMS[1:0] = 01b

Note: n = 1, 2

Figure 30.110 Example of Operations When Receiving a Start Frame While the CR1.PIBE Bit is 1

30.11.4 Detection of Bus Collisions

Detection of bus collisions operate for cases where output of the Break Field low width and transmission of data by the SCIn (n = 1, 2) are in progress when the ESMER.ESME bit and the SCIn.SCI.TE bit are set to 1.

Figure 30.111 shows an example of operations with bus collision detection. Signals output through TXDXn and input through RXDXn are sampled with the bus collision detection clock set with the CR2.BCCS[1:0] bits as the sampling clock, and the STR.BCDF flag is set to 1 if the signals fail to match three times in a row. An SCIX2 interrupt is also generated if the value of the ICR.BCDIE bit is 1.

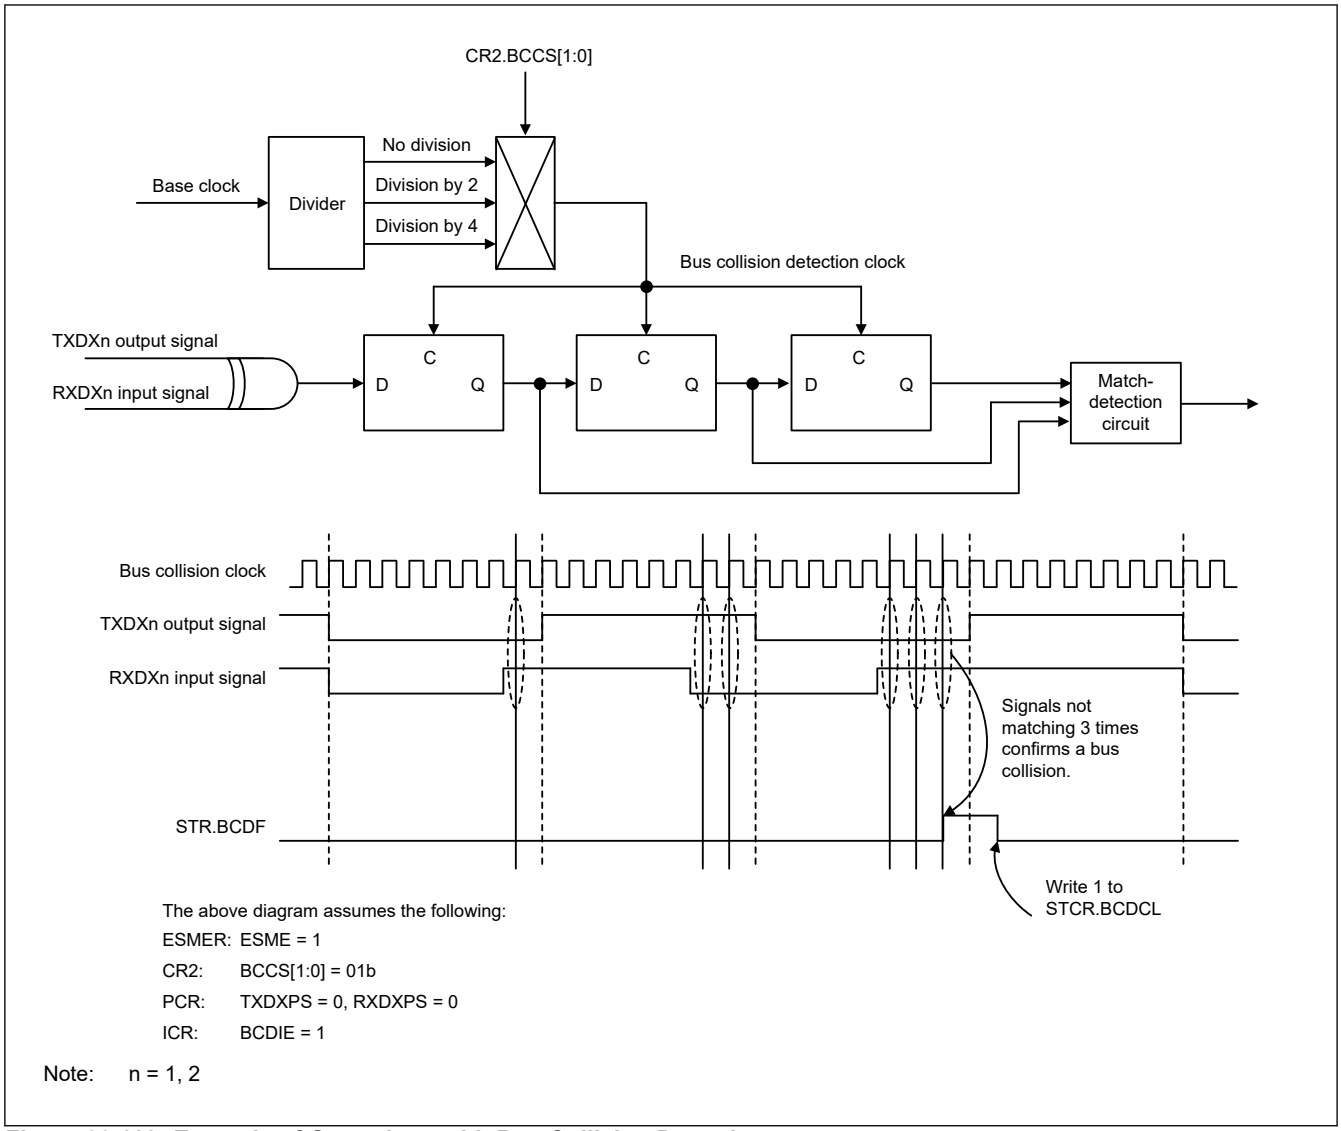


Figure 30.111 Example of Operations with Bus Collision Detection

30.11.5 Digital Filter for Input on the RXDXn (n = 1, 2) Pin

Signals input through the RXDXn pin can be passed through a digital filter before they are conveyed to the internal circuits. The digital filter consists of three flip-flop circuit stages connected in series and a match-detecting circuit. The CR2.DFCS[2:0] bits select the sampling clock for the RXDXn pin input signals. If the outputs of all three latches match, the given level is conveyed to subsequent circuits. If the levels do not match, the previous value is retained. In other words, levels are confirmed as being the signal if they are retained for at least three cycles of the sampling clock but judged to be noise rather than changes in the signal level if they change within three cycles of the sampling clock. Figure 30.112 shows an example of operations with the digital filter.

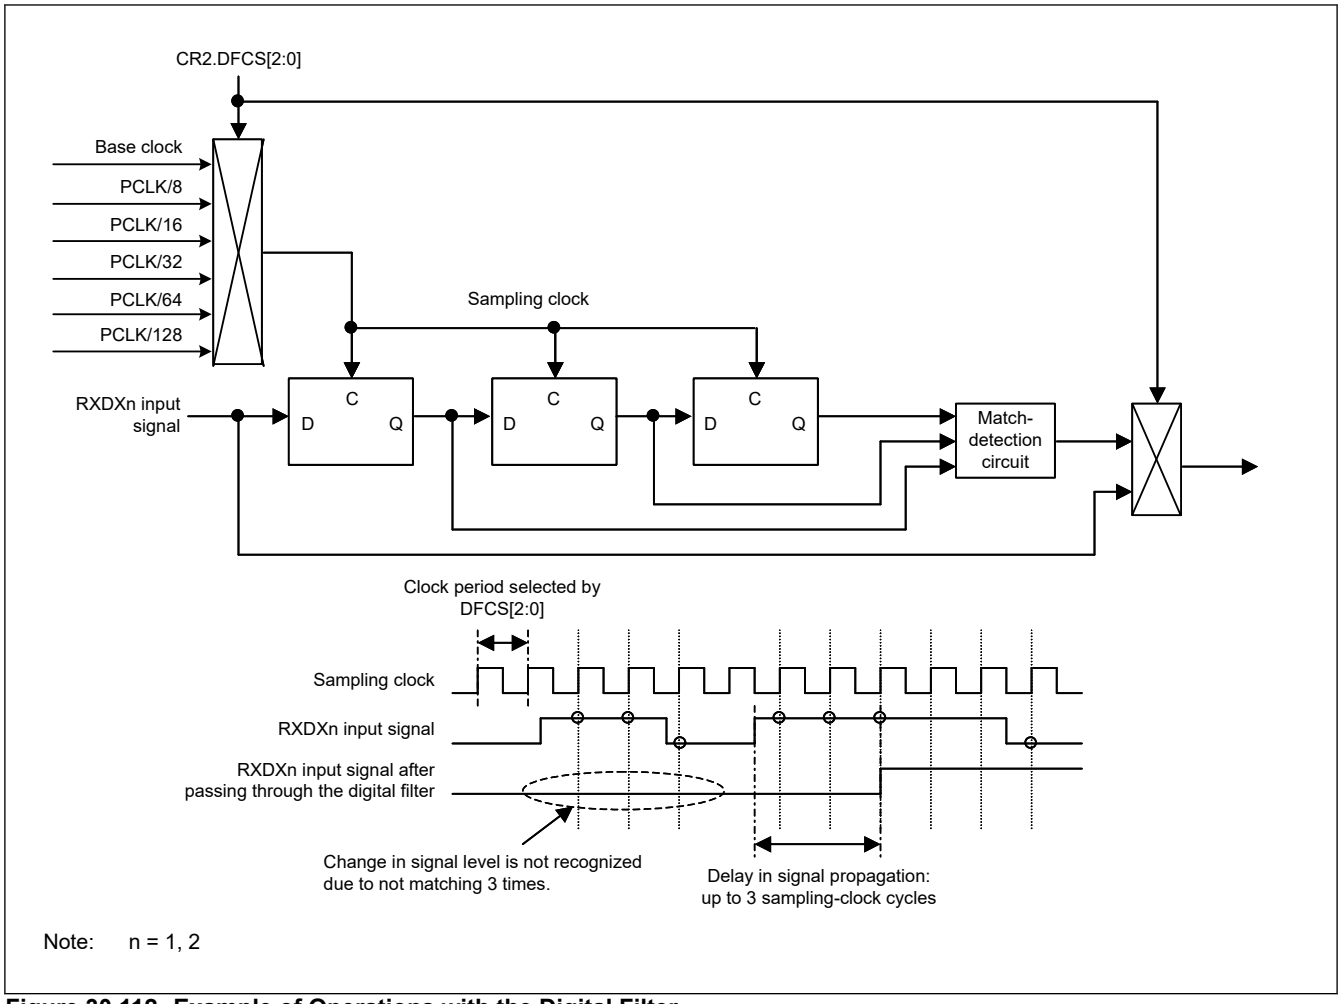

Figure 30.112 Example of Operations with the Digital Filter

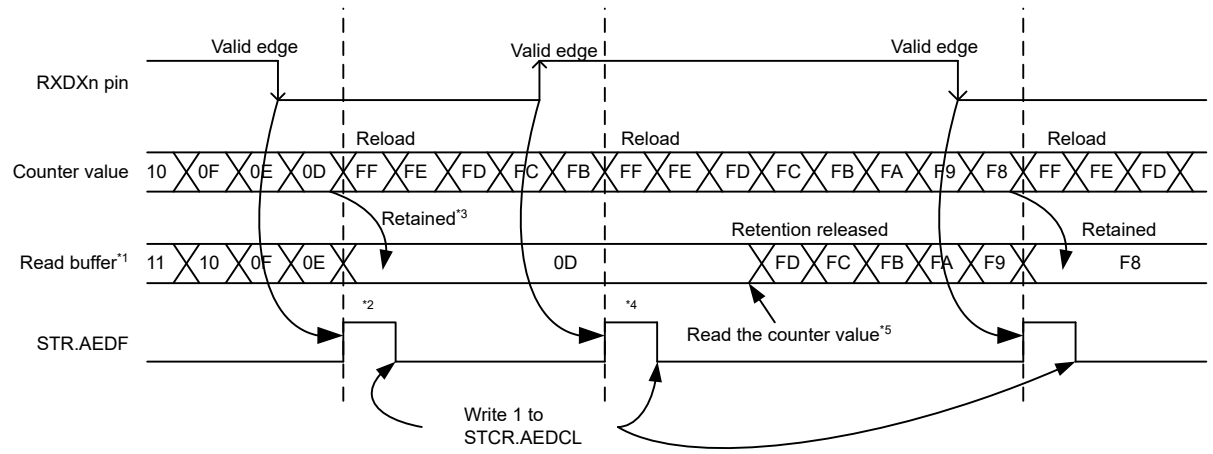
30.11.6 Bit Rate Measurement

The bit rate measurement function measures the intervals between rising and falling edges and between falling and rising edges of the signal input from the RXDXn (n = 1, 2) pin. Figure 30.113 shows an example of operations for bit rate measurement.

1. Writing 1 to the CR0.BRME bit enables bit rate measurement. Only set the BRME bit to 1 when you wish to proceed with bit rate measurement. Furthermore, bit rate measurement will not proceed during a Break Field, even if the BRME bit is set to 1.
2. After detection of the Break Field low width, bit rate measurement starts when the level input on the RXDXn pin becomes high.
3. Once bit rate measurement has started, counter values from the timer are retained in the read buffers on the input of valid edges from the RXDXn pin (rising and falling edges) and the counter is reloaded. An SCIX3 interrupt is also generated if the value of the ICR.AEDIE bit is 1. Retention by registers TCNT and TPRE is released by reading these registers.
4. The bit rate as calculated from the values counted during intervals between valid edges can be used for adjusting the rate by changing the settings of the SCIn. To disable the bit rate measurement after a match with Control Field 1, write 0 to the CR0.BRME bit.

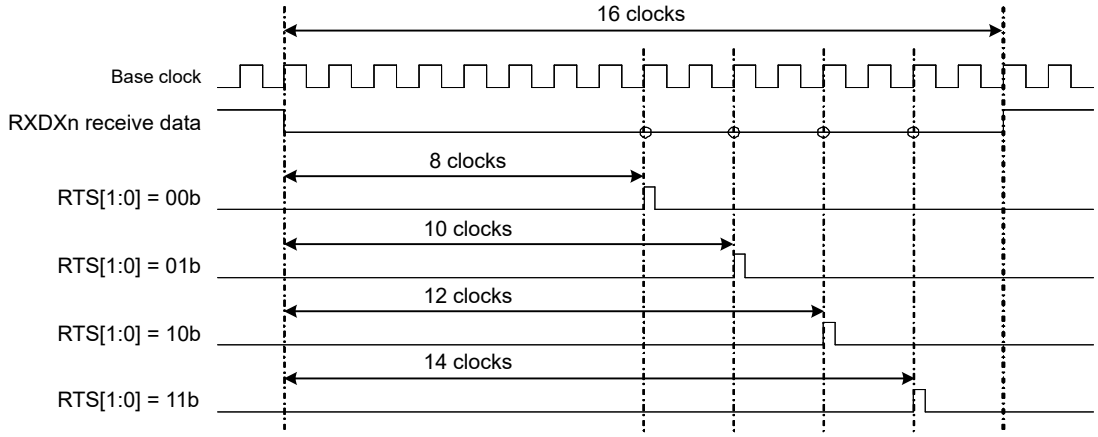


Note: n = 1, 2
Note 1. The TCNT or TPRE register indicates the contents of the read buffers.
Note 2. The STR.AEDF flag becomes 1 on detection of a valid edge.
Note 3. When an effective edge is detected, the current value of the counter is stored in the read buffer.
Note 4. The value retained in the read buffers due to one valid edge is not updated to the new value even if a further valid edge is detected.
Note 5. Retention of a value in a read buffer due to a valid edge is released by reading the TCNT or TPRE register.

Figure 30.113 Example of Operations for Bit Rate Measurement

30.11.7 Selectable Timing for Sampling Data Received through RXDXn (n = 1, 2)

The extended serial mode control section provides a way of adjusting the timing for the sampling of data received through the RXDXn pin of an SCIn by setting the CR2.RTS[1:0] bits to select the rising edges of 8th, 10th, 12th, or 14th cycle of the SCI base clock. If the value of the SEMR.ABCS bit is 1, the bits select the rising edges of 4th, 5th, 6th, or 7th cycle of the PCLK clock of the SCIn. Figure 30.114 shows timing for the sampling of data received through RXDXn.



The above diagram assumes the following:
SEMR.ABCS = 0

Note: n = 1, 2

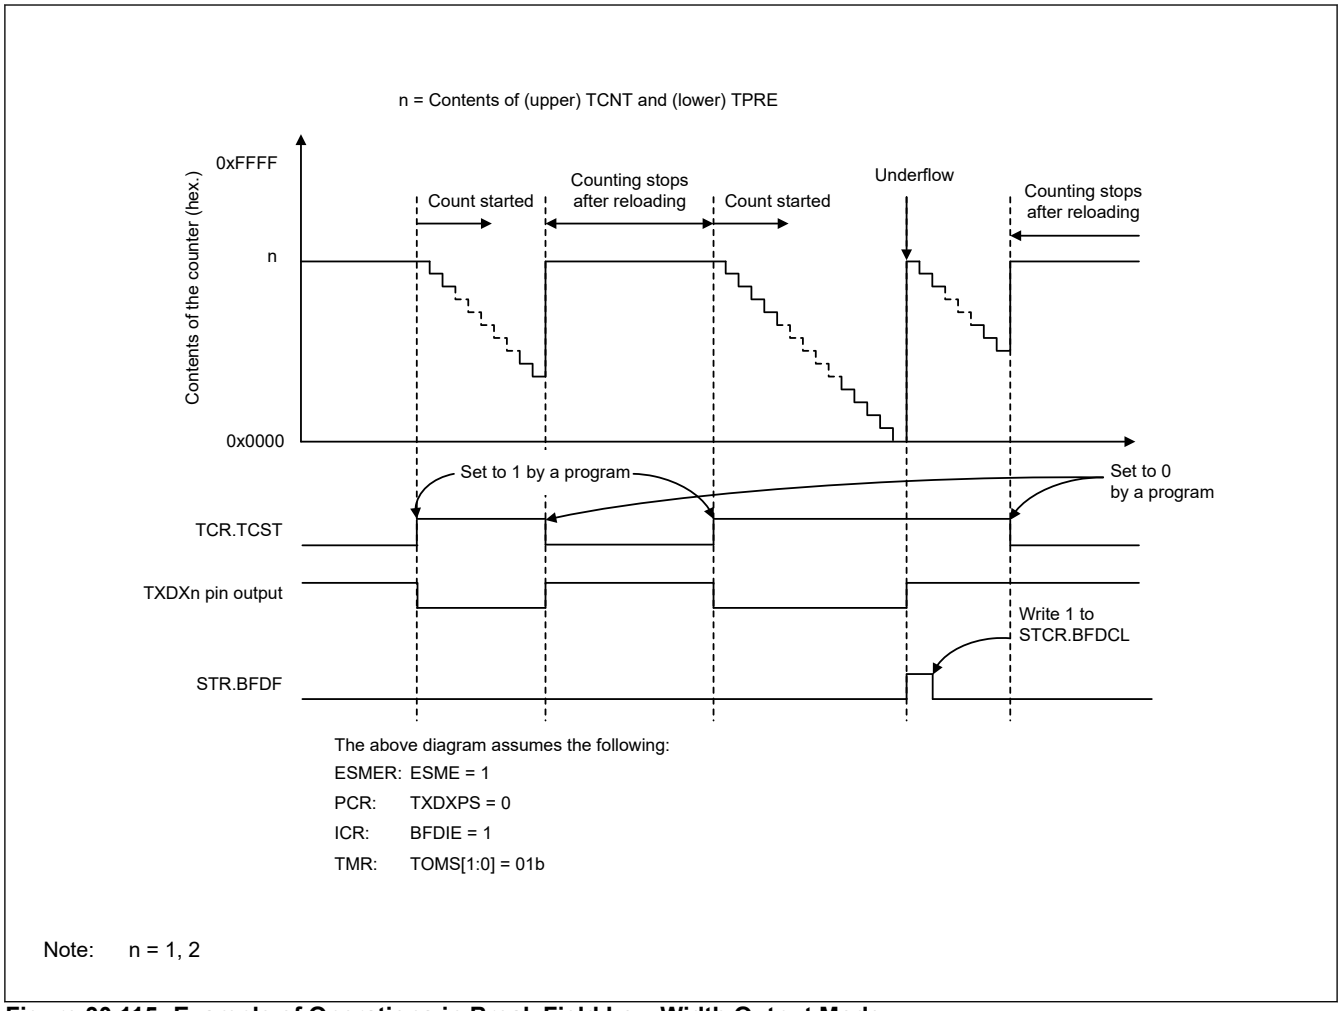
Figure 30.114 Timing for Sampling of Data Received through RXDXn

30.11.8 Timer

The timer has the following operating modes.

(1) Break Field Low Width Output Mode

This mode is for output through the TXDXn (n = 1, 2) pin of the low level over the Break Field low width at the transmission of a Start Frame. Setting the TMR.TOMS[1:0] bits to 10b switches operation to Break Field low width output mode. The TMR.TCSS[2:0] bits select the clock source for the counter. When the TCR.TCST bit is set to 1, the output on the TXDXn pin goes to the low level and counting starts. When the timer underflows, the output on the TXDXn pin goes to the high level and the STR.BFDF flag is set to 1. An SCIX0 interrupt is also generated if the value of the ICR.BFDIE bit is 1. When 0 is written to the TCR.TCST bit, counting stops after reloading of registers TPRE and TCNT. After output of the Break Field low width is completed, stop the timer before it underflows again. Figure 30.115 shows an example of operations in Break Field low width output mode.

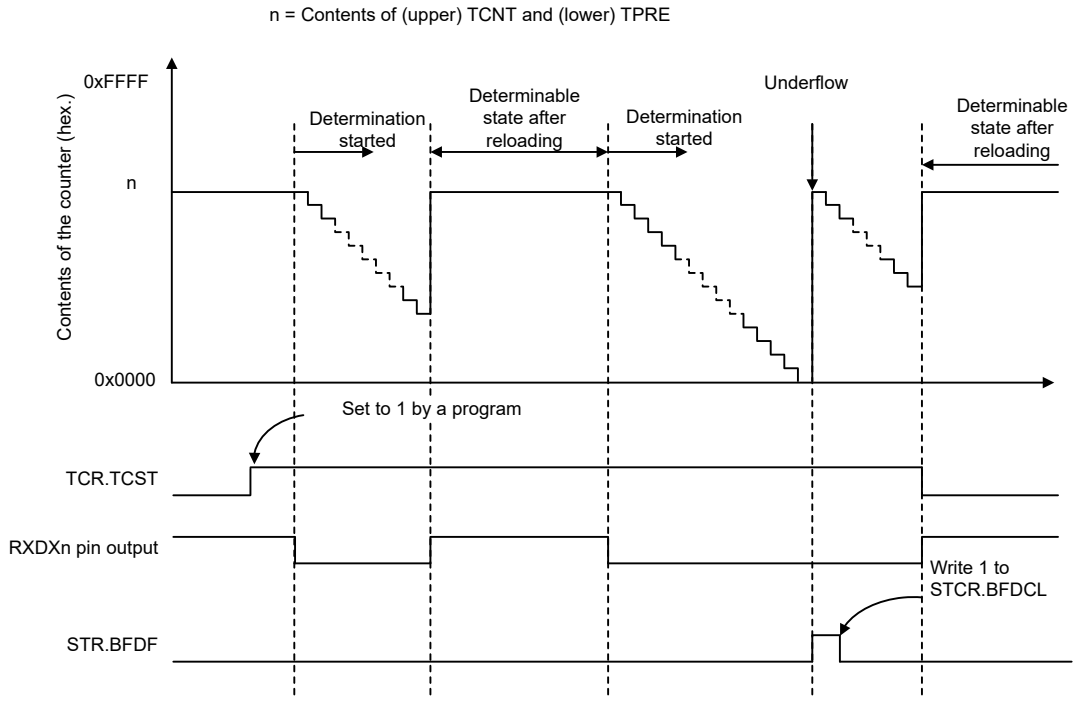


Note: n = 1, 2

Figure 30.115 Example of Operations in Break Field Low Width Output Mode

(2) Break Field Low Width Determination Mode

This mode is for determining the Break Field low width in the input signal on the RXDXn (n = 1, 2) pin at the reception of a Start Frame. Setting the TMR.TOMS[1:0] bits to 01b switches operation to Break Field low width determination mode. The TMR.TCSS[2:0] bits select the clock source for the counter. When the TCR.TCST bit is set to 1, the interface enters the Break Field low width determinable state. Determination starts when a low level is input from the RXDXn pin. When a high level is then input on the RXDXn pin, registers TPRE and TCNT are reloaded and the interface enters the Break Field low width determinable state. When the timer underflows during Break Field low width determination, the STR.BFDF flag is set to 1. An SCIX0 interrupt is also generated if the value of the ICR.BFDIE bit is 1. If an underflow of the timer during data transfer cause a problem in the form of interrupt generation, stop the timer after Break Field low width determination. Figure 30.116 shows an example of operations in Break Field low width output mode.



The above diagram assumes the following:

ESMER: ESME = 1
CR1: BFE = 0
PCR: RXDXPS = 0
ICR: BFDIE = 1
TMR: TOMS[1:0] = 01b

Note: n = 1, 2

Figure 30.116 Example of Operations in Break Field Low Width Determination Mode

(3) Timer Mode

This mode is for counting cycles of the internal clock as the clock source. Setting the TMR.TOMS[1:0] bits to 00b switches operation to timer mode. The TMR.TCSS[2:0] bits select the clock source for the counter. Counting starts when 1 is written to the TCR.TCST bit and stops when 0 is written to the TCST bit. Registers TPRE and TCNT both count down. The TPRE register counts cycles of the clock source for counting, and underflows of the TPRE register provide the clock source for counting by the TCNT register. When the timer underflows, the STR.BFDF flag is set to 1. An SCIX0 interrupt is also generated if the value of the ICR.BFDIE bit is 1.

30.12 Interrupt Sources

30.12.1 Buffer Operation for SCIn_TXI and SCIn_RXI Interrupts (Non-FIFO Selected)

If the conditions for an SCIn_TXI and SCIn_RXI interrupt are satisfied while the interrupt status flag in the ICU is 1, the ICU does not output the interrupt request but saves it internally with a capacity for retention of one request per source.

When the interrupt status flag in the ICU is set to 0, the interrupt request retained within the ICU is output. The internally retained interrupt request is automatically discarded when the actual interrupt is output. Clearing of the associated interrupt enable bit (the TIE or RIE bit in the SCR/SCR_SMCI) can also be used to discard an internally retained interrupt request.

30.12.2 Buffer Operation for SCIn_TXI and SCIn_RXI Interrupts (FIFO Selected)

When an interrupt status flag in the ICU is set to 1, the SCIn_TXI and SCIn_RXI interrupts do not output interrupt requests to the ICU. When an interrupt status flag of the ICU is set to 0, and if the conditions for an SCIn_TXI and SCIn_RXI interrupts are satisfied, an interrupt request is generated.

30.12.3 Interrupts in Asynchronous, Manchester, Clock Synchronous, and Simple SPI Modes

(1) Non-FIFO selected

Table 30.42 lists interrupt sources in asynchronous mode, Manchester mode, clock synchronous mode, and simple SPI mode.

A different interrupt vector can be assigned to each interrupt source. Individual interrupt sources can be enabled or disabled with the enable bits in the SCR register.

If the SCR.TIE bit is 1, an SCIn_TXI interrupt request is generated when transmit data is transferred from the TDR or TDRHL register*1 to the TSR register. An SCIn_TXI interrupt request can also be generated by using a single instruction to set the SCR.TE and SCR.TIE bits to 1 at the same time. An SCIn_TXI interrupt request can activate the DTC or DMAC to handle data transfer.

An SCIn_TXI interrupt request is not generated by setting the SCR.TE bit to 1 when SCR.TIE is 0 or by setting the SCR.TIE bit to 1 when the SCR.TE is 1.*2

When new data is not written by the time of transmission of the last bit of the current transmit data and SCR.TEIE is 1, the SSR.TEND flag is set to 1 and an SCIn_TEI interrupt request is generated. Additionally, when SCR.TE is 1, the SSR.TEND flag retains the value 1 until more transmit data is written to the TDR or TDRHL register*1, and setting SCR.TEIE to 1 leads to the generation of an SCIn_TEI interrupt request.

Writing data to the TDR or TDRHL register*1 leads to clearing of the SSR.TEND flag and, after a certain time, discarding of the SCIn_TEI interrupt request.

If the SCR.RIE bit is 1, an SCIn_RXI interrupt request is generated when received data is stored in the RDR register. An SCIn_RXI interrupt request can activate the DTC or DMAC to handle data transfer.

Setting any of the SSR.ORER, FER, PER and MER*3 flags to 1 when the SCR.RIE bit is 1 leads to the generation of an SCIn_ERI interrupt request.

An SCIn_RXI interrupt request is not generated in this case. Clearing all these flags (ORER, FER, PER, MER*3, SYER*3, PFER*3 and SBER*3) leads to discarding of the SCIn_ERI interrupt request.

Note 1. When asynchronous mode and 9-bit data length are selected.
Note 2. To temporarily prohibit SCIn_TXI interrupts on transmission of the last of the data when a new round of transmission is to be started, after handling the transmission-completed interrupt, control activation of the interrupt by using the interrupt request enable bit in the ICU rather than using the SCR.TIE bit. This approach can prevent the suppression of SCIn_TXI interrupt requests in the transfer of new data.
Note 3. MER, SYER, PFER, and SBER work as a factor of SCIn_ERI interrupt only in Manchester mode. SYER, PFER, and SBER also only work if its enable bits (SYEREN, PFEREN, SBEREN in MECR) are set to "1".

(2) FIFO selected

Table 30.43 lists interrupt sources in FIFO selected mode.

If the SCR.TIE bit is 1, an SCIn_TXI interrupt request is generated when the stored amount of data in the FTDRL register becomes the threshold value indicated in FCR.TTRG or below. An SCIn_TXI interrupt request can also be generated by using a single instruction to set the SCR.TIE and SCR.TE bits to 1 simultaneously or by setting SCR.TIE to 1 when SCR.TE is 1.

An SCIn_TXI interrupt request is not generated by setting SCR.TE to 1 when SCR.TIE is 0.

If SCR.TEIE is 1 and if the next data is not written to the FTDRL register by the time the last bit of the transmit data is sent, the SSR_FIFO.TEND flag is set to 1 and the SCIn_TEI interrupt request is generated.

If SCR.RIE is 1, the SCIn_RXI interrupt request is generated when the stored amount of data in the FRDRL register is equal to or greater than the threshold value indicated in FCR.RTRG. When RTRG is 0, an SCIn_RXI interrupt does not occur even when the amount of data in the receive FIFO is equal to 0.

If the SCR.RIE bit is 1, when the SSR_FIFO.ORER flag is set to 1 or data with a framing error or a parity error is stored in the FRDRL register, the SCIn_ERI interrupt request is generated. When the amount of data stored in the FRDRL register is at the threshold value or above, the SCIn_RXI interrupt request is also generated. The SCIn_ERI interrupt request can be canceled, in which case SSR_FIFO.ORER, FER, and PER flags are all cleared.

Table 30.42 SCI interrupt sources with non-FIFO selected

Name	Interrupt source	Interrupt flag	Interrupt enable	DTC or DMAC activation
SCIn_ERI (n = 0 to 9)	Receive error*1	SSR.ORER, SSR.FER, SSR.PER, DCCR.DFER, DCCR.DPER, (SSR.MER, MESR.SYER, MESR.PFER, MESR.SBER)*2	SCR.RIE	Not possible
SCIn_RXI (n = 0 to 9)	Receive data full	SSR.RDRF	SCR.RIE	Possible
	Address match	DCCR.DCMF	SCR.RIE	Possible
SCIn_AM (n = 0, 3 to 9)	Address match	DCCR.DCMF	—	Not possible
SCIn_TXI (n = 0 to 9)	Transmit data empty	SSR.TDRE	SCR.TIE	Possible
SCIn_TEI (n = 0 to 9)	Transmit end	SSR.TEND	SCR.TEIE	Not possible

Note 1. The interrupt flag is only ORER when in clock synchronous and simple SPI mode.
Note 2. MER, SYER, PFER, and SBER work as a factor of ERI interrupt only in Manchester mode. SYER, PFER, and SBER also only work if its enable bits (SYEREN, PFEREN, SBEREN in MECR) are set to 1.

Table 30.43 SCI interrupt sources with FIFO selected

Name	Interrupt source	Interrupt flag	Interrupt enable	DTC or DMAC activation
SCIn_ERI (n = 0 to 9)	Receive error*1	SSR_FIFO.ORER, SSR_FIFO.FER, SSR_FIFO.PER, DCCR.DFER, DCCR.DPER	SCR.RIE	Not possible
		SSR_FIFO.DR (when FCR.DRES = 1)	SCR.RIE	Not possible
SCIn_RXI (n = 0 to 9)	Receive data full	SSR_FIFO.RDF	SCR.RIE	Possible
	Receive data ready	SSR_FIFO.DR (when FCR.DRES = 0)	SCR.RIE	Possible
	Address match	DCCR.DCMF	SCR.RIE	Possible
SCIn_AM (n = 0, 3 to 9)	Address match	DCCR.DCMF	—	Not possible
SCIn_TXI (n = 0 to 9)	Transmit data empty	SSR_FIFO.TDFE	SCR.TIE	Possible
SCIn_TEI (n = 0 to 9)	Transmit end	SSR_FIFO.TEND	SCR.TEIE	Not possible

Note 1. The interrupt flag is only ORER when in clock synchronous and simple SPI mode.

30.12.4 Interrupts in Smart Card Interface Mode

Table 30.44 lists interrupt sources in smart card interface mode. A transmit end interrupt (SCIn_TEI) request and an address match (SCIn_AM) request cannot be used in this mode.

Table 30.44 SCI Interrupt sources (1 of 2)

Name	Interrupt source	Interrupt flag	Interrupt enable	DTC or DMAC activation
SCIn_ERI (n = 0 to 9)	Receive error or error signal detection	SSR_SMCI.ORER, SSR_SMCI.PER, SSR_SMCI.ERS	SCR_SMCI.RIE	Not possible
SCIn_RXI (n = 0 to 9)	Receive data full	SSR_SMCI.RDRF	SCR_SMCI.RIE	Possible

Table 30.44 SCI Interrupt sources (2 of 2)

Name	Interrupt source	Interrupt flag	Interrupt enable	DTC or DMAC activation
SCIn_TXI (n = 0 to 9)	Transmit data empty	SSR_SMCI.TEND	SCR_SMCI.TIE	Possible

Data transmission or reception using the DTC or DMAC is also possible in smart card interface mode, similar to normal SCI mode. In transmission, when the SSR_SMCI.TEND flag is set to 1, an SCIn_TXI interrupt request is generated. This SCIn_TXI interrupt request activates the DTC or DMAC, allowing transfer of transmit data if the SCIn_TXI request is previously specified as a source of DTC or DMAC activation. The TEND flag is automatically set to 0 when the DTC or DMAC transfers the data.

If an error occurs, the SCI automatically retransmits the same data. During the retransmission, the TEND flag is kept at 0 and the DTC or DMAC is not activated. Therefore, the SCI and DTC or DMAC automatically transmit the specified number of bytes, including retransmission after an error occurrence. However, the SSR_SMCI.ERS flag is not automatically set to 0 at error occurrence. Therefore, the ERS flag must be cleared by previously setting the SCR_SMCI.RIE bit to 1 to enable an SCIn_ERI interrupt request to be generated at error occurrence.

When transmitting or receiving data using the DTC or DMAC, always enable the DTC or DMAC before making the SCI settings. For DTC or DMAC settings, see section 17, Data Transfer Controller (DTC), section 16, DMA Controller (DMAC).

In reception, an SCIn_RXI interrupt request is generated when receive data is set to the RDR register. This SCIn_RXI interrupt request activates the DTC or DMAC, allowing transfer of the receive data if the SCIn_RXI request is previously specified as a source of DTC or DMAC activation. If an error occurs, the error flag is set. Therefore, the DTC or DMAC is not activated and an SCIn_ERI interrupt request is issued to the CPU instead. The error flag must be cleared.

30.12.5 Interrupts in Simple IIC Mode

Table 30.45 lists the interrupt sources in simple IIC mode. The STI interrupt is allocated to the transmit end interrupt (SCIn_TEI) request. The receive error interrupt (SCIn_ERI) and the address match (SCIn_AM) request cannot be used.

The DTC or DMAC can also be used to handle transfer in simple IIC mode.

When the SIMR2.IICINTM bit is 1:

- An SCIn_RXI request is generated on the falling edge of the SCLn signal for the 8th bit. If SCIn_RXI is previously set up as an activation source for the DTC or DMAC, the SCIn_RXI request activates the DTC or DMAC to handle transfer of the received data.
- An SCIn_TXI request is generated on the falling edge of the SCLn signal for the 9th bit (acknowledge bit). If SCIn_TXI is previously set up as an activation source for the DTC or DMAC, the SCIn_TXI request activates the DTC or DMAC to handle transfer of the transmit data.

When the SIMR2.IICINTM bit is 0:

- An SCIn_RXI request (ACK detection) is generated if the input on the SDAn pin is low on the rising edge of the SCLn signal for the 9th bit (acknowledge bit)
- An SCIn_TXI request (NACK detection) is generated if the input on the SDAn pin is high on the rising edge of the SCLn signal for the 9th bit (acknowledge bit)
- If SCIn_RXI is previously set up as an activation source for the DTC or DMAC, the SCIn_RXI request activates the DTC or DMAC to handle transfer of the received data.

If the DTC or DMAC is used for data transfer in reception or transmission, always set up and enable the DTC or DMAC before setting up the SCI.

When the IICSTAREQ, IICRSTAREQ, and IICSTPREQ bits in SIMR3 are used to generate a start condition, restart condition, or stop condition, the STI request is issued when generation is complete.

Table 30.45 SCI interrupt sources (1 of 2)

Name	Interrupt source	Interrupt flag	Interrupt enable	DTC or DMAC activation
SCIn_RXI (n = 0 to 9)	Reception, ACK detection	—	SCMR.RIE	Possible*1

Table 30.45 SCI interrupt sources (2 of 2)

Name	Interrupt source	Interrupt flag	Interrupt enable	DTC or DMAC activation
SCIn_TXI (n = 0 to 9)	Transmission, NACK detection	—	SCMR.TIE	Possible
SCIn_TEI(STIn) (n = 0 to 9)	Completion of generation of a start, restart, or stop condition	SIMR3.IICSTIF	SCMR.TEIE	Not possible

Note 1. Activation of the DTC or DMAC is only possible when the SIMR2.IICINTM bit is 1 (use reception and transmission interrupts)

30.12.6 Interrupt Requests from the Extended Serial Mode Control Section

The extended serial mode control section has a total of six types of interrupt request for generating the SCIX0 interrupt (Break Field low width detected), SCIX1 interrupt (Control Field 0 match, Control Field 1 match, priority interrupt bit detected), SCIX2 interrupt (bus collision detected), and SCIX3 interrupt (valid edge detected). When any of the interrupt factors is generated, the corresponding status flag is set to 1. Details of all of the interrupt requests are listed in Table 30.46.

Table 30.46 Interrupt Sources of the Extended Serial Mode Control Section

Interrupt Request	Status Flag	Interrupt Factors
SCIX0 interrupt (Break Field low width detected)	BFDF	• Detection of a Break Field low width longer than the interval corresponding to the timer setting • Completion of the output of a Break Field low width over the interval corresponding to the timer setting • Underflow of the timer
SCIX1 interrupt (Control Field 0 match)	CF0MF	The data received in Control Field 0 matching the value set in CF0DR
SCIX1 interrupt (Control Field 1 match)	CF1MF	The data received in Control Field 1 matching the value set in PCF1DR or SCF1DR
SCIX1 interrupt (priority interrupt bit detected)	PIBDF	The value of the bit specified as the priority interrupt bit matching the value set in PCF1DR
SCIX2 interrupt (bus collision detected)	BCDF	The output level on the RXDXn (n = 1, 2) pin and the input level on the RXDXn pin not matching on three consecutive cycles of the bus collision detection clock
SCIX3 interrupt (valid edge detected)	AEDF	Detection of a valid edge during bit rate measurement

30.13 Event Linking

By using interrupt request signals as event signals, the SCIn can provide linked operation through the ELC for modules selected in advance.

Event signals can be output regardless of the values of the associated interrupt request enable bits.

(1) Error event output (receive error or error signal detected) (SCIn_ERI, n = 0 to 9)

- Indicates abnormal termination because of a parity error during reception in asynchronous mode
- Indicates abnormal termination because of a framing error during reception in asynchronous mode
- Indicates abnormal termination because of an overrun error during reception
- Indicates detection of the error signal during transmission in smart card interface mode
- The SSR_FIFO.FER and PER flags are 0, and receive data less than the receive FIFO data trigger number is set in a reception FIFO buffer, and it indicates that 15 etus elapse when FIFO is selected and the FCR.DRES bit is 1

(2) Receive data full event output (SCIn_RXI, n = 0 to 9)

- Indicates that ACK is detected if the SIMR2.IICINTM bit is 0 in simple IIC mode
- Indicates that the 8th-bit SCLn falling edge is detected if the SIMR2.IICINTM bit is 1 in simple IIC mode
- When the SIMR2.IICINTM bit is 1 during master transmission in simple IIC mode, set the ELC so that receive data full events are not used

Non-FIFO selected

- Indicates that received data is set in the Receive Data Register (RDR or RDRHL).

FIFO selected

- Using this event output is prohibited.

(3) Transmit data empty event output (SCIn_TXI, n = 0 to 9)

- Indicates that the SCR/SCR_SMCI.TE bit is changed from 0 to 1
- Indicates that transmission is complete in smart card interface mode
- Indicates that NACK is detected if the SIMR2.IICINTM bit is 0 in simple IIC mode
- Indicates that the 9th-bit SCLn falling edge is detected if the SIMR2.IICINTM bit is 1 in simple IIC mode

Non-FIFO selected

- Indicates that transmit data is transferred from the Transmit Data Register (TDR or TDRHL) to the Transmit Shift Register (TSR).

FIFO selected

- Using this event output is prohibited.

(4) Transmit end event output (SCIn_TEI, n = 0 to 9)

- Indicates the completion of transmission
- Indicates that the starting condition, resumption condition, or termination condition is generated in simple IIC mode

Note: When FIFO is selected, using this event output is prohibited

(5) Address match event output (SCIn_AM, n = 0, 3 to 9)

- Indicates a match of the comparison data (CDR.CMPD) with one frame of receive data when DCCR.DCME is set to 1 in asynchronous mode, including multi-processor mode.

30.14 Address Non-match Event Output (SCI0_DCUF)

SCI0_DCUF indicates the non-match of comparison data (CDR.CMPD) with receive data that is one frame of the data that is received when DCCR.DCME is set to 1 in asynchronous mode, including multi-processor mode. This event can be used for Snooze end request only. For details, see section 10, Low Power Modes.

30.15 Noise Cancellation Function

Figure 30.117 shows the configuration of the noise filter used for noise cancellation. The noise filter consists of a 2-stage flip-flop circuit and a match detection circuit. When the input signals of the noise filter and the output signals of the 2- stage flip-flop circuits completely match, the matched level is conveyed as an internal signal. Unless otherwise matched, the previous value is retained. When the same level is retained for 3 cycles or longer on the sampling clock of the noise filter, it is considered as a valid receive signal. A change in pulse for 3 cycles or shorter is considered as noise, not as a receive signal.

In asynchronous mode, the noise cancellation function can be applied to the receive signal input to the RXDn pin. The receive level of the RXDn is taken in the flip-flop circuit of the noise filter on the base clock of asynchronous mode.

- When SEMR.ABCS = 0 and SEMR.ABCSE = 0, the cycle is 1/16 of a 1-bit period.
- When SEMR.ABCS = 1 and SEMR.ABCSE = 0, the cycle is 1/8 of a 1-bit period.
- When SEMR.ABCSE = 1, the cycle is 1/6 of a 1-bit period.

In simple IIC mode, this function can be used for each input on SDAn and SCLn. The sampling clock is selected from divided clock of baud rate generator settings SNFR.NFCS[2:0].

If the base clock is stopped once with the noise filter enabled and then the base clock input is restarted again, the noise filter operation resumes from the state where the clock was stopped. When SCR.TE and SCR.RE are set to 0 during base clock

input, all of the noise filter flip-flop values are initialized to 1. Accordingly, if the input data is 1 when reception operation resumes, the function determines that a level match is detected and the result is conveyed as an internal signal. When the level being input corresponds to 0, the initial output of the noise filter is retained until the level matches in three consecutive sampling cycles.

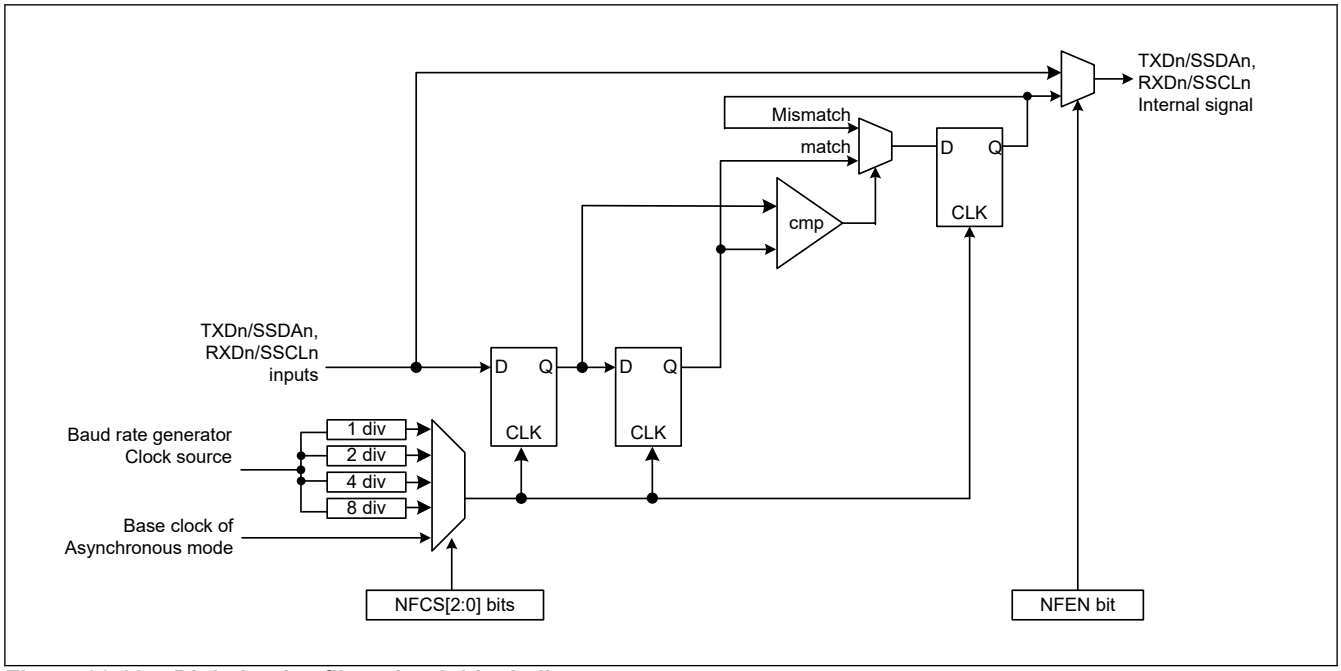


Figure 30.117 Digital noise filter circuit block diagram

30.16 Usage Notes

30.16.1 Settings for the Module-Stop Function

The Module Stop Control Register B (MSTPCRB) can enable or disable SCI operation. The SCI is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

30.16.2 SCI Operation during Low Power State

(1) Transmission

When setting the module to the stopped state or in transitions to Software Standby, stop operations (by setting the TIE, TE, and TEIE bits in the SCR/SCR_SMCI to 0) after switching the TXDn pin to the general I/O port pin function. When setting I/O port as an SCI connection, the SPTR register can control the state of the TXDn pin. Setting the TE bit to 0 initializes the TSR register and the TEND bit in the SSR/SSR_SMCI is initialized to 1 with non-FIFO selected, and the value is retained, with FIFO selected. Depending on the port settings and SPTR register settings, output pins might output the level before a transition to the low-power state is made after release from the module-stopped state or Software Standby mode. When transitions to these states are made during transmission, the transmitted data becomes indeterminate.

To transmit data in the same transmission mode after cancellation of the low-power state:

1. Set the TE bit to 1.
2. Read SSR/SSR_FIFO/SSR_SMCI.
3. Write data to TDR sequentially to start data transmission.

To transmit data with a different transmission mode, initialize the SCI first.

Figure 30.118 shows an example flow of transition to Software Standby mode during transmission. Figure 30.119 and Figure 30.120 show the port pin states during transition to Software Standby mode.

Before specifying the module-stop state or transitioning to Software Standby mode from the transmission mode using DTC or DMAC transfer, stop the transmit operations (TE = 0). To start transmission after cancellation using the DTC or DMAC, set the TE bit to 1. The SCIn_TXI interrupt flag is set to 1 and transmission starts using the DTC or DMAC.

(2) Reception

When address match function is not used as wakeup condition

Before specifying the module-stop state or transitioning to Software Standby mode, stop the receive operations (RE = 0 in SCR/SCR_SMCI). If transition is made during data reception, the received data is invalid.

Figure 30.121 shows an example flow of transition to Software Standby mode during reception.

When address match function is used as wakeup condition

Before specifying the module-stop state or transitioning to Software Standby mode:

1. Set the operations after cancellation of the low power state.
2. Set CDR.CMPD and DCCR.DCME to 1.
3. Set the receive operations (RE = 1 in SCR/SCR_SMCI).
4. Set the module-stop state or Software Standby mode.

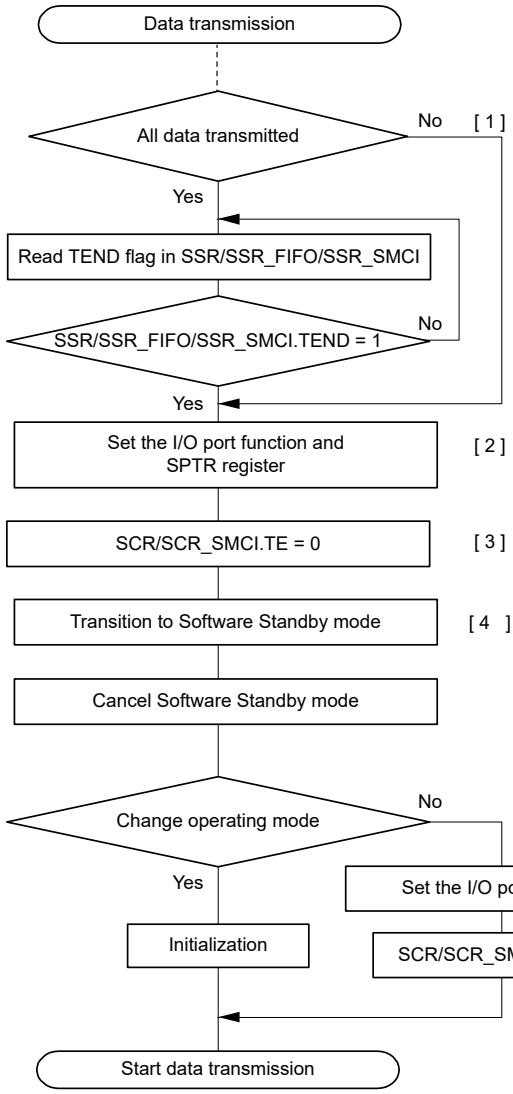
When SCI transfers to low power mode, if the receive data pin (RXD) is at the low level, set SEMR.RXDESEL = 0.

When setting SEMR.RXDESEL = 1, there is a possibility that a start bit (falling edge of RXD pin) cannot be detected on release of the low power mode.

Figure 30.122 shows an example flow of transition to Software Standby mode during reception with address match.

When using SCI0 in Snooze mode

When using SCI0 in Snooze mode, some restrictions apply, including maximum bit rates. For details, see section 10, Low Power Modes.



[1] Data being transmitted is lost. Data can be normally transmitted from the CPU by setting the TE bit in SCR/ SCR_SMCI to 1, reading SSR/SSR_FIFO/ SSR_SMCI, and writing in Software Standby mode. However, if the DMAC or DTC is activated, the data remaining in the DMAC or DTC is transmitted when both the TE and TIE bits in SCR/ SCR_SMCI are set to 1.

[2] Set the I/O port function and SPTR register settings to switch the TXDn pin to operate as a general I/O port.

[3] Set SCR/SCR_SMCI.TE bit to 0. If SCR/ SCR_SMCI.TIE = 1 and SCR/SCR_SMCI.TEIE = 1, these are set to 0 simultaneously with the SCR.TE bit.

[4] This includes the setting for the module-stop state.

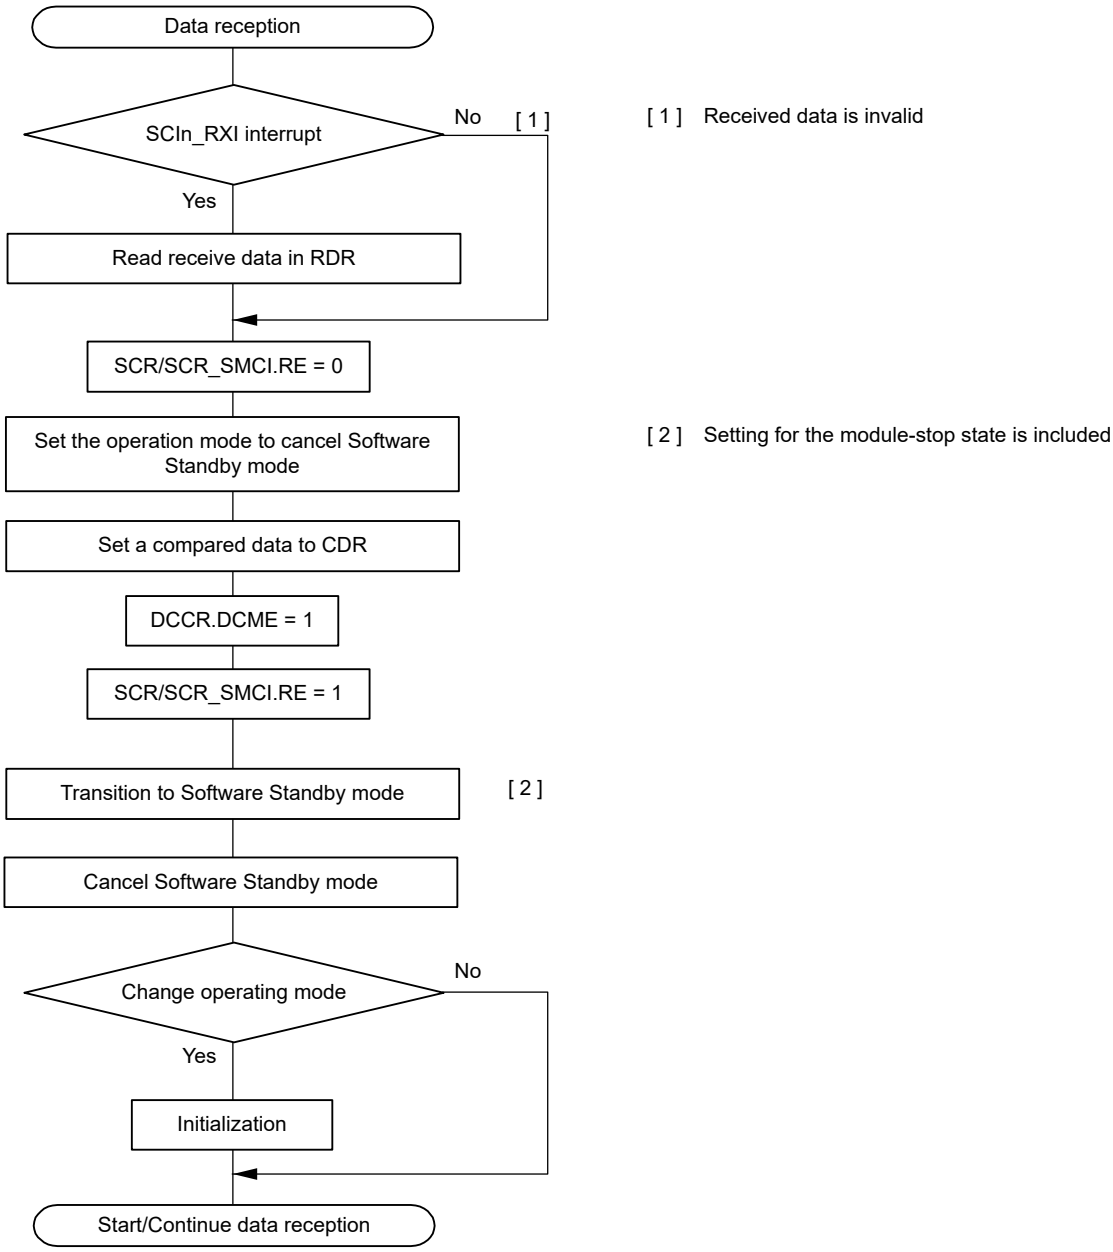

Figure 30.122 Example flow of transition to Software Standby mode during reception with address match

30.16.3 Break Detection and Processing

(1) Non-FIFO selected

When a framing error is detected, a break can be detected by reading the RXDn pin value directly. In a break, the input from the RXDn pin becomes all 0s, and the SSR.FER flag is set to 1 to indicate a framing error, and the SSR.PER flag might also be set to 1 to indicate a parity error. The SCI continues the receive operation even after a break is received. Therefore, even if the FER flag is 0, indicating that no framing error occurred, it is set to 1 again. When the SEMR.RXDESEL bit is 1, the SCI sets the SSR.FER flag to 1 and stops receiving operations until a start bit of the next data frame is detected. If the SSR.FER flag is set to 0, the SSR.FER flag retains 0 during the break.

When the RXDn pin is set to 1 and the break ends, detecting the beginning of the start bit on the first falling edge of the RXDn pin allows the SCI to start the receiving operation.

(2) FIFO selected

After a framing error is detected and when the SCI detects that continuous receive data is 0 for 1 frame, reception stops. When a framing error is detected, a break can be detected by reading the SPTR.RXDMON flag value. After the RXDn signal is in high and the break is finished, data reception to the FRDRHL register resumes.

30.16.4 Mark State and Production of Breaks

When the SCR/SCR_SMCI.TE bit is 0, disabling serial transmission, the state of the TXDn pin can be set using the SPTR.SPB2IO and SPTR.SPB2DT bits. With this approach, a TXDn pin can be placed in the mark state to transmit a break.

Before setting the SCR/SCR_SMCI.TE bit to 1, enabling serial transmission, set the SPB2IO and SPB2DT bits to put the communication line in the mark state (the state of 1), and change the TXDn pin using I/O port function. To output a break on data transmission, after setting the TXDn pin to output 0 by setting the SPB2IO and SPB2DT bits, change the TXDn pin using the I/O port function and set the SCR/SCR_SMCI.TE bit to 0. When the SCR/SCR_SMCI.TE bit is set to 0, the transmitter is initialized regardless of the current state of transmission.

30.16.5 Receive Error Flags and Transmit Operation in Clock Synchronous Mode and Simple SPI Mode

Transmission cannot start when a receive error flag (ORER) in SSR/SSR_FIFO is set to 1, even when data is written to TDR or FTDRL[*1]. Always set the receive error flags to 0 before starting transmission.

Note: The receive error flags cannot be set to 0 when the RE bit in SCR/SCR_SMCI is set to 0 (serial reception is disabled).

Note 1. Do not use the FTDRH register in simple SPI mode.

30.16.6 Restrictions on Clock Synchronous Transmission in Clock Synchronous Mode and Simple SPI Mode

When the external clock source is used as a synchronization clock, the following restrictions apply.

(1) Start of transmission

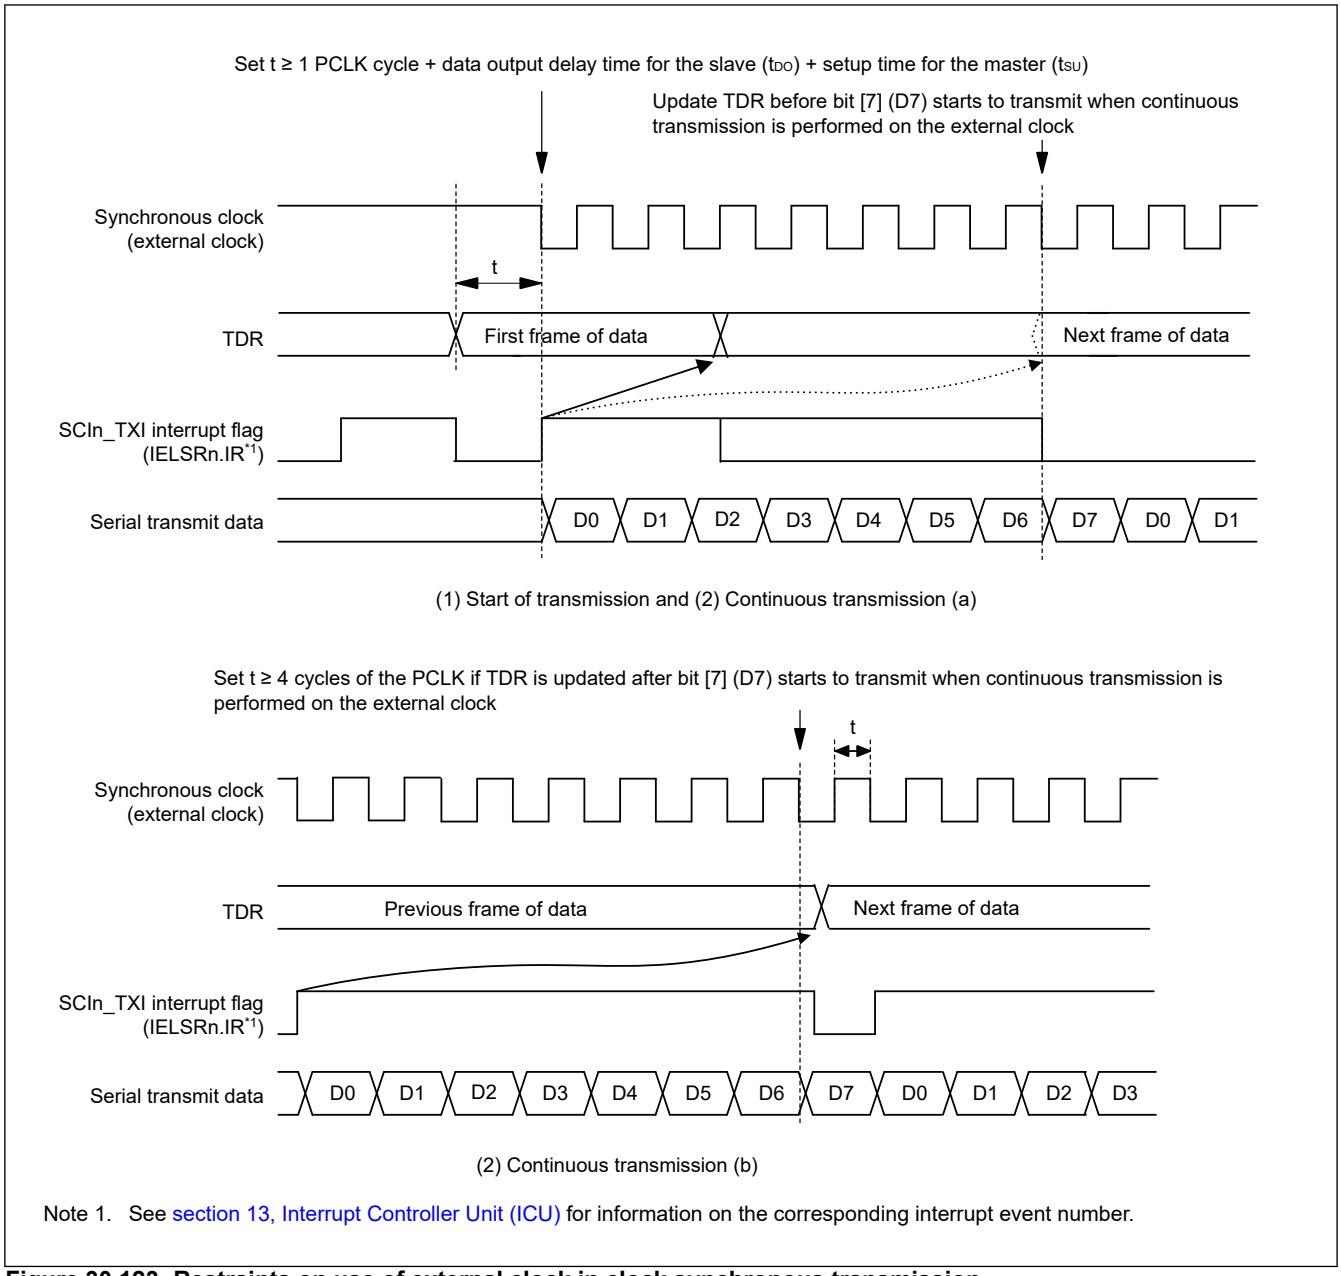
Wait at least the following time from writing transmit data to TDR to the start of the external clock input:

1 PCLK cycle + data output delay time for the slave (t_{DO}) + setup time for the master (t_{SU}). See Figure 30.123.

(2) Continuous transmission

Write the next transmit data to TDR or TDRHL before the falling edge of the transmit clock for bit [7] . See Figure 30.123.

When updating TDR after bit [7] has started to transmit, update TDR while the synchronization clock is in the low-level period, and set the high-level width of the transmit clock (bit [7]) to 4 PCLK cycles or longer. See Figure 30.123.



Note 1. See section 13, Interrupt Controller Unit (ICU) for information on the corresponding interrupt event number.

Figure 30.123 Restraints on use of external clock in clock synchronous transmission

30.16.7 Restrictions on Using DTC or DMAC

During transmission or reception operations using the DTC or DMAC, do not set transfer data for the DTC or DMAC.

(1) Writing data to TDR (FTDRHL)

Non-FIFO selected

Data can be written to TDR and TDRHL. However, if new data is written to TDR or TDRHL when transmit data remains in TDR or TDRHL, the previous data in TDR and TDRHL is lost because it was not transferred to TSR yet. When using DTC or DMAC, always write transmit data to TDR or TDRHL in the SCIn_TXI interrupt request handling routine.

FIFO selected

It is possible to write data to the FTDRH and FTDRL registers when SCR.TE is 1. Confirm the amount of writable data using the FDR.T[4:0] bits.

(2) Reading data from RDR (FRDRHL)

When using the DTC or DMAC to read RDR and RDRHL, always set the receive data full interrupt (SCIn_RXI) as the activation source of the relevant SCI.

30.16.8 Notes on Starting Transfer

At the point where transfer starts when the interrupt status flag (IELSRn.IR flag) in the ICU is 1, follow the procedure in this section to clear interrupt requests before permitting operations (by setting the SCR/SCR_SMCI.TE or SCR/SCR_SMCI.RE bit to 1). For details on the interrupt status flag, see section 13, Interrupt Controller Unit (ICU).

1. Confirm that transfer has stopped (the SCR/SCR_SMCI.TE or SCR/SCR_SMCI.RE bit is 0)
2. Set the associated interrupt enable bit (SCR/SCR_SMCI.TIE or SCR/SCR_SMCI.RIE bit) to 0
3. Read the associated interrupt enable bit (SCR/SCR_SMCI.TIE or SCR/SCR_SMCI.RIE bit) to check that it actually becomes 0
4. Set the interrupt status flag, IELSRn.IR, in the ICU to 0

30.16.9 External Clock Input in Clock Synchronous Mode and Simple SPI Mode

In clock synchronous mode and simple SPI mode, the external clock SCKn must be input as follows:

High-pulse period, low-pulse period = 2 PCLK cycles or more, period = 6 PCLK cycles or more.

30.16.10 Limitations on Simple SPI Mode

(1) Master mode

- Use a resistor to pull up or pull down the clock line matching the initial settings for the transfer clock set in the SPMR.CKPH and CKPOL bits when the SPMR.SSE bit is 1.

  This prevents the clock line from being placed in the high-impedance state when the SCR.TE bit is set to 0 or unexpected edges from being generated on the clock line when the SCR.TE bit changes from 0 to 1. When the SPMR.SSE bit is 0 in single master mode, pulling up or pulling down the clock line is not required because the clock line is not placed in the high-impedance state even when the SCR.TE bit is set to 0.
- For the clock delay setting (SPMR.CKPH bit is 1), the receive data full interrupt (SCIn_RXI) is generated before the final clock edge on the SCKn pin as indicated in Figure 30.124. If the TE and RE bits in the SCR register become 0 before the final edge of the clock signal on the SCKn pin, the SCKn pin is placed in the high-impedance state, so the width of the last clock pulse of the transfer clock is shortened. Additionally, an SCIn_RXI interrupt might lead to the input signal on the SSn pin of a connected slave going to the high level before the final edge of the clock signal on the SCKn pin, leading to incorrect operation of the slave.
- In a multi-master configuration, the SCKn pin output goes to high-impedance while the input on the SSn pin is at the low level if a mode fault error occurs while a character is being transferred, stopping supply of the clock signal to the connected slave. Reset the connected slave to avoid misaligned bits when transfer is restarted.

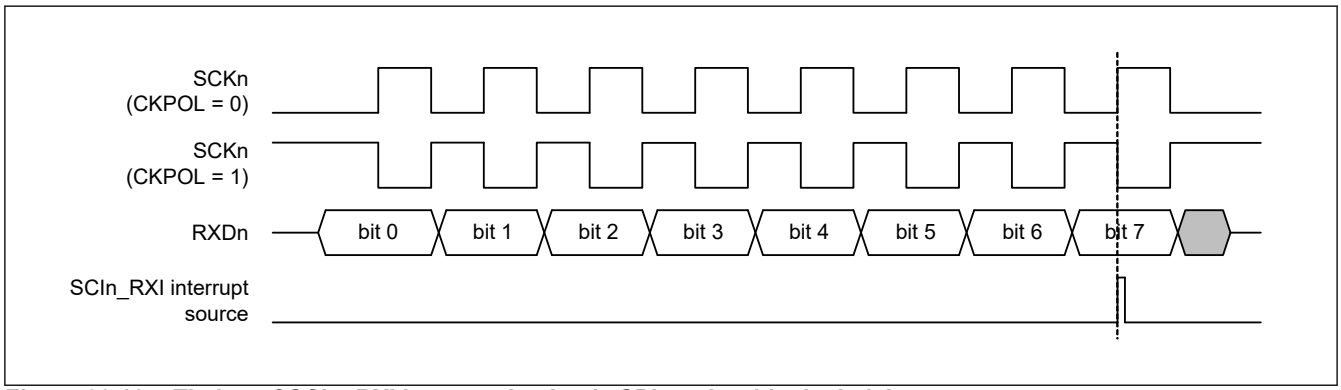


Figure 30.124 Timing of SCIn_RXI interrupt in simple SPI mode with clock delay

(2) Slave mode

- Wait at least the following time from writing transmit data in the TDR register to the start of the external clock input.

  1 PCLK cycle + data output delay for the slave (t_{DO}) + setup time for the master (t_{SU})

  Also wait at least 5 PCLK cycles from the input of the low level on the SSn pin to the start of the external clock input.
- Provide an external clock signal to the master the same as the data length for transfer
- Control the input on the SSn pin before the start and after the end of data transfer
- When the input level on the SSn pin is to be changed from low to high while a character is being transferred, set the TE and RE bits in the SCR register to 0 and, after restoring the settings, restart transfer of the first byte

30.16.11 Notes on Transmit Enable Bit (SCR.TE)

In initial register value, when SCR.TE = 0, the state of the TXDn pin is high impedance. The TXDn line should not be high impedance by the following one of ways.

1. The pull-up resistance is connected to the TXDn line.
2. Before setting the SCR.TE bit to 0, the function of the pin should be changed to a general-purpose output port. After that, set the SCR.TE bit to 1, and then change the function of the pin to TXDn.
3. In asynchronous mode, set SPTR and decided level of TXDn pin during SCR.TE = 0.

In the Simple SPI mode slave operation, the MISOn pin operates in the same way as the above TXDn pin. The MISOn pin, the same as TXDn pin, should not be high impedance by the above list number 1 or list number 2.

30.16.12 Limitation 1 on Usage of the Extended Serial Mode Control Section

When the PCR.SHARPS bit is set to 1, output on the TXDXn/RXDXn (n = 1, 2) pin is only possible when the following conditions apply.

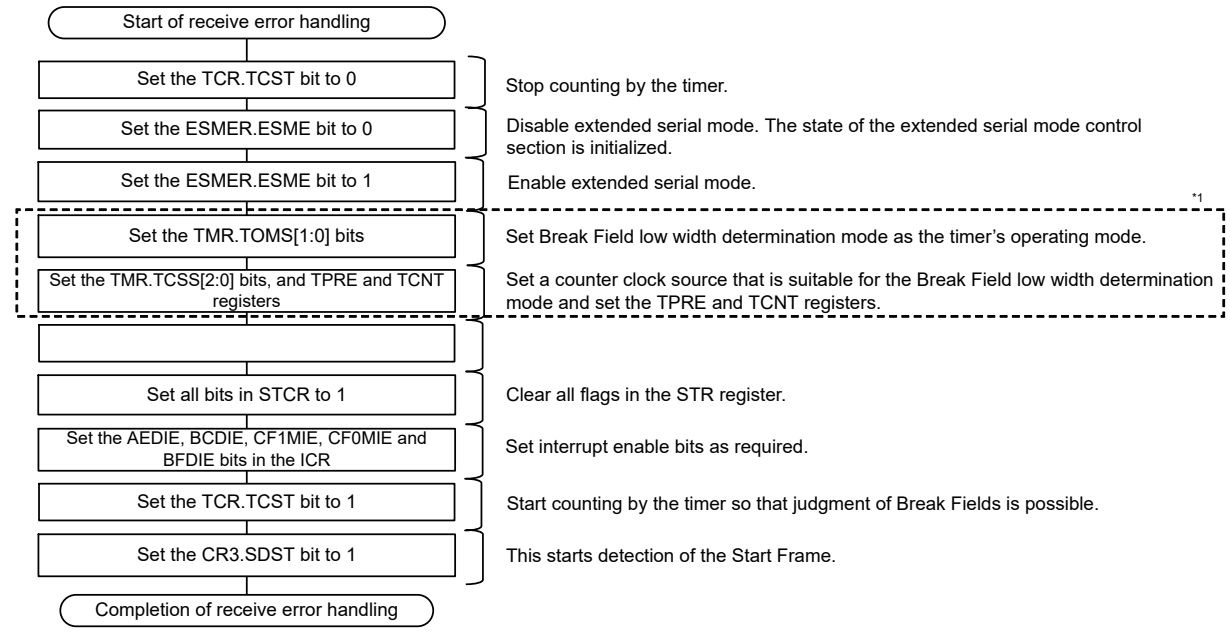
- The timer of the SCIh module is in Break Field low width output mode and the value of the TCR.TCST bit is 1 (when the TCST bit is set to 1, the high level continues to be output for up to one cycle of the clock source for counting by the timer counter before output of the low level)
- The value of the SCIn.SCR.TE bit is 1.

30.16.13 Limitation 2 on Usage of the Extended Serial Mode Control Section

An SCIg interrupt request is generated even if the extended serial mode is enabled. However, the SCIg interrupt should not be used during reception of a Start Frame because SCIh uses an SCIg interrupt request.

The two ways of dealing with this are described below. When a receive error is detected, clear the error flag of the SCIg and initialize the control section of the SCIh.

1. Set the SCR.RIE bit of the SCIg to 0 to disable the output of interrupt requests. Check the error flags in the SSR register for SCIg on completion of the reception of a Start Frame, because an ERI interrupt is not generated if a receive error occurs. After reception of the Start Frame is completed, set the SCR.RIE bit of the SCIg to 1 by the time the first byte of the Information Frame is received.
2. Set the SCR.RIE bit of the SCIg to 1 to disable RXI interrupts and enable ERI interrupts for ICU.
   Clear the IRn.IR flag to enable the acceptance of RXI interrupts by ICU by the time the first byte of the Information Frame is received after the completion of Start Frame reception.



Note 1. The setting in this step is not necessary if the setting conditions have not been changed.

Figure 30.125 Example of Flowchart for Receive Error Handling (during Reception of the Start Frame)

30.16.14 Note on Stopping Reception When Using the RTS Function in Asynchronous Mode

One clock cycle of PCLK is required for the time from setting the SCR.RE bit to 0 to stopping the RTS signal generator in asynchronous mode.

When reading the RDR (or RDRL) register after setting the SCR.RE bit to 0, confirm that the RE bit has been set to 0 before reading the RDR (or RDRL) register to prevent these two processes from being performed consecutively.

31. I2C Bus Interface (IIC)

31.1 Overview

The I2C bus interface (IIC) has 3 channels. The IIC module conforms with and provides a subset of the NXP I2C (Inter-Integrated Circuit) bus interface functions.

Table 31.1 lists the IIC specifications, Figure 31.1 shows a block diagram, and Figure 31.2 shows an example of I/O pin connections to external circuits, with an I2C bus configuration. Table 31.2 lists the I/O pins.

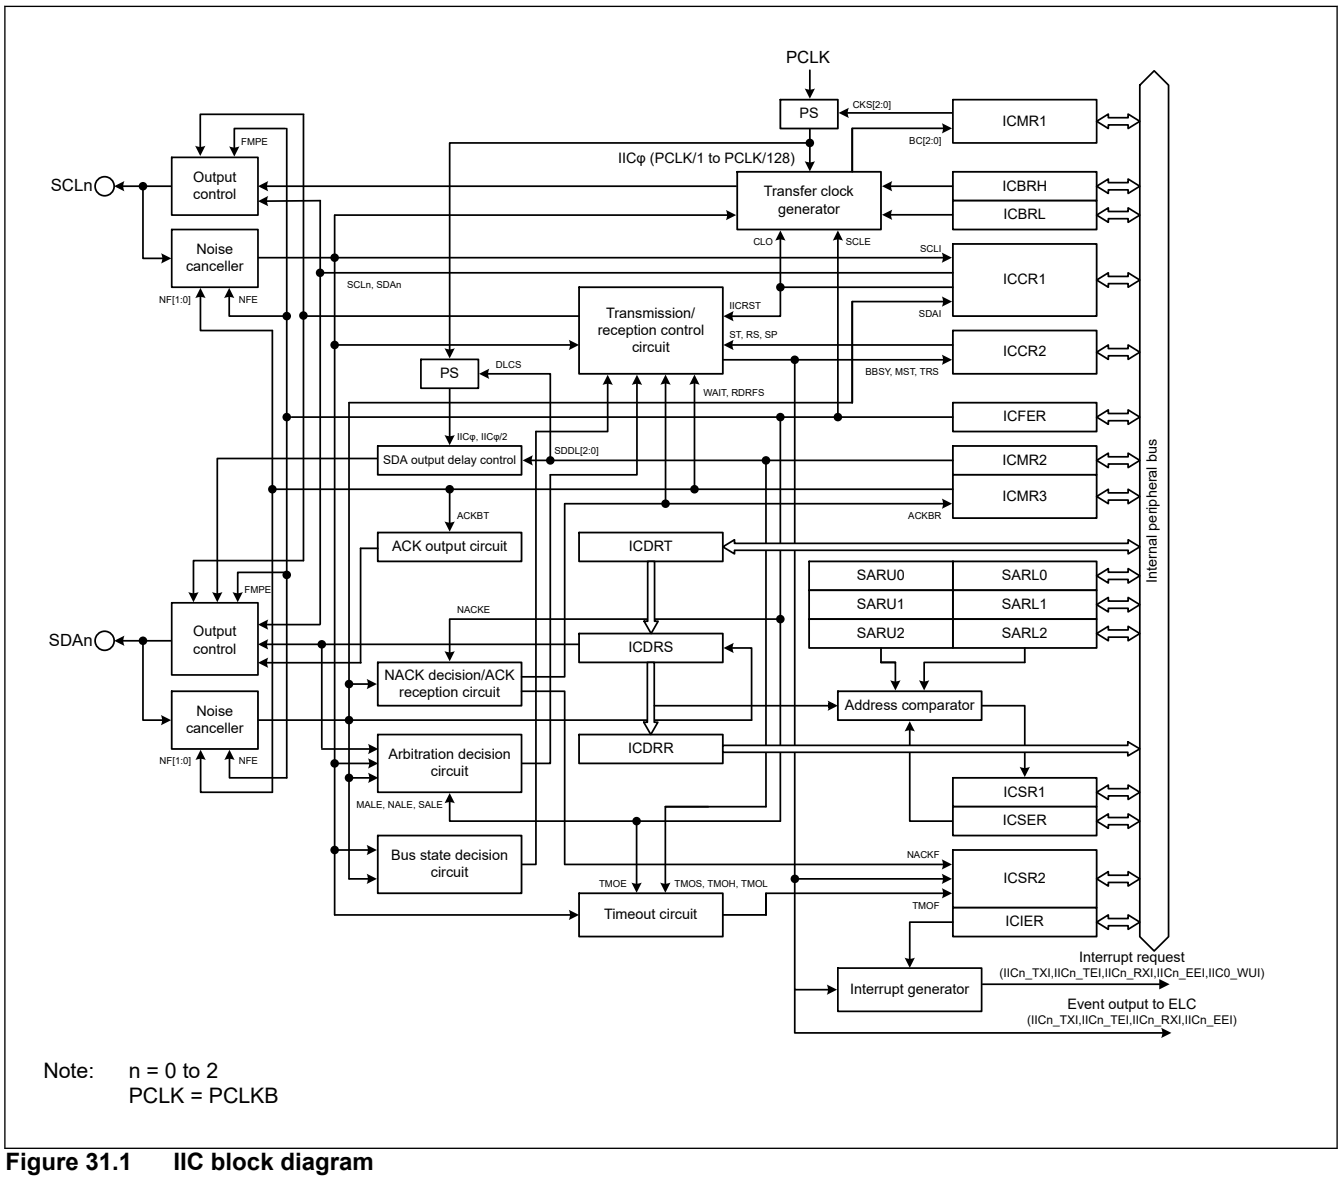
Table 31.1 IIC specifications (1 of 2)

Parameter	Specifications
Communications format	• I2C-bus format or SMBus format • Master or slave mode selectable • Automatic securing of the setup times, hold times, and bus-free times for the transfer rate
Transfer rate	• Fast-mode Plus supported, up to 1 Mbps
SCL clock	For master operation, the duty cycle of the SCL clock is selectable in the range from 4% to 96%
Issuing and detecting conditions	• Start, restart, and stop conditions are automatically generated • Start conditions (including restart conditions) and stop conditions are detectable
Slave address	• Configurable for up to three different slave addresses • 7- and 10-bit address formats supported, including simultaneous use • General call addresses, device ID addresses, and SMBus host addresses detectable
Acknowledgment	• For transmission, automatic loading of the acknowledge bit Transfer of the next transmit data can be automatically suspended on detection of a not-acknowledge bit. • For reception, automatic transmission of the acknowledge bit If a wait between the 8th and 9th clock cycles is selected, the software can control the value in the acknowledge field in response to the received value.
Wait function	During reception, the following wait periods are available by holding the SCL clock low: • Waiting between the eighth and ninth clock cycles • Waiting between the ninth clock cycle and the 1st clock cycle of the next transfer
SDA output delay function	Output timing of transmitted data, including the acknowledge bit, can be delayed
Arbitration	• For multi-master operation: – SCL clock synchronization is possible when conflict occurs with the SCL signal from another master – When issuing the start condition creates conflict on the bus, loss of arbitration is detected by testing for a mismatch between the internal signal for the SDA line and the level on the SDA line – In master operation, loss of arbitration is detected by testing for non-matching between the signal on the SDA line and the internal signal for the SDA line • Loss of arbitration because the start condition occurs while the bus is busy is detectable, to prevent the issuing of double start conditions • Loss of arbitration is detectable on transfer of a not-acknowledge bit because the internal signal for the SDA line and the level on the SDA line do not match • Loss of arbitration because a mismatch of internal and line levels for data is detectable in slave transmission
Timeout function	Internal detection of long-interval stops of the SCL clock
Noise cancellation	• Digital noise filters for both the SCL and SDA signals • Programmable window for noise cancellation by the filters
Interrupt sources	• Transfer error or event occurrence (arbitration-lost, NACK, timeout, start or restart condition, or stop condition) • Receive data full, including matching with a slave address • Transmit data empty, including matching with a slave address • Transmit end
Module-stop function	Module-stop state can be set
IIC operating modes	• Master transmit • Master receive • Slave transmit • Slave receive

Table 31.1 IIC specifications (2 of 2)

Parameter	Specifications
Event link function (output)	• Transfer error or event occurrence (arbitration-lost, NACK, timeout, start or restart condition, or stop condition) • Receive data full, including matching with a slave address • Transmit data empty, including matching with a slave address • Transmit end
Wakeup function*1	CPU can return from Software Standby mode using a wakeup event
TrustZone Filter	Security attribution can be set for each channels

Note 1. This function is only available for IIC channel IIC0. IIC1 and IIC2 are not supported.



Note: n = 0 to 2
PCLK = PCLKB

Figure 31.1 IIC block diagram

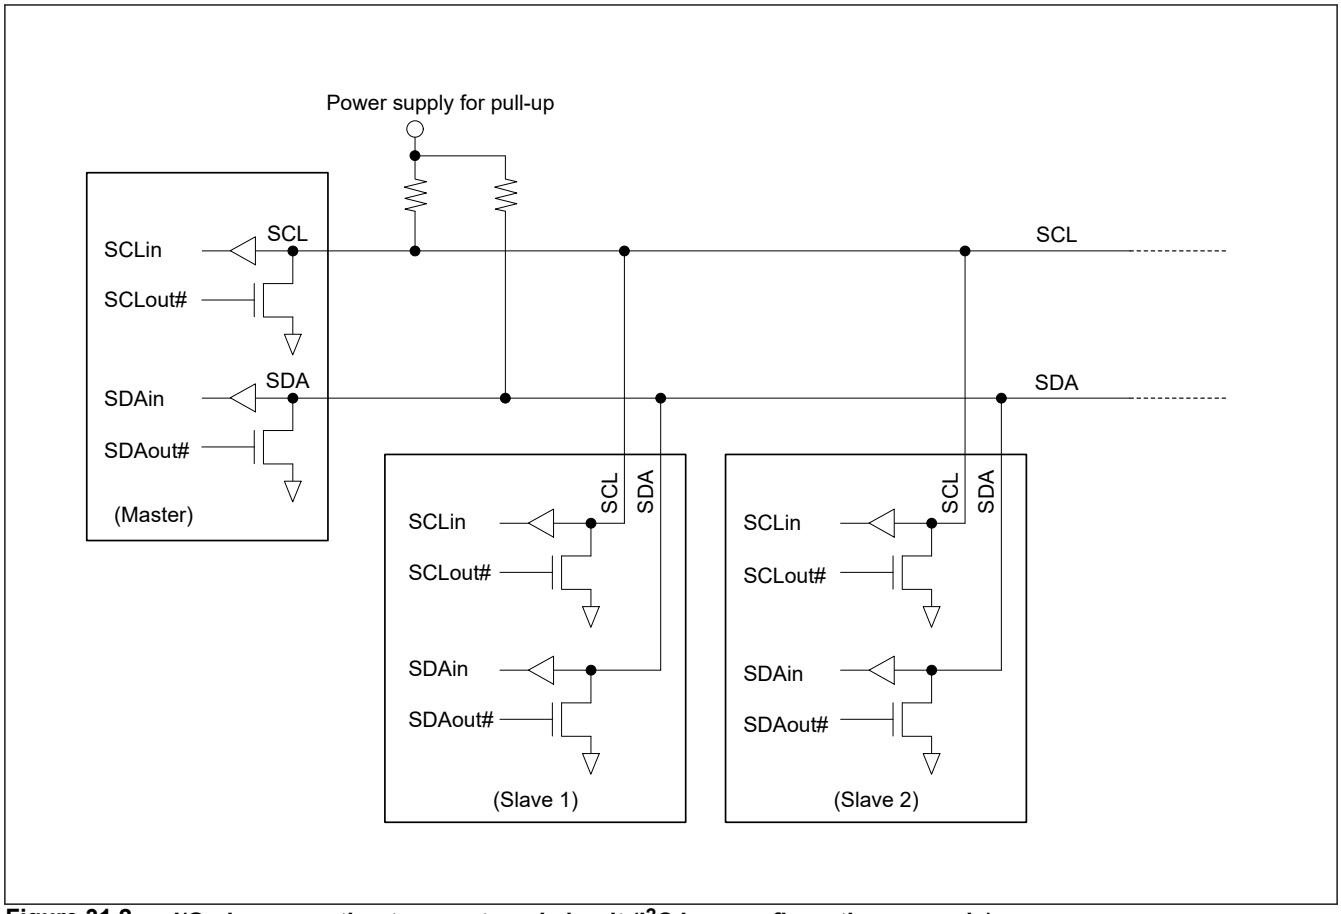


Figure 31.2 I/O pin connection to an external circuit (I^2C bus configuration example)

The input level of the signals for IIC is CMOS when I^2C bus is selected (ICMR3.SMBS = 0), or TTL when SMBus is selected (ICMR3.SMBS = 1).

Table 31.2 IIC I/O pins

Channel	Pin name	I/O	Function
IICn	SCLn	I/O	IICn serial clock I/O pin
	SDAn	I/O	IICn serial data I/O pin

Note: n = 0 to 2

31.2 Register Descriptions

31.2.1 ICCR1 : I^2C Bus Control Register 1

Base address: IICn = 0x4009_F000 + 0x0100 × n (n = 0 to 2)

Offset address: 0x00

Bit position:	7	6	5	4	3	2	1	0
Bit field:	ICE	IICRST	CLO	SOWP	SCLO	SDAO	SCLI	SDAI
Value after reset:	0	0	0	1	1	1	1	1

Bit	Symbol	Function	R/W
0	SDAI	SDA Line Monitor 0: SDAn line is low 1: SDAn line is high	R

Bit	Symbol	Function	R/W
1	SCLI	SCL Line Monitor 0: SCLn line is low 1: SCLn line is high	R
2	SDAO	SDA Output Control/Monitor 0: Read: IIC drives SDAn pin low Write: IIC drives SDAn pin low 1: Read: IIC releases SDAn pin Write: IIC releases SDAn pin	R/W
3	SCLO	SCL Output Control/Monitor Use an external pull-up resistor to drive the signal high. 0: Read: IIC drives SCLn pin low Write: IIC drives SCLn pin low 1: Read: IIC releases SCLn pin Write: IIC releases SCLn pin	R/W
4	SOWP	SCLO/SDAO Write Protect This bit is read as 1. 0: Write enable SCLO and SDAO bits 1: Write protect SCLO and SDAO bits	W
5	CLO	Extra SCL Clock Cycle Output This bit clears automatically after 1 clock cycle is output. 0: Do not output extra SCL clock cycle (default) 1: Output extra SCL clock cycle	R/W
6	IICRST	I2C Bus Interface Internal Reset This setting clears the bit counter and the SCLn/SDAn output latch. 0: Release IIC reset or internal reset 1: Initiate IIC reset or internal reset	R/W
7	ICE	I2C Bus Interface Enable Used in combination with the IICRST bit to select either IIC or internal reset. 0: Disable (SCLn and SDAn pins in inactive state) 1: Enable (SCLn and SDAn pins in active state)	R/W

SDAO bit (SDA Output Control/Monitor) and SCLO bit (SCL Output Control/Monitor)

The SDAO and SCLO bits directly control the SDAn and SCLn signals output from the IIC. When writing to these bits, also write 0 to the SOWP bit. Setting these bits results in input to the IIC by the input buffer. When slave mode is selected, a start condition might be detected and the bus might be released, depending on the bit settings.

Do not rewrite these bits during a start condition, stop condition, restart condition, transmission, or reception. Operation after rewriting under these conditions is not guaranteed. When reading these bits, the state of signals output from the IIC can be read.

CLO bit (Extra SCL Clock Cycle Output)

The CLO bit allows output of an extra SCL clock cycle for debugging or error processing. Normally, set this bit to 0. Setting the bit to 1 in a normal communication state causes a communication error. For details on this function, see section 31.12.2. Extra SCL Clock Cycle Output Function.

IICRST bit (I2C Bus Interface Internal Reset)

The IICRST bit initiates an internal state reset of the IIC. Setting this bit to 1 initiates an IIC reset or internal reset. Whether an IIC reset or internal reset is initiated is determined by the settings of this bit in combination with the ICE bit. Table 31.3 lists the IIC resets.

The IIC reset initializes all registers except ICCR1.ICE and ICCR1.IICRST bits and internal states of the IIC. In addition to the internal states of the IIC, the internal reset initializes the following:

- Bit counter (ICMR1.BC[2:0] bits)
- I2C Bus Shift Register (ICDRS)
- I2C Bus Status Registers (ICSR1 and ICSR2)
- SDAO and SCLO Output Control/Monitor (ICCR1.SDAO and ICCR1.SCLO bits)

- I²C Bus Control Register 2 (except ICCR2.BBSY bit)

For the reset conditions for each register, see section 31.15. State of Registers When Issuing Each Condition.

An internal reset initiated with the IICRST bit set to 1 during operation (with the ICE bit set to 1) resets the internal states of the IIC without initializing the port settings and the control and setting registers of the IIC. If the IIC hangs in a low-level output state, resetting the internal states cancels the low-level output state and releases the bus with the SCLn pin and SDAn pin at high impedance.

Note: If an internal reset is initiated using the IICRST bit for a bus hang-up that occurs during communication with the master device in slave mode, the slave and master devices might enter different states, because the bit counter information differs. For this reason, do not initiate an internal reset in slave mode. Initiate recovery processing from the master device. If an internal reset is required because the IIC hangs with the SCLn line in a low-level output state in slave mode, initiate an internal reset, then issue a restart condition from the master device, or issue a stop condition and resume communication from the start condition. If communication is restarted by initiating a reset solely in the slave device without issuing a start or restart condition from the master device, synchronization is lost because the master and slave devices operate asynchronously.

Table 31.3 IIC resets

IICRST	ICE	State	Specifications
1	0	IIC reset	Resets all registers except ICCR1.IICRST and ICCR1.ICE bits, and the internal states of the IIC
	1	Internal reset	Reset the following: • ICMR1.BC[2:0] bits • ICSR1, ICSR2, ICDRS registers • SDAO and SCLO Output Control/Monitor (ICCR1.SDAO and ICCR1.SCLO bits) • I²C Bus Control Register 2 (except ICCR2.BBSY bit) • Internal states of the IIC

ICE bit (I²C Bus Interface Enable)

The ICE bit selects the active or inactive state of the SCLn and SDAn pins. It can also be combined with the IICRST bit to initiate two types of resets. See Table 31.3 for the reset descriptions.

Set the ICE bit to 1 when using the IIC. The SCLn and SDAn pins are placed in the active state when the ICE bit is set to 1. Set the ICE bit to 0 when the IIC is not used. The SCLn and SDAn pins are placed in the inactive state when the ICE bit is set to 0. Do not assign the SCLn or SDAn pin to the IIC when setting up the pin function control. Slave address comparison is performed if the pins are assigned to the IIC.

31.2.2 ICCR2 : I²C Bus Control Register 2

Base address: IICn = 0x4009_F000 + 0x0100 × n (n = 0 to 2)

Offset address: 0x01

Bit position:	7	6	5	4	3	2	1	0
Bit field:	BBSY	MST	TRS	—	SP	RS	ST	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	—	This bit is read as 0. The write value should be 0.	R/W
1	ST	Start Condition Issuance Request 0: Do not issue a start condition request 1: Issue a start condition request	R/W
2	RS	Restart Condition Issuance Request 0: Do not issue a restart condition request 1: Issue a restart condition request	R/W

Bit	Symbol	Function	R/W
3	SP	Stop Condition Issuance Request 0: Do not issue a stop condition request 1: Issue a stop condition request	R/W
4	—	This bit is read as 0. The write value should be 0.	R/W
5	TRS	Transmit/Receive Mode 0: Receive mode 1: Transmit mode	R/W*1
6	MST	Master/Slave Mode 0: Slave mode 1: Master mode	R/W*1
7	BBSY	Bus Busy Detection Flag 0: I2C bus released (bus free state) 1: I2C bus occupied (bus busy state)	R

Note 1. The MST and TRS bits can be written to when the ICMR1.MTWP bit is set to 1.

ST bit (Start Condition Issuance Request)

The ST bit requests transition to master mode and triggers a start condition. When this bit is set to 1, a start condition is issued when the BBSY flag is set to 0 (bus free state). For details on this function, see section 31.11. Start, Restart, and Stop Condition Issuing Function.

[Setting condition]

- When 1 is written to the ST bit.

[Clearing conditions]

- When 0 is written to the ST bit
- When a start condition is issued (a start condition is detected)
- When the AL (arbitration-lost) flag in ICSR2 is set to 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

Note: Only set the ST bit to 1 (start condition request) when the BBSY flag is set to 0 (bus free state). Arbitration might be lost if the ST bit is set to 1 (start condition request) when the BBSY flag is 1 (bus busy state).

RS bit (Restart Condition Issuance Request)

The RS bit requests that a restart condition be issued in master mode. When this bit is set to 1 to request a restart condition, a restart condition is issued when the BBSY flag is set to 1 (bus busy state) and the MST bit is set to 1 (master mode). For details on this function, see section 31.11. Start, Restart, and Stop Condition Issuing Function.

[Setting condition]

- When 1 is written to the RS bit with the BBSY flag in ICCR2 set to 1.

[Clearing conditions]

- When 0 is written to the RS bit
- When a restart condition is issued (a start condition is detected)
- When the AL (arbitration-lost) flag in ICSR2 is set to 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

Note: Do not set the RS bit to 1 while issuing a stop condition.
Note: If 1 (restart condition request) is written to the RS bit in slave mode, the restart condition is not issued, but the RS bit remains set to 1. If the operating mode changes to master mode without the bit being cleared, a restart condition might be issued.

SP bit (Stop Condition Issuance Request)

The SP bit requests that a stop condition be issued in master mode. When this bit is set to 1, a stop condition is issued when the BBSY flag is set to 1 (bus busy state) and the MST bit is set to 1 (master mode). For details on this function, see section 31.11. Start, Restart, and Stop Condition Issuing Function.

[Setting condition]

- When 1 is written to the SP bit with both the BBSY flag and the MST bit in ICCR2 set to 1.

[Clearing conditions]

- When 0 is written to the SP bit
- When a stop condition is issued (a stop condition is detected)
- When the AL (arbitration-lost) flag in ICSR2 is set to 1
- When a start condition and a restart condition are detected
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

Note: Writing to the SP bit is not possible while the BBSY flag is 0 (bus free state).
Note: Do not set the SP bit to 1 while a restart condition is being issued.

TRS bit (Transmit/Receive Mode)

The TRS bit indicates transmit or receive mode. The IIC is in receive mode when the TRS bit is 0 and in transmit mode when the bit is 1. The combination of this bit and the MST bit indicates the IIC operating mode.

The value of the TRS bit automatically changes to 1 for transmit mode or 0 for receive mode when a start condition is issued or detected and the R/W# bit is set. Although writing to the TRS bit is possible when the MTWP bit in ICMR1 is set to 1, writing to this bit is not required during normal usage.

[Setting conditions]

- When a start condition is issued normally because of a start condition request (when a start condition is detected with the ST bit set to 1)
- When a restart condition is issued normally because of a restart condition request (when a restart condition is detected with the RS bit set to 1)
- When the R/W# bit appended to the slave address is set to 0 in master mode
- When the address received in slave mode matches the address enabled in ICSER, with the R/W# bit set to 1
- When 1 is written to the TRS bit with the MTWP bit in ICMR1 set to 1.

[Clearing conditions]

- When a stop condition is detected
- When the AL (arbitration-lost) flag in ICSR2 is set to 1
- When the R/W# bit appended to the slave address is set to 1 in master mode
- In slave mode, on a match between the received address and the address enabled in ICSER when the value of the received R/W# bit is 0, including when the received address is the general call address
- In slave mode, when a restart condition is detected (a restart condition is detected with ICCR2.BBSY = 1 and ICCR2.MST = 0)
- When 0 is written to the TRS bit with the MTWP bit in ICMR1 set to 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

MST bit (Master/Slave Mode)

The MST bit indicates master or slave mode. The IIC is in slave mode when the MST bit is 0 and is in master mode when the bit is 1. The combination of this bit and the TRS bit indicates the IIC operating mode.

The value of the MST bit automatically changes to 1 for master mode or 0 for slave mode when a start condition is issued or a stop condition is issued or detected. Although writing to the MST bit is possible when the MTWP bit in ICMR1 is set to 1, writing to this bit is not required during normal usage.

[Setting conditions]

- When a start condition is issued normally because of a start condition request (when a start condition is detected with the ST bit set to 1)
- When 1 is written to the MST bit with the MTWP bit in ICMR1 set to 1.

[Clearing conditions]

- When a stop condition is detected
- When the AL (arbitration-lost) flag in ICSR2 is set to 1
- When 0 is written to the MST bit with the MTWP bit in ICMR1 set to 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

BBSY flag (Bus Busy Detection Flag)

The BBSY flag indicates whether the I^2C bus is occupied (bus busy state) or released (bus free state). The flag is set to 1 when the SDAn line changes from high to low when the SCLn line is high, assuming that a start condition was issued. The flag is set to 0 if a start condition is not detected for the bus free time (ICBRL setting), assuming that a stop condition was issued.

[Setting condition]

- When a start condition is detected.

[Clearing conditions]

- When a start condition is not detected for the bus free time (ICBRL setting) after detecting a stop condition
- When 1 is written to the IICRST bit in ICCR1 with the ICE bit in ICCR1 set to 0 (IIC reset).

31.2.3 ICMR1 : I^2C Bus Mode Register 1

Base address: IICn = 0x4009_F000 + 0x0100 × n (n = 0 to 2)

Offset address: 0x02

Bit position:	7	6	5	4	3	2	1	0
Bit field:	MTWP	CKS[2:0]			BCWP	BC[2:0]		
Value after reset:	0	0	0	0	1	0	0	0

Bit	Symbol	Function	R/W
2:0	BC[2:0]	Bit Counter 0 0 0: 9 bits 0 0 1: 2 bits 0 1 0: 3 bits 0 1 1: 4 bits 1 0 0: 5 bits 1 0 1: 6 bits 1 1 0: 7 bits 1 1 1: 8 bits	R/W*1
3	BCWP	BC Write Protect This bit is read as 1. 0: Write enable BC[2:0] bits 1: Write protect BC[2:0] bits	W*1
6:4	CKS[2:0]	Internal Reference Clock Select Select the internal reference clock source (IICφ) for the IIC. IICφ = (PCLKB / $2^{CKS[2:0]}$) clock	R/W
7	MTWP	MST/TRS Write Protect 0: Write protect MST and TRS bits in ICCR2 1: Write enable MST and TRS bits in ICCR2	R/W

Note 1. Rewrite the BC[2:0] bits and set the BCWP bit to 0 at the same time.

BC[2:0] bits (Bit Counter)

The BC[2:0] bits function as a counter indicating the number of bits remaining to be transferred on detection of a rising edge on the SCLn line. Although BC[2:0] are read/write bits, it is not required to access these bits under normal conditions.

To write to these bits, specify the number of bits to be transferred plus one, for an additional acknowledge bit, between transferred frames when the SCLn line is at a low level. The value in the BC[2:0] bits returns to 000b at the end of a data transfer, including the acknowledge bit, or when a start or restart condition is detected.

31.2.4 ICMR2 : I2C Bus Mode Register 2

Base address: IICn = 0x4009_F000 + 0x0100 × n (n = 0 to 2)

Offset address: 0x03

Bit position:	7	6	5	4	3	2	1	0
Bit field:	DLCS	SDDL[2:0]			—	TMOH	TMOL	TMOS
Value after reset:	0	0	0	0	0	1	1	0

Bit	Symbol	Function	R/W
0	TMOS	Timeout Detection Time Select 0: Select long mode 1: Select short mode	R/W
1	TMOL	Timeout L Count Control 0: Disable count while SCLn line is low 1: Enable count while SCLn line is low	R/W
2	TMOH	Timeout H Count Control 0: Disable count while SCLn line is high 1: Enable count while SCLn line is high	R/W
3	—	This bit is read as 0. The write value should be 0.	R/W
6:4	SDDL[2:0]	SDA Output Delay Counter 0 0 0: No output delay 0 0 1: 1 IICφ cycle (When ICMR2.DLCS = 0 (IICφ)) 1 or 2 IICφ cycles (When ICMR2.DLCS = 1 (IICφ/2)) 0 1 0: 2 IICφ cycles (When ICMR2.DLCS = 0 (IICφ)) 3 or 4 IICφ cycles (When ICMR2.DLCS = 1 (IICφ/2)) 0 1 1: 3 IICφ cycles (When ICMR2.DLCS = 0 (IICφ)) 5 or 6 IICφ cycles (When ICMR2.DLCS = 1 (IICφ/2)) 1 0 0: 4 IICφ cycles (When ICMR2.DLCS = 0 (IICφ)) 7 or 8 IICφ cycles (When ICMR2.DLCS = 1 (IICφ/2)) 1 0 1: 5 IICφ cycles (When ICMR2.DLCS = 0 (IICφ)) 9 or 10 IICφ cycles (When ICMR2.DLCS = 1 (IICφ/2)) 1 1 0: 6 IICφ cycles (When ICMR2.DLCS = 0 (IICφ)) 11 or 12 IICφ cycles (When ICMR2.DLCS = 1 (IICφ/2)) 1 1 1: 7 IICφ cycles (When ICMR2.DLCS = 0 (IICφ)) 13 or 14 IICφ cycles (When ICMR2.DLCS = 1 (IICφ/2))	R/W
7	DLCS	SDA Output Delay Clock Source Select 0: Select internal reference clock (IICφ) as the clock source for SDA output delay counter 1: Select internal reference clock divided by 2 (IICφ/2) as the clock source for SDA output delay counter*1	R/W

Note 1. The setting DLCS = 1 (IICφ/2) is only valid when SCL is low. When SCL is high, the DLCS = 1 setting becomes invalid and the clock source becomes the internal reference clock (IICφ).

TMOS bit (Timeout Detection Time Select)

The TMOS bit selects long or short mode for the timeout detection time when the timeout function is enabled (ICFER.TMOE = 1). When this bit is set to 0, long mode is selected. When it is set to 1, short mode is selected. In long mode, the timeout detection internal counter functions as a 16 bit-counter. In short mode, the counter functions as a 14- bit counter. While the SCLn line is in the state that enables this counter as specified in the TMOH and TMOL bits, the counter counts up in synchronization with the internal reference clock (IICφ) as a count source. For details on this function, see section 31.12.1. Timeout Function.

TMOL bit (Timeout L Count Control)

The TMOL bit enables or disables up-counting on the internal counter of the timeout function while the SCLn line is held low and the timeout function is enabled (ICFER.TMOE = 1).

TMOH bit (Timeout H Count Control)

The TMOH bit enables or disables up-counting on the internal counter of the timeout function while the SCLn line is held high and the timeout function is enabled (ICFER.TMOE = 1).

SDDL[2:0] bits (SDA Output Delay Counter)

The SDDL[2:0] bits can be used to delay the SDA output. This counter works with the clock source selected in the DLCS bit. This setting can be used for all types of SDA output, including transmission of the acknowledge bit.

Set the SDA output delay to meet the I2C bus standard for the data enable time/acknowledge enable time,*1 or the SMBus standard, within [data hold time (300 ns or more + the SCL clock low-level period) - the data setup time (250 ns)]. If a value outside the standard is set, communication between devices might malfunction or falsely indicate a start or stop condition, depending on the bus state.

For details on this function, see section 31.5. SDA Output Delay Function.

Note 1. Data enable time/acknowledge enable time.
3,450 ns for up to 100 kbps: Standard mode (Sm)
900 ns for up to 400 kbps: Fast mode (Fm)
450 ns for up to 1 Mbps: Fast-mode Plus (Fm+)

31.2.5 ICMR3 : I2C Bus Mode Register 3

Base address: IICn = 0x4009_F000 + 0x0100 × n (n = 0 to 2)

Offset address: 0x04

Bit position:	7	6	5	4	3	2	1	0
Bit field:	SMBS	WAIT	RDRFS	ACKWP	ACKBT	ACKBR	NF[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	NF[1:0]	Noise Filter Stage Select 0 0: Filter out noise of up to 1 IICφ cycle (single-stage filter) 0 1: Filter out noise of up to 2 IICφ cycles (2-stage filter) 1 0: Filter out noise of up to 3 IICφ cycles (3-stage filter) 1 1: Filter out noise of up to 4 IICφ cycles (4-stage filter)	R/W
2	ACKBR	Receive Acknowledge 0: 0 received as the acknowledge bit (ACK reception) 1: 1 received as the acknowledge bit (NACK reception)	R
3	ACKBT	Transmit Acknowledge 0: Send 0 as the acknowledge bit (ACK transmission) 1: Send 1 as the acknowledge bit (NACK transmission)	R/W*1
4	ACKWP	ACKBT Write Protect 0: Write protect ACKBT bit 1: Write enable ACKBT bit	R/W
5	RDRFS	RDRF Flag Set Timing Select Low-hold is released by writing to ACKBT. 0: Set the RDRF flag on the rising edge of the 9th SCL clock cycle. The SCLn line is not held low on the falling edge of the 8th clock cycle. 1: Set the RDRF flag on the rising edge of the 8th SCL clock cycle. The SCLn line is held low on the falling edge of the 8th clock cycle.	R/W*2

Bit	Symbol	Function	R/W
6	WAIT	Low-hold is released by reading ICDRR. 0: No wait (The SCLn line is not held low during the period between the 9th clock cycle and the 1st clock cycle.) 1: Wait (The SCLn line is held low during the period between the 9th clock cycle and the 1st clock cycle.)	R/W*2
7	SMBS	SMBus/I2C Bus Select 0: Select I2C Bus 1: Select SMBus	R/W

Note 1. Write to the ACKBT bit only while the ACKWP bit is already 1. If the application writes 1 to the ACKWP and ACKBT bits at the same time, the ACKBT bit is not set to 1.
Note 2. The WAIT and RDRFS bits are only valid in receive mode (invalid in transmit mode).

NF[1:0] bits (Noise Filter Stage Select)

The NF[1:0] bits select the number of stages in the digital noise filter. For details on this function, see section 31.6. Digital Noise Filter Circuits

Note: Set the noise range to be filtered within a range less than the SCLn line high- or low-level period. If the noise range is set to a value of [SCL clock width: high- or low-level period, whichever is shorter] - [1.5 internal reference clock (IICφ) cycles + analog noise filter: 120 ns (reference values)] or more, the SCL clock is regarded as noise, which might prevent the IIC from operating normally.

ACKBR bit (Receive Acknowledge)

The ACKBR bit stores the acknowledge bit information received from the receive device in transmit mode.

[Setting condition]

- When 1 is received as the acknowledge bit with the TRS bit in ICCR2 set to 1.

[Clearing conditions]

- When 0 is received as the acknowledge bit with the TRS bit in ICCR2 set to 1
- When 1 is written to the IICRST bit in ICCR1 while the ICE bit in ICCR1 is 0 (IIC reset).

ACKBT bit (Transmit Acknowledge)

The ACKBT bit sets the acknowledge bit to be sent in receive mode

[Setting condition]

- When 1 is written to this bit with the ACKWP bit set to 1.

[Clearing conditions]

- When 0 is written to this bit with the ACKWP bit set to 1
- When stop condition request is detected with the SP bit in ICCR2 set to 1
- When 1 is written to the IICRST bit in ICCR1 while the ICE bit in ICCR1 is 0 (IIC reset).

ACKWP bit (ACKBT Write Protect)

The ACKWP bit controls write enabling of the ACKBT bit.

RDRFS bit (RDRF Flag Set Timing Select)

The RDRFS bit selects the RDRF flag set timing in receive mode and also selects whether to hold the SCLn line low on the falling edge of the 8th SCL clock cycle.

When the RDRFS bit is 0, the SCLn line is not held low on the falling edge of the 8th SCL clock cycle, and the RDRF flag is set to 1 on the rising edge of the 9th SCL clock cycle.

When the RDRFS bit is 1, the RDRF flag is set to 1 on the rising edge of the 8th SCL clock cycle, and the SCLn line is held low on the falling edge of the 8th SCL clock cycle. The low-hold of the SCLn line is released by a write to the ACKBT bit.

After data is received with this setting, the SCLn line is automatically held low before the acknowledge bit is sent. This enables processing to send ACK (ACKBT = 0) or NACK (ACKBT = 1), based on the receive data.

WAIT bit (WAIT)

The WAIT bit controls whether to force a low-hold between the ninth SCL clock cycle and the first SCL clock cycle, until the receive data buffer (ICDRR) is completely read each time single-byte data is received in receive mode.

When the WAIT bit is 0, the receive operation continues without a low-hold between the ninth and the first SCL clock cycle. When both the RDRFS and WAIT bits are 0, continuous receive operation is enabled with the double buffer.

When the WAIT bit is 1, the SCLn line is held low from the falling edge of the ninth clock cycle until the ICDRR value is read each time single-byte data is received. This enables receive operation in byte units.

Note: When the value of the WAIT bit is to be read, always read ICDRR first.

SMBS bit (SMBus/I2C Bus Select)

Setting the SMBS bit to 1 selects the SMBus and enables the HOAE bit in ICSER.

31.2.6 ICFER : I2C Bus Function Enable Register

Base address: IICn = 0x4009_F000 + 0x0100 × n (n = 0 to 2)

Offset address: 0x05

Bit position:	7	6	5	4	3	2	1	0
Bit field:	FMPE	SCLE	NFE	NACKE	SALE	NALE	MALE	TMOE
Value after reset:	0	1	1	1	0	0	1	0

Bit	Symbol	Function	R/W
0	TMOE	Timeout Function Enable 0: Disable 1: Enable	R/W
1	MALE	Master Arbitration-Lost Detection Enable 0: Disable the arbitration-lost detection function and disable automatic clearing of the MST and TRS bits in ICCR2 when arbitration is lost 1: Enable the arbitration-lost detection function and enable automatic clearing of the MST and TRS bits in ICCR2 when arbitration is lost	R/W
2	NALE	NACK Transmission Arbitration-Lost Detection Enable 0: Disable 1: Enable	R/W
3	SALE	Slave Arbitration-Lost Detection Enable 0: Disable 1: Enable	R/W
4	NACKE	NACK Reception Transfer Suspension Enable 0: Do not suspend transfer operation during NACK reception (disable transfer suspension) 1: Suspend transfer operation during NACK reception (enable transfer suspension)	R/W
5	NFE	Digital Noise Filter Circuit Enable 0: Do not use the digital noise filter circuit 1: Use the digital noise filter circuit	R/W
6	SCLE	SCL Synchronous Circuit Enable 0: Do not use the SCL synchronous circuit 1: Use the SCL synchronous circuit	R/W
7	FMPE*1	Fast-Mode Plus Enable 0: Do not use the Fm+ slope control circuit for the SCLn and SDAn pins 1: Use the Fm+ slope control circuit for the SCLn and SDAn pins.	R/W

Note 1. The Fast-mode Plus enable bit (FMPE) is supported by IIC0 (SCL0_A, SDA0_A) and IIC1(SCL1_A, SDA1_A). Bit [7] is the reserved bit in the not supported channel.

TMOE bit (Timeout Function Enable)

The TMOE bit enables or disables the timeout function. For details on this function, see section 31.12.1. Timeout Function.

MALE bit (Master Arbitration-Lost Detection Enable)

The MALE bit specifies whether to use the arbitration-lost detection function in master mode. Normally, set this bit to 1.

NALE bit (NACK Transmission Arbitration-Lost Detection Enable)

The NALE bit specifies whether to cause arbitration to be lost when ACK is detected during transmission of NACK in receive mode, for example when slaves with the same address exist on the bus or when two or more masters select the same slave device simultaneously with a different number of receive bytes.

SALE bit (Slave Arbitration-Lost Detection Enable)

The SALE bit specifies whether to cause arbitration to be lost when a value different from the value being transmitted is detected on the bus in slave transmit mode, for example when slaves with the same address exist on the bus or when a mismatch with the transmit data occurs because of noise.

NACKE bit (NACK Reception Transfer Suspension Enable)

The NACKE bit specifies whether to continue or discontinue the transfer operation when NACK is received in transmit mode. Normally, set this bit to 1.

When NACK is received with the NACKE bit set to 1, the next transfer operation is suspended. When the NACKE bit is 0, the next transfer operation continues regardless of the received acknowledge content.

For details, see section 31.9.2. NACK Reception Transfer Suspension Function.

SCLE bit (SCL Synchronous Circuit Enable)

The SCLE bit specifies whether to synchronize the SCL clock with the SCL input clock. Normally, set this bit to 1.

When the SCLE bit is set to 0 (no SCL synchronous circuit used), the IIC does not synchronize the SCL clock with the SCL input clock. With this setting, the IIC outputs the SCL clock at the transfer rate set in ICBRH and ICBRL, regardless of the SCLn line state. For this reason, if the bus load of the I^2C bus line is much larger than the specification value, or if the SCL clock output overlaps in multiple masters, a short-cycle SCL clock that does not meet the specification might be output. When no SCL synchronous circuit is used, it also affects the issuing of the start, restart, and stop conditions, and the continuous output of extra SCL clock cycles.

Do not set this bit to 0 except when checking the output of the set transfer rate.

FMPE bit (Fast-Mode Plus Enable)

The FMPE bit specifies whether to use a slope control circuit for Fast-mode Plus (Fm+).

When this bit is set to 1, a slope control circuit conforming to the I^2C bus Fast-mode Plus (Fm+) standard (tof) is selected. When this bit is set to 0, a slope control circuit conforming to the I^2C bus Standard-mode (Sm) and Fast-mode (Fm) standards (tof) is selected.

Set this bit to 1 when using transmission rates up to 1 Mbps (Fast-mode Plus (Fm+) standard). Set it to 0 when using other transmission rates (up to 100 kbps (Sm) or up to 400 kbps (Fm)) or for SMBus (10 to 100 kbps).

31.2.7 ICSER : I^2C Bus Status Enable Register

Base address: IICn = 0x4009_F000 + 0x0100 × n (n = 0 to 2)

Offset address: 0x06

Bit position:	7	6	5	4	3	2	1	0
Bit field:	HOAE	—	DIDE	—	GCAE	SAR2E	SAR1E	SAR0E
Value after reset:	0	0	0	0	1	0	0	1

Bit	Symbol	Function	R/W
0	SAR0E	Slave Address Register 0 Enable 0: Disable slave address in SARL0 and SARU0 1: Enable slave address in SARL0 and SARU0	R/W

Bit	Symbol	Function	R/W
1	SAR1E	Slave Address Register 1 Enable 0: Disable slave address in SARL1 and SARU1 1: Enable slave address in SARL1 and SARU1	R/W
2	SAR2E	Slave Address Register 2 Enable 0: Disable slave address in SARL2 and SARU2 1: Enable slave address in SARL2 and SARU2	R/W
3	GCAE	General Call Address Enable 0: Disable general call address detection 1: Enable general call address detection	R/W
4	—	This bit is read as 0. The write value should be 0.	R/W
5	DIDE	Device-ID Address Detection Enable 0: Disable device-ID address detection 1: Enable device-ID address detection	R/W
6	—	This bit is read as 0. The write value should be 0.	R/W
7	HOAE	Host Address Enable 0: Disable host address detection 1: Enable host address detection	R/W

SARyE bit (Slave Address Register y Enable) (y = 0 to 2)

The SARyE bit enables or disables the received slave address and the slave address set in SARLy and SARUy.

When this bit is set to 1, the slave address set in SARLy and SARUy is enabled and is compared with the received slave address. When this bit is set to 0, the slave address set in SARLy and SARUy is disabled and is ignored even if it matches the received slave address.

GCAE bit (General Call Address Enable)

The GCAE bit specifies whether to ignore the general call address (0000 000b + 0 [W]: All 0) when it is received.

When this bit is set to 1, if the received slave address matches the general call address, the IIC recognizes the received slave address as the general call address independently of the slave addresses set in SARLy and SARUy (y = 0 to 2) and performs the data receive operation. When this bit is set to 0, the received slave address is ignored even if it matches the general call address.

DIDE bit (Device-ID Address Detection Enable)

The DIDE bit specifies whether to recognize and execute the device-ID address when a device ID (1111 100b) is received in the first frame after a start or restart condition is detected.

When this bit is set to 1, if the received first frame matches the device ID, the IIC recognizes that the device-ID address was received. When the next R/W# bit is 0 (W), the IIC recognizes the second and the subsequent frames as slave addresses and continues the receive operation. When this bit is set to 0, the IIC ignores the received first frame even if it matches the device-ID address, and it recognizes the first frame as a normal slave address.

For details on this function, see section 31.7.3. Device-ID Address Detection.

HOAE bit (Host Address Enable)

The HOAE bit specifies whether to ignore the received host address (0001 000b) when the SMBS bit in ICMR3 is 1.

When this bit is set to 1 while the SMBS bit in ICMR3 is 1, if the received slave address matches the host address, the IIC recognizes the received slave address as the host address independently of the slave addresses set in SARLy and SARUy (y = 0 to 2) and performs the receive operation.

When the SMBS bit in ICMR3 or the HOAE bit is set to 0, the received slave address is ignored even if it matches the host address.

31.2.8 ICIER : I²C Bus Interrupt Enable Register

Base address: IICn = 0x4009_F000 + 0x0100 × n (n = 0 to 2)

Offset address: 0x07

Bit position:	7	6	5	4	3	2	1	0
Bit field:	TIE	TEIE	RIE	NAKIE	SPIE	STIE	ALIE	TMOIE
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TMOIE	Timeout Interrupt Request Enable 0: Disable timeout interrupt (TMOI) request 1: Enable timeout interrupt (TMOI) request	R/W
1	ALIE	Arbitration-Lost Interrupt Request Enable 0: Disable arbitration-lost interrupt (ALI) request 1: Enable arbitration-lost interrupt (ALI) request	R/W
2	STIE	Start Condition Detection Interrupt Request Enable 0: Disable start condition detection interrupt (STI) request 1: Enable start condition detection interrupt (STI) request	R/W
3	SPIE	Stop Condition Detection Interrupt Request Enable 0: Disable stop condition detection interrupt (SPI) request 1: Enable stop condition detection interrupt (SPI) request	R/W
4	NAKIE	NACK Reception Interrupt Request Enable 0: Disable NACK reception interrupt (NAKI) request 1: Enable NACK reception interrupt (NAKI) request	R/W
5	RIE	Receive Data Full Interrupt Request Enable 0: Disable receive data full interrupt (IICn_RXI) request 1: Enable receive data full interrupt (IICn_RXI) request	R/W
6	TEIE	Transmit End Interrupt Request Enable 0: Disable transmit end interrupt (IICn_TEI) request 1: Enable transmit end interrupt (IICn_TEI) request	R/W
7	TIE	Transmit Data Empty Interrupt Request Enable 0: Disable transmit data empty interrupt (IICn_TXI) request 1: Enable transmit data empty interrupt (IICn_TXI) request	R/W

TMOIE bit (Timeout Interrupt Request Enable)

The TMOIE bit enables or disables timeout interrupt (TMOI) requests when the TMOF flag in ICSR2 is 1. To cancel a TMOI interrupt request, set the TMOF flag or the TMOIE bit to 0.

ALIE bit (Arbitration-Lost Interrupt Request Enable)

The ALIE bit enables or disables arbitration-lost interrupt (ALI) requests when the AL flag in ICSR2 is 1. To cancel an ALI interrupt request, set the AL flag or the ALIE bit to 0.

STIE bit (Start Condition Detection Interrupt Request Enable)

The STIE bit enables or disables start condition detection interrupt (STI) requests when the START flag in ICSR2 is 1. To cancel an STI interrupt request, set the START flag or the STIE bit to 0.

SPIE bit (Stop Condition Detection Interrupt Request Enable)

The SPIE bit enables or disables stop condition detection interrupt (SPI) requests when the STOP flag in ICSR2 is 1. To cancel an SPI interrupt request, set the STOP flag or the SPIE bit to 0.

NAKIE bit (NACK Reception Interrupt Request Enable)

The NAKIE bit enables or disables NACK reception interrupt (NAKI) requests when the NACKF flag in ICSR2 is 1. To cancel an NAKI interrupt request, set the NACKF flag or the NAKIE bit to 0.

RIE bit (Receive Data Full Interrupt Request Enable)

The RIE bit enables or disables receive data full interrupt (IICn_RXI) requests when the RDRF flag in ICSR2 is 1.

TEIE bit (Transmit End Interrupt Request Enable)

The TEIE bit enables or disables transmit end interrupt (IICn_TEI) requests when the TEND flag in ICSR2 is 1. To cancel an IICn_TEI interrupt request, set the TEND flag or the TEIE bit to 0.

TIE bit (Transmit Data Empty Interrupt Request Enable)

The TIE bit enables or disables transmit data empty interrupt (IICn_TXI) requests when the TDRE flag in ICSR2 is 1.

31.2.9 ICSR1 : I2C Bus Status Register 1

Base address: IICn = 0x4009_F000 + 0x0100 × n (n = 0 to 2)

Offset address: 0x08

Bit position:	7	6	5	4	3	2	1	0
Bit field:	HOA	—	DID	—	GCA	AAS2	AAS1	AAS0
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	AAS0	Slave Address 0 Detection Flag 0: Slave address 0 not detected 1: Slave address 0 detected	R/(W)*1
1	AAS1	Slave Address 1 Detection Flag 0: Slave address 1 not detected 1: Slave address 1 detected	R/(W)*1
2	AAS2	Slave Address 2 Detection Flag 0: Slave address 2 not detected 1: Slave address 2 detected	R/(W)*1
3	GCA	General Call Address Detection Flag 0: General call address not detected 1: General call address detected	R/(W)*1
4	—	This bit is read as 0. The write value should be 0.	R/W
5	DID	Device-ID Address Detection Flag This bit is set to 1 when the first frame received immediately after a start condition is detected matches a value of (device ID (1111 100b) + 0[W]). 0: Device-ID command not detected 1: Device-ID command detected	R/(W)*1
6	—	This bit is read as 0. The write value should be 0.	R/W
7	HOA	Host Address Detection Flag This bit is set to 1 when the received slave address matches the host address (0001 000b). 0: Host address not detected 1: Host address detected	R/(W)*1

Note 1. Only 0 can be written to clear the flag.

AASy flag (Slave Address y Detection flag) (y = 0 to 2)

The AASy flag indicates whether slave address y was detected.

[Setting conditions]

For 7-bit address format (SARUy.FS = 0):

- When the received slave address matches the SVA[6:0] value in SARLy, with the SARyE bit in ICSER set to 1 (slave address y detection enabled).
  The AASy flag is set to 1 on the rising edge of the ninth SCL clock cycle in the frame.

For 10-bit address format: (SARUy.FS = 1):

- When the received slave address matches a value of (11110b + SVA[1:0] in SARUy), and the subsequent address matches the SARLy value, with the SARyE bit in ICSER set to 1 (slave address y detection enabled).
  The AASy flag is set to 1 on the rising edge of the ninth SCL clock cycle in the frame.

[Clearing conditions]

- When 0 is written to the AASy flag after reading AASy = 1
- When a stop condition is detected
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

For 7-bit address format (SARUy.FS = 0):

- When the received slave address does not match the SVA[6:0] value in SARLy, with the SARyE bit in ICSER set to 1 (slave address y detection enabled).
  The AASy flag is set to 0 on the rising edge of the ninth SCL clock cycle in the frame.

For 10-bit address format (SARUy.FS = 1):

- When the received slave address does not match a value of (11110b + SVA[1:0] in SARUy), with the SARyE bit in ICSER set to 1 (slave address y detection enabled)
  The AASy flag is set to 0 on the rising edge of the ninth SCL clock cycle in the frame.
- When the received slave address matches a value of (11110b + SVA[1:0] in SARUy), and the subsequent address does not match the SARLy value, with the SARyE bit in ICSER set to 1 (slave address y detection enabled).
  The AASy flag is set to 0 on the rising edge of the ninth SCL clock cycle in the frame.

GCA flag (General Call Address Detection Flag)

The GCA flag indicates whether the general call address was detected.

[Setting condition]

- When the received slave address matches the general call address (0000 000b + 0 [W]), with the GCAE bit in ICSER set to 1 (general call address detection enabled).
  The GCA flag is set to 1 on the rising edge of the ninth SCL clock cycle in the frame.

[Clearing conditions]

- When 0 is written to the GCA flag after reading GCA = 1
- When a stop condition is detected
- When the received slave address does not match the general call address (0000 000b + 0 [W]), with the GCAE bit in ICSER set to 1 (general call address detection enabled)
  The GCA flag is set to 0 on the rising edge of the ninth SCL clock cycle in the frame.
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

DID flag (Device-ID Address Detection Flag)

The DID flag indicates whether the device-ID address was detected.

[Setting condition]

- When the first frame received immediately after a start or restart condition is detected matches a value of (device ID (1111 100b) + 0 [W]), with the DIDE bit in ICSER set to 1 (device-ID address detection enabled).
  The DID flag is set to 1 on the rising edge of the ninth SCL clock cycle in the frame.

[Clearing conditions]

- When 0 is written to the DID flag after reading DID = 1
- When a stop condition is detected
- When the first frame received immediately after a start or restart condition is detected does not match a value of (device ID (1111 100b)), with the DIDE bit in ICSER set to 1 (device-ID address detection enabled)
  The DID flag is set to 0 on the rising edge of the ninth SCL clock cycle in the frame.

- When the first frame received immediately after a start or restart condition is detected matches a value of (device ID (1111 100b) + 0 [W]), and the second frame does not match any slave address from 0 to 2, with the DIDE bit in ICSER set to 1 (device-ID address detection enabled)
  The DID flag is set to 0 on the rising edge of the ninth SCL clock cycle in the frame.
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

HOA flag (Host Address Detection Flag)

The HOA flag indicates whether the host address was detected.

[Setting condition]

- When the received slave address matches the host address (0001 000b), with the HOAE bit in ICSER set to 1 (host address detection enabled).
  The HOA flag is set to 1 on the rising edge of the ninth SCL clock cycle in the frame.

[Clearing conditions]

- When 0 is written to the HOA flag after reading HOA = 1
- When a stop condition is detected
- When the received slave address does not match the host address (0001 000b), with the HOAE bit in ICSER set to 1 (host address detection enabled)
  The HOA flag is set to 0 on the rising edge of the ninth SCL clock cycle in the frame.
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

31.2.10 ICSR2 : I2C Bus Status Register 2

Base address: IICn = 0x4009_F000 + 0x0100 × n (n = 0 to 2)

Offset address: 0x09

Bit position:	7	6	5	4	3	2	1	0
Bit field:	TDRE	TEND	RDRF	NACKF	STOP	START	AL	TMOF
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TMOF	Timeout Detection Flag 0: Timeout not detected 1: Timeout detected	R/(W)*1
1	AL	Arbitration-Lost Flag 0: Arbitration not lost 1: Arbitration lost	R/(W)*1
2	START	Start Condition Detection Flag 0: Start condition not detected 1: Start condition detected	R/(W)*1
3	STOP	Stop Condition Detection Flag 0: Stop condition not detected 1: Stop condition detected	R/(W)*1
4	NACKF	NACK Detection Flag 0: NACK not detected 1: NACK detected	R/(W)*1
5	RDRF	Receive Data Full Flag 0: ICDRR contains no receive data 1: ICDRR contains receive data	R/(W)*1
6	TEND	Transmit End Flag 0: Data being transmitted 1: Data transmit complete	R/(W)*1

Bit	Symbol	Function	R/W
7	TDRE	Transmit Data Empty Flag 0: ICDRT contains transmit data 1: ICDRT contains no transmit data	R

Note 1. Only 0 can be written, to clear the flag.

TMOF flag (Timeout Detection Flag)

The TMOF flag is set to 1 when the IIC detects a timeout because the SCLn line state remains unchanged for the set period.

[Setting condition]

- When the SCLn line state remains unchanged for the period specified in the ICMR2.TMOH, TMOL, and TMOS bits while the ICFER.TMOE bit is 1 (timeout function enabled) in master or in slave mode and the received slave address matches.

[Clearing conditions]

- When 0 is written to the TMOF flag after reading TMOF = 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

AL flag (Arbitration-Lost Flag)

The AL flag indicates that bus mastership was lost in arbitration because of a bus conflict or some other reason when a start condition was issued or an address and data was transmitted. The IIC monitors the level on the SDAn line during transmission and, if the level on the line does not match the value of the bit being output, is set the value of the AL flag to 1 to indicate that the bus is occupied by another device.

The IIC can also set the AL flag to indicate the detection of arbitration loss during NACK transmission or during data transmission.

[Setting conditions]

When master arbitration-lost detection is enabled (ICFER.MALE = 1):

- When the internal SDA output state does not match the SDAn line level on the rising edge of the SCL clock except for the ACK period during data transmission in master transmit mode
- When a start condition is detected while the ST bit in ICCR2 is 1 (start condition requested) or the internal SDA output state does not match the SDAn line level
- When the ST bit in ICCR2 is 1 (start condition requested), with the BBSY flag in ICCR2 set to 1.

When NACK arbitration-lost detection is enabled (ICFER.NALE = 1):

- When the internal SDA output state does not match the SDAn line level on the rising edge of the SCL clock in the ACK period during NACK transmission in receive mode.

When slave arbitration-lost detection is enabled (ICFER.SALE = 1):

- When the internal SDA output state does not match the SDAn line level on the rising edge of the SCL clock, except for the ACK period during data transmission in slave transmit mode.

[Clearing conditions]

- When 0 is written to the AL flag after reading AL = 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

Table 31.4 Relationship between arbitration-lost generation sources and arbitration-lost enable functions

ICFER			ICSR2		
MALE	NALE	SALE	AL	Error	Arbitration-lost generation source
1	x	x	1	Start condition issuance error	When internal SDA output state does not match SDAn line level when a start condition is detected, while the ST bit in ICCR2 is 1
					When ST in ICCR2 is set to 1 while BBSY in ICCR2 is 1
			1	Transmit data mismatch	When transmit data (including slave address) does not match the bus state in master transmit mode
x	1	x	1	NACK transmission mismatch	When ACK is detected during transmission of NACK in master or slave receive mode
x	x	1	1	Transmit data mismatch	When transmit data does not match the bus state in slave transmit mode

x: Don’t care

START flag (Start Condition Detection Flag)

The START flag indicates whether a start or restart condition was detected.

[Setting condition]

- When a start or restart condition is detected.

[Clearing conditions]

- When 0 is written to the START flag after reading START = 1
- When a stop condition is detected
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

STOP flag (Stop Condition Detection Flag)

The STOP flag indicates whether a stop condition was detected.

[Setting condition]

- When a stop condition is detected.

[Clearing conditions]

- When 0 is written to the STOP flag after reading STOP = 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

NACKF flag (NACK Detection Flag)

The NACKF flag indicates whether a NACK was detected.

[Setting condition]

- When acknowledge is not received (NACK received) from the receive device in transmit mode, with the NACKE bit in ICFER set to 1 (transfer suspension enabled).

[Clearing conditions]

- When 0 is written to the NACKF flag after reading NACKF = 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

Note: When the NACKF flag is set to 1, the IIC suspends data transmission and reception. Writing to ICDRT in transmit mode or reading from ICDRR in receive mode with the NACKF flag set to 1 does not enable data transmit or receive operation. To restart data transmission or reception, set the NACKF flag to 0.

RDRF flag (Receive Data Full Flag)

The RDRF flag indicates whether the ICDRR contains receive data.

[Setting conditions]

- When receive data is transferred from ICDRS to ICDRR
  The RDRF flag is set to 1 on the rising edge of the eighth or ninth SCL clock cycle (selected in the RDRFS bit in ICMR3).
- When the received slave address matches after a start or restart condition is detected with the TRS bit in ICCR2 set to 0.

[Clearing conditions]

- When 0 is written to the RDRF flag after reading RDRF = 1
- When data is read from ICDRR
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

TEND flag (Transmit End Flag)

The TEND flag indicates completion of transmission.

[Setting condition]

- On the rising edge of the ninth SCL clock cycle while the TDRE flag is 1.

[Clearing conditions]

- When 0 is written to the TEND flag after reading TEND = 1
- When data is written to ICDRT
- When a stop condition is detected
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

TDRE flag (Transmit Data Empty Flag)

The TDRE flag indicates whether the ICDRT contains transmit data.

[Setting conditions]

- When data is transferred from ICDRT to ICDRS and ICDRT becomes empty
- When the TRS bit in ICCR2 is set to 1
- When the received slave address matches while the TRS bit is 1.

[Clearing conditions]

- When data is written to ICDRT
- When the TRS bit in ICCR2 is set to 0
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

Note: When the NACKF flag is set to 1 while the NACKE bit in ICFER is 1, the IIC suspends data transmission and reception. In this case, if the TDRE flag is 0 (next transmit data written), data is transferred to the ICDRS register and the ICDRT register becomes empty on the rising edge of the 9th clock cycle, but the TDRE flag does not set to 1.

31.2.11 ICWUR : I2C Bus Wakeup Unit Register

Base address: IIC0WU = 0x4009_F014

Offset address: 0x02

Bit position:	7	6	5	4	3	2	1	0
Bit field:	WUE	WUIE	WUF	WUACK	—	—	—	WUAFA
Value after reset:	0	0	0	1	0	0	0	0

Bit	Symbol	Function	R/W
0	WUAFA	Wakeup Analog Filter Additional Selection 0: Do not add the wakeup analog filter 1: Add the wakeup analog filter	R/W
3:1	—	These bits are read as 0. The write value should be 0.	R/W
4	WUACK	ACK Bit for Wakeup Mode Choice of four response modes in combination with ICCR1.IICRST and WUACK. See Table 31.5.	R/W
5	WUF	Wakeup Event Occurrence Flag 0: Slave address not matching during wakeup 1: Slave address matching during wakeup	R/W
6	WUIE	Wakeup Interrupt Request Enable 0: Disable wakeup interrupt request (IIC0_WUI) 1: Enable wakeup interrupt request (IIC0_WUI)	R/W
7	WUE	Wakeup Function Enable 0: Disable wakeup function 1: Enable wakeup function	R/W

Table 31.5 Wakeup mode

IICRST	WUACK	Operation mode	Description
0	0	Normal wakeup mode 1	ACK response on 9th SCL, and SCL low-hold after 9th SCL.
0	1	Normal wakeup mode 2	No ACK response immediately and SCL low-hold between 8th and 9th SCL. SCL low-hold release and ACK response on 9th SCL.
1	0	Command recovery mode	ACK response on 9th SCL and no SCL low-hold.
1	1	EEP response mode	NACK response on 9th SCL and no SCL low-hold.

WUF flag (Wakeup Event Occurrence Flag)

The WUF flag indicates whether the slave address is matching during wakeup.

[Setting condition]

- When PCLKB is supplied after a slave-address match in the first 8th SCL low during wakeup mode.

[Clearing conditions]

- When 0 is written to the WUF flag after reading WUF = 1
- When ICE = 0 and IICRST = 1.

31.2.12 ICWUR2 : I2C Bus Wakeup Unit Register 2

Base address: IIC0WU = 0x4009_F014

Offset address: 0x03

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	WUSYF	WUASYF	WUSEN
Value after reset:	1	1	1	1	1	1	0	1

Bit	Symbol	Function	R/W
0	WUSEN	Wakeup Function Synchronous Enable 0: IIC asynchronous circuit enable 1: IIC synchronous circuit enable	R/W
1	WUASYF	Wakeup Function Asynchronous Operation Status Flag 0: IIC synchronous circuit enable condition 1: IIC asynchronous circuit enable condition	R

Bit	Symbol	Function	R/W
2	WUSYF	Wakeup Function Synchronous Operation Status Flag 0: IIC asynchronous circuit enable condition 1: IIC synchronous circuit enable condition	R
7:3	—	These bits are read as 1. The write value should be 1.	R/W

WUSEN bit (Wakeup Function Synchronous Enable)

The WUSEN bit is used in combination with the WUASYF flag (or WUSYF flag) to switch between the PCLKB synchronous and asynchronous operation, when the wakeup effective function is enabled (ICWUR.WUE = 1).

The PCLKB operation switches from synchronous to asynchronous operation:

When the ICCR2.BBSY flag is 0, if 0 is written to the WUSEN bit while the WUASYF flag is 0, the reception occurs independently of the operation of PCLKB (with PCLKB stopped) after it switches to the PCLKB asynchronous operation, on wakeup event detection.

The PCLKB operation switches from asynchronous to synchronous operation:

- When 1 is written to the WUSEN bit, with the WUASYF flag at 1, when a wakeup event is detected. After writing 1, the WUASYF flag immediately becomes 0.
- When the stop condition is detected with a wakeup event undetected.

WUASYF flag (Wakeup Function Asynchronous Operation Status Flag)

The WUASYF flag can place the IIC in PCLKB asynchronous operation when the wakeup effective function is enabled (ICWUR.WUE = 1).

[Setting condition]

- When the ICCR2.BBSY flag is 0, and the WUSEN bit is set to 0 with the ICWUR.WUE bit set to 1.

[Clearing conditions]

- When 1 is written to the WUSEN bit after detecting the wake-up event with ICWUR.WUE bit set to 1.
- When a stop condition is detected with WUSEN bit set to 1 before detecting the wake-up event with WUASY flag set to 1 with ICWUR.WUE bit set to 1.
- When you write 1 in the WUSEN bit with the WUASYF flag detected 1 and the wake-up event in the state of ICWUR.WUE = 1.
- ICCR1.ICE = 0 and ICCRST = 1 (ICC reset)
- ICWUR.WUE = 0.

WUSYF flag (Wakeup Function Synchronous Operation Status Flag)

It is shown that IIC is in the PCLKB synchronous operation at wake-up effective function (ICWUR.WUE = 1). This flag is a value in which the WUASYF flag is always reserved.

[Setting conditions]

- When 1 is written to the WUSEN bit after detecting the wake-up event with ICWUR.WUE bit set to 1 with WUSYF flag set to 0 with ICWUR.WUE bit set to 1.
- When a stop condition is detected with WUSEN bit set to 1 before detecting the wake-up event with WUSYF flag set to 0 with ICWUR.WUE bit set to 1.
- ICCR1.ICE = 0 and ICCRST = 1 (ICC reset)
- ICWUR.WUE = 0.

[Clearing condition]

- When the ICCR2.BBSY flag is 0 with the ICWUR.WUE bit set to 1 after writing 0 to the WUSEN bit.

31.2.13 SARLy : Slave Address Register Ly (y = 0 to 2)

Base address: IICn = 0x4009_F000 + 0x0100 × n (n = 0 to 2)

Offset address: 0x0A + 0x02 × y

Bit position:	7	6	5	4	3	2	1	0
Bit field:	SVA[6:0]							SVA0
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SVA0	10-bit Address LSB Slave address setting.	R/W
7:1	SVA[6:0]	7-bit Address/10-bit Address Lower Bits Slave address setting.	R/W

SVA0 bit (10-bit Address LSB)

When the 10-bit address format is selected (SARUy.FS = 1), the SVA0 bit functions as the LSB of a 10-bit address and is combined with the SVA[6:0] bits to form the lower 8 bits of a 10-bit address.

This bit is valid when the SARyE bit in ICSER is set to 1 (SARLy and SARUy enabled) and the SARUy.FS bit is 1. When the SARUy.FS or SARyE bit is 0, the setting in this bit is ignored.

SVA[6:0] bits (7-bit Address/10-bit Address Lower Bits)

When the 7-bit address format is selected (SARUy.FS = 0), the SVA[6:0] bits function as a 7-bit address. When the 10- bit address format is selected (SARUy.FS = 1), these bits combine with the SVA0 bit to form the lower 8 bits of a 10-bit address.

When the SARyE bit in ICSER is 0, the setting in these bits is ignored.

31.2.14 SARUy : Slave Address Register Uy (y = 0 to 2)

Base address: IICn = 0x4009_F000 + 0x0100 × n (n = 0 to 2)

Offset address: 0x0B + 0x02 × y

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	SVA[1:0]		FS
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	FS	7-bit/10-bit Address Format Select 0: Select 7-bit address format 1: Select 10-bit address format	R/W
2:1	SVA[1:0]	10-bit Address Upper Bits Slave address setting.	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W

FS bit (7-bit/10-bit Address Format Select)

The FS bit selects 7- or 10-bit format for slave address y (in SARLy and SARUy).

When the SARyE bit in ICSER is set to 1 (SARLy and SARUy enabled) and the SARUy.FS bit is 0, the 7-bit address format is selected for slave address y, the SVA[6:0] setting in SARLy is valid, and the SVA[1:0] and SVA0 settings in SARLy are ignored.

When the SARyE bit in ICSER is set to 1 (SARLy and SARUy enabled) and the SARUy.FS bit is 1, the 10-bit address format is selected for slave address y and the SVA[1:0] and SARLy settings are valid.

When the SARyE bit in ICSER is 0 (SARLy and SARUy disabled), the SARUy.FS setting is invalid.

SVA[1:0] bits (10-bit Address Upper Bits)

When the 10-bit address format is selected (FS = 1), the SVA[1:0] bits function as the upper 2 bits of a 10-bit address.

These bits are valid when the SARyE bit in ICSER is set to 1 (SARLy and SARUy enabled) and the SARUy.FS bit is 1. When the SARUy.FS or SARyE bit is 0, the setting in these bits is ignored.

31.2.15 ICBRL : I2C Bus Bit Rate Low-Level Register

Base address: IICn = 0x4009_F000 + 0x0100 × n (n = 0 to 2)

Offset address: 0x10

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	BRL[4:0]				
Value after reset:	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
4:0	BRL[4:0]	Bit Rate Low-Level Period Low-level period of SCL clock.	R/W
7:5	—	These bits are read as 1. The write value should be 1.	R/W

BRL[4:0] bits (Bit Rate Low-Level Period)

The BRL[4:0] bits set the low-level period of the SCL clock. ICBRL counts the low-level period with the internal reference clock source (IICφ) specified by the CKS[2:0] bits in ICMR1. ICBRL also generates the data setup time for automatic SCL low-hold operation, see section 31.9. Automatic Low-Hold Function for SCL. When the IIC is used in slave mode, the BRL[4:0] bits must be set to a value longer than the data setup time*1.

If the digital noise filter is enabled (NFE bit in ICFER is 1), set the BRL[4:0] bits to a value at least one greater than the number of stages in the noise filter. For details on the number of stages, see the description of the NF[1:0] bits in section 31.2.5. ICMR3 : I2C Bus Mode Register 3.

Note 1. Data setup time (t_{SU}: DAT)

250 ns for up to 100 kbps: Standard-mode (Sm)

100 ns for up to 400 kbps: Fast-mode (Fm)

50 ns for up to 1 Mbps: Fast-mode Plus (Fm+)

31.2.16 ICBRH : I2C Bus Bit Rate High-Level Register

Base address: IICn = 0x4009_F000 + 0x0100 × n (n = 0 to 2)

Offset address: 0x11

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	BRH[4:0]				
Value after reset:	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
4:0	BRH[4:0]	Bit Rate High-Level Period High-level period of SCL clock.	R/W
7:5	—	These bits are read as 1. The write value should be 1.	R/W

BRH[4:0] bits (Bit Rate High-Level Period)

The BRH[4:0] bits set the high-level period of SCL clock. BRH[4:0] bits are valid in master mode. If the IIC is used only in slave mode, do not set the BRH[4:0] bits.

ICBRH counts the high-level period with the internal reference clock source (IICφ) specified in the CKS[2:0] bits in ICMR1.

If the digital noise filter is enabled (the NFE bit in ICFER is 1), set these bits to a value at least one greater than the number of stages in the noise filter. For the number of stages in the noise filter, see the description of the NF[1:0] bits in section 31.2.5. ICMR3 : I2C Bus Mode Register 3.

The IIC transfer rate and the SCL clock duty are calculated using the following expressions (1) to (5):

1. ICFER.SCLE = 0
   Transfer rate = 1/[{(BRH + 1) + (BRL + 1)}/IICφ*1 + tr*2 + tf*2]
   Duty cycle = [tr + {(BRH + 1)/IICφ}]/[tr + tf + {(BRH + 1) + (BRL + 1)}/IICφ]
2. ICFER.SCLE = 1 and ICFER.NFE = 0 and CKS[2:0] = 000b (IICφ = PCLKB)
   Transfer rate = 1/[{(BRH + 3) + (BRL+ 3)}/IICφ + tr + tf]
   Duty cycle = [tr + {(BRH + 3)/IICφ}]/[tr + tf + {(BRH + 3) + (BRL + 3)}/IICφ]
3. ICFER.SCLE = 1 and ICFER.NFE = 1 and CKS[2:0] = 000b (IICφ = PCLKB)
   Transfer rate = 1/[{(BRH + 3 + nf*3) + (BRL + 3 + nf)}/IICφ + tr + tf]
   Duty cycle = [tr + {(BRH + 3 + nf)/IICφ}]/[tr + tf + {(BRH + 3 + nf) + (BRL + 3 + nf)}/IICφ]
4. ICFER.SCLE = 1 and ICFER.NFE = 0 and CKS[2:0] ≠ 000b
   Transfer rate = 1/[{(BRH + 2) + (BRL + 2)}/IICφ + tr + tf]
   Duty cycle = [tr + {(BRH + 2)/IICφ}]/[tr + tf + {(BRH + 2) + (BRL + 2)}/IICφ]
5. ICFER.SCLE = 1 and ICFER.NFE = 1 and CKS[2:0] ≠ 000b
   Transfer rate = 1/[{(BRH + 2 + nf) + (BRL + 2 + nf)}/IICφ + tr + tf]
   Duty cycle = [tr + {(BRH + 2 + nf)/IICφ}]/[tr + tf + {(BRH + 2 + nf) + (BRL + 2 + nf)}/IICφ]

Note 1. IICφ = PCLKB × division ratio
Note 2. The SCLn line rise time (tr) and SCLn line fall time (tf) depend on the total bus line capacitance (Cb) and the pull-up resistor (Rp). For details, see the I2C bus standard from NXP Semiconductors.
Note 3. nf = Number of digital noise filters selected in the ICMR3.NF bit.

Table 31.6 Example of ICBRH/ICBRL Settings for Transfer Rate IIC when SCLE = 0

Transfer rate (kbps)	CKS[2:0] (ICMR1)	BRH[4:0] (ICBRH)	BRL[4:0] (ICBRL)	PCLKB (MHz)	NF[1:0]	Computation expression

31.2.17 ICDRT : I2C Bus Transmit Data Register

Base address: IICn = 0x4009_F000 + 0x0100 × n (n = 0 to 2)

Offset address: 0x12

Bit position:	7	6	5	4	3	2	1	0
Bit field:								
Value after reset:	1	1	1	1	1	1	1	1

When ICDRT detects a space in the I2C Bus Shift Register (ICDRS), it transfers the transmit data that was written to ICDRT to ICDRS and starts transmitting data in transmit mode. The double-buffer structure of ICDRT and ICDRS allows continuous transmit operation if the next transmit data is written to ICDRT while the ICDRS data is being transmitted.

ICDRT can always be read and written to. Write transmit data to ICDRT once when a transmit data empty interrupt (IICn_TXI) request is generated.

31.2.18 ICDRR : I2C Bus Receive Data Register

Base address: IICn = 0x4009_F000 + 0x0100 × n (n = 0 to 2)

Offset address: 0x13

Bit position:	7	6	5	4	3	2	1	0
Bit field:								
Value after reset:	0	0	0	0	0	0	0	0

When 1 byte of data is received, the received data is transferred from the I2C Bus Shift Register (ICDRS) to ICDRR to enable the next data to be received. The double-buffer structure of ICDRS and ICDRR allows continuous receive operation if the received data is read from ICDRR while ICDRS is receiving data. ICDRR cannot be written to. Read data from ICDRR once when a receive data full interrupt (IICn_RXI) request is generated.

If ICDRR receives the next receive data before the current data is read from ICDRR (while the RDRF flag in ICSR2 is 1), the IIC automatically holds the SCL clock low 1 cycle before the RDRF flag is set to 1 next.

31.2.19 ICDRS : I2C Bus Shift Register

Base address: n/a

Offset address: n/a

Bit position:	7	6	5	4	3	2	1	0
Bit field:								
Value after reset:	—	—	—	—	—	—	—	—

ICDRS is an 8-bit shift register for data transmit and receive. During transmission, transmit data is transferred from ICDRT to ICDRS and is transmitted from the SDAn pin. During reception, data is transferred from ICDRS to ICDRR after 1 byte of data is received. ICDRS cannot be accessed directly.

31.3 Operation

31.3.1 Communication Data Format

The I2C bus format consists of 8-bit data and 1-bit acknowledge. The frame following a start or restart condition is an address frame that specifies a slave device with which the master device communicates. The specified slave is valid until a new slave is specified or a stop condition is issued.

Figure 31.3 shows the I2C bus format, and Figure 31.4 shows the I2C bus timing.

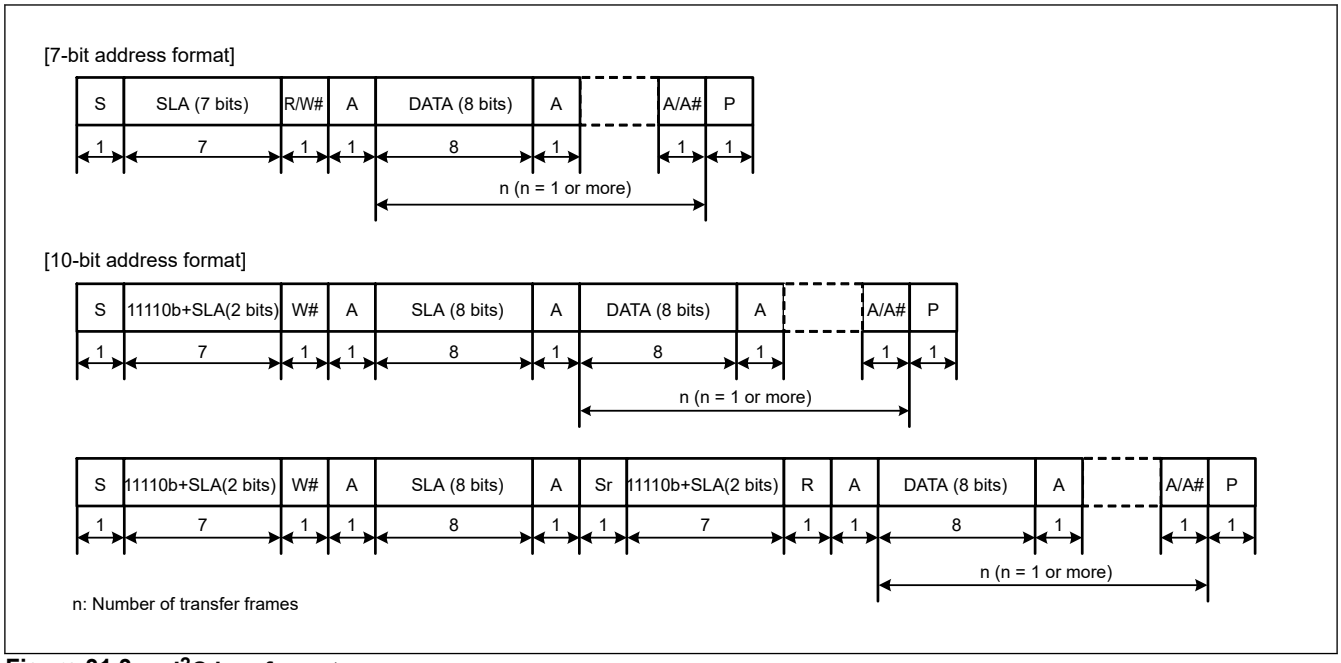

Figure 31.3 I²C bus format

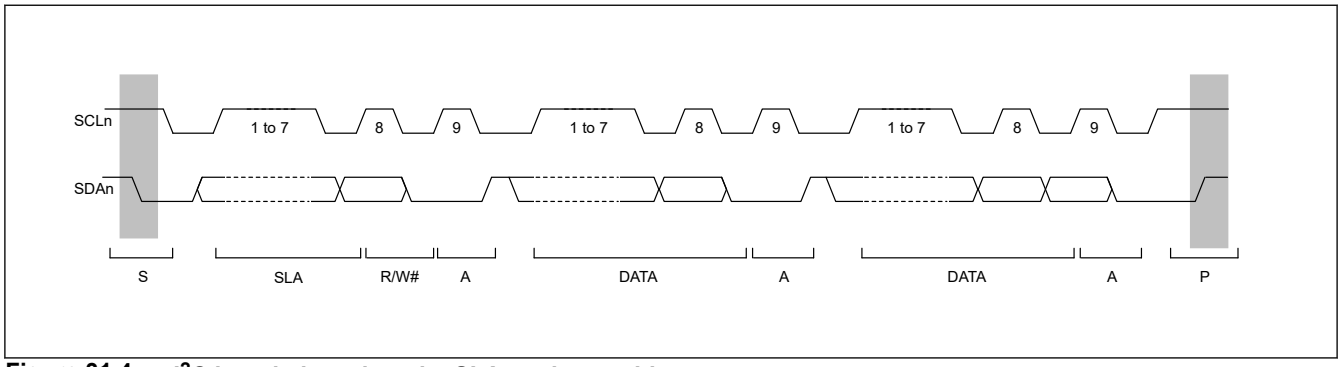

Figure 31.4 I²C bus timing when the SLA setting = 7 bits

S:	Start condition. The master device drives the SDAn line low from high while the SCLn line is high.
SLA:	Slave address, by which the master device selects a slave device.
R/W#:	Indicates the direction of data transfer: from the slave device to the master device when R/W# is 1, or from the master device to the slave device when R/W# is 0.
A:	Acknowledge. The receive device drives the SDAn line low. In master transmit mode, the slave device returns acknowledge. In master receive mode, the master device returns acknowledge.
A#:	Not Acknowledge. The receive device drives the SDAn line high.
Sr:	Restart condition. The master device drives the SDAn line low from the high level after the setup time has elapsed with the SCLn line high.
DATA:	Transmitted or received data.
P:	Stop condition. The master device drives the SDAn line high from low while the SCLn line is high.

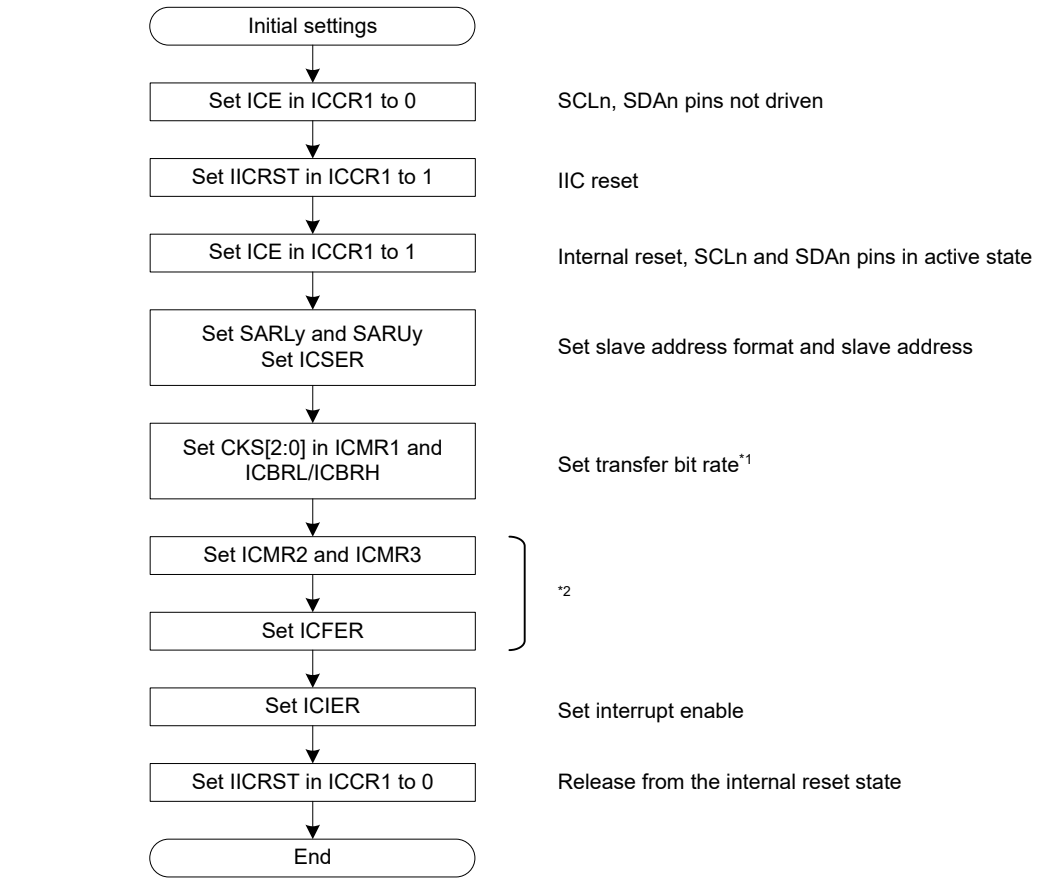
31.3.2 Initial Settings

Before starting data transmission or reception, initialize the IIC using the procedure shown in Figure 31.5.

1. Set the ICCR1.ICE bit to 0 to set the SCLn and SDAn pins to the inactive state.
2. Set the ICCR1.IICRST bit to 1 to initiate IIC reset.
3. Set the ICCR1.ICE bit to 1 to initiate internal reset.
4. Set the SARLy, SARUy, ICSER, ICMR1, ICBRH, and ICBRL registers (y = 0 to 2), and set the other registers as required. For initial settings of the IIC, see Figure 31.5.

5. When the required register settings are complete, set the ICCR1.IICRST bit to 0 to release the IIC reset.

This procedure is not required if the IIC initialization is already complete.



Note: n = 0
Note 1. When the IIC is used only in slave mode, set the ICBRL register to a value longer than the data setup time.
Note 2. Set these registers as required.

Figure 31.5 Example IIC initialization flow

31.3.3 Master Transmit Operation

In master transmit operation, the IIC outputs the SCL clock and transmitted data signals as the master device, and the slave device returns acknowledgments. Figure 31.6 shows an example of master transmission, and Figure 31.7 to Figure 31.9 show the operation timing in master transmission.

To set up and perform master transmission:

1. Process initial settings. For details, see section 31.3.2. Initial Settings.
2. Read the BBSY flag in ICCR2 to check that the bus is free, and then set the ST bit in ICCR2 to 1 (start condition request). On receiving the request, the IIC issues a start condition. At the same time, the BBSY and START flags in ICSR2 automatically set to 1 and the ST bit automatically is set to 0. At this time, if the start condition is detected and the internal levels for the SDA output state and the levels on the SDAn line match while the ST bit is 1, the IIC recognizes that issuance of the start condition as requested by the ST bit is successfully complete, and the MST and TRS bits in ICCR2 automatically set to 1, placing the IIC in master transmit mode. The TDRE flag in ICSR2 also automatically is set to 1 in response to the setting of the TRS bit to 1.

3. Check that the TDRE flag in ICSR2 is 1, and then write the value for transmission (the slave address and the R/W# bit) to ICDRT. When the transmit data is written to ICDRT, the TDRE flag automatically is set to 0, the data is transferred from ICDRT to ICDRS, and the TDRE flag again is set to 1. After the byte containing the slave address and R/W# bit is transmitted, the value of the TRS bit automatically updates to select master transmit or master receive mode based on the value of the transmitted R/W# bit. If the value of the R/W# bit was 0, the IIC continues in master transmit mode. Because the ICSR2.NACKF flag being 1 at this time indicates that no slave device recognized the address or there was an error in communications, write 1 to the ICCR2.SP bit to issue a stop condition.
   For data transmission with an address in the 10-bit format, start by writing 11110b, the 2 higher-order bits of the slave address, and W to ICDRT as the first address transmission. For the second address transmission, write the 8 lower-order bits of the slave address to ICDRT.
4. Check that the TDRE flag in ICSR2 is 1, and then write the transmit data to the ICDRT register. The IIC automatically holds the SCLn line low until the transmit data is ready or a stop condition is issued.
5. After all bytes of transmit data are written to the ICDRT register, wait until the value in the TEND flag in ICSR2 returns to 1, and then set the SP bit in ICCR2 to 1 (stop condition requested). On receiving a stop condition request, the IIC issues the stop condition. Regarding issuing a stop condition, see section 31.11.3. Issuing a Stop Condition.
6. On detecting the stop condition, the IIC automatically sets the MST and TRS bits in ICCR2 to 00b and enters slave receive mode. Additionally, it automatically sets the TDRE and TEND flags to 0, and sets the STOP flag in ICSR2 to 1.
7. Check that the ICSR2.STOP flag is 1, and then set the ICSR2.NACKF and STOP flags to 0 for the next transfer operation.

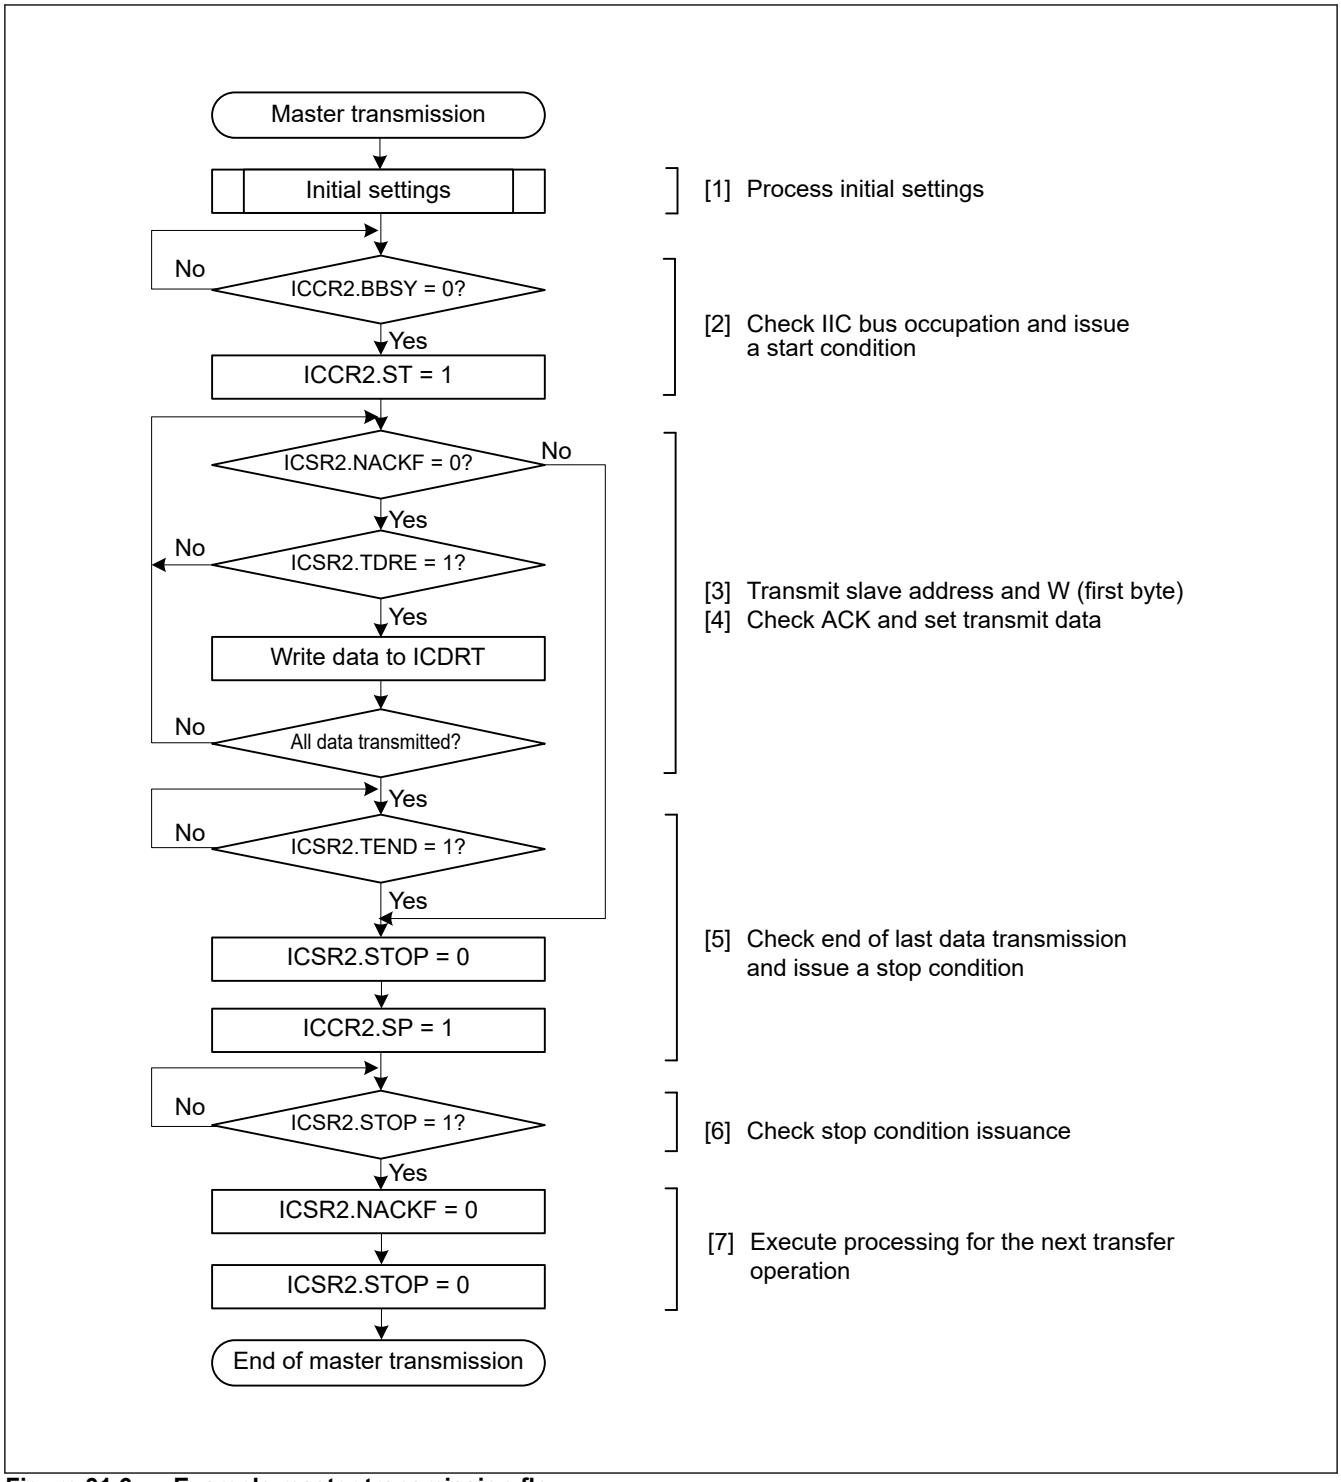


Figure 31.6 Example master transmission flow

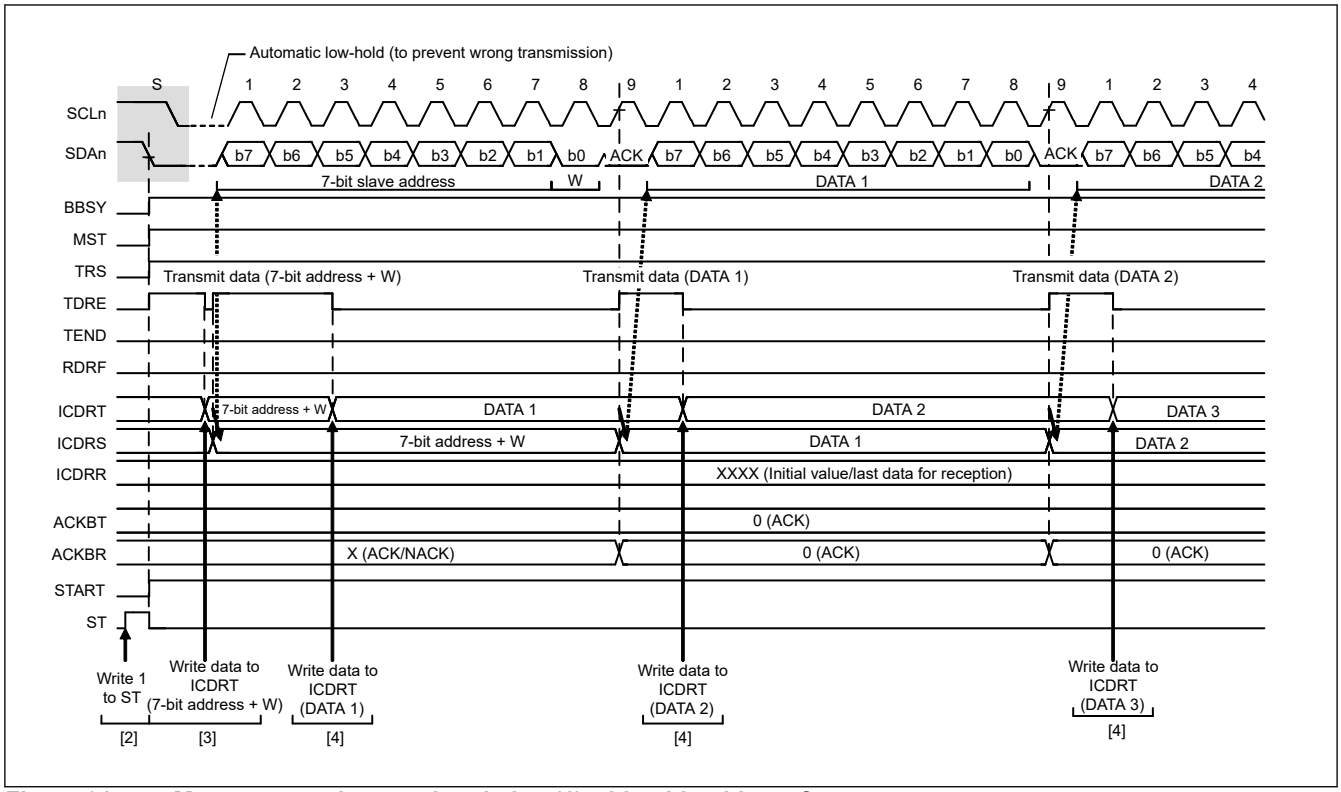

Figure 31.7 Master transmit operation timing (1) with 7-bit address format

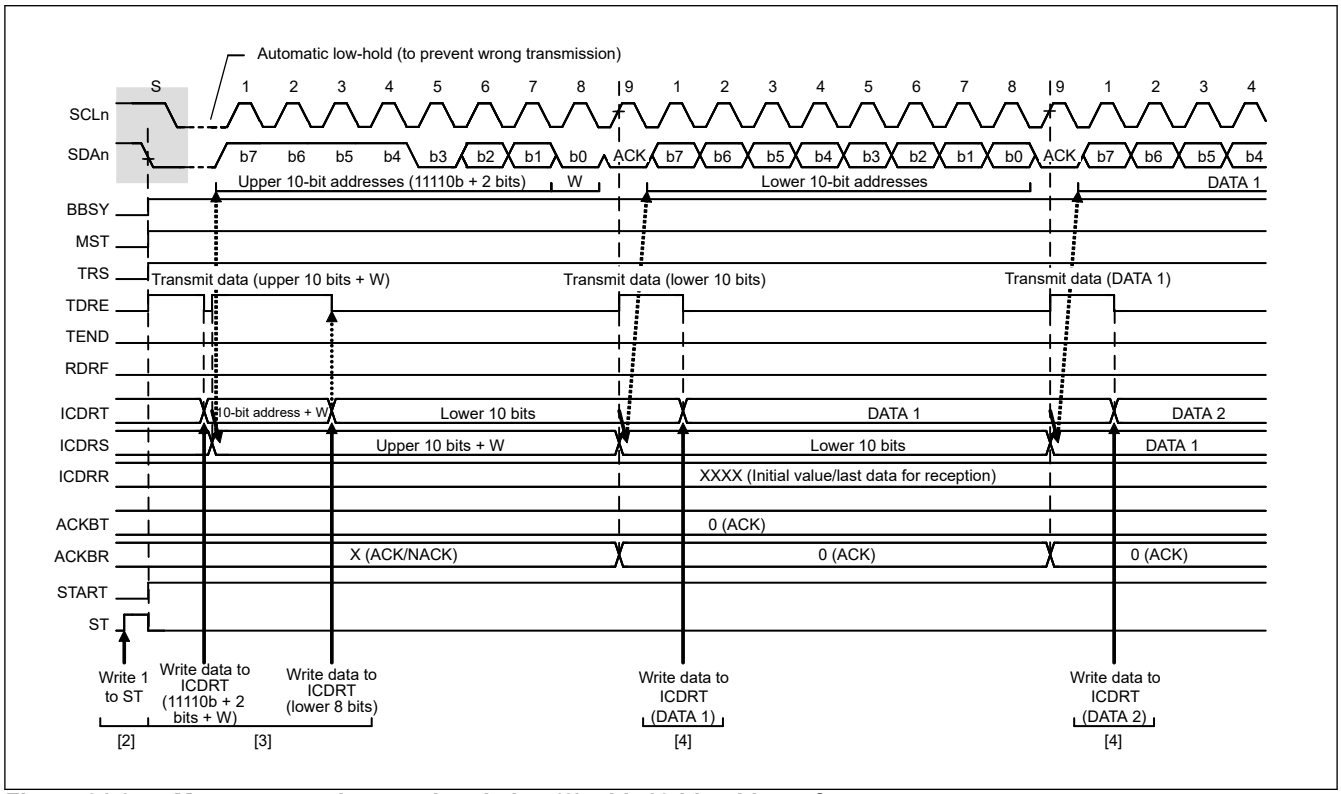

Figure 31.8 Master transmit operation timing (2) with 10-bit address format

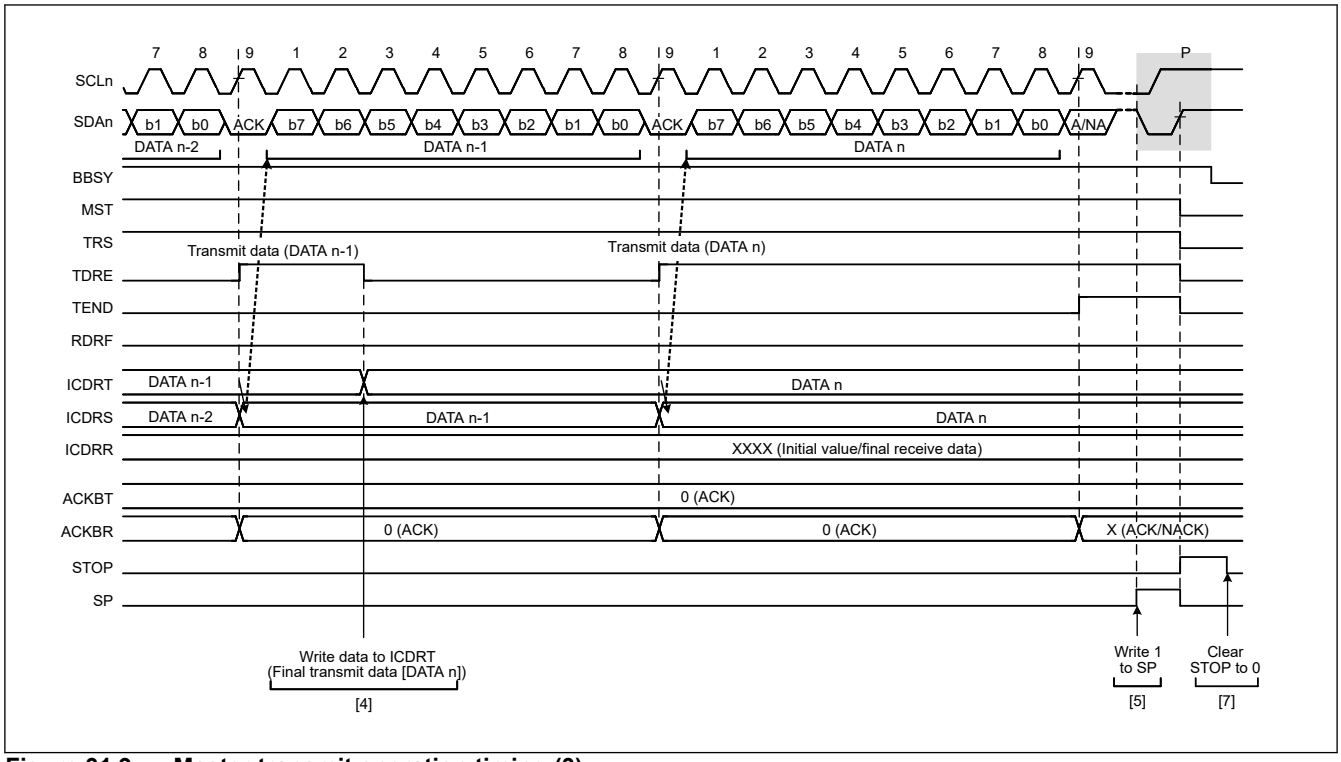

Figure 31.9 Master transmit operation timing (3)

31.3.4 Master Receive Operation

In master receive operation, the IIC as a master device outputs the SCL clock, receives data from the slave device, and returns acknowledgments. Because the IIC must start by sending a slave address to the associated slave device, this part of the procedure is performed in master transmit mode, but the subsequent steps are in master receive mode.

Figure 31.10 and Figure 31.11 show examples of master reception (7-bit address format), and Figure 31.12 to Figure 31.14 show the operation timing in master reception.

To set up and perform master reception:

1. Process initial settings. For details, see section 31.3.2. Initial Settings.
2. Read the BBSY flag in ICCR2 to check that the bus is free, and then set the ST bit in ICCR2 to 1 (start condition request). On receiving the request, the IIC issues a start condition. When the IIC detects the start condition, the BBSY and START flags in ICSR2 automatically set to 1, and the ST bit automatically is set to 0. At this time, if the start condition is detected and the levels for the SDA output and the levels on the SDAn line match while the ST bit is 1, the IIC recognizes that issuance of the start condition as requested by the ST bit is successfully complete, and the MST and TRS bits in ICCR2 automatically set to 1, placing the IIC in master transmit mode. The TDRE flag in ICSR2 also automatically is set to 1 in response to the setting of the TRS bit to 1.
3. Check that the TDRE flag in ICSR2 is 1, and then write the value for transmission (the first byte indicates the slave address and value of the R/W# bit) to ICDRT. When the transmit data is written to ICDRT, the TDRE flag automatically is set to 0, the data is transferred from ICDRT to ICDRS, and the TDRE flag again is set to 1. When the byte containing the slave address and R/W# bit is transmitted, the value of the ICCR2.TRS bit automatically updates to select transmit or receive mode based on the value of the transmitted R/W# bit. If the value of the R/W# bit is 1, the TRS bit is set to 0 on the rising edge of the ninth cycle of the SCL clock, placing the IIC in master receive mode. At this time, the TDRE flag is set to 0 and the ICSR2.RDRF flag automatically is set to 1.
   Because the ICSR2.NACKF flag being 1 at this time indicates that no slave device recognized the address or there was an error in communications, write 1 to the ICCR2.SP bit to issue a stop condition.
   For master reception from a device with a 10-bit address, start by using master transmission to issue the 10-bit address, and then issue a restart condition. After that, transmitting 11110b, the two higher-order bits of the slave address, and the R bit places the IIC in master receive mode.
4. Dummy read ICDRR after confirming that the RDRF flag in ICSR2 is 1. This makes the IIC start output of the SCL clock and start data reception.

5. After 1 byte of data is received, the RDRF flag in ICSR2 is set to 1 on the rising edge of the 8th or 9th cycle of the SCL clock, as selected in the RDRFS bit in ICMR3. Reading ICDRR at this time produces the received data, and the RDRF flag is automatically set to 0 at the same time. Additionally, the value of the acknowledgment field received during the ninth cycle of the SCL clock is returned as the value set in the ICMR3.ACKBT bit. If the next byte to be received is the second-to-last byte, set the ICMR3.WAIT bit to 1 for wait insertion before reading ICDRR, containing the second-to-last byte. In addition to enabling NACK output, even when interrupts or other operations result in delays in setting the ICMR3.ACKBT bit to 1 (NACK) in step (6), this fixes the SCLn line to the low level on the rising edge of the ninth clock cycle in reception of the last byte, which enables the issuing of a stop condition.
6. When the ICMR3.RDRFS bit is 0, and the slave device must be notified that it is to end transfer for data reception after transfer of the next and final byte, set the ICMR3.ACKBT bit to 1 (NACK).
7. After reading the second-to-last byte from the ICDRR register, if the value of the ICSR2.RDRF flag is 1, write 1 to the SP bit in ICCR2 (stop condition requested), and then read the last byte from ICDRR. When ICDRR is read, the IIC is released from the wait state and issues the stop condition after low-level output in the ninth clock cycle is complete or the SCLn line is released from the low-hold state.
8. On detecting the stop condition, the IIC automatically sets the MST and TRS bits in ICCR2 to 00b and enters slave receive mode. Additionally, detection of the stop condition sets the ICSR2.STOP flag to 1.
9. Check that the ICSR2.STOP flag is 1, then set the ICSR2.NACKF and STOP flags to 0 for the next transfer operation.

31.3.5 Slave Transmit Operation

In slave transmit operation, the master device outputs the SCL clock, the IIC transmits data as a slave device, and the master device returns acknowledgments.

Figure 31.15 shows an example of slave transmission, and Figure 31.16 and Figure 31.17 show the operation timing in slave transmission.

To set up and perform slave transmission:

1. Initialize the IIC using the procedure in section 31.3.2. Initial Settings.
   After initialization, the IIC stays in the standby state until it receives a slave address that matches.
2. After receiving a matching slave address, the IIC sets one of the associated ICSR1.HOA, GCA, and AASy flags (y = 0 to 2) to 1 on the rising edge of the ninth cycle of the SCL clock and outputs the value set in the ICMR3.ACKBT bit to the acknowledge bit on the ninth cycle of the SCL clock. If the value of the R/W# bit is 1, the IIC automatically places itself in slave transmit mode by setting both the ICCR2.TRS bit and the ICSR2.TDRE flag to 1.
3. Check that the ICSR2.TDRE flag is 1, then write the transmit data to the ICDRT register. If the IIC receives no acknowledge from the master device (receives an NACK signal) while the ICFER.NACKE bit is 1, the IIC suspends transfer of the next data.
4. Wait until the ICSR2.TEND flag is set to 1 while the ICSR2.TDRE flag is 1, after the ICSR2.NACKF flag is set to 1 or the last byte for transmission is written to the ICDRT register. When the ICSR2.NACKF flag or the TEND flag is 1, the IIC drives the SCLn line low on the ninth falling edge of the SCL clock.
5. When the ICSR2.NACKF or ICSR2.TEND flag is 1, dummy read ICDRR to complete the processing. This releases the SCLn line.
6. On detecting the stop condition, the IIC automatically sets the ICSR1.HOA, GCA, and AASy flags (y = 0 to 2), the ICSR2.TDRE and TEND flags, and the ICCR2.TRS bit to 0, and enters slave receive mode.
7. Check that the ICSR2.STOP flag is 1, then set the ICSR2.NACKF and STOP flags to 0 for the next transfer operation.

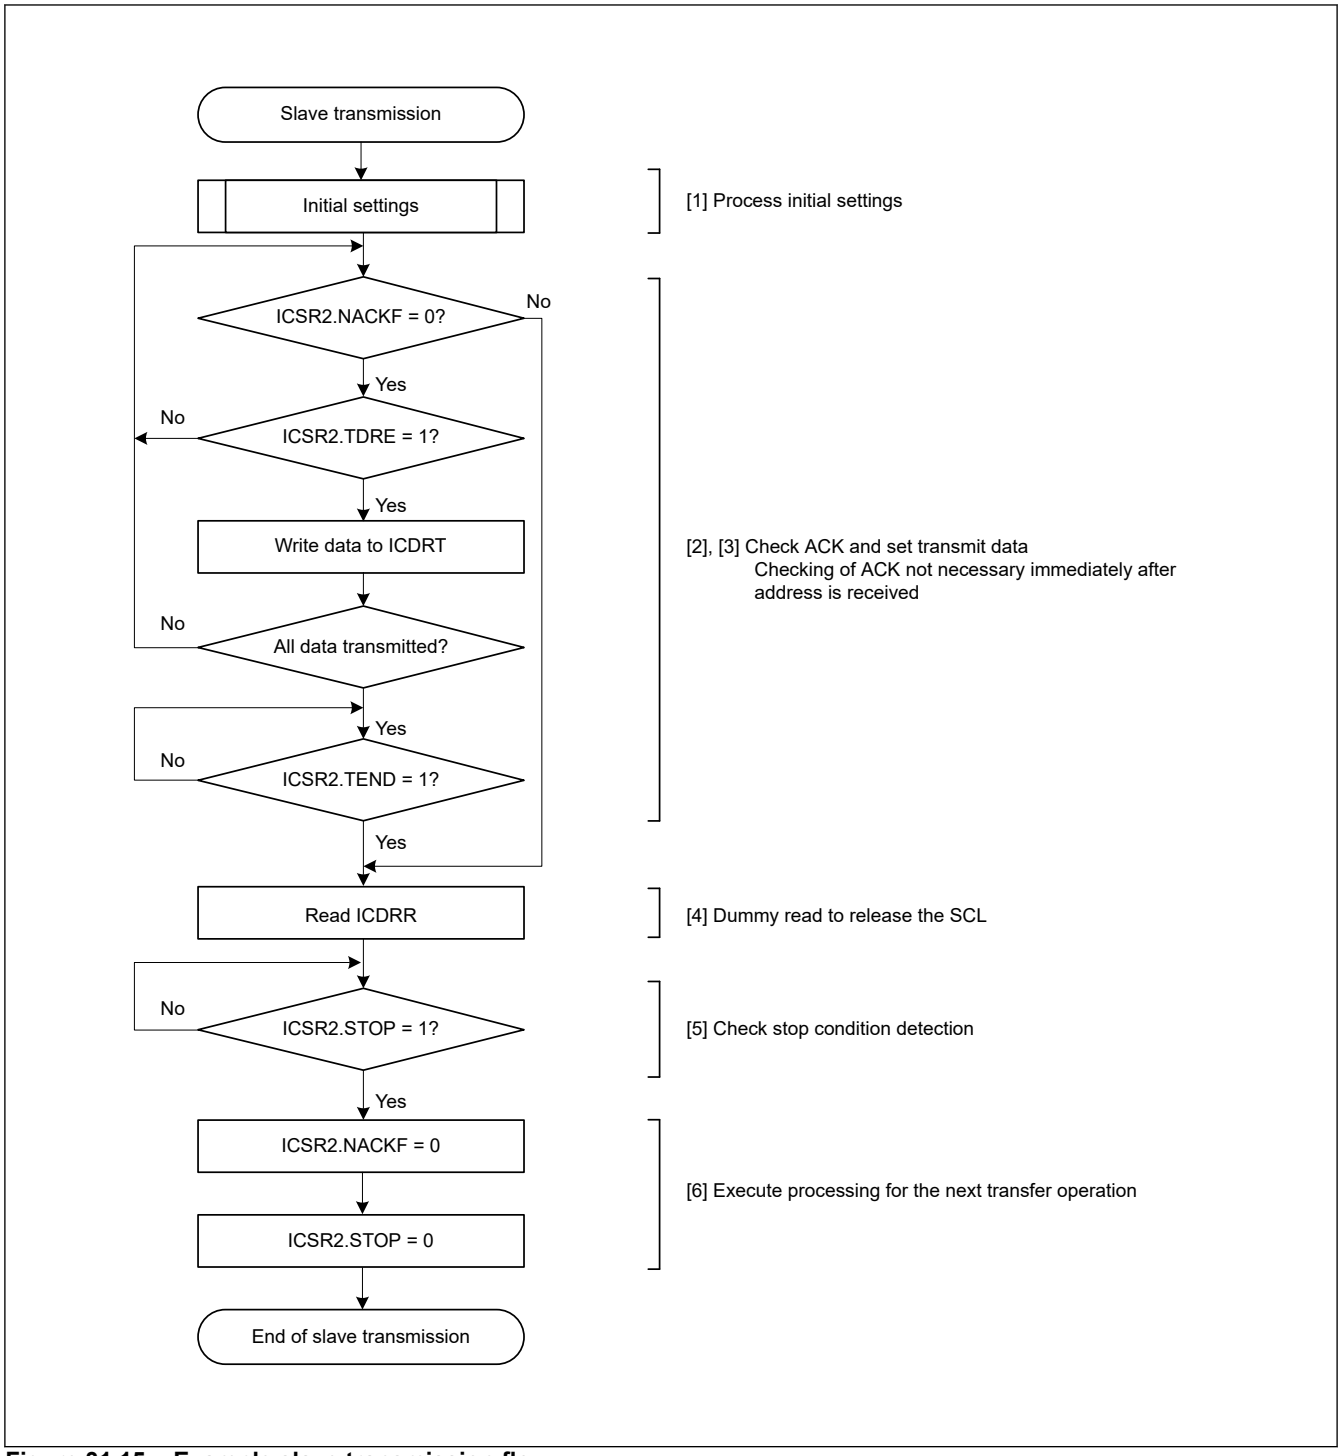

Figure 31.15 Example slave transmission flow

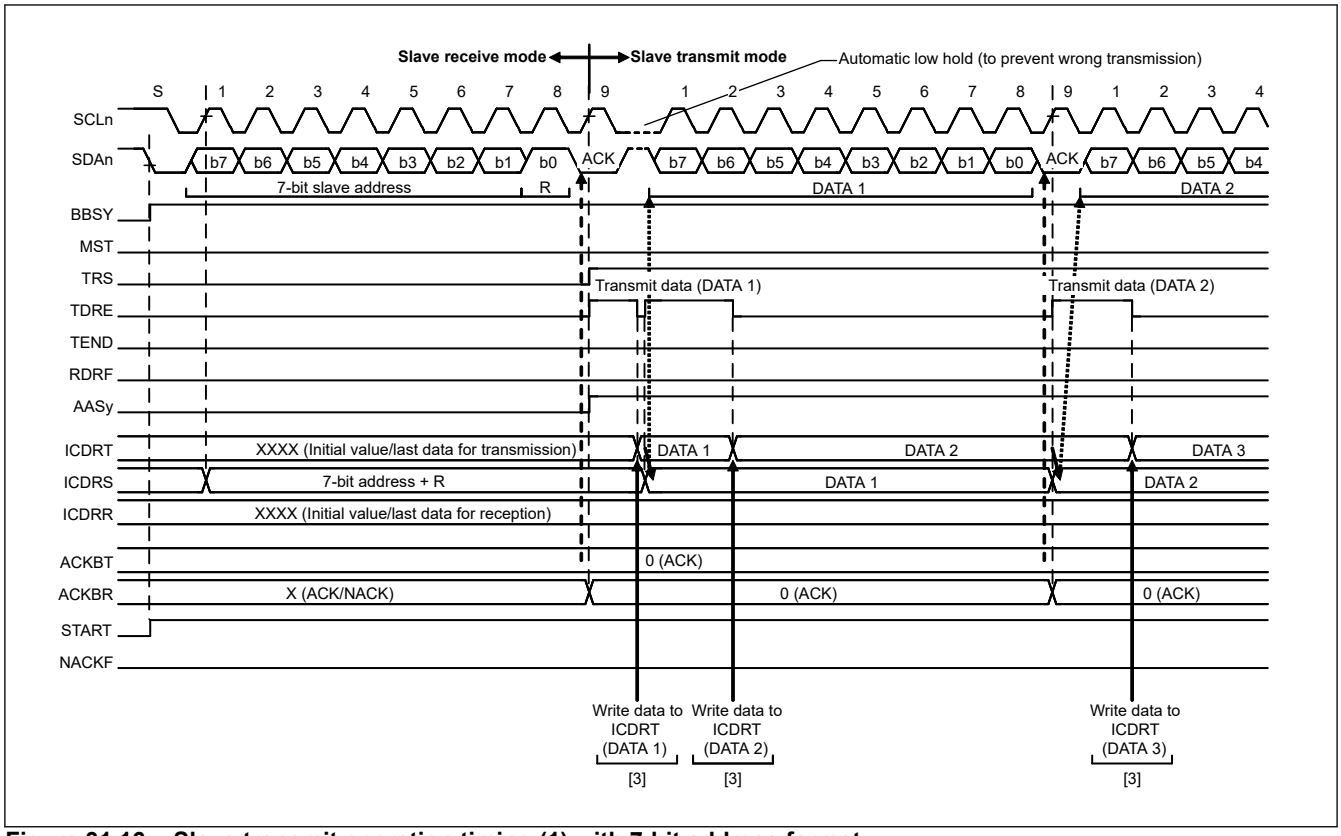

Figure 31.16 Slave transmit operation timing (1) with 7-bit address format

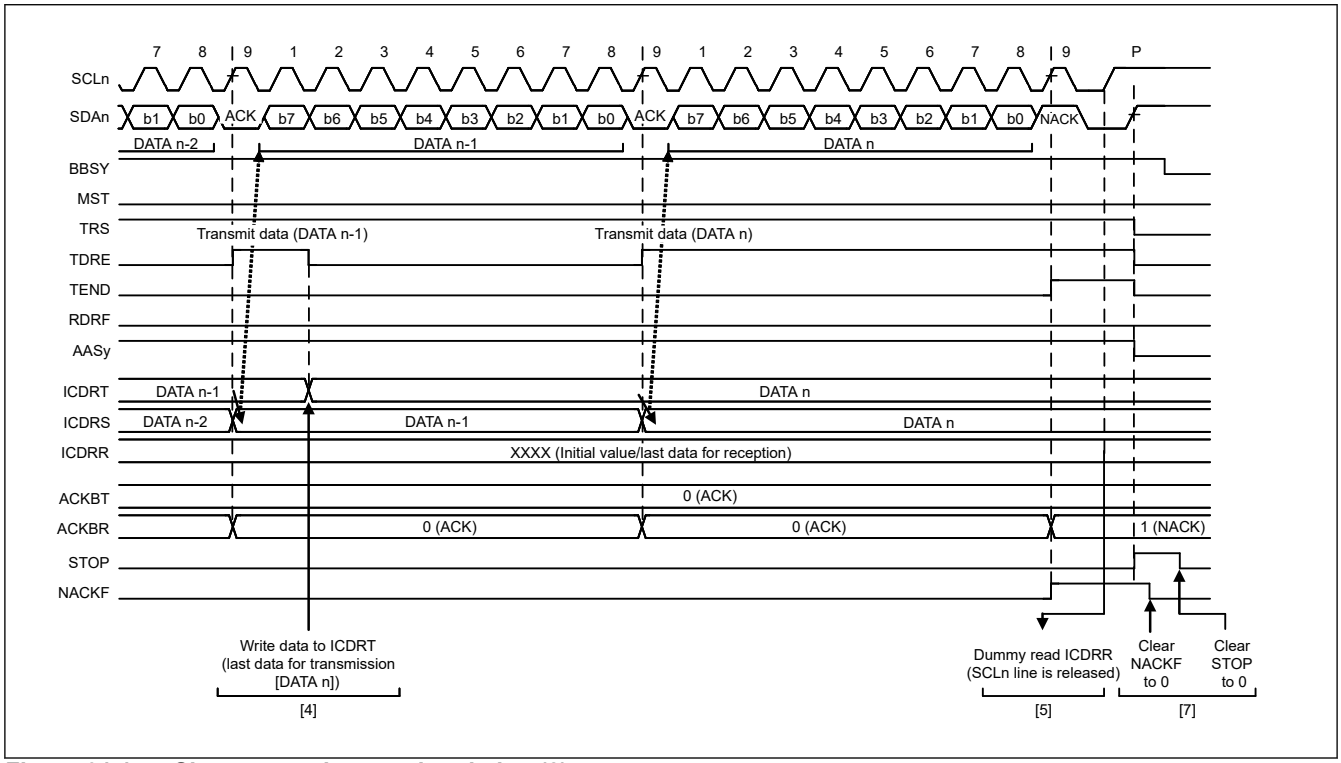

Figure 31.17 Slave transmit operation timing (2)

31.3.6 Slave Receive Operation

In slave receive operation, the master device outputs the SCL clock and transmit data, and the IIC returns acknowledgments as a slave device.

Figure 31.18 shows an example of slave reception, and Figure 31.19 and Figure 31.20 show the operation timing in slave reception.

To set up and perform slave reception:

1. Initialize the IIC using the procedure in section 31.3.2. Initial Settings.
   After initialization, the IIC stays in the standby state until it receives a slave address that matches.
2. After receiving a matching slave address, the IIC sets one of the associated ICSR1.HOA, GCA, and AASy flags (y = 0 to 2) to 1 on the rising edge of the ninth cycle of the SCL clock and outputs the value set in the ICMR3.ACKBT bit to the acknowledge bit on the ninth cycle of the SCL clock. If the value of the R/W# bit is 0, the IIC continues to place itself in slave receive mode and sets the RDRF flag in ICSR2 to 1.
3. Check that the ICSR2.STOP flag is 0 and the ICSR2.RDRF flag is 1, then dummy read ICDRR. The dummy value consists of the slave address and R/W# bit when the 7-bit address format is selected, or the lower 8 bits when the 10-bit address format is selected.
4. When ICDRR is read, the IIC automatically sets the ICSR2.RDRF flag to 0. If reading of ICDRR is delayed and a next byte is received while the RDRF flag is still set to 1, the IIC holds the SCLn line low until 1 SCL cycle before the point where RDRF must be set. In this case, reading ICDRR releases the SCLn line from being held low.
   When the ICSR2.STOP flag is 1 and the ICSR2.RDRF flag is also 1, read ICDRR until all the data is completely received.
5. On detecting the stop condition, the IIC automatically clears the ICSR1.HOA, GCA, and AASy flags (y = 0 to 2) to 0.
6. Check that the ICSR2.STOP flag is 1, then set the ICSR2.STOP flag to 0 for the next transfer operation.

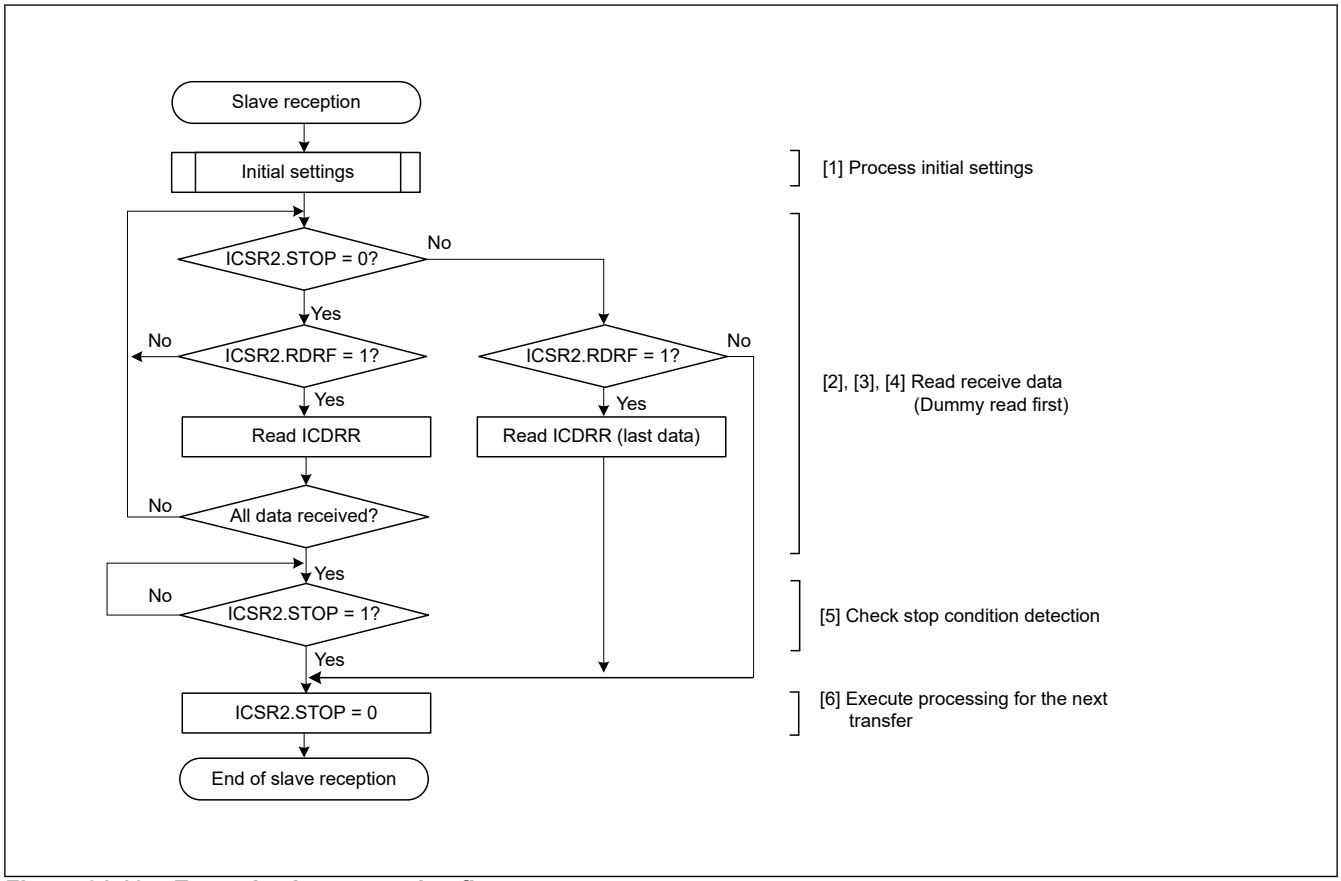

Figure 31.18 Example slave reception flow

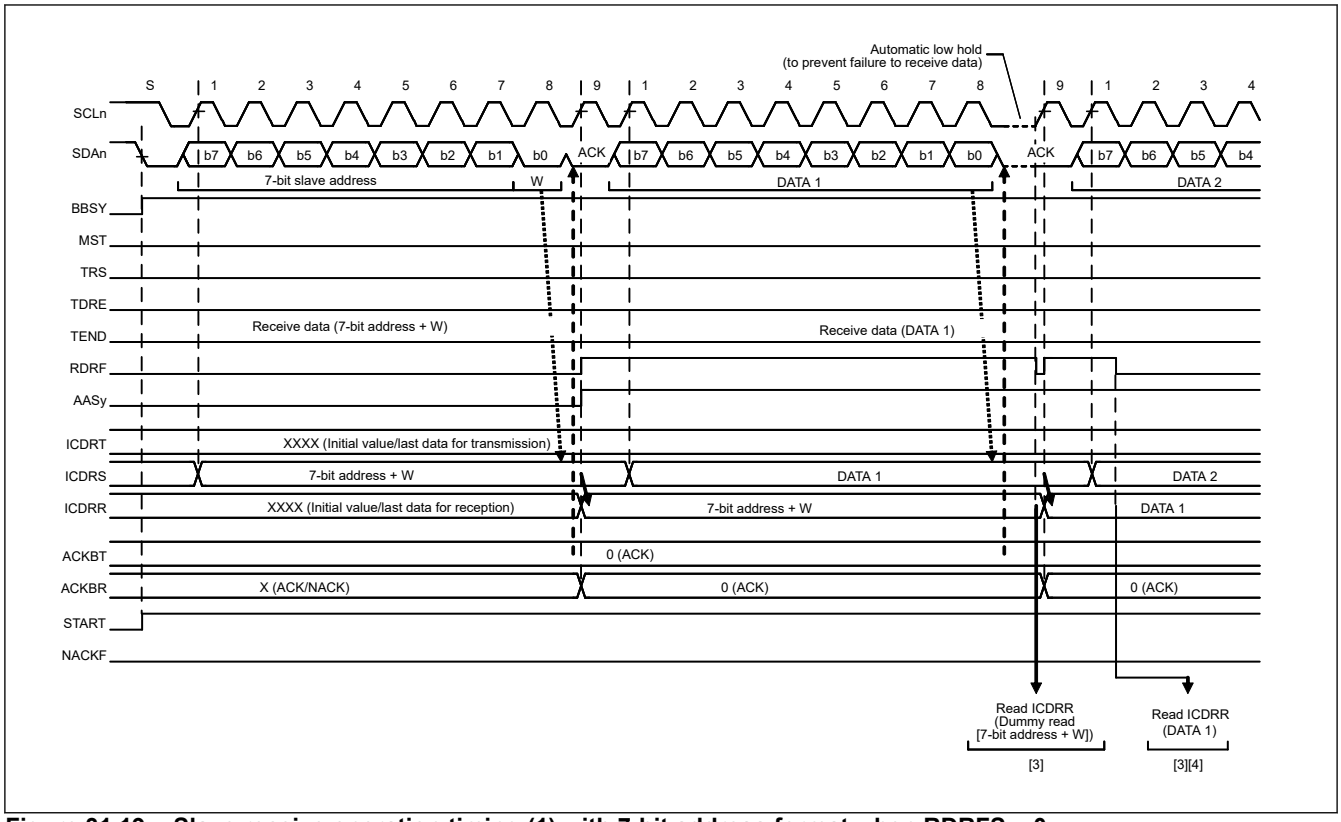

Figure 31.19 Slave receive operation timing (1) with 7-bit address format when RDRFS = 0

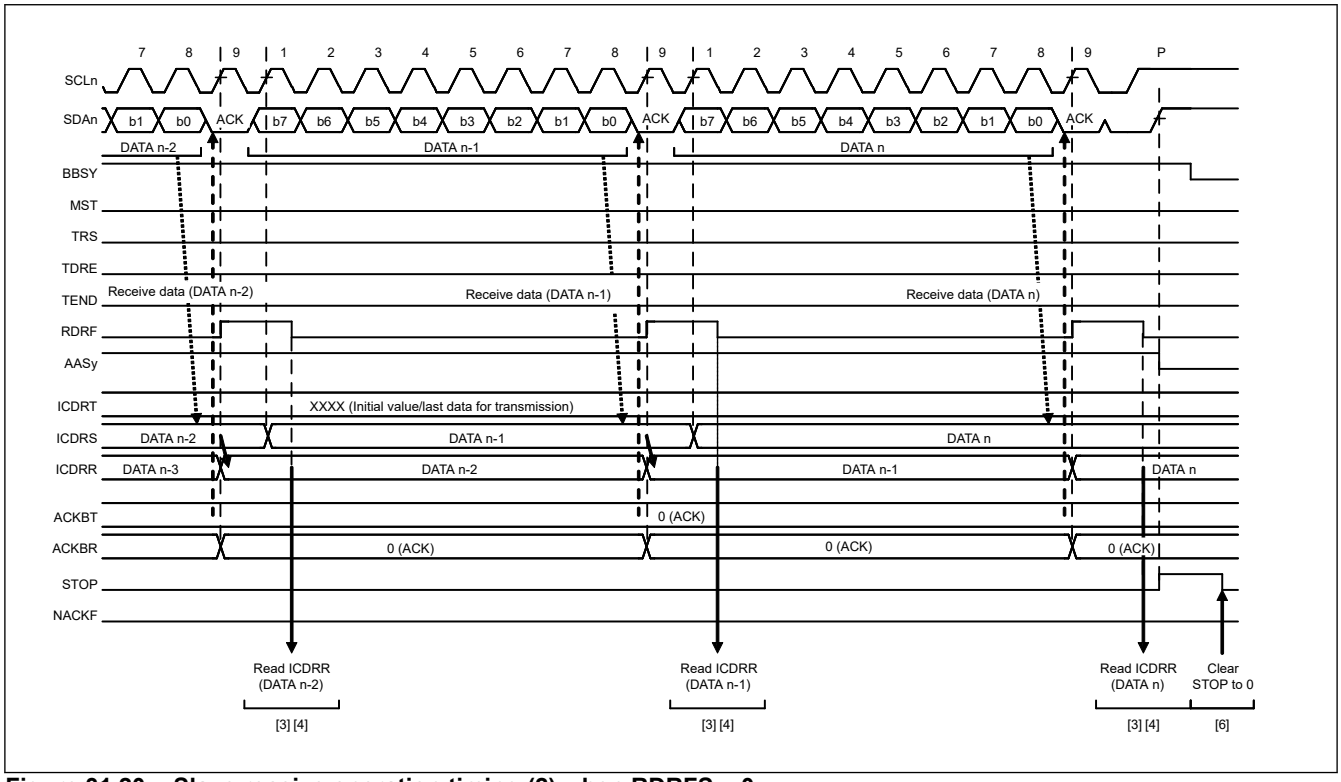

Figure 31.20 Slave receive operation timing (2) when RDRFS = 0

31.4 SCL Synchronization Circuit

For generation of the SCL clock, the IIC starts counting the value for the high-level period specified in ICBRH when it detects a rising edge on the SCLn line, and it drives the SCLn line low when it completes counting. When the IIC detects the falling edge of the SCLn line, it starts counting the value for the low-level period specified in ICBRL, and then it stops

driving the SCLn line, releasing the line, when it completes counting. The IIC repeats this process to generate the SCL clock.

If multiple master devices are connected to the I^2C bus, a collision of SCL signals might arise because of contention with another master device. In such cases, the master devices must synchronize their SCL signals. Because this synchronization of SCL signals must be bit-by-bit, the IIC is equipped with an SCL synchronization circuit to obtain bit-by-bit synchronization of the SCL clock signals by monitoring the SCLn line while in master mode.

When the IIC detects a rising edge on the SCLn line and starts counting the high-level period specified in ICBRH.BRH[4:0], and the level on the SCLn line falls because an SCL signal is being generated by another master device, the IIC performs the following:

1. Stops counting when it detects the falling edge.
2. Drives the level on the SCLn line low.
3. Starts counting the low-level period specified in ICBRL.BRL[4:0].

When the IIC finishes counting the low-level period, it stops driving the SCLn line low to release the line. If the low-level period of the SCL clock signal from the other master device is longer than the low-level period set in the IIC, the low-level period of the SCL signal is extended. When the low-level period for the other master device ends, the SCL signal rises because the SCLn line is released.

When the IIC finishes outputting the low-level period of the SCL clock, the SCLn line is released and the SCL clock rises. That is, when SCL signals from more than one master are contending, the high-level period of the SCL signal is synchronized with that of the clock with the narrower period, and the low-level period of the SCL signal is synchronized with that of the clock with the broader period. However, such synchronization of the SCL signal is only enabled when the SCLE bit in ICFER is set to 1.

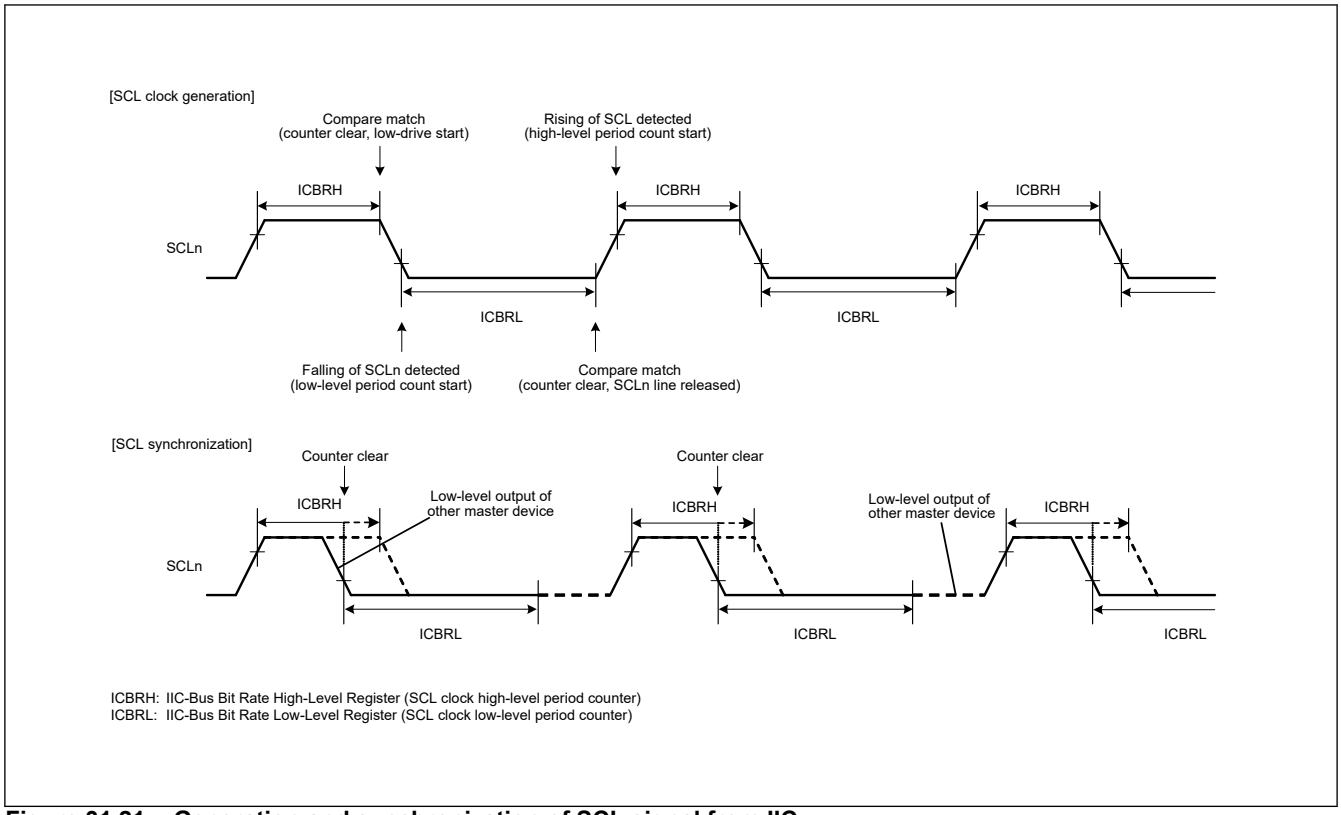

Figure 31.21 Generation and synchronization of SCL signal from IIC

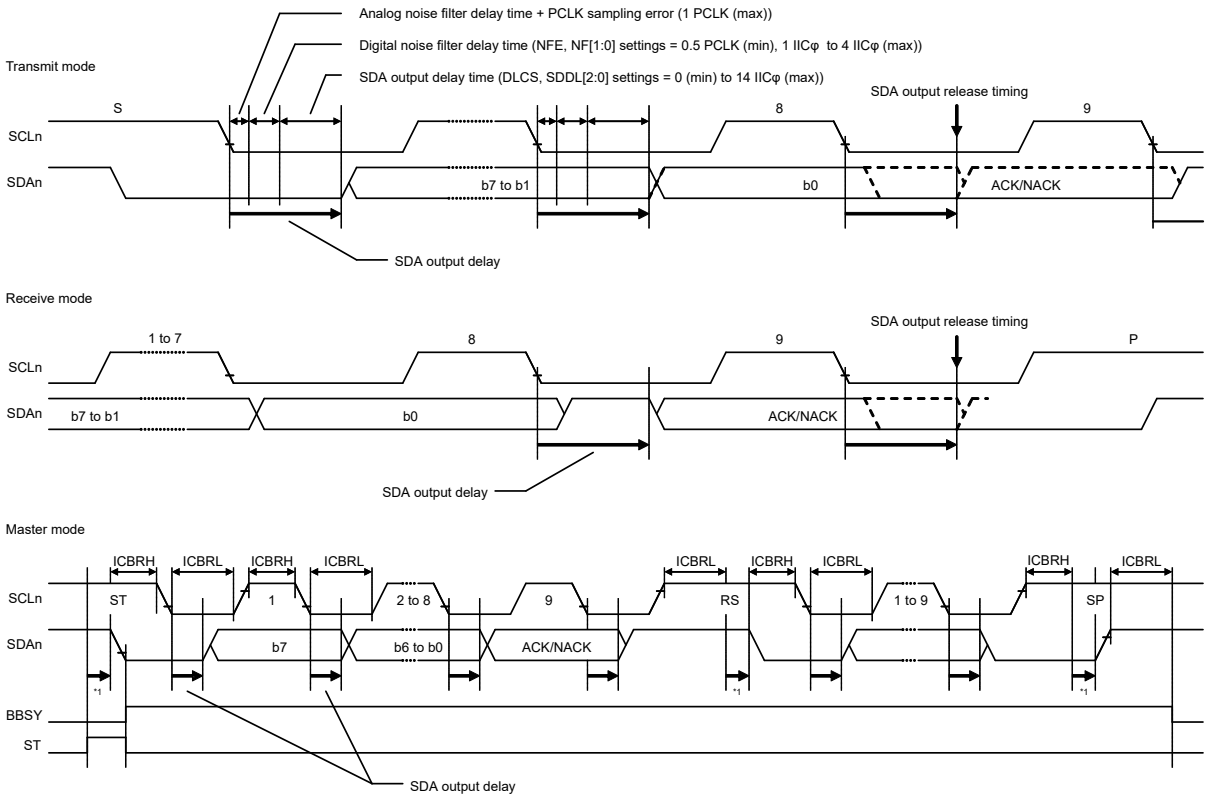
31.5 SDA Output Delay Function

The IIC module incorporates a function for delaying output on the SDA line. The delay can be applied to all output on the SDA line, including issuing of the start, restart, and stop conditions, data, and the ACK and NACK signals.

With this function, SDA output is delayed from the detection of a falling edge of the SCL signal to ensure that the SDA signal is output within the interval during which the SCL clock is low. This approach helps prevent erroneous operation of communications devices, with the aim of satisfying the 300-ns minimum data-hold time requirement of the SMBus specification. The output delay function is enabled by setting the SDDL[2:0] bits in ICMR2 to a value other than 000b, and disabled by setting the same bits to 000b.

When the SDA output delay function is enabled, for example, the DLCS bit in ICMR2 selects the clock source for the SDA output delay counter, either as the internal base clock (IICφ) for the IIC module or as the internal base clock divided by 2 (IICφ/2). The counter counts the number of cycles set in the SDDL[2:0] bits in ICMR2. When the delay cycles count is reached, the IIC module places the required output (start, restart, or stop condition, data, or an ACK or NACK signal) on the SDA line.



Note: PCLK = PCLKB
Note 1. The output delay function is set by the DLCS and SDDL[2:0] bits when a start (ST), restart (RS), or stop (SP) condition is issued.

Figure 31.22 SDA output delay function

31.6 Digital Noise Filter Circuits

The internal circuitry sees the states of the SCLn and SDAn pins through analog and digital noise-filter circuits. Figure 31.23 shows a block diagram of the digital noise-filter circuit.

The on-chip digital noise-filter circuit of the IIC consists of four flip-flop circuit stages connected in series and a match-detection circuit. The number of valid stages in the digital noise filter is selected in the NF[1:0] bits in ICMR3. The selected number of valid stages determines the noise-filtering capability as a period from 1 to 4 IICφ cycles.

The input signal to the SCLn pin (or SDAn pin) is sampled on falling edges of the IICφ signal. When the input signal level matches the output level of the number of valid flip-flop circuit stages as selected in the NF[1:0] bits in ICMR3, the signal level is seen in the subsequent stage. If the signal levels do not match, the previous value is saved.

If the ratio between the frequency of the internal operating clock (PCLKB) and the transfer rate is small, for example, if data transfer is 400 kbps with PCLKB = 4 MHz, the characteristics of the digital noise filter might lead to the elimination of

required signals as noise. In such cases, it is possible to disable the digital noise-filter circuit by setting the ICFER.NFE bit to 0, and use only the analog noise filter circuit.

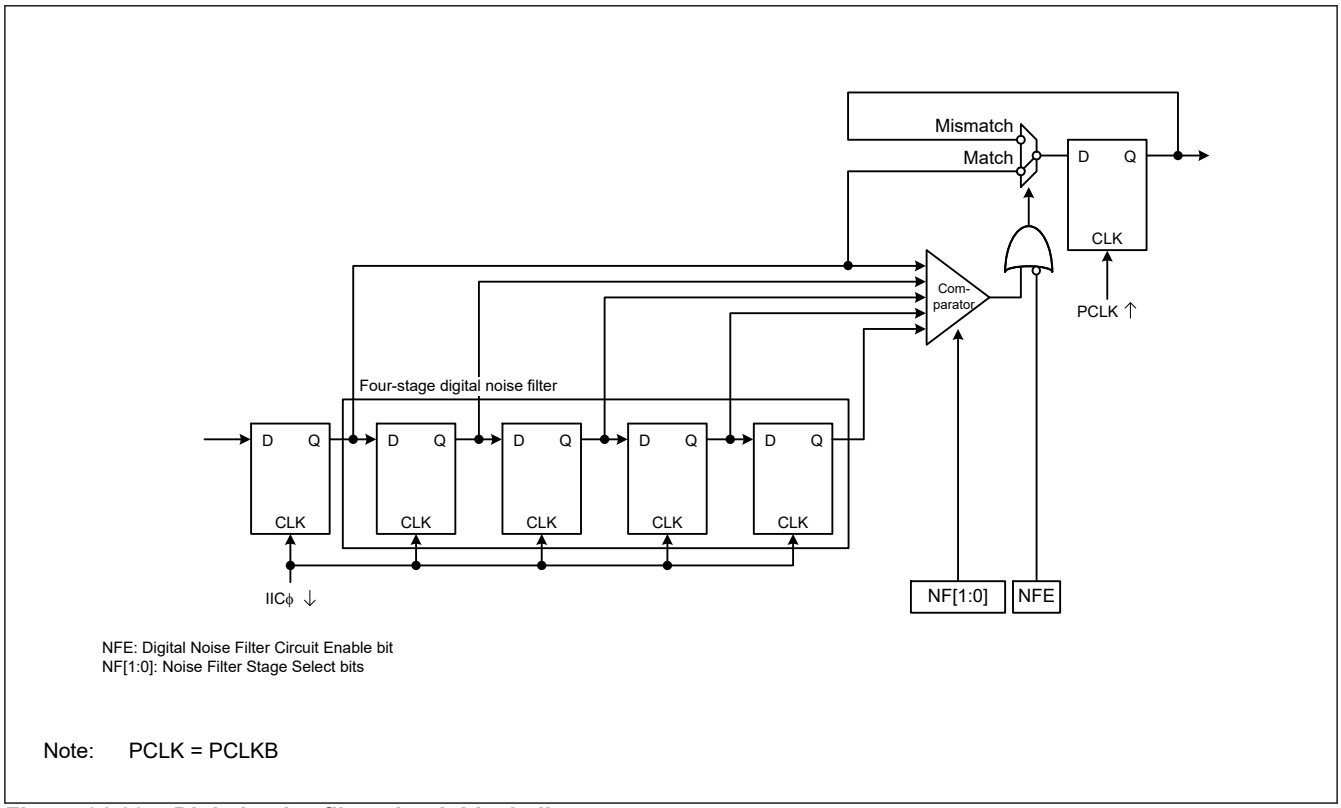


Figure 31.23 Digital noise filter circuit block diagram

31.7 Address Match Detection

The IIC can set three unique slave addresses in addition to the general call address and host address. The slave addresses can be 7-bit or 10-bit slave addresses.

31.7.1 Slave-Address Match Detection

The IIC can set three unique slave addresses and has a slave address detection function for each unique slave address. When the SARyE bit (y = 0 to 2) in ICSER is set to 1, the slave addresses set in SARUy and SARLy (y = 0 to 2) can be detected.

When the IIC detects a match of the set slave address, the associated AASy flag (y = 0 to 2) in ICSR1 is set to 1 on the rising edge of the ninth SCL clock cycle, and the RDRF flag in ICSR2 or the TDRE flag in ICSR2 is set to 1 by the subsequent R/W# bit. This causes a receive data full interrupt (IICn_RXI) or transmit data empty interrupt (IICn_TXI) to be generated. The AASy flag identifies which slave address is specified.

Figure 31.24 to Figure 31.26 show the AASy flag set timing in three cases.

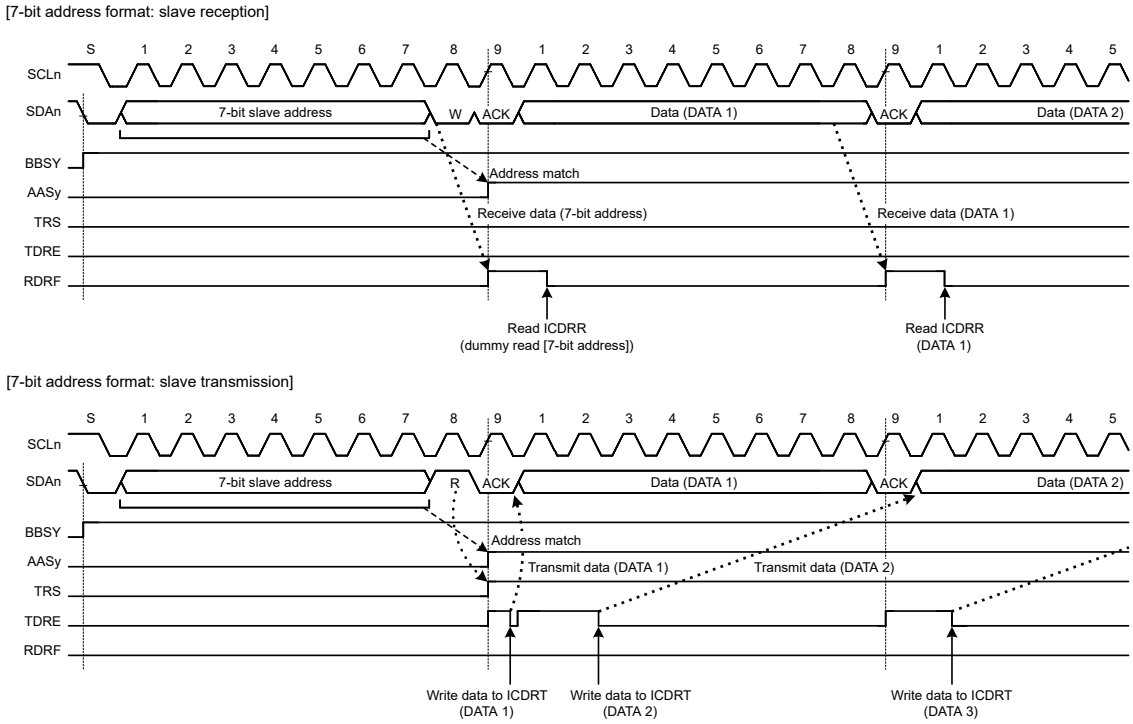

Figure 31.24 AASy flag set timing with 7-bit address format

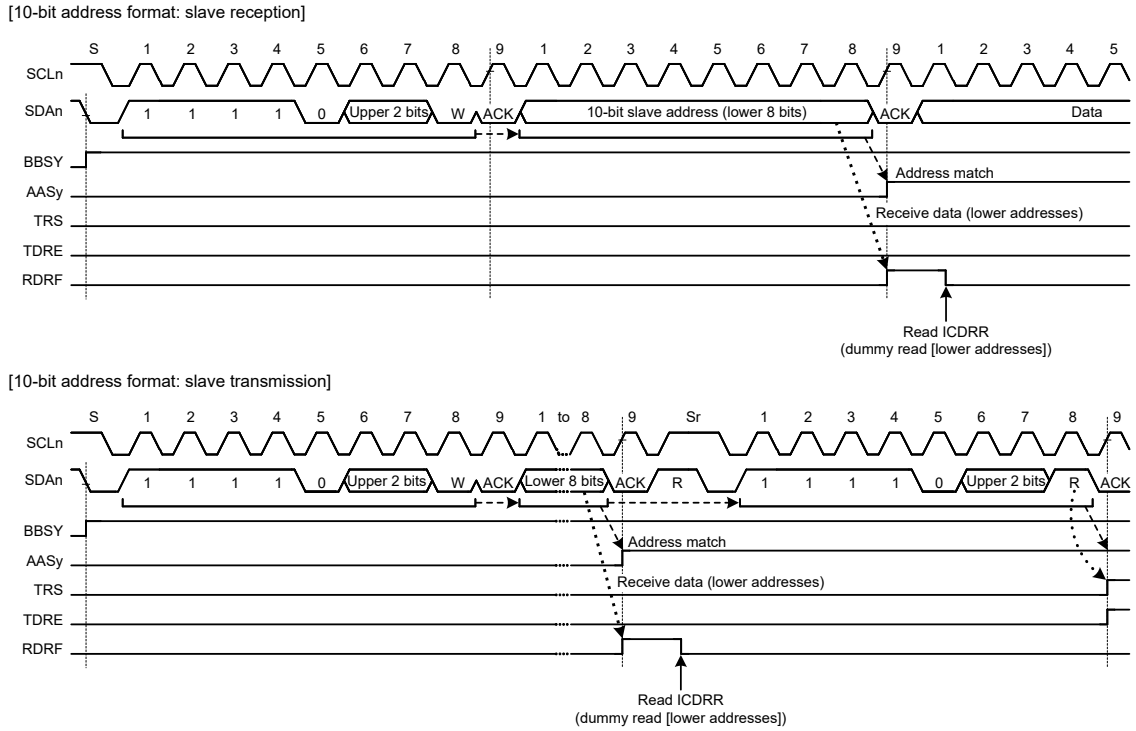

Figure 31.25 AASy flag set timing with 10-bit address format

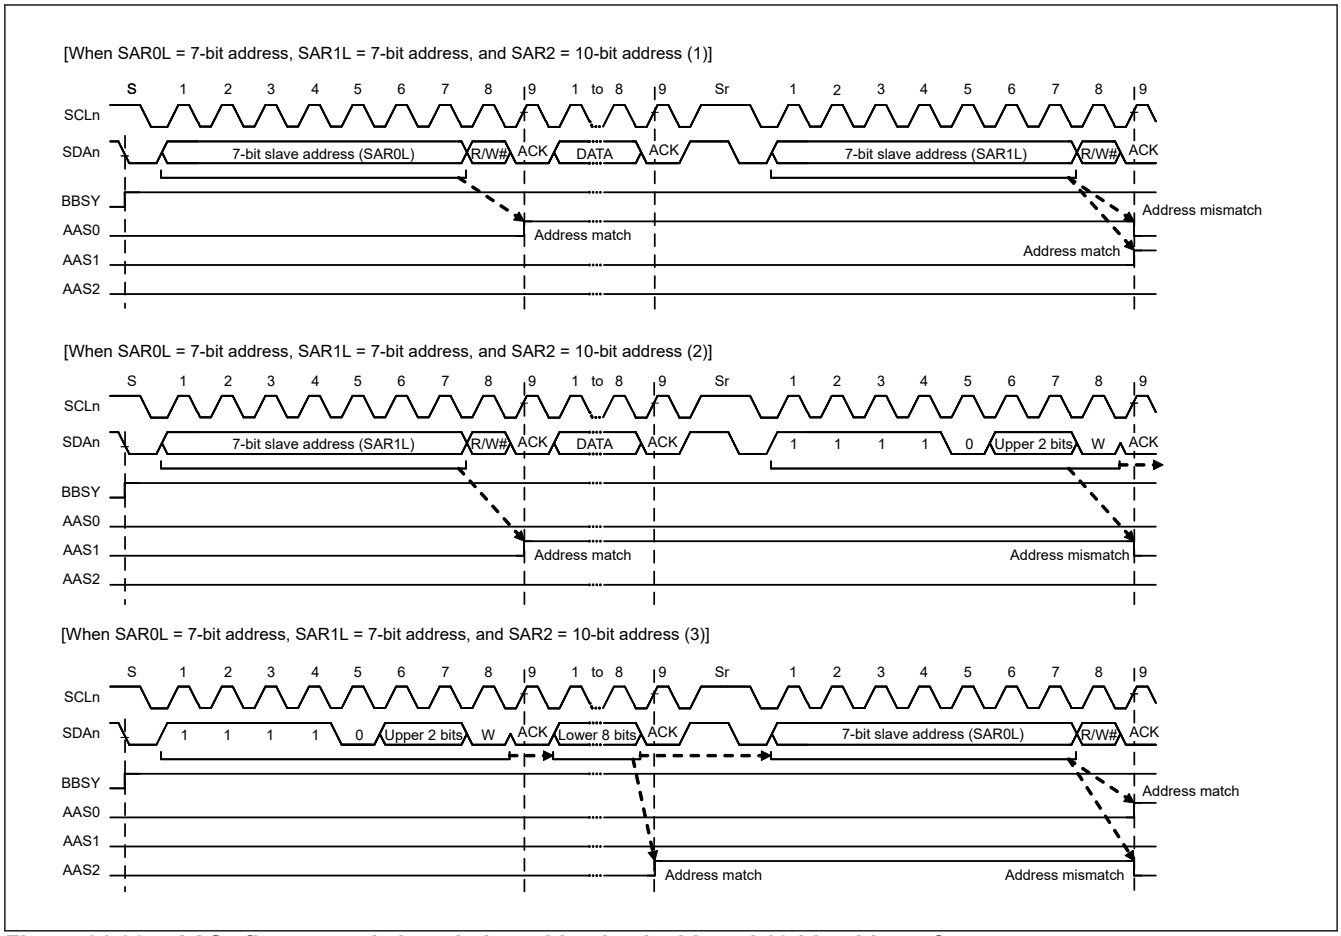

Figure 31.26 AASy flag set and clear timing with mixed 7-bit and 10-bit address formats

31.7.2 Detection of General Call Address

The IIC provides detection of the general call address (0000 000b + 0 [W]). This is enabled by setting the GCAE bit in ICSER to 1.

If the address received after a start or restart condition is issued is 0000 000b + 1[R] (start byte), the IIC recognizes this as the address of a slave device with an all-zero address, but not as the general call address.

When the IIC detects the general call address, both the GCA flag in ICSR1 and the RDRF flag in ICSR2 set to 1 on the rising edge of the ninth cycle of the SCL clock. This leads to the generation of a receive data full interrupt (IICn_RXI). The value of the GCA flag can be checked to confirm that the general call address was transmitted.

Operation after detection of the general call address is the same as normal slave receive operation.

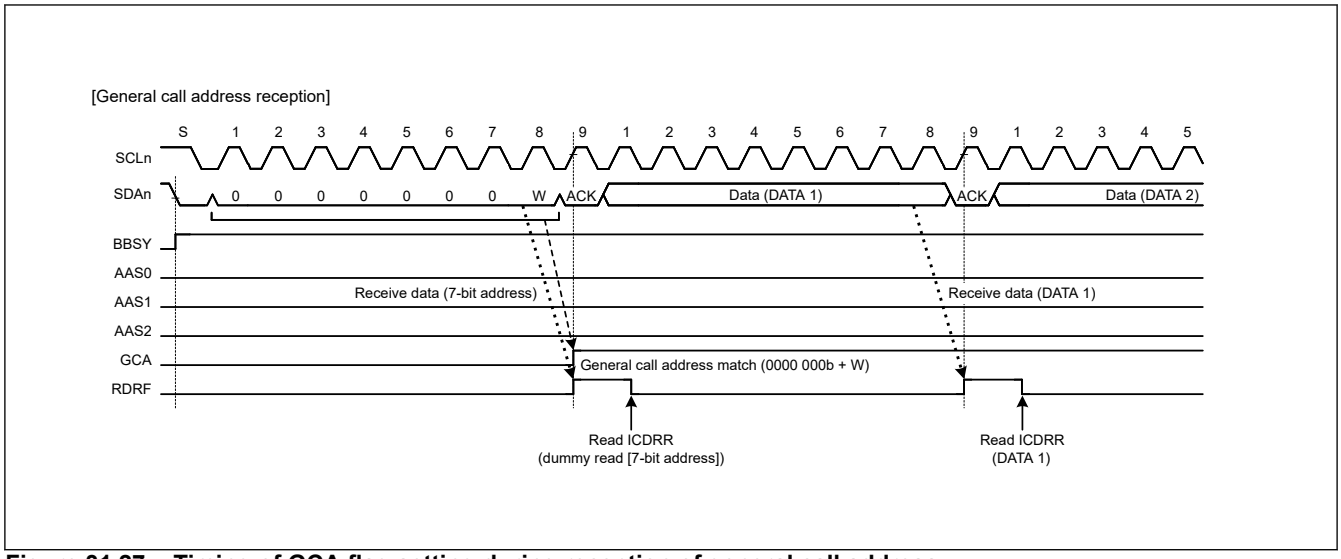

Figure 31.27 Timing of GCA flag setting during reception of general call address

31.7.3 Device-ID Address Detection

The IIC module provides detection of device-ID address compliant with the I^2C bus specification (revision 03). When the IIC receives 1111 100b as the first byte after a start or restart condition is issued with the DIDE bit in ICSER set to 1, it recognizes the address as a device ID, sets the DID flag in ICSR1 to 1 on the rising edge of the ninth SCL clock cycle when the subsequent R/W# bit is 0, then compares the second and subsequent bytes with its own slave address. If the address matches the value in the slave address register, the IIC sets the associated AASy flag (y = 0 to 2) in ICSR1 to 1.

When the first byte received after the issue of a start or restart condition matches the device ID address (1111 100b) again and the subsequent R/W# bit is 1, the IIC does not compare the second and subsequent bytes and sets the ICSR2.TDRE flag to 1.

In the device ID address detection function, the IIC sets the DID flag to 0 if a match with the IIC slave address is not obtained or a match with the device ID address is not obtained after a match with the IIC slave address and a restart condition is not detected. If the first byte after detection of a start or restart condition matches the device ID address (1111 100b), and the R/W# bit is 0, the IIC sets the DID flag to 1 and compares the second and subsequent bytes with the slave address of the IIC. If the R/W# bit is 1, the DID flag holds the previous value and the IIC does not compare the second and subsequent bytes. Therefore, the reception of a device ID address can be checked by reading the DID flag after confirming that TDRE = 1.

Additionally, prepare the device ID fields (3 bytes: 12 bits indicating the manufacturer + 9 bits identifying the part + 3 bits indicating the revision) that must be sent to the host after reception of a continuous device-ID field as normal transmit data. For details on the information that must be included in device ID fields, contact NXP Semiconductors.

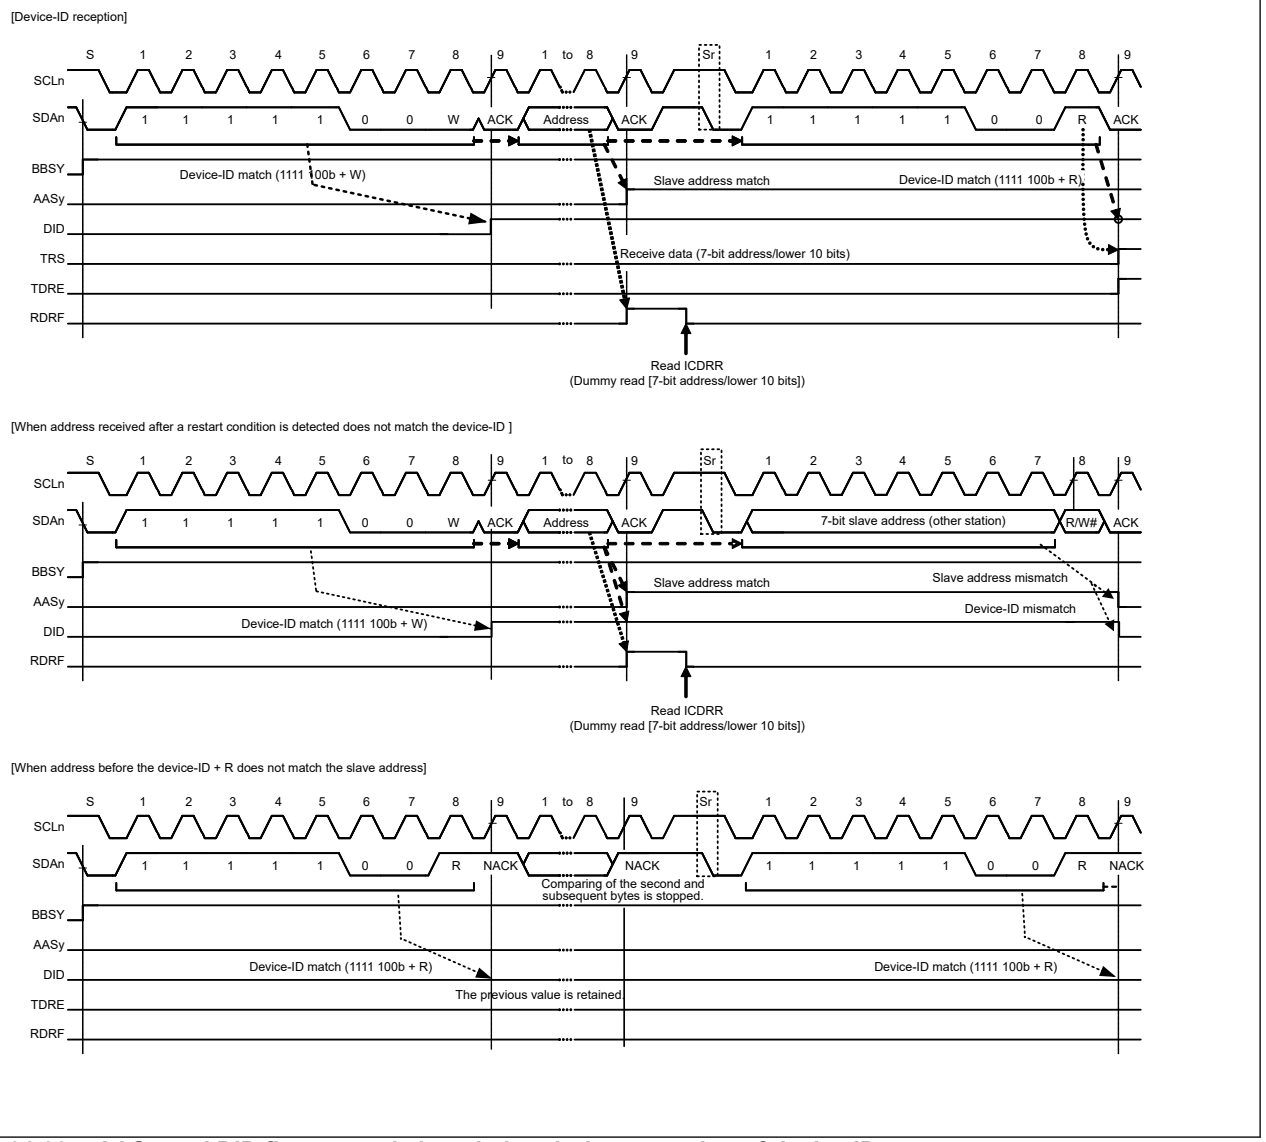

Figure 31.28 AASy and DID flag set and clear timing during reception of device ID

31.7.4 Host Address Detection

The IIC provides host address detection when operating in SMBus. When the HOAE bit in ICSER is set to 1 while the SMBS bit in ICMR3 is 1, the IIC can detect the host address (0001 000b) in slave receive mode (MST and TRS bits = 00b in ICCR2).

When the IIC detects the host address, the HOA flag in ICSR1 is set to 1 on the rising edge of the 9th SCL clock cycle, and at the same time, the RDRF flag in ICSR2 is set to 1 when the R/W# bit is 0 (Wr bit). This causes a receive data full interrupt (IICn_RXI) to be generated. The HOA flag indicates that the host address was sent from another device.

If the bit following the host address (0001 000b) is an Rd bit (R/W# bit = 1), the IIC can also detect the host address. After the host address is detected, the IIC operates in the same manner as in normal slave operation.

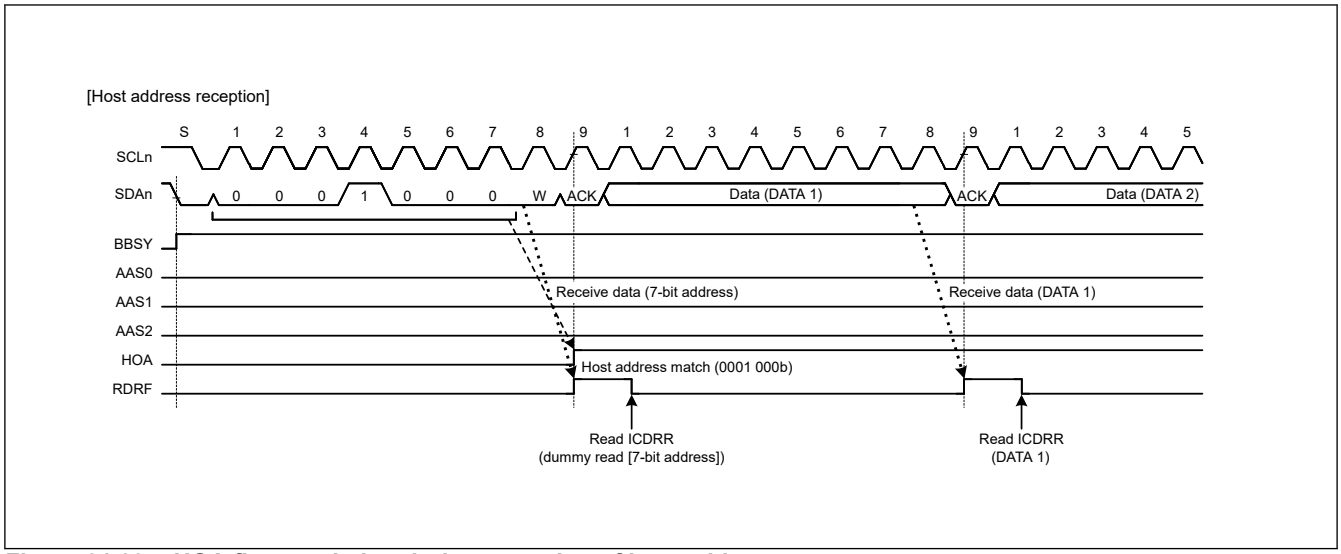

Figure 31.29 HOA flag set timing during reception of host address

31.8 Wakeup Function

The IIC provides a wakeup function that causes the MCU to transition from Software Standby mode or Snooze mode to normal operation. The wakeup function enables the reception of data when the system clock (PCLKB) is stopped, and generates a wakeup interrupt signal on a match of the slave address of the received data. This wakeup interrupt signal triggers the return to normal operation. After the wakeup interrupt occurs, switch the IIC to PCLKB synchronous operation so that communication can continue.

The wakeup function has four operation modes:

- Normal wakeup mode 1
- Normal wakeup mode 2
- Command recovery mode
- EEP response mode

Table 31.9 describes the behavior in these modes.

Table 31.9 Wakeup operation modes

Operation mode	ACK response timing	ACK response before wakeup to PCLKB synchronous operation	SCL state during wakeup to PCLKB synchronous operation
Normal wakeup mode 1	Before wakeup to PCLKB synchronous operation*1	ACK	Fixed low
Normal wakeup mode 2	After wakeup to PCLKB synchronous operation*2	Before wakeup: no response (NACK level retained) After wakeup: ACK response	Fixed low
Command recovery mode	Before wakeup to PCLKB synchronous operation*1	ACK	Open
EEP response mode	Before recovery to PCLKB synchronous operation*1	NACK	Open

Note 1. Switching timing from PCLKB asynchronous operation to PCLKB synchronous operation is the falling edge of the 9th clock of the SCL.
Note 2. Switching timing from PCLKB asynchronous operation to PCLKB synchronous operation is the falling edge of the 8th clock of the SCL.

The following can be selected as wakeup interrupt sources:

- Host address detection (valid when ICSER.HOAE = 1)
- General call address detection (valid when ICSER.GCAE = 1)
- Slave address 0*1 detection (valid when ICSER.SAR0E = 1)

- Slave address 1[*1] detection (valid when ICSER.SAR1E = 1)
- Slave address 2[*1] detection (valid when ICSER.SAR2E = 1)

Note 1. Only 7-bit address can be set. Set the FS bit in SARUy (y = 0 to 2) to 0.

Precautions on the use of the wakeup function

- Do not change the content of the IIC registers except the WUSEN bit in ICWUR2 while the WUASYF flag in ICWUR2 is 1 (during PCLKB asynchronous operation).
- Set ICWUR.WUE and ICWUR.WUIE to 1, and ICCR2.MST and ICCR2.TRS to 0 (slave reception mode) before switching to PCLKB asynchronous mode.
- The device ID and the 10-bit slave address cannot be selected for the wakeup interrupt source. Set the DIDE bit in ICSER and FS bit in SARUy (y = 0 to 2) to 0.
- Set bits TIE, TEIE, RIE, NAKIE, SPIE, STIE, ALIE, and TMOIE in the ICIER register to 0 (interrupt disabled) before switching to the asynchronous operation.
- When the wakeup function is enabled, do not use the timeout function (ICWUR.WUE = 1)
- Even when a wakeup interrupt is generated during PCLKB asynchronous operation (when ICWUR2.WUASYF = 1), if the slave addresses match in PCLKB synchronous mode (ICWUR2.WUASYF = 0), the wakeup interrupt does not occur and the WUF flag is not set.
- If the timing of writing 0 to the ICWUR2.WUSEN bit and the timing of detecting a start condition conflict, the IIC might start the next reception in PCLKB synchronous operation mode. In this case, ICWUR2.WUASYF flag becomes 1 (switch to PCLKB asynchronous mode) when data communication is complete, a stop condition is detected, and detection of a wakeup event starts.
- After writing 0 to the WUSEN bit in ICWUR2, do not change registers relate to the IIC operation mode setting (ICMR3, ICSER, and SARLy) until the mode is switched to PCLKB asynchronous operation from PCLKB synchronous operation (while the ICWUR2.WUASYF flag is 1). If the register value changes during this period by an interrupt handling or another factor, the IIC might malfunction before switching to the asynchronous operation.

31.8.1 Normal Wakeup Mode 1

This section describes the behavior, the timing, and an example operation of normal wakeup mode 1.

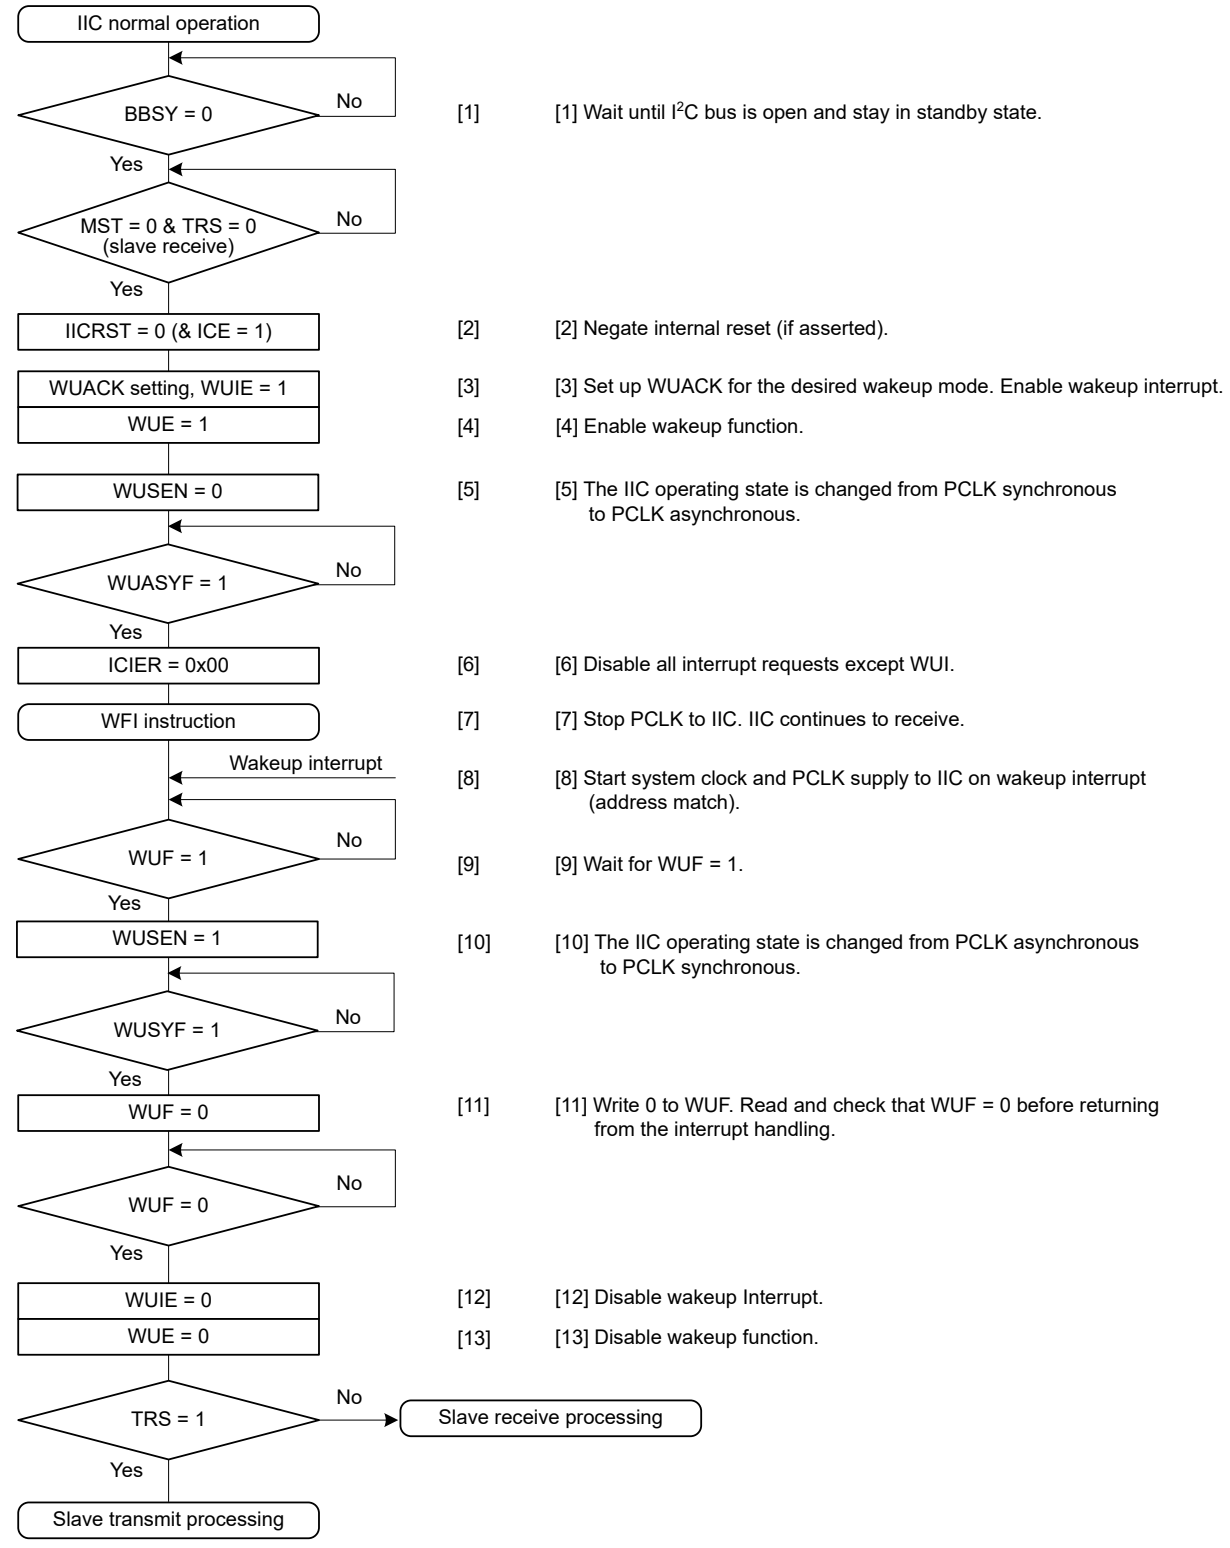
In normal wakeup mode 1, a wakeup interrupt triggered by the match of the slave address initiates the transition to normal operation as follows:

Before wakeup:	ACK is sent in response to the data received with its own slave address of the IIC.
During wakeup:	ACK response is made on the 9th clock cycle of SCL, after which SCL is held low[*1].
After wakeup:	Normal operation continues.

Note 1. Between the 9th clock cycle and 1st clock cycle during wakeup, WAIT = 1 is invalid.

If the slave address does not match, the SCL line is not held low after the 9th clock cycle of SCL, and the slave operation continues. Figure 31.30 shows an operation example, and Figure 31.32 shows the detailed timing.

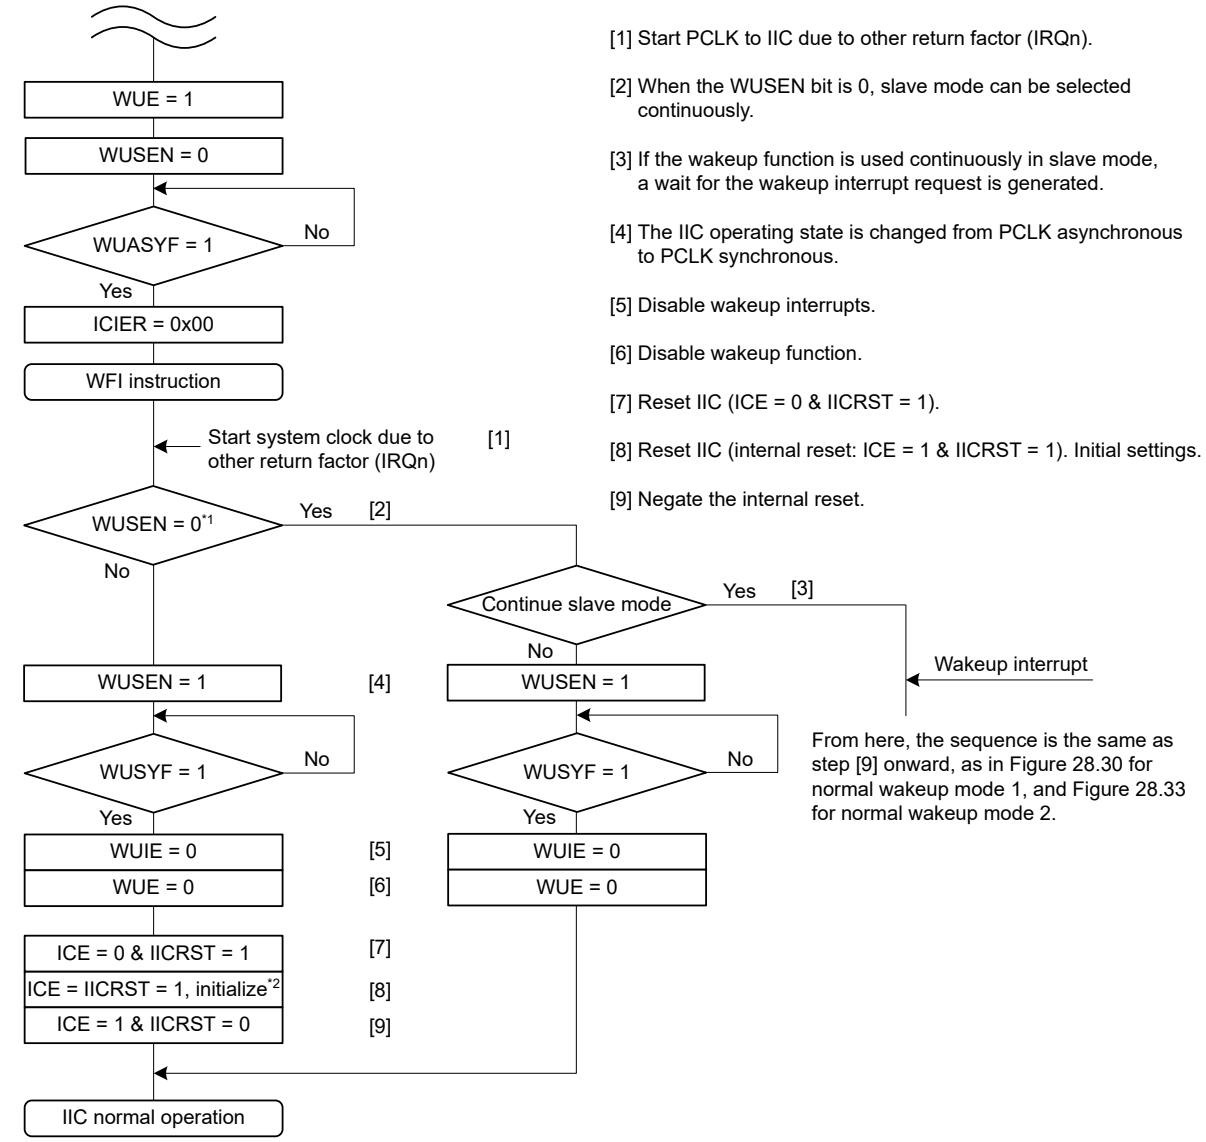
If the transition from Software Standby mode or Snooze mode is triggered by an interrupt other than a wakeup interrupt, for example the IRQn, the WUF flag is not set to 1. Figure 31.31 shows an operation example.



Note: PCLK = PCLKB

Figure 31.30 Example operation of normal wakeup mode 1 when wakeup is triggered by a wakeup interrupt on match of the slave address

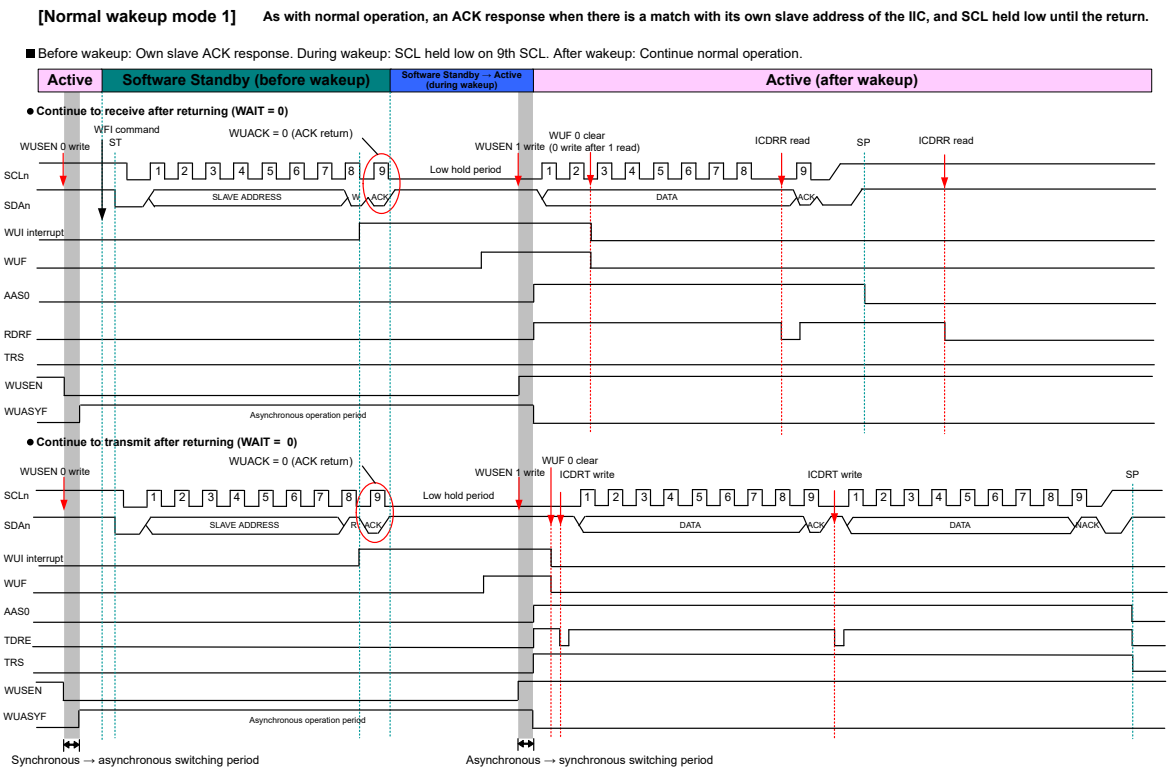
Note: See Precautions on the use of the wakeup function.



Note: PCLK = PCLKB
Note 1. In the MCU, WUSEN bit is always 0 in the IIC.
Note 2. For details on the IIC initial settings, see section 31.3.2. Initial Settings.

Figure 31.31 Example operation of normal wakeup modes 1 and 2 when wakeup is triggered by an interrupt other than IIC wakeup interrupt, for example, the IRQn

Note: For details on the IIC initial settings, see section 31.3.2. Initial Settings.



Note: n = 0

Figure 31.32 Timing of normal wakeup mode 1

31.8.2 Normal Wakeup Mode 2

This section describes the behavior, the timing, and an example operation of normal wakeup mode 2.

In normal wakeup mode 2, a wakeup interrupt triggered by a match of the slave address initiates the transition to normal operation as follows:

Before wakeup:	No response to data received with its own slave address until the end of the 8th SCL cycle.
During wakeup:	SCL line held low during the 8th and 9th clock cycles.
After wakeup:	ACK returns on the 9th clock cycle of SCL, and normal operation continues.

If the slave address does not match, the SCL line is not held low after the 8 th SCL clock cycle, and the slave operation continues. Figure 31.33 shows an example operation, and Figure 31.34 shows the detailed timing.

If the transition from Software Standby mode or Snooze mode is triggered by an interrupt other than a wakeup interrupt, such as the IRQn, for example, the WUF flag is not set to 1. Figure 31.31 shows an operation example.

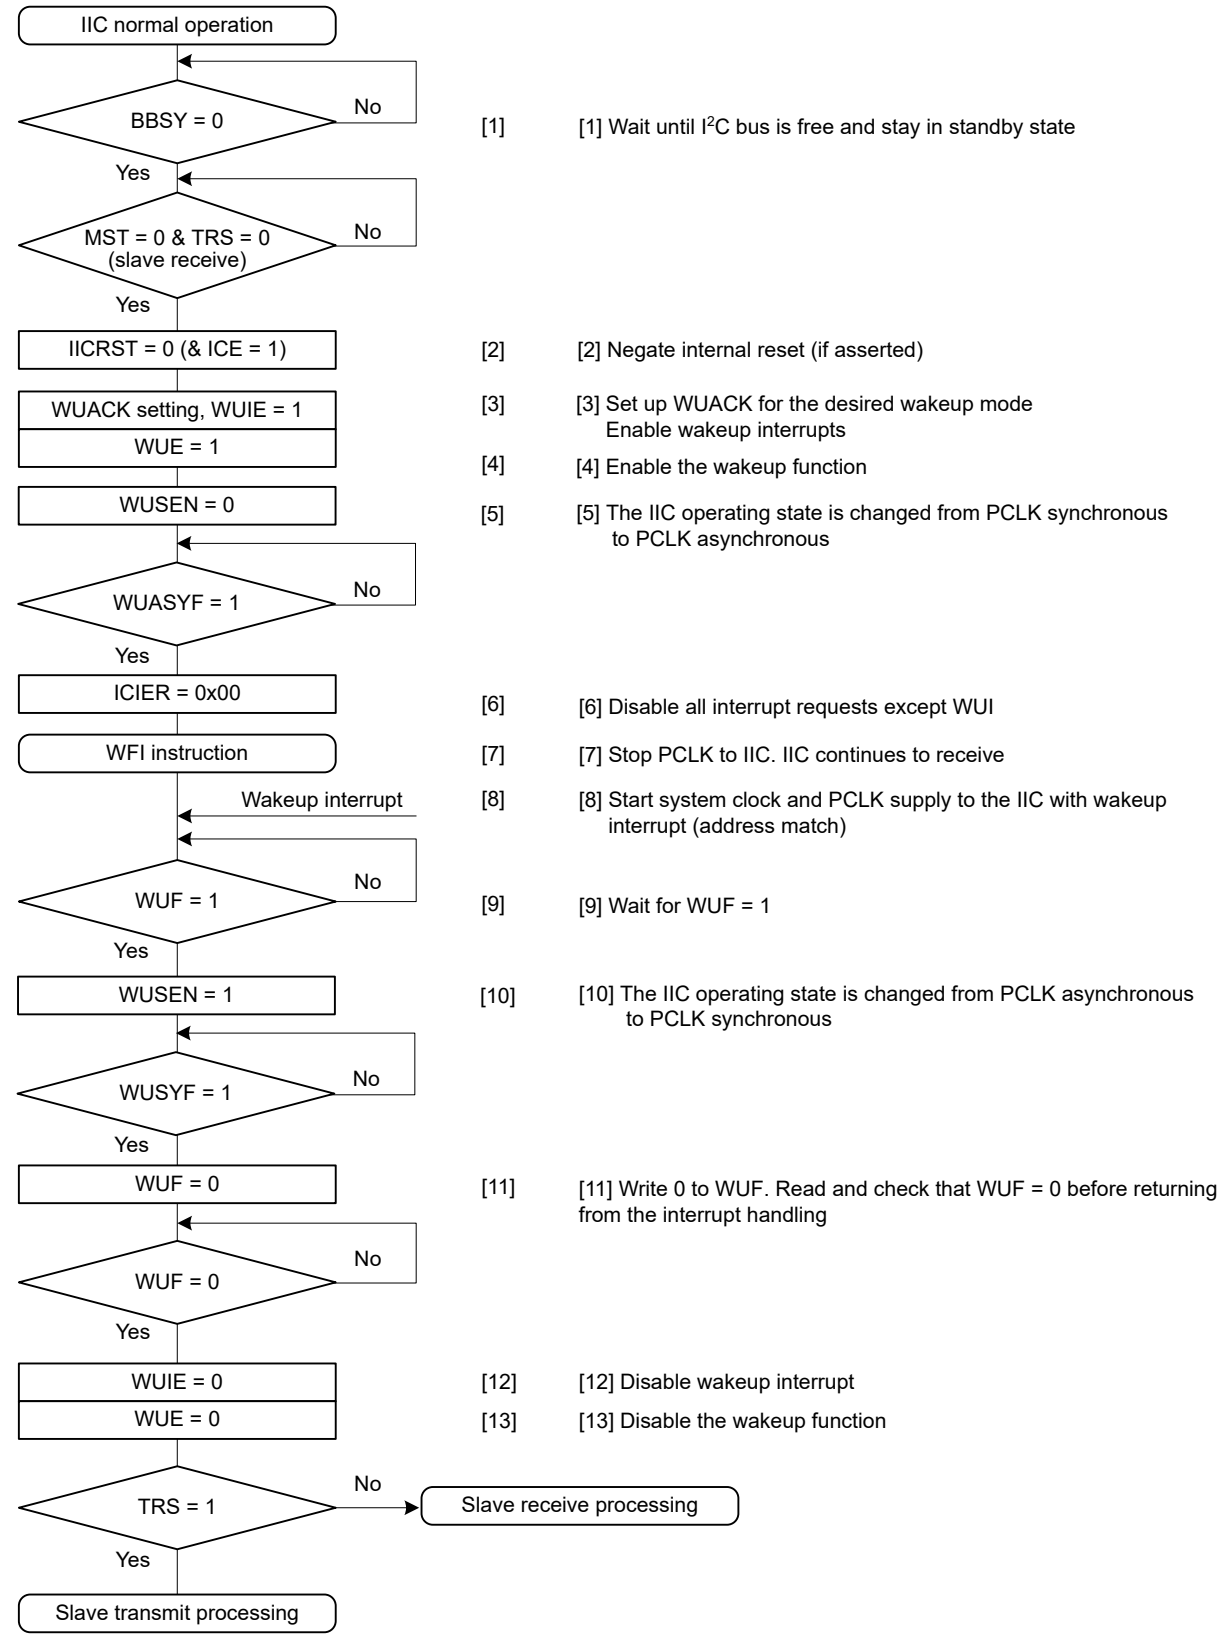


Figure 31.33 Example operation of normal wakeup mode 2 when wakeup is triggered by a wakeup interrupt on match of the slave address

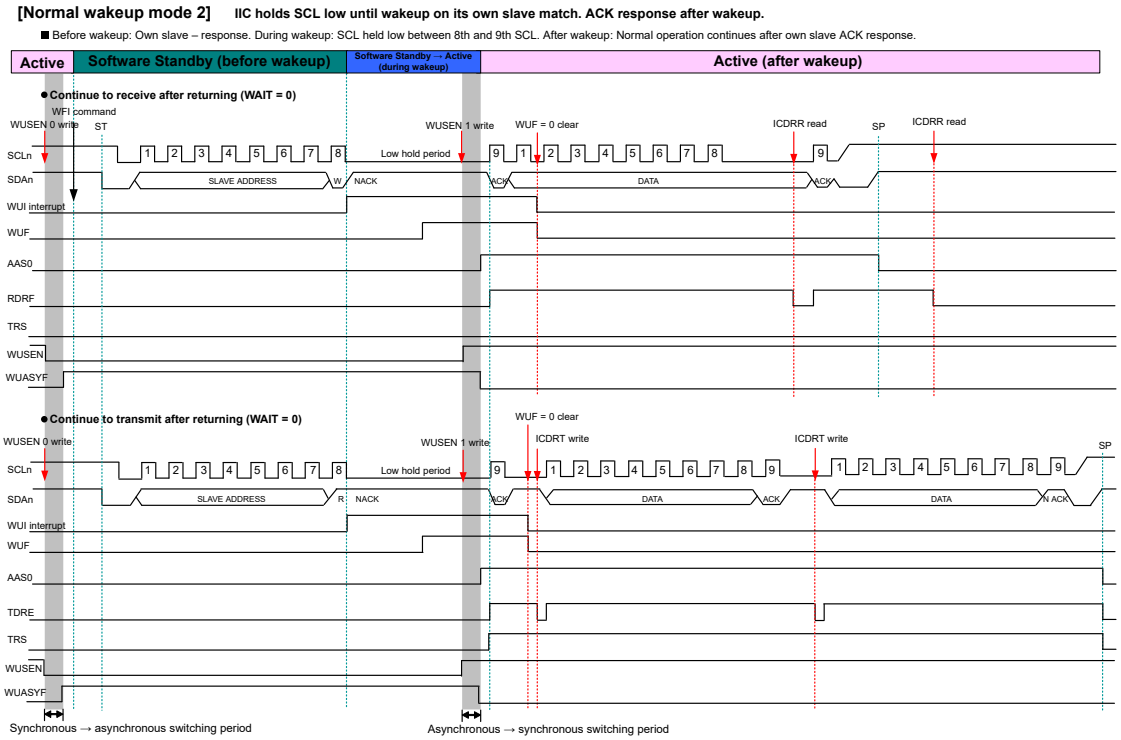
Note: See Precautions on the use of the wakeup function.



Note: n = 0

Figure 31.34 Timing of normal wakeup mode 2

31.8.3 Command Recovery Mode and EEP Response Mode (Special Wakeup Modes)

This section describes the behavior, the timing, and example operations of the command recovery and EEP response modes.

In the command recovery and EEP response modes, the SCL line is not held low during the wakeup period (after the rise of the 9th clock cycle of SCL). Therefore, other IIC devices can use the I^2C bus during this period.

A wakeup interrupt triggered by a match of the slave address initiates the transition to normal operation as follows:

Before wakeup:	In response to the data received with its own slave address, the IIC returns ACK (command recovery mode) or NACK (EEP response mode).
During wakeup:	The SCL line is not held low.
After wakeup:	Normal operation continues after IIC initialization.

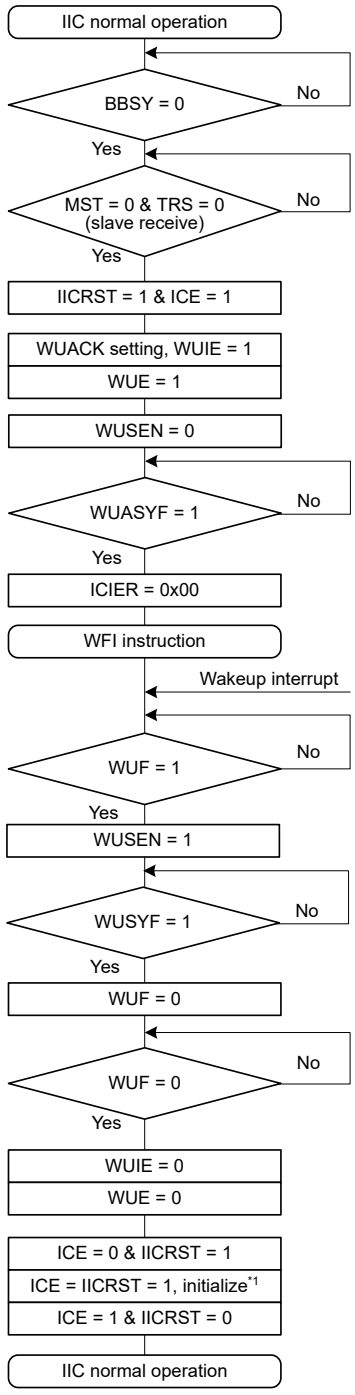
If the slave address does not match, the slave operation continues.

Note: Because the SCL line is not held low during wakeup, transmission or reception of the data that follows the slave address is not possible.

Note: The command recovery and EEP response modes are internal reset states (ICE = IICRST = 1). Therefore, the match of the slave address does not set the flags, HOA, GCA, ASS0, ASS1, and ASS2 in the ICSR1 register.

Figure 31.35 shows an example operation in recovery and EEP response modes. Figure 31.37 shows the detailed timing.

If the transition from Software Standby mode or Snooze mode is triggered by an interrupt other than a wakeup interrupt, such as IRQn for example, the WUF flag is not set to 1. Follow the processing shown in Figure 31.36.



[1] [1] Wait until I^2C bus is open and stay in standby state.

[2] [2] Internal reset is asserted.

[3] [3] Set up WUACK for the desired wakeup mode. Enable wakeup interrupt.

[4] [4] Enable wakeup function.

[5] [5] The IIC operating state is changed from PCLK synchronous to PCLK asynchronous.

[6] [6] Disable all interrupt requests except WUI.

[7] [7] Stop PCLK to IIC. IIC continues to receive.

[8] [8] Start system clock and PCLK supply to the IIC with wakeup interrupt (address match).

[9] [9] Wait for WUF = 1.

[10] [10] The IIC operating state is changed from PCLK asynchronous to PCLK synchronous.

[11] [11] Write 0 to WUF. Read and check that WUF = 0 before returning from the interrupt handling.

[12] [12] Disable wakeup interrupt.

[13] [13] Disable wakeup function.

[14] [14] Reset IIC (ICE = 0 & IICRST = 1).

[15] [15] Reset IIC (internal reset: ICE = 1 & IICRST = 1). Initial settings.

[16] [16] Negate the internal reset.

Note: PCLK = PCLKB

Note 1. For details on IIC initialization, see section 31.3.2. Initial Settings.

31.9 Automatic Low-Hold Function for SCL

31.9.1 Function to Prevent Wrong Transmission of Transmit Data

If the I^2C Bus Shift Register (ICDRS) is empty and data has not been written to the I^2C Bus Transmit Data Register (ICDRT) with the IIC in transmission mode (TRS bit = 1 in ICCR2), the SCLn line is automatically held low over the subsequent intervals. This low-hold period is extended until the transmit data is written, which prevents the unintended transmission of erroneous data.

Master transmit mode:

- Low-level interval after a start or restart condition is issued
- Low-level interval between the 9th clock cycle of one transfer and the 1st clock cycle of the next.

Slave transmit mode:

- Low-level interval between the 9th clock cycle of one transfer and the 1st clock cycle of the next.

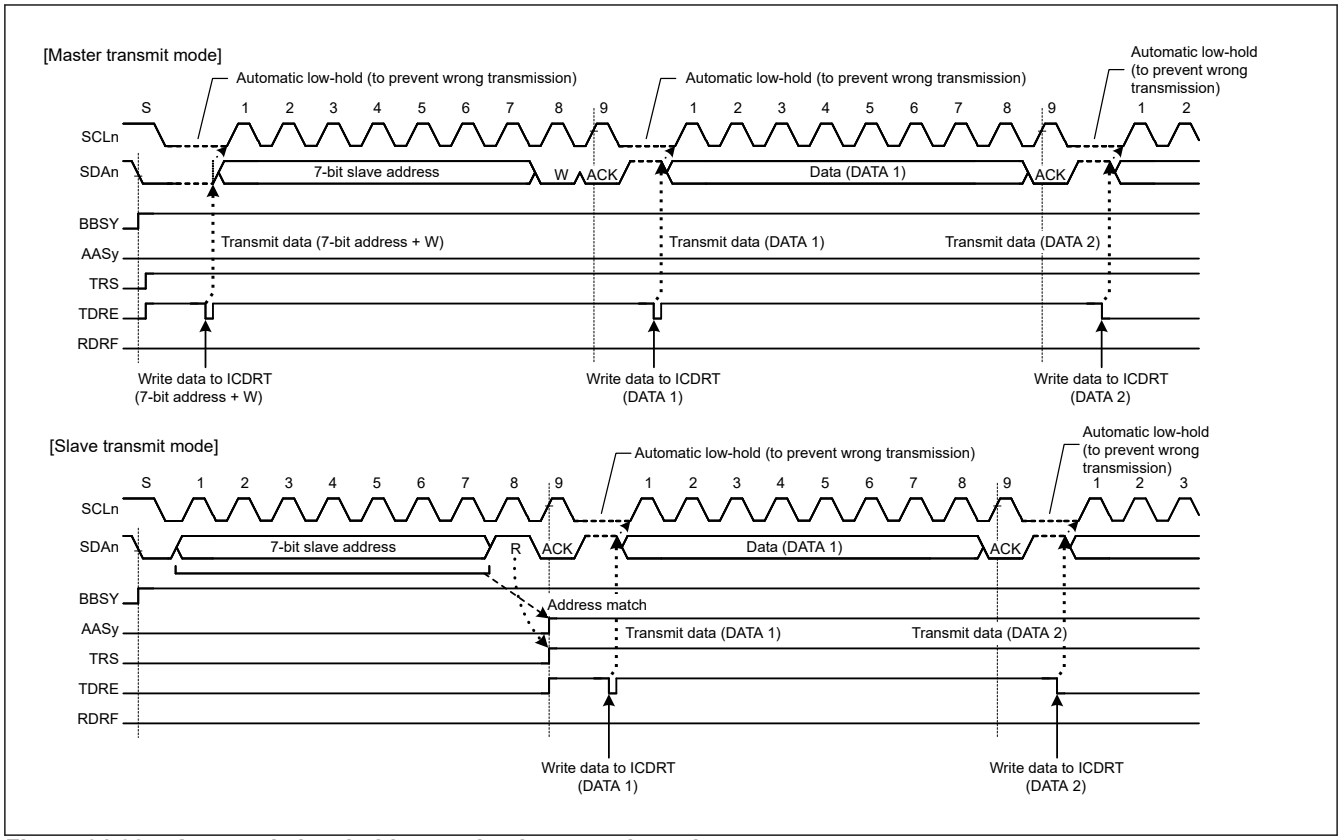

Figure 31.38 Automatic low-hold operation in transmit mode

31.9.2 NACK Reception Transfer Suspension Function

This function suspends transfer operation when NACK is received in transmit mode (TRS bit = 1 in ICCR2). This function is enabled when the NACKE bit in ICFER is set to 1. If the next transmit data is already written (TDRE flag = 0 in ICSR2) when NACK is received, the next data transmission on the falling edge of the 9th SCL clock cycle is automatically suspended. This prevents the SDAn line output level from being held low when the MSB of the next transmit data is 0.

If the transfer operation is suspended by this function (NACKF flag = 1 in ICSR2), transmit and receive operations are discontinued. To restore transmit or receive operation, after issuing the restart condition, you need to set the NACKF flag to 0 and try again, or set the NACKF flag to 0 after issuing the stop condition and then start again from issuing the start condition.

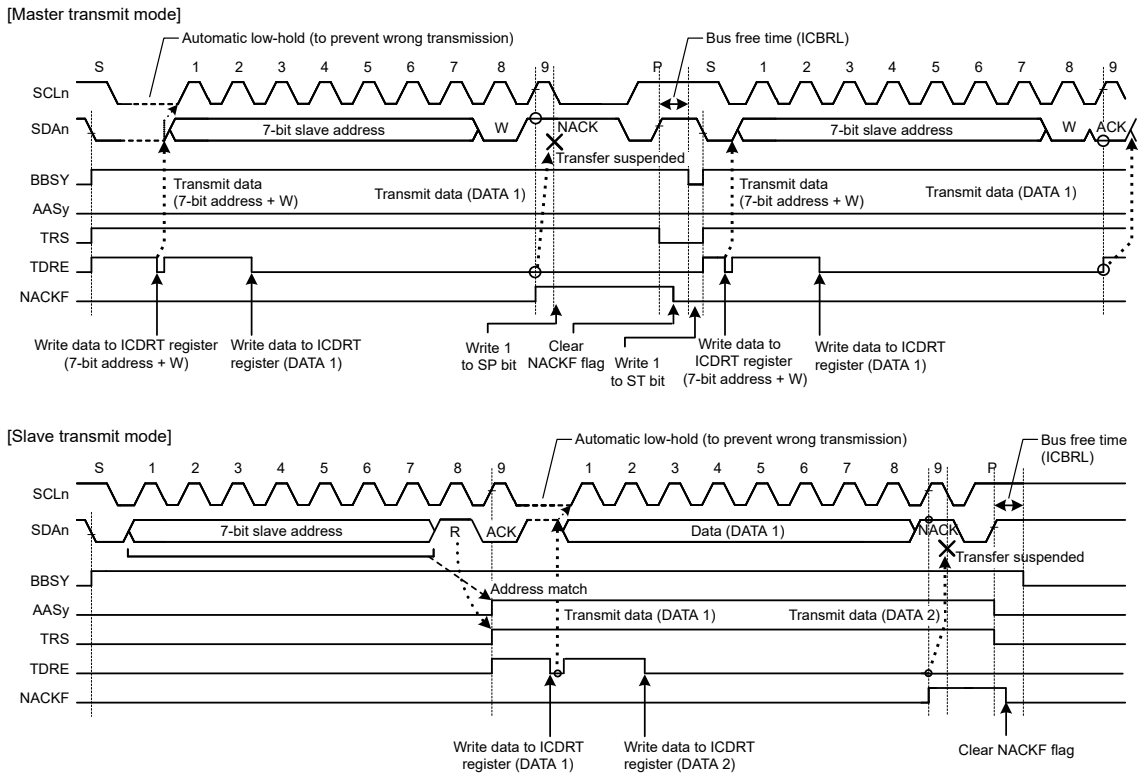

Figure 31.39 Suspension of data transfer when NACK is received, when NACKE = 1

31.9.3 Function to Prevent Failure to Receive Data

If response processing is delayed when receive data (ICDRR) read is delayed for a period of one transfer frame or more with receive data full (RDRF flag = 1 in ICSR2) in receive mode (TRS = 0 in ICCR2), the IIC holds the SCLn line low automatically immediately before the next data is received to prevent a failure to receive data.

This function is enabled even if the read processing of the final receive data is delayed and, in the meantime, the IIC slave address is designated after a stop condition is issued. This function does not interfere with other communication because the IIC does not hold the SCLn line low when a mismatch with its own slave address occurs after a stop condition is issued.

Periods in which the SCLn line is held low can be selected with a combination of the WAIT and RDRFS bits in ICMR3.

(1) 1-byte receive operation and automatic low-hold function using the WAIT bit

When the WAIT bit in ICMR3 is set to 1, the IIC performs a 1-byte receive operation using the WAIT bit function. Additionally, when the ICMR3.RDRFS bit is 0, the IIC automatically sends the ACKBT bit value in ICMR3 for the acknowledge bit in the period from the falling edge of the 8th SCL clock cycle to the falling edge of the 9th SCL clock cycle, and automatically holds the SCLn line low on the falling edge of the 9th SCL clock cycle using the WAIT bit function. This low-hold is released by reading data from ICDRR, which enables byte-wise receive operation.

The WAIT bit function is enabled for receive frames after a match with the IIC slave address, including the general call address and host address, is obtained in master or slave receive mode.

(2) 1-byte receive operation (ACK/NACK transmission control) and automatic low-hold function using the RDRFS bit

When the RDRFS bit in ICMR3 is set to 1, the IIC performs a 1-byte receive operation using the RDRFS bit function. When the RDRFS bit is set to 1, the RDRF flag in ICSR2 is set to 1 (receive data full) on the rising edge of the eighth SCL clock cycle, and the SCLn line is automatically held low on the falling edge of the eighth SCL clock cycle. This low-hold is released by writing a value to the ACKBT bit in ICMR3, but cannot be released by reading data from ICDRR, which enables receive operation through the ACK or NACK transmission control based on the data received in byte units.

The RDRFS bit function is enabled for receive frames after a match with the IIC slave address, including the general call address and host address, is obtained in master or slave receive mode.

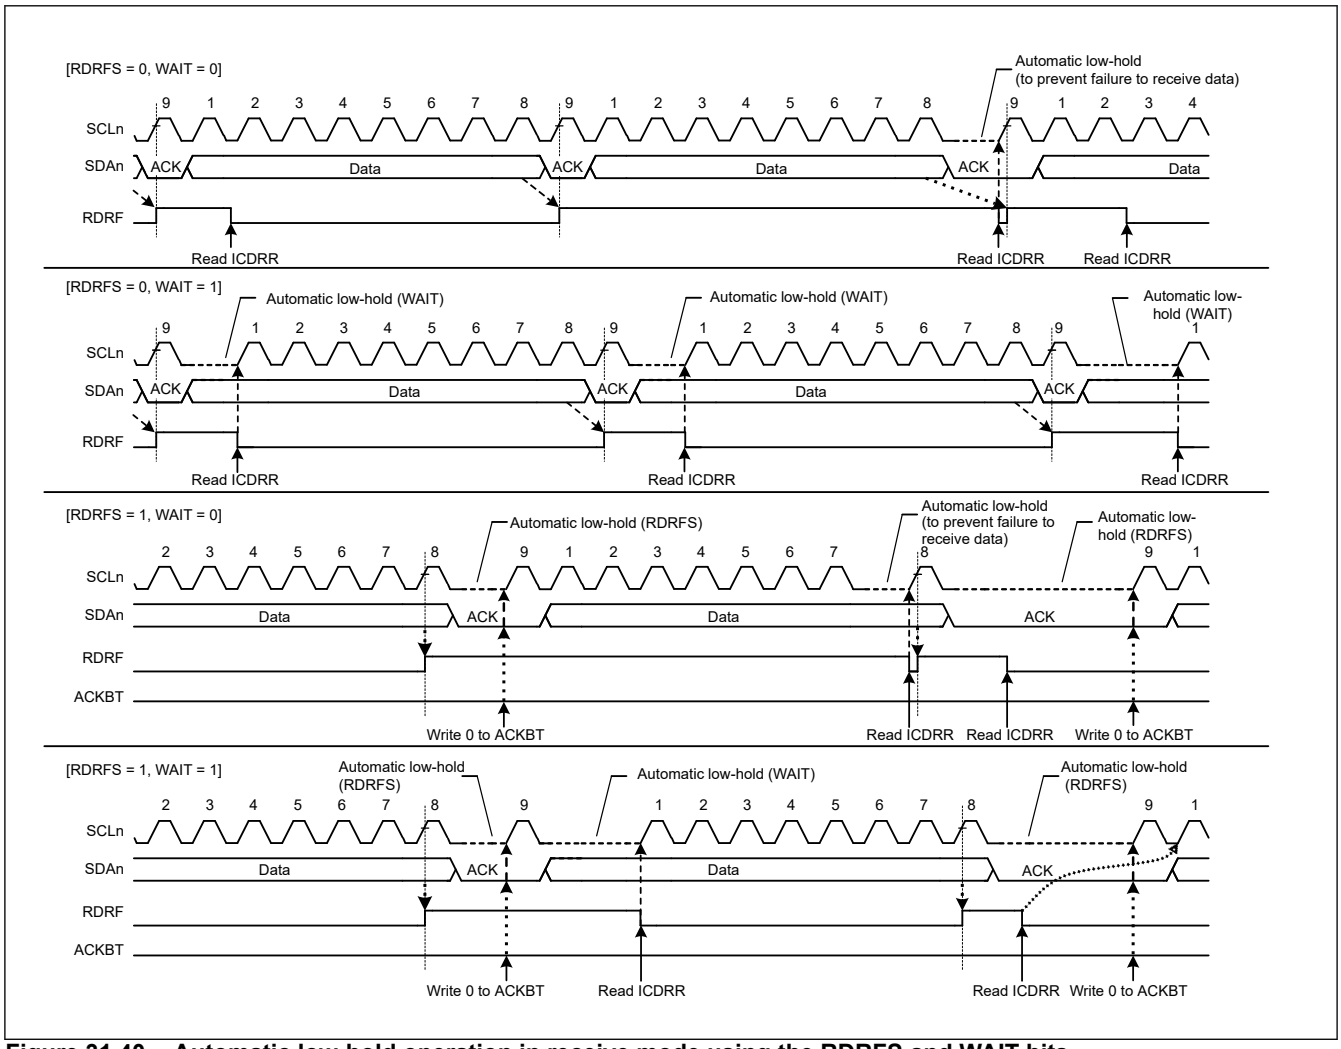

Figure 31.40 Automatic low-hold operation in receive mode using the RDRFS and WAIT bits

31.10 Arbitration-Lost Detection Functions

In addition to the normal arbitration-lost detection function defined by the I^2C bus standard, the IIC provides functions to prevent double-issue of a start condition, detect arbitration-lost during transmission of NACK, and detect arbitration-lost in slave transmit mode.

31.10.1 Master Arbitration-Lost Detection (MALE Bit)

The IIC drives the SDAn line low to issue a start condition. However, if the SDAn line was already driven low by another master device issuing a start condition, the IIC regards its own start condition as an error and considers this a loss in arbitration. Priority is given to transfer by the other master device. Similarly, if a request to issue a start condition is made by setting the ST bit in ICCR2 to 1 while the bus is busy (BBSY flag = 1 in ICCR2), the IIC regards this as a double-issuing-of-start-condition error and considers itself to have lost in arbitration. This prevents a failure of transfer resulting from a start condition being issued while transfer is in progress.

When a start condition is issued successfully, if the transmit data including the address bits (internal SDA output level) and the level on the SDAn line do not match (high output as the internal SDA output, meaning the SDAn pin is in the high-impedance state and a low level is detected on the SDAn line), the IIC loses in arbitration.

After a loss in arbitration of mastership, the IIC immediately enters slave receive mode. If a slave address, including the general call address, matches its own address at this time, the IIC continues in slave operation.

A loss in arbitration of mastership is detected when the following conditions are met while the MALE bit in ICFER is 1 (master arbitration-lost detection enabled).

[Master arbitration-lost conditions]

- Mismatching of the internal level for output on SDA and the level on the SDAn line after a start condition was issued by setting the ST bit in ICCR2 to 1 while the BBSY flag in ICCR2 is set to 0 (erroneous issuing of a start condition)
- Setting of the ST bit in ICCR2 to 1 (start condition double-issue error) while the BBSY flag is 1
- When the transmit data excluding acknowledge (internal SDA output level) does not match the level on the SDAn line in master transmit mode (MST and TRS bits = 11b in ICCR2).

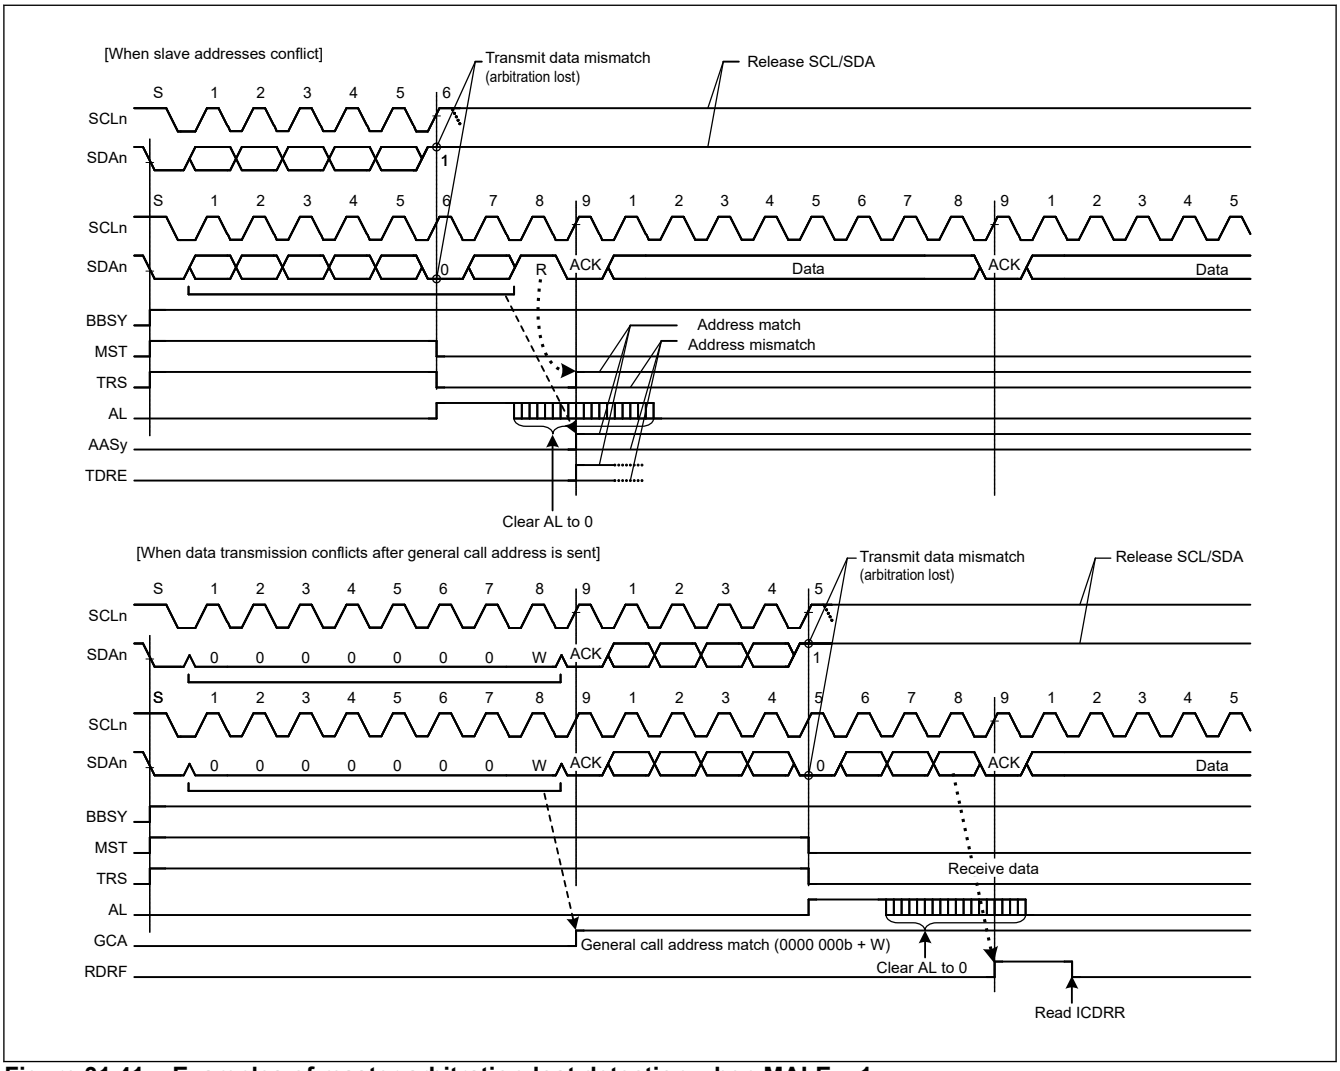

Figure 31.41 Examples of master arbitration-lost detection when MALE = 1

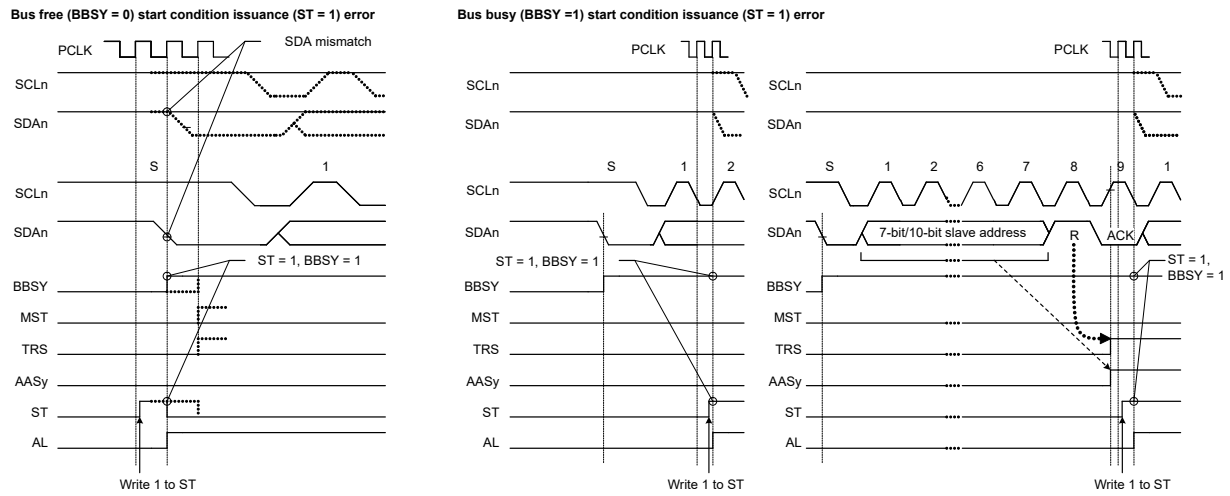

Figure 31.42 Arbitration-lost when start condition is issued when MALE = 1

31.10.2 Function to Detect Loss of Arbitration during NACK Transmission (NALE Bit)

This function causes arbitration to be lost if the internal SDA output level does not match the level on the SDAn line (high output as the internal SDA output, meaning the SDAn pin is in the high-impedance state) and the low level is detected on the SDAn line during transmission of NACK in receive mode. Arbitration is lost because of a conflict between NACK and ACK transmissions when two or more master devices receive data from the same slave device simultaneously in a multi-master system. Such a conflict occurs when multiple master devices send or receive the same information through a single slave device. Figure 31.43 shows an example of arbitration-lost detection during transmission of NACK.

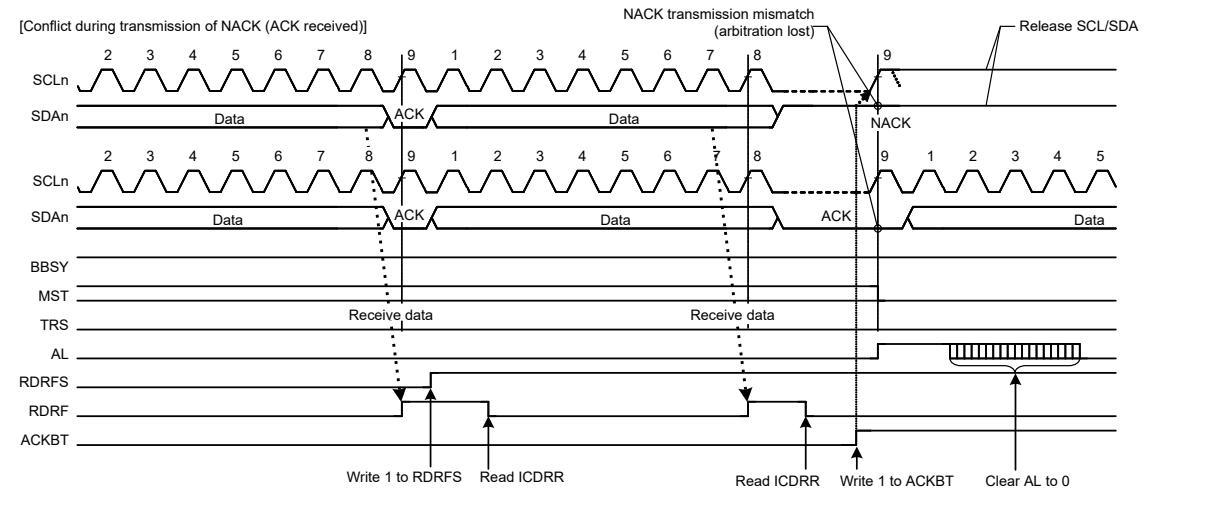

Figure 31.43 Example of arbitration-lost detection during transmission of NACK when NALE = 1

The following explains arbitration-lost detection using an example in which two master devices (master A and master B) and a single slave device are connected through the bus. In this example, master A receives 2 bytes of data from the slave device, and master B receives 4 bytes of data from the slave device.

If master A and master B access the slave device simultaneously, because the slave address is identical, arbitration is not lost in either master A or master B during access to the slave device. Therefore, both master A and master B recognize that they have obtained the bus mastership and operate as such. Master A sends NACK when it has received 2 final bytes of data from the slave device. Meanwhile, master B sends ACK because it has not received the required 4 bytes of data. At this time, the NACK transmission from master A and the ACK transmission from master B conflict. In general, if a conflict like

this occurs, master A cannot detect the ACK transmitted by master B and issues a stop condition. The stop condition issue conflicts with the SCL clock output of master B, which disrupts communication.

When the IIC receives ACK during transmission of NACK, it detects a defeat in conflict with other master devices and causes arbitration to be lost. If arbitration is lost during transmission of NACK, the IIC immediately cancels the slave match condition and enters slave receive mode. This prevents a stop condition from being issued, preventing a communication failure on the bus.

Similarly, in the ARP command processing of SMBus, the function to detect loss of arbitration during transmission of NACK is also available for eliminating the extra clock cycle processing, such as 0xFF transmission processing, which is required if the UDID (Unique Device Identifier) of the assigned address does not match in the Get UDID general processing after the Assign Address command.

The IIC detects arbitration-lost during transmission of NACK when the following condition is met with the NALE bit in ICFER set to 1 (arbitration-lost detection during NACK transmission enabled).

[Condition for arbitration-lost during NACK transmission]

- When the internal SDA output level does not match the SDAn line (ACK is received) during transmission of NACK (ACKBT bit = 1 in ICMR3).

31.10.3 Slave Arbitration-Lost Detection (SALE Bit)

This function causes arbitration to be lost if the transmit data (internal SDA output level) and the level on the SDAn line do not match (high output as the internal SDA output, meaning the SDAn pin is in the high-impedance state), and the low level is detected on the SDAn line in slave transmit mode. This arbitration-lost detection function is mainly used when transmitting a UDID (Unique Device Identifier) over an SMBus.

When the IIC loses slave arbitration, the IIC is immediately released from the slave-matched state and enters slave receive mode. This function can detect conflicts of data during transmission of UDIDs over an SMBus and eliminates subsequent redundant processing for the transmission of 0xFF.

The IIC detects slave arbitration-lost when the following condition is met with the SALE bit in ICFER set to 1 (slave arbitration-lost detection enabled).

[Condition for slave arbitration-lost]

- When transmit data excluding acknowledge (internal SDA output level) does not match the SDAn line in slave transmit mode (MST and TRS bits = 01b in ICCR2).

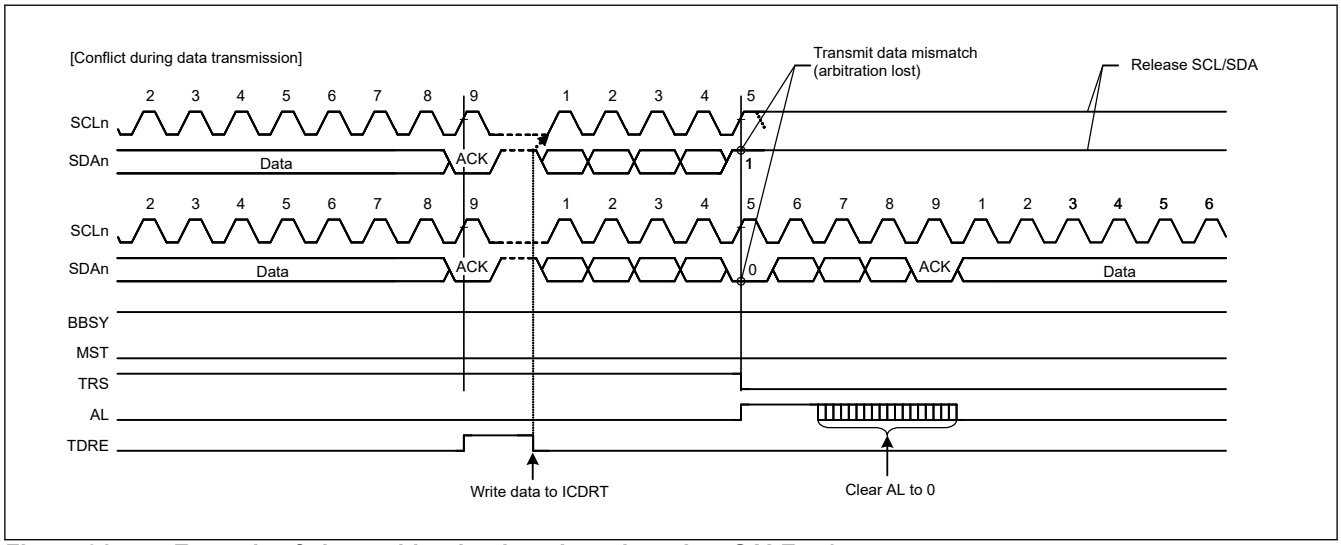

Figure 31.44 Example of slave arbitration-lost detection when SALE = 1

31.11 Start, Restart, and Stop Condition Issuing Function

31.11.1 Issuing a Start Condition

The IIC issues a start condition when the ST bit in ICCR2 is set to 1. When the ST bit is set to 1, a start condition request is made, and the IIC issues a start condition when the BBSY flag in ICCR2 is 0 (bus free state). When a start condition is issued normally, the IIC automatically shifts to the master transmit mode.

To issue a start condition:

1. Drive the SDAn line low (high level to low level).
2. Ensure that the time set in ICBRH and the start condition hold time elapse.
3. Drive the SCLn line low (high level to low level).
4. Detect low level on the SCLn line and ensure the low-level period of the SCLn line set in ICBRL elapses.

31.11.2 Issuing a Restart Condition

The IIC issues a restart condition when the RS bit in ICCR2 is set to 1. When the RS bit is set to 1, a restart condition request is made, and the IIC issues a restart condition when the BBSY flag in ICCR2 is 1 (bus busy state) and the MST bit in ICCR2 is 1 (master mode).

To issue a restart condition:

1. Release the SDAn line.
2. Ensure the low-level period of the SCLn line set in ICBRL elapses.
3. Release the SCLn line (low level to high level).
4. Detect a high level on the SCLn line and ensure the time set in ICBRL and the restart condition setup time elapse.
5. Drive the SDAn line low (high level to low level).
6. Ensure the time set in ICBRH and the restart condition hold time elapse.
7. Drive the SCLn line low (high level to low level).
8. Detect a low level on the SCLn line and ensure the low-level period of the SCLn line set in ICBRL elapses.

Note: When issuing restart condition requests, write the slave address to ICDRT after confirming that ICCR2.RS = 0. Data written while ICCR2.RS = 1 is not forwarded because of the retransmission condition before the occurrence.

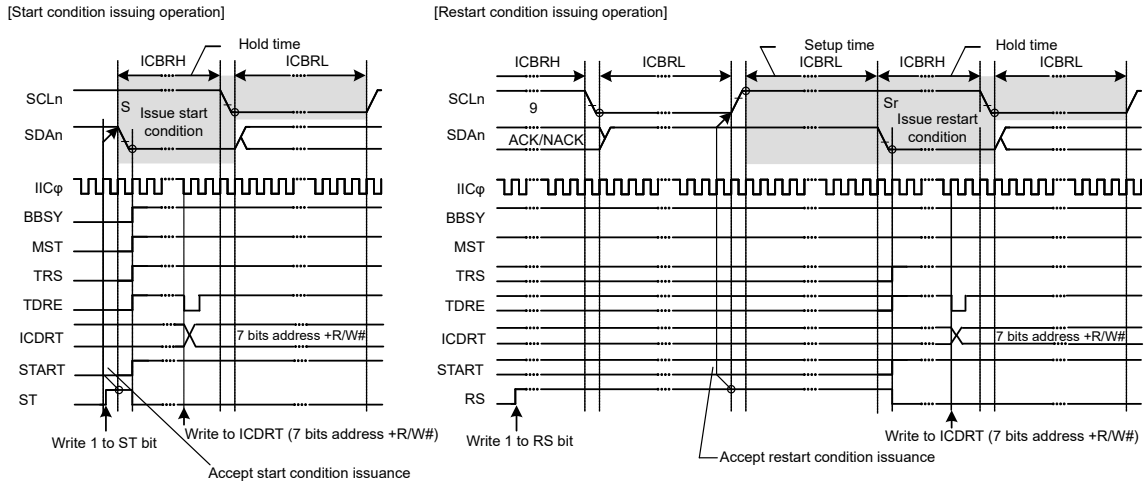

Figure 31.45 Start and restart condition issue timing using the ST and RS bits

Figure 31.46 shows the operation timing when a restart condition is issued after the master transmission.

[To issue a restart condition after the master transmission:]

1. Initialize the IIC using the procedure in section 31.3.2. Initial Settings.
2. Read the BBSY flag in ICCR2 to check that the bus is open, then set the ST bit in ICCR2 to 1 (start condition issuance request). On receiving the request, the IIC issues a start condition. At the same time, the BBSY and the START flags in ICSR2 are automatically set to 1 and the ST bit is automatically set to 0. If the start condition is detected and the internal levels for the SDA output state and the levels on the SDAn line match while the ST bit is 1, the IIC recognizes that a start condition is successfully issued as requested by the ST bit has been successfully completed. The MST and TRS bits in ICCR2 are automatically set to 1, placing the IIC in master transmit mode. The TDRE flag in ICSR2 is also automatically set to 1 when the TRS bit is set to 1.
3. Check that the TDRE flag in ICSR2 is 1, and then write the value for transmission (the slave address and the R/W# bit) to ICDRT. After the data for transmission is written to ICDRT, the TDRE flag is automatically set to 0, data is transferred from ICDRT to ICDRS, and the TDRE flag is again set to 1. After the byte containing the slave address and R/W# bit has been transmitted, the value of the TRS bit is automatically updated to select master transmit or master receive mode according to the value of the transmitted R/W# bit. If the value of the R/W# bit is 0, the IIC continues in master transmit mode. If the ICSR2.NACKF flag is 1 at this time, indicating that no slave device recognized the address or that there was an error in communications, write 1 to ICCR2.SP bit to issue a stop condition. To transmit data with an address in the 10-bit format, start by writing 1111 0b, the 2 upper bits of the slave address, and W to ICDRT as the first address transmission. Then, as the second address transmission, write the 8 lower bits of the slave address to ICDRT.
4. After confirming that the TDRE flag in ICSR2 is 1, write data for transmission to the ICDRT register. The IIC automatically holds the SCLn line low until data for transmission is ready, a restart condition is issued or a stop condition is issued.
5. After all bytes of data for transmission are written to the ICDRT register, wait until the value of the TEND flag in ICSR2 returns to 1. Then after checking that the START flag in ICSR2 is 1, set the START flag in ICSR2 to 0.
6. Set the RS bit in ICCR2 to 1 (restart condition issue request). On receiving the request, the IIC issues a restart condition.
7. After checking that the START flag in ICSR2 is 1, write the value for transmission (the slave address and the R/W# bit) to ICDRT.

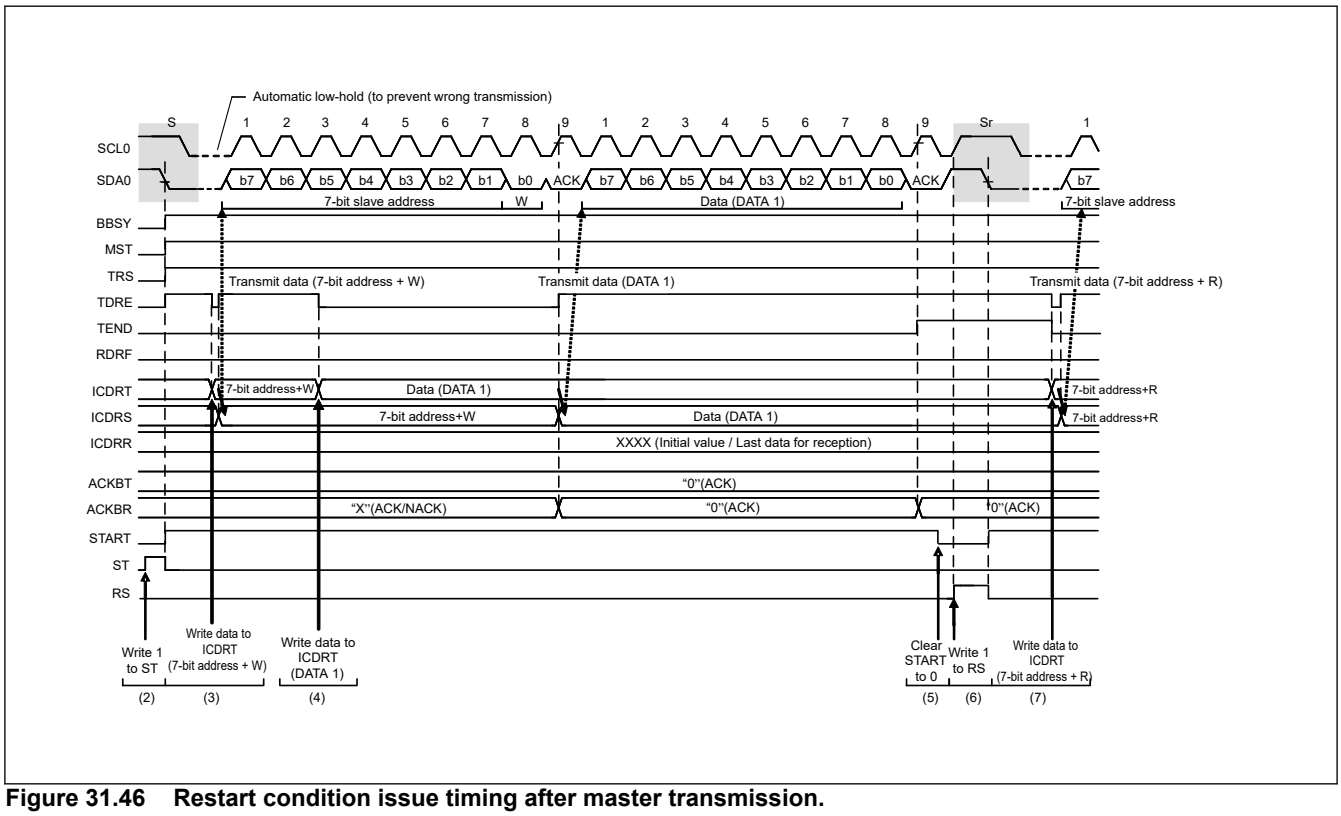

Figure 31.46 Restart condition issue timing after master transmission.

31.11.3 Issuing a Stop Condition

The IIC issues a stop condition when the SP bit in ICCR2 is set to 1. When the SP bit is set to 1, a stop condition request is made, and the IIC issues a stop condition when the BBSY flag in ICCR2 is 1 (bus busy state) and the MST bit in ICCR2 is 1 (master mode).

To issue a stop condition:

1. Drive the SDAn line low (high level to low level).
2. Ensure the low-level period of the SCLn line set in ICBRL elapses.
3. Release the SCLn line (low level to high level).
4. Detect a high level on the SCLn line and ensure the time set in ICBRH and the stop condition setup time elapse.
5. Release the SDAn line (low level to high level).
6. Ensure the time set in ICBRL and the bus free time elapse.
7. Clear the BBSY flag to 0 to release the bus mastership.

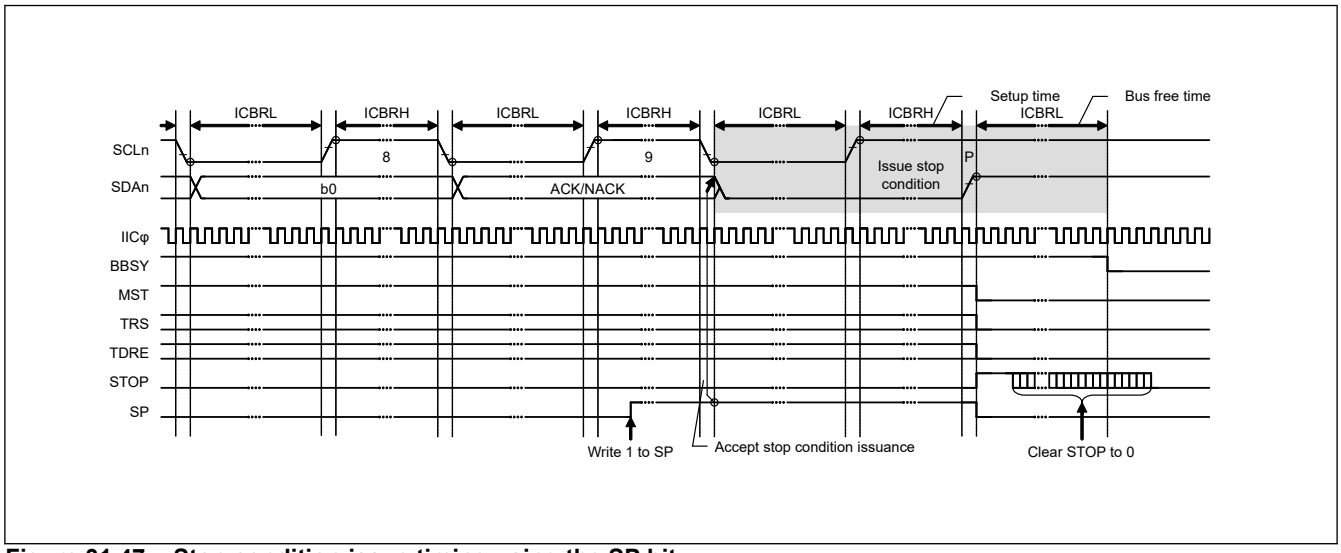

Figure 31.47 Stop condition issue timing using the SP bit

31.12 Bus Hanging

If the clock signals from the master and slave devices are out of synchronization because of noise or other factors, the I^2C bus might hang with a fixed level on the SCLn line or SDAn line.

To manage bus hanging, the IIC has a timeout function to detect hanging by monitoring the SCLn line, and a function for outputting an extra SCL clock cycle to release the bus from:

- A timeout function to detect hanging by monitoring the SCLn line
- The IIC reset function
- An internal reset function.

By checking the SCLO, SDAO, SCLI, and SDAI bits in ICCR1, it is possible to see whether the IIC or its communicating partner is placing the low level on the SCLn or SDAn line.

31.12.1 Timeout Function

The timeout function can detect when the SCLn line is stuck longer than the predetermined time. The IIC can detect an abnormal bus state by monitoring that the SCLn line is stuck low or high for a predetermined time.

The timeout function monitors the SCLn line state and counts the low- or high-level period using the internal counter. The timeout function resets the internal counter each time the SCLn line changes (rises or falls), but continues to count unless the SCLn line changes. If the internal counter overflows because no SCLn line changes, the IIC can detect the timeout and report the bus hung state.

This timeout function is enabled when the ICFER.TMOE bit is 1. It detects a hung state when the SCLn line is stuck low or high during the following conditions:

- The bus is busy (ICCR2.BBSY flag is 1) in master mode (ICCR2.MST bit is 1)
- The IIC slave address is detected (ICSR1 register is not 0x00) and the bus is busy (ICCR2.BBSY flag is 1) in slave mode (ICCR2.MST bit is 0)
- The bus is open (ICCR2.BBSY flag is 0) while a start condition is requested (ICCR2.ST bit is 1).

The internal counter of the timeout function uses the internal reference clock (IICφ) set in the CKS[2:0] bits in ICMR1 as a count source. It functions as a 16-bit counter when long mode is selected (TMOS bit = 0 in ICMR2) or a 14-bit counter when short mode is selected (TMOS bit = 1).

The SCLn line level (low, high, or both levels) during which this counter is activated can be selected in the TMOH and TMOL bits in ICMR2. If both TMOL and TMOH bits are set to 0, the internal counter is disabled.

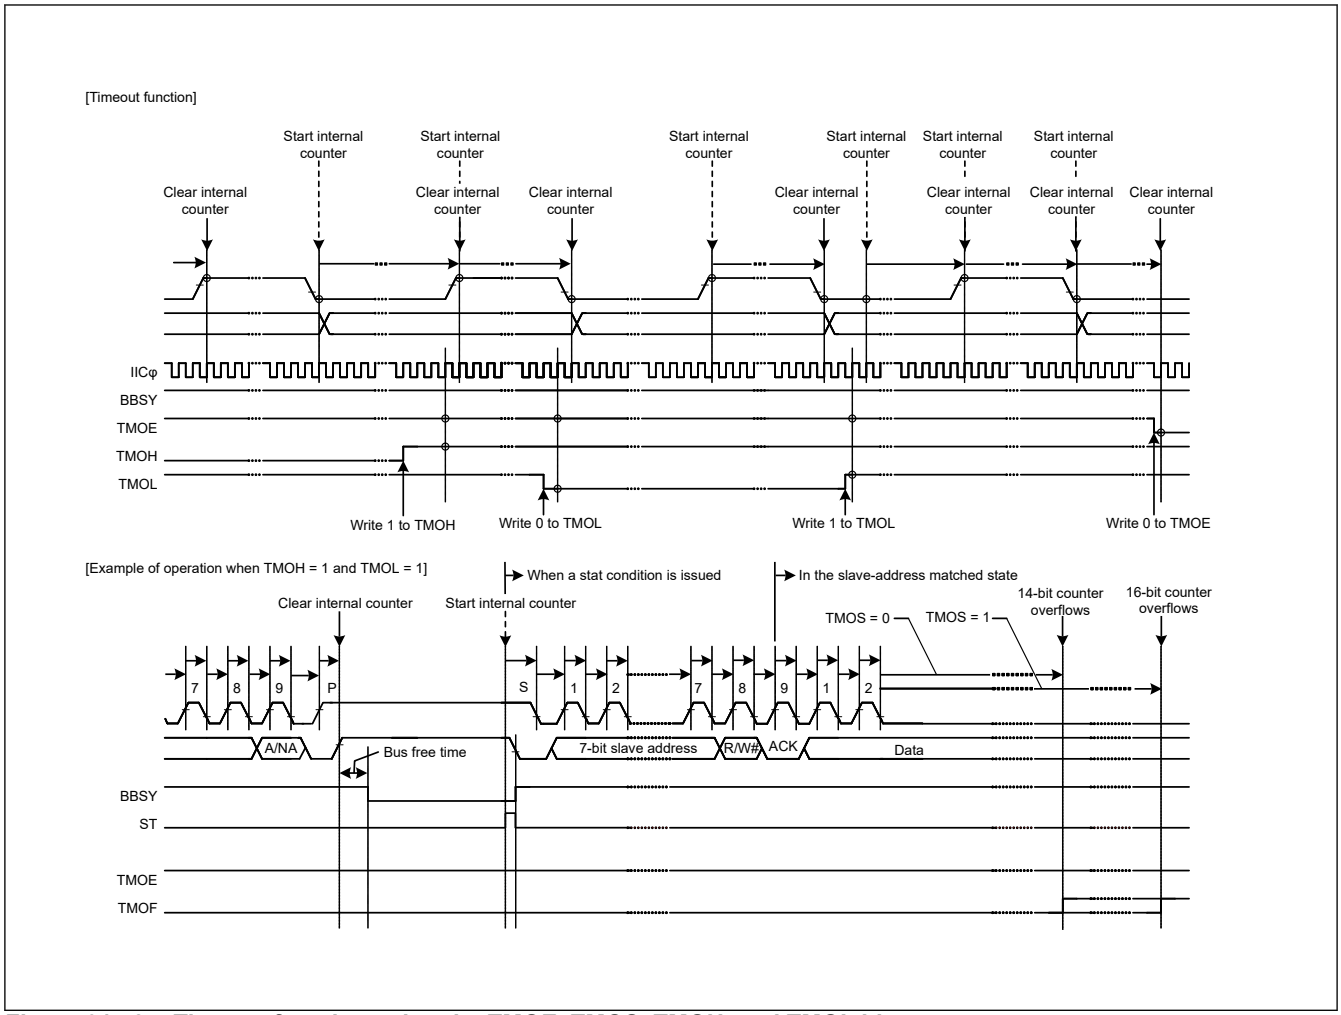

Figure 31.48 Timeout function using the TMOE, TMOS, TMOH, and TMOL bits

31.12.2 Extra SCL Clock Cycle Output Function

In master mode, this function outputs extra SCL clock cycles to release the SDAn line of the slave device from being held low because the master is out of synchronization with the slave device. This function is mainly used in master mode to release the SDAn line of the slave device from being fixed low by including extra cycles of SCL output from the IIC. It uses single cycles of the SCL clock for a bus error where the IIC cannot issue a stop condition because the slave device is holding the SDAn line at the low level. Do not use this function in normal situations. Using it when communications are proceeding correctly leads to malfunctions.

When the CLO bit in ICCR1 is set to 1 in master mode, a single cycle of the SCL clock at the frequency specified in the CKS[2:0] bits in ICMR1, and in the ICBRH and ICBRL registers, is output as an extra clock cycle. After output of this

single cycle of the SCL clock, the CLO bit is automatically set to 0. At this time, if ICCR2.BBSY = 1, the SCL pin goes low, and when ICCR2.BBSY = 0, the SCL pin goes high. After confirming that the CLO bit is 0 by software, write 1 to the CLO bit to output the additional clock continuously.

When the IIC module is in master mode and the slave device is holding the SDAn line low because synchronization with the slave device is lost because of effects like noise, the output of a stop condition is not possible. This function can be used to output extra cycles of SCL one by one to make the slave device release the SDAn line from being held low, and so recover the bus from an unusable state. Release of the SDAn line by the slave device can be monitored by reading the SDAI bit in ICCR1. After confirming the release of the SDAn line by the slave device, complete communications by reissuing the stop condition.

[Output conditions for using the CLO bit in ICCR1]

- When the bus is open (BBSY flag in ICCR2 = 0) or in master mode (MST bit = 1 and BBSY flag = 1 in ICCR2)
- When the communication device does not hold the SCLn line low.

Figure 31.49 shows the operation timing of the extra SCL clock cycle output function (CLO bit).

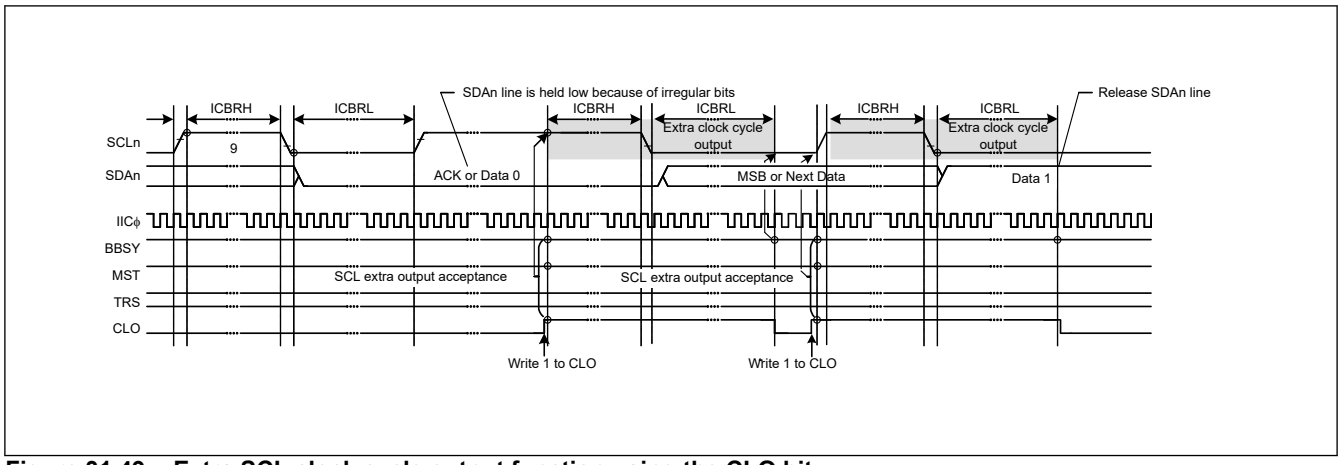

Figure 31.49 Extra SCL clock cycle output function using the CLO bit

31.12.3 IIC Reset and Internal Reset

The IIC module incorporates a function for resetting itself. It uses two types of resets:

- An IIC reset, which initializes all registers, including the BBSY flag in ICCR2.
- An internal reset, which releases the IIC from the slave-address matched state and initializes the internal counter while saving other settings.

After issuing a reset, always set the IICRST bit in ICCR1 to 0. Both types of resets are valid for release from bus-hung states, because both restore the output state of the SCLn and SDAn pins to the high-impedance state.

Issuing a reset during slave operation might lead to a loss of synchronization between the master device clock and the slave device clock, so avoid this when possible. In addition, monitoring of the bus state, such as for the presence of a start condition, is not possible during an IIC reset (ICE and IICRST bits = 01b in ICCR1).

For a detailed description of the IIC and internal resets, see section 31.15. State of Registers When Issuing Each Condition.

31.13 SMBus Operation

The IIC supports data communication conforming to the SMBus Specification (version 2.0). To perform SMBus communication, set the SMBS bit in ICMR3 to 1. To use the transfer rate within a range of 10 to 100 kbps of the SMBus standard, set the CKS[2:0] bits in ICMR1, the ICBRH, and ICBRL registers. In addition, specify the values in the DLCS bit in ICMR2 and the SDDL[2:0] bits in ICMR2 to meet the data hold time specification of 300 ns or more. When the IIC is used only as a slave device, the transfer rate setting is not required, but ICBRL must be set to a value longer than the data setup time (250 ns).

For the SMBus device default address (1100 001b), use one of the slave address registers L0 to L2 (SARL0, SARL1, and SARL2), and set the associated FS bit (7- or 10-bit address format select) in SARUy (y = 0 to 2) to 0 (7-bit address format).

When transmitting the UDID (Unique Device Identifier), set the SALE bit in ICFER to 1 to enable the slave arbitration-lost detection function.

31.13.1 SMBus Timeout Measurement

(1) Measuring slave device timeout

The following period (timeout interval: $T_{LOW:\ SEXT}$) must be measured for slave devices in SMBus communication:

- From start condition to stop condition.

To measure timeout for slave devices, measure the period from start condition detection to stop condition detection with the GPT using the IIC start condition detection interrupt (STIn) and stop condition detection interrupt (SPIn). The measured timeout period must be within the total clock low-level period [slave device] $T_{LOW:\ SEXT}$: 25 ms (maximum) of the SMBus standard.

If the time measured with the GPT exceeds the clock low-level detection timeout $T_{TIMEOUT}$: 25 ms (minimum) of the SMBus standard, the slave device must release the bus by writing 1 to the IICRST bit in ICCR1 to issue an internal reset of the IIC. When an internal reset is issued, the IIC stops driving the bus for the SCLn and SDAn pins, making them output high-impedance, which releases the bus.

(2) Measuring master device timeout

The following periods (timeout interval: $T_{LOW:\ MEXT}$) must be measured for master devices in SMBus communication:

- From start condition to acknowledge bit
- Between acknowledge bits
- From acknowledge bit to stop condition.

To measure timeout for master devices, measure these periods with the GPT using the IIC start condition detection interrupt (STIn), stop condition detection interrupt (SPIn), transmit end interrupt (IICn_TEI), or receive data full interrupt (IICn_RXI). The measured timeout period must be within the total clock low-level extended period (master device) $T_{LOW:\ MEXT}$: 10 ms (maximum) of the SMBus standard, and the total of all $T_{LOW:\ MEXT}$ values from start condition to stop condition must be within $T_{LOW:\ SEXT}$: 25 ms (maximum).

For the ACK receive timing (rising edge of the 9th SCL clock cycle), monitor the TEND flag in ICSR2 in master transmit mode (master transmitter) and the RDRF flag in ICSR2 in master receive mode (master receiver). Perform byte-wise transmit operations in master transmit mode, and hold the RDRFS bit in ICMR3 at 0 until the byte immediately before reception of the final byte in master receive mode. While the RDRFS bit is 0, the RDRF flag is set to 1 on the rising edge of the 9th SCL clock cycle.

If the period measured with the GPT exceeds the total clock low-level extended period (master device) $T_{LOW:\ MEXT}$: 10 ms (maximum) of the SMBus standard or the total of measured periods exceeds the clock low-level detection timeout $T_{TIMEOUT}$: 25 ms (minimum) of the SMBus standard, the master device must stop the transaction by issuing a stop condition. In master transmit mode, immediately stop the transmit operation (stop writing data to ICDRT).

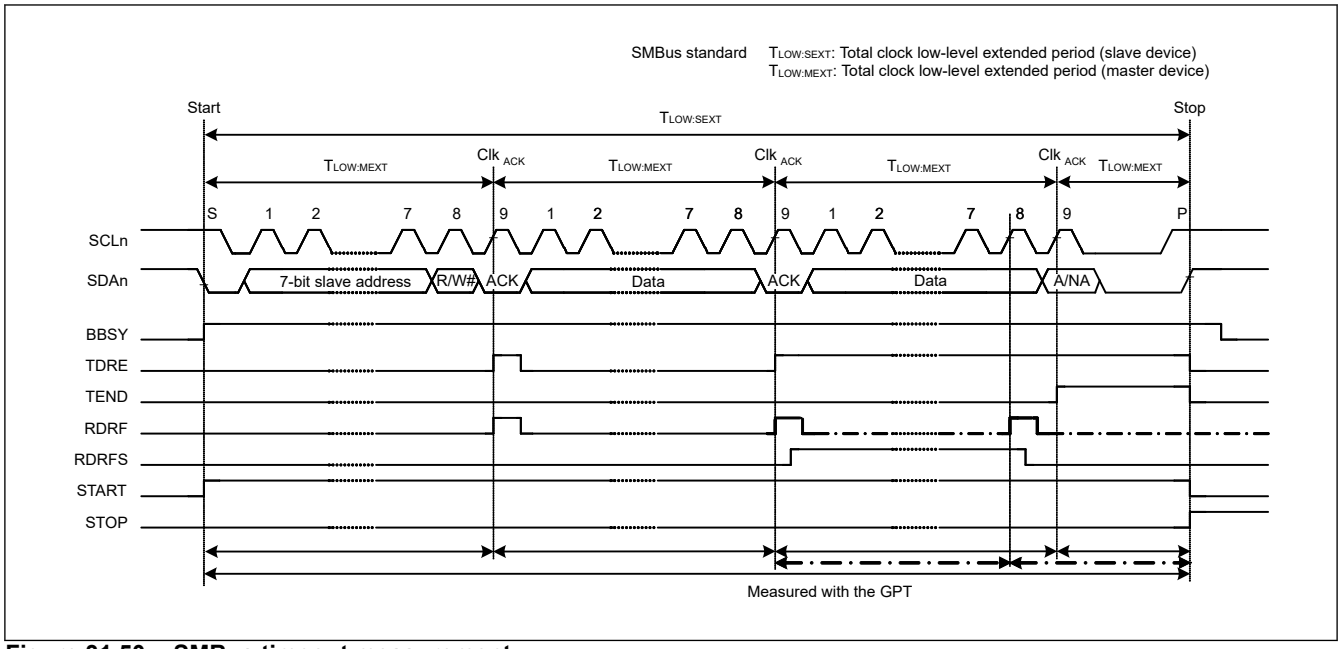

Figure 31.50 SMBus timeout measurement

31.13.2 Packet Error Code (PEC)

The MCU provides a CRC calculator that enables transmission of a Packet Error Code (PEC) or allows checking of the received data in SMBus data communication for the IIC. For the CRC-generating polynomials of the CRC calculator, see section 40, Cyclic Redundancy Check (CRC).

In master transmit mode, the PEC data can be generated by writing all transmit data to the CRC Data Input Register (CRCDIR) in the CRC calculator.

In master receive mode, the PEC data can be checked by writing all receive data to CRCDIR in the CRC calculator and comparing the obtained value in the CRC Data Output Register (CRCDOR) with the received PEC data.

To send ACK or NACK based on the match or mismatch result when the final byte is received as a result of the PEC code check, set the RDRFS bit in ICMR3 to 1 before the rising edge of the 8th SCL clock cycle during reception of the final byte, and hold the SCLn line low on the falling edge of the 8th clock cycle.

31.13.3 SMBus Host Notification Protocol (Notify ARP Master Command)

In communicating over an SMBus, a slave device can temporarily act as a master device to notify the SMBus host (or ARP master) of its own slave address, or to request its own slave address from the SMBus host.

For a product using the MCU to operate as an SMBus host or ARP master, the host address (0001 000b) sent from the slave device must be detected as a slave address, and so the IIC provides a function for detecting the host address. To detect the host address as a slave address, set the SMBS bit in ICMR3 and the HOAE bit in ICSER to 1. Operation after the host address is detected is the same as normal slave operation.

31.14 Interrupt Sources

The IIC issues five types of interrupt requests:

- Transfer error or event generation (arbitration-lost, NACK detection, timeout detection, start condition detection, and stop condition detection)
- Receive data full
- Transmit data empty
- Transmit end
- Address match during wakeup function

Table 31.10 lists details about the interrupt requests. The receive data full and transmit data empty interrupts can activate data transfer by the DTC or DMAC.

Table 31.10 Interrupt sources

Symbol	Interrupt source	Interrupt flag	DTC or DMAC activation	Interrupt condition
IICn_EEI*5	Transfer error or event occurrence	AL	Not possible	AL = 1, ALIE = 1
		NACKF		NACKF = 1, NAKIE = 1
		TMOF		TMOF = 1, TMOIE = 1
		START		START = 1, STIE = 1
		STOP		STOP = 1, SPIE = 1
IICn_RXI*2 *5	Receive data full	RDRF	Possible	RDRF = 1, RIE = 1
IICn_TXI*1 *5	Transmit data empty	RDRF	Possible	TDRE = 1, TIE = 1
IICn_TEI*3 *5	Transmit end	TEND	Not possible	TEND = 1, TEIE = 1
IIC0_WUI*4	Slave address match during wakeup function	WUF	Not possible	Slave address match Slave receive complete RWAK operation ASY0 = 1 WUIE = 1

Note: There is a delay between the execution of a write instruction for a peripheral module by the CPU and the actual writing to the module. When an interrupt flag is cleared or masked, read the relevant flag again to check whether clearing or masking is complete, then return from interrupt handling. Not doing so creates the possibility of repeated processing of the same interrupt.
Note 1. Because IICn_TXI is edge-detected, it does not require clearing. Additionally, the TDRE flag in ICSR2 (condition for IICn_TXI) is automatically set to 0 when transmit data is written to the ICDRT register or a stop condition is detected (STOP flag = 1 in ICSR2).
Note 2. Because IICn_RXI is edge-detected, it does not require clearing. Additionally, the RDRF flag in ICSR2 (condition for IICn_RXI) is automatically set to 0 when data is read from ICDRR.
Note 3. When using the IICn_TEI interrupt, clear the TEND flag in ICSR2 in the IICn_TEI interrupt handling. The TEND flag in ICSR2 automatically is set to 0 when transmit data is written to the ICDRT register or a stop condition is detected (STOP flag = 1 in ICSR2).
Note 4. Only channel 0 has a wakeup function, so IIC0_WUI is for channel 0 only.
Note 5. Channel number (n = 0 to 2).

Clear or mask each flag during interrupt handling.

31.14.1 Buffer Operation for IICn_TXI and IICn_RXI Interrupts

If the conditions for generating an IICn_TXI or IICn_RXI interrupt are satisfied while the associated IR flag is 1, the interrupt request is not output for the ICU but is saved internally. One request per source can be saved internally.

An interrupt request that is saved in the ICU is output when the ICU.IELSRn.IR flag becomes 0. Internally saved interrupt requests are automatically cleared under normal conditions. They can also be cleared by writing 0 to the interrupt enable bit within the associated peripheral module.

31.15 State of Registers When Issuing Each Condition

The IIC has two dedicated resets, IIC reset and Internal reset. Table 31.11 lists the registers states when issuing each condition.

Table 31.11 Register states when issuing each condition (1 of 2)

Registers		Reset	IIC reset (ICE = 0, IICRST = 1)	Internal reset (ICE = 1, IICRST = 1)	Start or restart condition detection	Stop condition detection
ICCR1	ICE, IICRST	In reset	Saved	Saved	Saved	Saved
	SCLO, SDAO		In reset	In reset		
	Others			Saved		
ICCR2	BBSY	In reset	In reset	Saved	Set	In reset
	ST, RS			In reset	In reset	Saved
	SP					In reset
	TRS				Set or saved	
	MST					

Table 31.11 Register states when issuing each condition (2 of 2)

Registers		Reset	IIC reset (ICE = 0, IICRST = 1)	Internal reset (ICE = 1, IICRST = 1)	Start or restart condition detection	Stop condition detection
ICMR1	BC[2:0]	In reset	In reset	In reset	In reset	Saved
	Others			Saved	Saved

Timeout function		In reset	In reset	In reset	Operating	Operating
Bus free time measurement		In reset	In reset	Operating	Operating	Operating
ICWUR2	WUSEN	In reset	In reset	Saved	Saved	Saved
	Others					Saved or set or reset

31.16 Event Link Output

The IIC0 module handles the event output for the Event Link Controller (ELC) for the following sources:

(1) Transfer error event

When a transfer error event occurs, the associated event signal can be output to another module by the ELC.

(2) Receive data full

When a receive data register becomes full, the associated event signal can be output to another module by the ELC.

(3) Transmit data empty

When a transmit data register becomes empty, the associated event signal can be output to another module by the ELC.

(4) Transmit end

On completion of the transfer, the associated event signal can be output to another module by the ELC.

31.16.1 Interrupt Handling and Event Linking

Each of the IIC interrupt types (see Table 31.10) has an enable bit to control enabling and disabling of the associated interrupt signal. An interrupt request signal is output to the CPU when an interrupt source condition is satisfied while the associated enable bit is set.

The associated event link output signals are sent to other modules as event signals by the ELC when the interrupt source conditions are satisfied, regardless of the interrupt enable bit settings. For details on interrupt sources, see Table 31.10.

31.17 Usage Notes

31.17.1 Settings for the Module-Stop Function

The Module Stop Control Register B (MSTPCRB) can enable or disable IIC operation. The IIC is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

31.17.2 Notes on Starting Transfer

If the IR flag associated with the IIC interrupt is 1 when transfer is started (ICCR1.ICE bit = 1), follow the procedure in this section to clear the interrupts before enabling operations. Starting transfer with the IR flag set to 1 while the ICCR1.ICE bit is 1 leads to an interrupt request being internally saved after transfer starts, and this can lead to unexpected behavior of the IR flag.

To clear interrupts before starting transfer operation:

1. Confirm that the ICCR1.ICE bit is 0.
2. Set the relevant interrupt enable bits, such as ICIER.TIE to 0.
3. Read the relevant interrupt enable bits, such as ICIER.TIE, and confirm that the value is 0.
4. Set the IR flag to 0.

32. CAN with Flexible Data-rate (CANFD)

32.1 Overview

The CAN with Flexible Data-rate (CANFD) supports the following functions:

- Multiple channel operation
- Gateway function
- CAN with Flexible Data-rate.*1

Note 1. This feature is not available in the classical CAN function.

The CANFD module has a flexible message buffer and FIFO structure that meet the requirements of various applications. It also provides test modes to achieve high testability of the module that can be useful for power-on testing.

This specification describes a 2 channel implementation of the CANFD module.

The CANFD mode is only available in certain products that support it.

32.1.1 CAN-FD Module

Table 32.1 CAN-FD module specifications (1 of 2)

Parameter	Specifications
Communication	CAN functionality conforms to CAN-FD ISO 11898-1 (2015)
Gateway function	CAN 2.0 ↔ CAN 2.0 CAN 2.0 ↔ CAN-FD gateway (only 8-byte payload)*1 CAN-FD ↔ CAN-FD*1
Data transfer rate	Up to 1 Mbps for arbitration phase and up to 8 Mbps for data phase, individually for each CAN channel
Operation frequency Peripheral clock/APB clock	50 MHz (PCLKB) RAM clock: 100 MHz (PCLKA)
Data Link Layer (DLL) clock	Max ≤ 40 MHz
Input/Output pins	TX/RX
CAN channels	2 channels
Selectable ID type	11-bit Standard ID
	11-bit Standard ID + 18-bit Extended ID
Selectable frame type	Data frame (RTR = 0) (CAN and CAN-FD frames)
	Remote frame (RTR = 1) (only CAN frames)
Variable data byte count for data frames	DLC range: 0 to F
Message buffer	Up to 16 × 2 reception message buffers, shared among all the CAN channels
	16 transmit message buffers per channel
	4 transmission queues per channel Automatic message transfer into transmission queues supported
FIFO number	8 reception FIFO buffers Up to 3 × 2 FIFOs individually configurable as: ● Reception FIFO ● Transmission FIFO ● CAN-to-CAN Gateway FIFO
Automatic delay interval timer for transmission	The delay timer can be applied to: ● Transmission FIFO ● CAN-to-CAN Gateway FIFO

Table 32.1 CAN-FD module specifications (2 of 2)

Parameter	Specifications
Enhanced reception filtering	Support of 11 bits and 29 bits CAN identifier
	Programmable 29 bits CAN identifier acceptance filter mask for each entry
	Programmable gateway routing capability for each channel (up to 8 routing destinations)
	RTR and IDE masking
	Data Length Code (DLC) filter
	Message buffer payload overload protection
	Payload filter
	Updating Acceptance Filter List (AFL) entry during communication
General software support	Automatic label information added to receive message (for upper software layer support)
Timer	TX and RX Timestamp function
Power down function	Module start stop function for each CAN node (Channel and Global Sleep modes)
RAM	RAM ECC protected (2 bits error detection, 1-bit error correction)
Bus traffic measurement	CAN bus traffic measurement of each channel is possible
TrustZone Filter	One security attribution can be set, and the attribution of the two channels are the same

Note 1. This feature is not available in the classical CAN function.

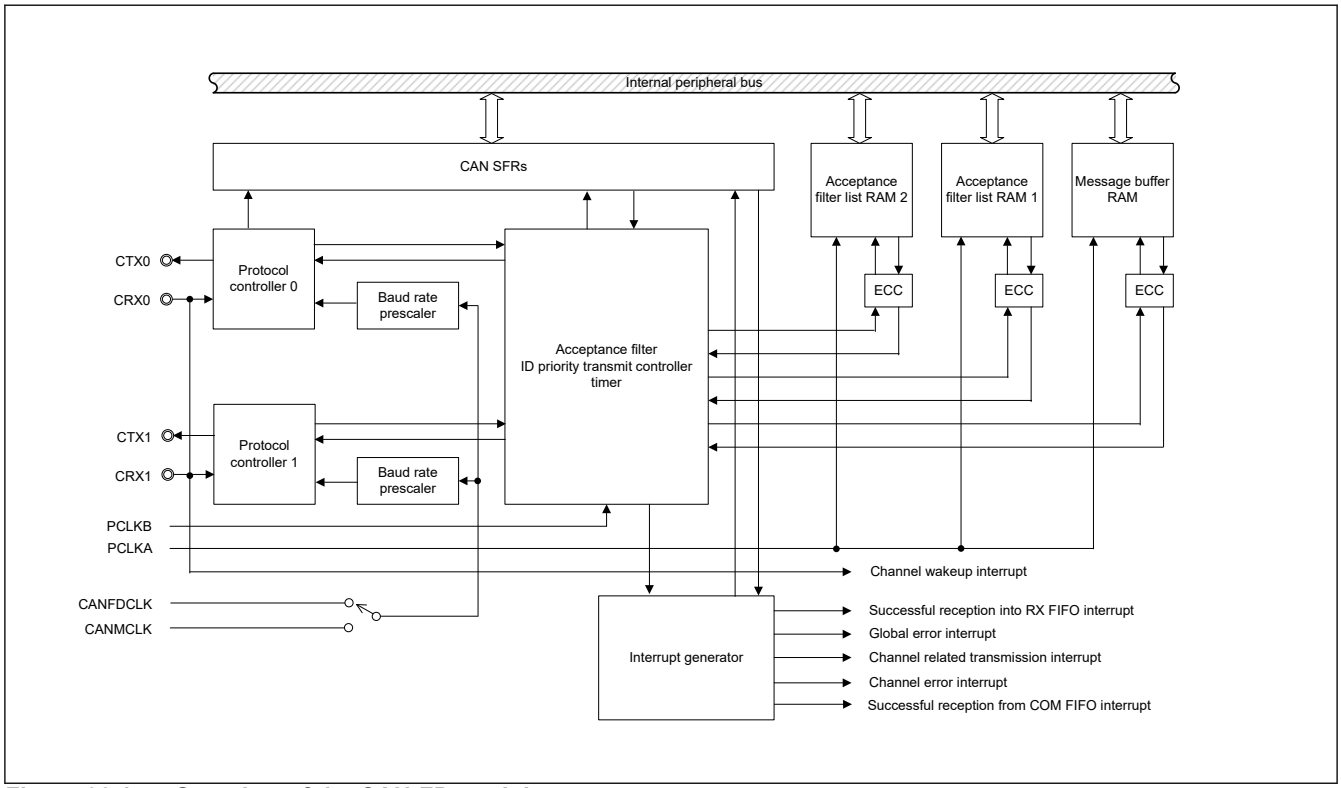

Figure 32.1 Overview of the CAN-FD module

- TX/RX:
  Input/Output, CRXn/CTXn, pins of the CAN module
- Protocol controller:
  Handles CAN protocol processing such as bus arbitration, bit timing at transmission and reception, stuffing, error handling
- Acceptance filter list RAM:

This RAM is used to store the message acceptance filtering entries for all channels. Each acceptance filter entry has an individual ID, data length code, data field, message pointer for upper layer application usage and message direction pointer. The AFLRAM is divided in two parts to accelerate the Acceptance Filter List (AFL) access process.

- Message buffer RAM:
  This RAM is used to store messages after reception or for transmission using a normal message buffer or a FIFO. Each message entry has an individual ID, data length code, data field, message pointer for upper layer application usage and a time stamp.
- Acceptance filter:
  Performs filtering of received messages. The entries in the Acceptance filter list RAM are used for the filtering process.
- Two timers:
  - Reception Timestamp function
  - Transmission separation time for FIFO buffers
- Interrupt generator:
  Generates several types of global and channel interrupts
- CAN Special Function Registers (SFRs):
  Registers associated with CAN. See section 32.2.87. Message Buffer Component Structure.

32.2 Register Descriptions

32.2.1 Register Table

The reset value shown for the RAM area, consisting of CFDGAFLIDn, CFDGAFLMn, CFDGAFLP0n, CFDGAFLP1n, CFDRMBCPn, CFDRFMBCPn, CFDCFMBCPn, CFDTMBCPn, CFDTHLACC0n, CFDTHLACC1n and CFDRPGACCn is valid after initialization of a hardware reset. See section 32.4.2. CAN Module Configuration after Hardware Reset for details of the initialization process.

If a write access with a size of 8 or 16 bits is performed for the RAM area, then the CAN-FD module does a read-modify write-access to the RAM location, because the RAM requires a 32-bit access through the ECC module.

For single bit error, the correct data is written back. For multiple bit errors, unknown data is written back.

Do not access the space where the register is not assigned.

The read data from the space where the register is not assigned is unknown.

32.2.2 Legend

For all repetitive registers and bits, a lowercase index is used to indicate which slice is being referenced. If an index is being used, it is defined and described in the Register table it is being used in.

There is one global index used across all the registers and bits that need it.

Table 32.2 CANFD Registers (1 of 5)

Register name	Symbol	Reset value	Offset Address	Access size
Channel n Nominal Bitrate Configuration Register n	CFDCnNCFG	0x00000000	0x0000 + n × 0x0010	8, 16, 32
Channel n Control Registers	CFDCnCTR	0x00000005	0x0004 + n × 0x0010	8, 16, 32
Channel n Status Registers	CFDCnSTS	0x00000005	0x0008 + n × 0x0010	8, 16, 32
Channel n Error Flag Registers	CFDCnERFL	0x00000000	0x000C + n × 0x0010	8, 16, 32
Global Configuration Register	CFDGCFG	0x00000000	0x0084	8, 16, 32
Global Control Register	CFDGCTR	0x00000005	0x0088	8, 16, 32
Global Status Register	CFDGSTS	0x0000000D	0x008C	8, 16, 32
Global Error Flag Register	CFDGERFL	0x00000000	0x0090	8, 16, 32
Global Timestamp Counter Register	CFDGTSC	0x00000000	0x0094	16, 32

Table 32.2 CANFD Registers (2 of 5)

Register name	Symbol	Reset value	Offset Address	Access size
Global Acceptance Filter List Entry Control Register	CFDGAFLECTR	0x00000000	0x0098	8, 16, 32
Global Acceptance Filter List Configuration Register n	CFDGAFLCFG0	0x00000000	0x009C	8, 16, 32

RX Message Buffer ID Registers	CFDRMID	0x00000000*1	See section 32.2.87.2. CFDRMIDn_i : RX Message Buffer ID Register n Channel i (n = 0 to 15, i = 0, 1)	8, 16, 32
RX Message Buffer Pointer Registers	CFDRMPTR	0x00000000*1	See section 32.2.87.3. CFDRMPTRn_i : RX Message Buffer Pointer Register n Channel i (n = 0 to 15, i = 0, 1)	8, 16, 32
RX Message Buffer CAN-FD Status Register	CFDRMFDSTS	0x00000000*1	See section 32.2.87.4. CFDRMFDSTSn_i : RX Message Buffer CAN-FD Status Register n Channel i (n = 0 to 15, i = 0, 1)	8, 16, 32
RX Message Buffer Data Field p Registers Channel i	CFDRMDFp_n_i	0x00000000*1	See section 32.2.87.5. CFDRMDFp_n_i : RX Message Buffer Data Field p Register n Channel i (p = 0 to 15, n = 0 to 15, i = 0, 1)	8, 16, 32
TX Message Buffer ID Registers	CFDTMID	0x00000000*1	See section 32.2.87.14. CFDTMIDn_i : TX Message Buffer ID Register n Channel i (n = 0 to 7, 32 to 39, i = 0, 1)	8, 16, 32

Table 32.2 CANFD Registers (5 of 5)

Register name	Symbol	Reset value	Offset Address	Access size
TX Message Buffer Pointer Registers	CFDTMPTR	0x00000000*1	See section 32.2.87.15. CFDTMPTRn_i : TX Message Buffer Pointer Register n Channel i (n = 0 to 7, 32 to 39, i = 0, 1)	8, 16, 32
TX Message Buffer CAN-FD Control Register	CFDTMFDCTR	0x00000000*1	See section 32.2.87.16. CFDTMFDCTRn_i : TX Message Buffer CANFD Control Register n Channel i (n = 0 to 7, 32 to 39, i = 0, 1)	8, 16, 32
TX Message Buffer Data Field p Registers n Channel i	CFDTMDFp_n_i	0x00000000*1	See section 32.2.87.17. CFDTMDFp_n_i : TX Message Buffer Data Field p Register n Channel i (p = 0 to 15, n = 0 to 7, 32 to 39, i = 0, 1)	8, 16, 32

Note: For the range of subscripts (n, f, i, p), refer to the explanation of each register.
Note 1. The RAM area is initialized after a hardware reset, see section 32.4.2. CAN Module Configuration after Hardware Reset.
Note 2. These registers are not available in the classical CAN function.

32.2.3 CFDCnNCFG : Channel n Nominal Bitrate Configuration Register (n = 0, 1)

Base address: CANFD = 0x400B_0000

Offset address: 0x0000 + 0x10 × n

Bit position:	31						25	24						17	16						10	9						0
Bit field:	NTSEG2[6:0]							NTSEG1[7:0]							NSJW[6:0]							NBRP[9:0]						
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
9:0	NBRP[9:0]	Channel Nominal Baud Rate Prescaler Nominal baud rate prescaler division ratio	R/W
16:10	NSJW[6:0]	Resynchronization Jump Width 0x00: 1 Tq 0x01: 2 Tq ⋮ 0x7E: 127 Tq 0x7F: 128 Tq	R/W
24:17	NTSEG1[7:0]	Timing Segment 1 0x00: Reserved 0x01: 2 Tq 0x02: 3 Tq 0x03: 4 Tq ⋮ 0xFE: 255 Tq 0xFF: 256 Tq	R/W
31:25	NTSEG2[6:0]	Timing Segment 2 0x00: Reserved 0x01: 2 Tq ⋮ 0x7E: 127 Tq 0x7F: 128 Tq	R/W

Note: Tq means time quantum.

This register configures the transmission/reception nominal baud rate parameters of the channels.

NBRP[9:0] bits (Channel Nominal Baud Rate Prescaler)

The NBRP[9:0] bits are used to define the peripheral bus clock periods contained in a time quantum.

Do not write to these bits in CH_OPERATION or CH_SLEEP mode.

Only write to these bits when the CANFD channel is in CH_RESET or CH_HALT mode.

NSJW[6:0] bits (Resynchronization Jump Width)

The NSJW[6:0] bits set the synchronization jump width. A value from 1 to 128 time quanta can be set.

Do not write to these bits in CH_OPERATION or CH_SLEEP mode.

Only write to these bits when the CANFD channel is in CH_RESET or CH_HALT mode.

NTSEG1[7:0] bits (Timing Segment 1)

The NTSEG1[7:0] bits set the segment TSEG1 to compensate for edges on the CAN bus with a positive phase error. These bits contain the propagation segment.

Do not write to these bits in CH_OPERATION or CH_SLEEP mode.

Only write to these bits when the CANFD channel is in CH_RESET or CH_HALT mode.

Additionally, configure a Tq value only between 2 and 256, inclusive. See section 32.4.1.2. CAN Bit Timing for more details.

NTSEG2[6:0] bits (Timing Segment 2)

The NTSEG2[6:0] bits set the segment TSEG2 to compensate for edges on the CAN bus with a negative phase error.

Do not write to these bits in CH_OPERATION or CH_SLEEP mode.

Only write to these bits when the CANFD channel is in CH_RESET or CH_HALT mode.

Additionally, configure a Tq value only between 2 and 128, inclusive.

32.2.4 CFDCnCTR : Channel n Control Registers (n = 0, 1)

Base address: CANFD = 0x400B_0000

Offset address: 0x0004 + 0x10 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	ROM	CRCT	—	—	—	CTMS[1:0]		CTME	ERRD	BOM[1:0]		—	TDCV FIE	SOCO IE	EOCO IE	TAIE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ALIE	BLIE	OLIE	BORIE	BOEIE	EPIE	EWIE	BEIE	—	—	—	—	RTBO	CSLP R	CHMDC[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	1

Bit	Symbol	Function	R/W
1:0	CHMDC[1:0]	Channel Mode Control 0 0: Channel operation mode request 0 1: Channel reset request 1 0: Channel halt request 1 1: Keep current value	R/W
2	CSLPR	Channel Sleep Request 0: Channel sleep request disabled 1: Channel sleep request enabled	R/W
3	RTBO	Return from Bus-Off 0: Channel is not forced to return from bus-off 1: Channel is forced to return from bus-off	R/W
7:4	—	These bits are read as 0. The write value should be 0.	R/W
8	BEIE	Bus Error Interrupt Enable 0: Bus error interrupt disabled 1: Bus error interrupt enabled	R/W

Bit	Symbol	Function	R/W
9	EWIE	Error Warning Interrupt Enable 0: Error warning interrupt disabled 1: Error warning interrupt enabled	R/W
10	EPIE	Error Passive Interrupt Enable 0: Error passive interrupt disabled 1: Error passive interrupt enabled	R/W
11	BOEIE	Bus-Off Entry Interrupt Enable 0: Bus-off entry interrupt disabled 1: Bus-off entry interrupt enabled	R/W
12	BORIE	Bus-Off Recovery Interrupt Enable 0: Bus-off recovery interrupt disabled 1: Bus-off recovery interrupt enabled	R/W
13	OLIE	Overload Interrupt Enable 0: Overload interrupt disabled 1: Overload interrupt enabled	R/W
14	BLIE	Bus Lock Interrupt Enable 0: Bus lock interrupt disabled 1: Bus lock interrupt enabled	R/W
15	ALIE	Arbitration Lost Interrupt Enable 0: Arbitration lost interrupt disabled 1: Arbitration lost interrupt enabled	R/W
16	TAIE	Transmission Abort Interrupt Enable 0: TX abort interrupt disabled 1: TX abort interrupt enabled	R/W
17	EOCOIE	Error Occurrence Counter Overflow Interrupt Enable 0: Error occurrence counter overflow interrupt disabled 1: Error occurrence counter overflow interrupt enabled	R/W
18	SOCOIE	Successful Occurrence Counter Overflow Interrupt Enable 0: Successful occurrence counter overflow interrupt disabled 1: Successful occurrence counter overflow interrupt enabled	R/W
19	TDCVFIE*1	Transceiver Delay Compensation Violation Interrupt Enable 0: Transceiver delay compensation violation interrupt disabled 1: Transceiver delay compensation violation interrupt enabled	R/W
20	—	This bit is read as 0. The write value should be 0.	R/W
22:21	BOM[1:0]	Channel Bus-Off Mode 0 0: Normal mode (comply with ISO 11898-1) 0 1: Entry to Halt mode automatically at bus-off start 1 0: Entry to Halt mode automatically at bus-off end 1 1: Entry to Halt mode (during bus-off recovery period) by software	R/W
23	ERRD	Channel Error Display 0: Only the first set of error codes displayed 1: Accumulated error codes displayed	R/W
24	CTME	Channel Test Mode Enable 0: Channel test mode disabled 1: Channel test mode enabled	R/W
26:25	CTMS[1:0]	Channel Test Mode Select 0 0: Basic test mode 0 1: Listen-only mode 1 0: Self-test mode 0 (External loopback mode) 1 1: Self-test mode 1 (Internal loopback mode)	R/W
29:27	—	These bits are read as 0. The write value should be 0.	R/W
30	CRCT	CRC Error Test 0: First data bit of reception stream not inverted 1: First data bit of reception stream inverted	R/W

Bit	Symbol	Function	R/W
31	ROM*1	Restricted Operation Mode 0: Restricted operation mode disabled 1: Restricted operation mode enabled	R/W

Note 1. These bits are not available in the classical CAN function.

Each Channel Control register controls the modes of the related channel. It is used to enable generation of interrupts if errors are detected on the CAN bus connected to this channel. It is also used to configure the channel in test mode.

CHMDC[1:0] bits (Channel Mode Control)

The CHMDC[1:0] bits can be used to configure modes of the CAN channel.

CAN mode transitions are described in more details in section 32.3.3. Channel Modes.

Setting CHMDC[1:0] bits to 11b has no effect. When the CANFD module is in GL_HALT mode, these bits can only be set to 10b or 01b. These bits cannot be set in CH_SLEEP mode.

These bits can change automatically when transitioning to Halt mode by the CFDCnCTR.BOM settings.

If CPU write access to CFDCnCTR.CHMDC occurs at the same time when the CAN channel enters Halt mode (at the start of bus-off when CFDCnCTR.BOM = 01b, or at the end of bus-off when CFDCnCTR.BOM = 10b), then the CPU write access has the highest priority.

The CAN channel changes the value of CFDCnCTR.CHMDC within the Channel Control Registers for the specified cases only if the CFDCnCTR.CHMDC value is 00b (Operation mode).

CSLPR bit (Channel Sleep Request)

When the CSLPR bit is 1, a Sleep mode request is generated for the corresponding CAN channel

When this bit is 0, a request to exit Sleep mode is generated for the related CANFD channel.

Only write to this bit when the related CANFD channel is in CH_RESET or CH_SLEEP mode.

RTBO bit (Return from Bus-Off)

When the protocol controller of the CAN channel enters bus-off state, you can force a recovery from bus-off state by setting the RTBO bit in the Channel Control Register to 1.

The error state changes from bus-off state to integrating with a maximum delay of 1 CAN bit time.

When the RTBO bit is set to 1, the REC and TEC registers are initialized and the Bus-Off Status bit (Channel Bus-off Status, CFDCnSTS.BOSTS) is set to 0.

Registers other than the REC and TEC registers are not initialized by this command. Even if CFDCnCTR.BORIE is set, a bus-off recovery interrupt is not generated by this recovery from the bus-off state.

The RTBO bit cannot be set in CH_SLEEP mode. Setting this bit in any state other than bus-off state has no effect and the bit is cleared immediately. The read value is always 0.

Return from the Bus-Off command should be used only when CFDCnCTR.BOM is set to 00b.

Only write to this bit when the related CANFD channel is in CH_OPERATION mode. This bit is automatically cleared when set by software.

BEIE bit (Bus Error Interrupt Enable)

When the BEIE and the CFDCnERFL.BEF bits are both 1, an error interrupt request is generated.

This bit cannot be set in CH_SLEEP mode. Only write to this bit when the related CANFD channel is in CH_RESET mode.

EWIE bit (Error Warning Interrupt Enable)

When the EWIE and the CFDCnERFL.EWF bits are both 1, an error interrupt request is generated.

The EWIE bit cannot be set in CH_SLEEP mode. Only write to this bit when the related CANFD channel is in CH_RESET mode.

EPIE bit (Error Passive Interrupt Enable)

An error interrupt request is generated when the EPIE bit and the CFDCnERFL.EPF are both 1.

The EPIE bit cannot be set in CH_SLEEP mode. Only write to this bit when the related CANFD channel is in CH_RESET mode.

BOEIE bit (Bus-Off Entry Interrupt Enable)

When the BOEIE and the CFDCnERFL.BOEF bits are both 1, an error interrupt request is generated.

The BOEIE bit cannot be set in CH_SLEEP mode. Only write to this bit when the related CANFD channel is in CH_RESET mode.

BORIE bit (Bus-Off Recovery Interrupt Enable)

When the BORIE and the CFDCnERFL.BORF bits are both 1, an error interrupt request is generated.

The BORIE bit cannot be set in CH_SLEEP mode. Only write to this bit when the related CANFD channel is in CH_RESET mode.

OLIE bit (Overload Interrupt Enable)

When the OLIE and the CFDCnERFL.OVLF bits are both 1, an error interrupt request is generated.

Do not write to this bit in CH_SLEEP mode. Only write to this bit when the related CANFD channel is in CH_RESET mode.

BLIE bit (Bus Lock Interrupt Enable)

When the BLIE and the CFDCnERFL.BLF bits are both 1, an error interrupt request is generated.

Do not write to this bit in CH_SLEEP mode. Only write to this bit when the related CANFD channel is in CH_RESET mode.

ALIE bit (Arbitration Lost Interrupt Enable)

When the ALIE and the CFDCnERFL.ALF bits are both 1, an error interrupt request is generated.

Do not write to this bit in CH_SLEEP mode. Only write to this bit when the related CANFD channel is in CH_RESET mode.

TAIE bit (Transmission Abort Interrupt Enable)

When the TAIE bit is 1 and a transmission is successfully aborted from a TX MB belonging to the corresponding CAN channel, an interrupt request is generated.

Do not write to this bit in CH_SLEEP mode. Only write to this bit when the related CANFD channel is in CH_RESET mode.

EOCOIE bit (Error Occurrence Counter Overflow Interrupt Enable)

When the EOCOIE bit is 1 and the CFDCnFDSTS.EOCO bit belonging to the corresponding CAN channel is 1, an error interrupt request is generated.

The EOCOIE bit cannot be set in CH_SLEEP mode. Only write to this bit when the related CANFD channel is in CH_RESET mode.

SOCOIE bit (Successful Occurrence Counter Overflow Interrupt Enable)

When the SOCOIE bit is 1 and the CFDCnFDSTS.SOCO bit belonging to the corresponding CAN channel is 1, an error interrupt request is generated.

The SOCOIE bit cannot be set in CH_SLEEP mode. Only write to this bit when the related CANFD channel is in CH_RESET mode.

TDCVFIE bit (Transceiver Delay Compensation Violation Interrupt Enable)

When the TDCVFIE bit is 1 and the CFDCnFDSTS.TDCVF bit belonging to the corresponding CAN channel is 1, an error interrupt request is generated.

The TDCVFIE bit cannot be set in CH_SLEEP mode.

Only write to this bit when the related CANFD channel is in CH_RESET mode. Do not set this bit when in Classical CAN mode.

Note: This bit is not available in the classical CAN function.

BOM[1:0] bits (Channel Bus-Off Mode)

The BOM[1:0]bits control the timing of the recovery from Bus-Off mode of the CANFD Channel.

Do not write to these bits in CH_SLEEP mode. Only write to these bits when the related CANFD channel is in CH_RESET mode.

Only write to these bits when the related CANFD channel is in CH_RESET mode.

ERRD bit (Channel Error Display)

The ERRD bit controls the display mode of the error flag bits [14:8] in the Channel Error Flag Register (CFDCnERFL).

If the ERRD bit is 0 and more than one error occur at the same time, the error flag bits are set for all the errors that occurred at the same time. No further errors are flagged until CFDCnERFL[14:8] is cleared.

Do not write to the ERRD bit in CH_SLEEP mode. Only write to this bit when the related CANFD channel is in CH_RESET or CH_HALT mode.

CTME bit (Channel Test Mode Enable)

The CTME bit enables the channel test modes.

Do not write to this bit in CH_SLEEP mode. Only write to this bit when the related CANFD channel is in CH_HALT mode.

CTMS[1:0] bits (Channel Test Mode Select)

The CTMS[1:0] bits are used to select the required test mode.

Do not write to these bits in CH_SLEEP or CH_RESET mode. Only write to these bits when the related CANFD channel is in CH_HALT mode.

These bits are cleared automatically when the related CANFD channel is in CH_RESET mode.

CRCT bit (CRC Error Test)

The CRCT bit checks the internal CRC generator logic of the protocol controller.

The internal generated CRC value is always observed in the following registers:

- CFDCnERFL.CRCREG (Classical CAN frames)
- CFDCnFDCRC.CRCREG (CANFD frames).*1

Note 1. This feature is not available in the classical CAN function.

Some restriction exist when using this bit:

- It is not possible to use this feature with CAN nodes connected to the MCU externally, only with nodes connected to the internal CAN bus communication can be used
- One CAN node can send a reference message and the receiver node can invert one bit of the incoming bit stream.

Note: The transmitter and receiver modes share the same CRC generator, therefore it is not necessary to consider the modes separately when testing.

The CRC Error test mode is enabled if the CRCT (new control signal that inverts the first bit of the bit stream) and CTME bits are both 1.

Do not write to the CRCT bit in CH_SLEEP mode. Only write to this bit when the related CANFD channel is in CH_HALT mode.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode.

ROM bit (Restricted Operation Mode)

When the ROM and CTME bits are both 1, the restricted operation mode is enabled. This mode should only be used in basic test mode (CFDCnCTR.CTMS[1:0] = 00b).

The ROM bit cannot be set in CH_SLEEP mode. Only write to this bit when the related CANFD channel is in CH_HALT mode.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode. Do not set this bit when in Classical CAN mode.

Note: This bit is not available in the classical CAN function.

32.2.5 CFDCnSTS : Channel n Status Registers (n = 0, 1)

Base address: CANFD = 0x400B_0000

Offset address: 0x0008 + 0x10 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	TEC[7:0]								REC[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	ESIF	COMSTS	RECSTS	TRMSTS	BOSTS	EPSTS	CSLPSTS	CHLTSTS	CRSTSTS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	1

Bit	Symbol	Function	R/W
0	CRSTSTS	Channel Reset Status 0: Channel not in Reset mode 1: Channel in Reset mode	R
1	CHLTSTS	Channel Halt Status 0: Channel not in Halt mode 1: Channel in Halt mode	R
2	CSLPSTS	Channel Sleep Status 0: Channel not in Sleep mode 1: Channel in Sleep mode	R
3	EPSTS	Channel Error Passive Status 0: Channel not in error passive state 1: Channel in error passive state	R
4	BOSTS	Channel Bus-Off Status 0: Channel not in bus-off state 1: Channel in bus-off state	R
5	TRMSTS	Channel Transmit Status 0: Channel is not transmitting 1: Channel is transmitting	R
6	RECSTS	Channel Receive Status 0: Channel is not receiving 1: Channel is receiving	R
7	COMSTS	Channel Communication Status 0: Channel is not ready for communication 1: Channel is ready for communication	R
8	ESIF*1	Error State Indication Flag 0: No CANFD message has been received when the ESI flag was set 1: At least one CANFD message was received when the ESI flag was set	R/W
15:9	—	These bits are read as 0. The write value should be 0.	R/W
23:16	REC[7:0]	Reception Error Count These bits increment or decrement the counter value according to error status of the CAN channel during reception.	R
31:24	TEC[7:0]	Transmission Error Count These bits increment or decrement the counter value according to error status of the CAN channel during transmission.	R

Note 1. This bit is not available in the classical CAN function.

Each Channel Status Register shows the mode, error and transmission or reception status of the related channel together with its reception and transmission error count values.

CRSTSTS bit (Channel Reset Status)

The CRSTSTS bit indicates whether the related CAN channel is in Reset mode.

This bit is set automatically when the related CAN channel enters Channel Reset mode. When the mode is changed from Reset mode to Sleep mode, the CRSTSTS bit remains 1.

This bit is cleared automatically when the related CAN channel exits the Channel Reset mode, except when changing to Sleep mode.

CHLTSTS bit (Channel Halt Status)

The CHLTSTS bit indicates whether the related CAN channel is in Halt mode.

This bit is set automatically when the related CAN module enters Halt mode, and is cleared automatically when the related CAN module exits Halt mode.

CSLPSTS bit (Channel Sleep Status)

The CSLPSTS bit indicates whether the related CAN channel is in Sleep mode.

This bit is set automatically when the related CANFD channel enters Sleep mode, and is cleared automatically when the related CANFD channel exits Sleep mode.

EPSTS bit (Channel Error Passive Status)

The EPSTS bit indicates whether the related CANFD channel has entered the error passive state.

This bit is set automatically when the value of the CAN Transmission or Reception Counter Register exceeds the value of 0x7F.

This bit is cleared automatically when the related CANFD channel exits the error passive state or enters Reset mode.

BOSTS bit (Channel Bus-Off Status)

The BOSTS bit indicates whether the related CANFD channel has entered the error bus-off state.

This bit is set automatically when the value of the related CAN Transmission Error Count Register exceeds 0xFF and the related CANFD channel is in the bus-off state (CAN Transmission Error Count Register > 0xFF).

This bit is cleared automatically when the related CANFD channel exits bus-off state.

TRMSTS bit (Channel Transmit Status)

The TRMSTS bit indicates whether the related CANFD channel is transmitting a message.

This bit is set automatically when the related CANFD channel is operating as a transmitter node or is in the bus-off state.

This bit is cleared automatically when the related CANFD channel is in the bus-idle state or starts operating as a receiver node.

RECSTS bit (Channel Receive Status)

The RECSTS bit indicates whether the related CANFD channel is receiving a message.

This bit is set automatically when the related CANFD channel is operating as a receiver node.

This bit is cleared automatically when the related CANFD channel is in the bus-idle state or starts operating as a transmitter node.

COMSTS bit (Channel Communication Status)

The COMSTS bit indicates whether the related CANFD channel is ready for communication.

This bit is set automatically when the related CANFD channel is ready to perform communication following the detection of 11 consecutive recessive bits after exiting the Reset or Halt mode.

This bit is cleared automatically when the related CANFD channel is in CH_RESET or CD_HALT mode.

Note: This bit is 1 during bus-off state.

ESIF bit (Error State Indication Flag)

The ESIF bit is set when the ESI bit is sampled recessively for a reception CAN message without any error. When in Loopback or Mirror mode, the self-transmitted messages are considered reception messages.

If a set from the CANFD channel occurs simultaneously with a clear by a write access, then the bit is set.

This bit is cleared by writing 0 to it. This bit is cleared automatically when the related CANFD channel is in CH_RESET mode.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

Note: This bit is not available in the classical CAN function.

REC[7:0] bits (Reception Error Count)

The REC[7:0] bits increment or decrement the counter value according to error status of the CANFD channel during reception, and display the value of the REC error counter.

The value in bus-off state is indeterminate.

These bits are cleared automatically when the CANFD module enters GL_RESET or the CANFD channel is in CH_RESET mode.

TEC[7:0] bits (Transmission Error Count)

The TEC[7:0] bits increment or decrement the counter value according to error status of the CANFD channel during transmission, and display the value of the TEC error counter.

Only write to these bits when in test mode and CANFD channel is in CH_HALT mode.

These bits are cleared automatically when CANFD module is in GL_RESET or CANFD channel is in CH_RESET mode.

32.2.6 CFDCnERFL : Channel n Error Flag Registers (n = 0, 1)

Base address: CANFD = 0x400B_0000

Offset address: 0x000C + 0x10 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	CRCREG[14:0]														
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	BEF	Bus Error Flag 0: Channel bus error not detected 1: Channel bus error detected	R/W
1	EWF	Error Warning Flag 0: Channel error warning not detected 1: Channel error warning detected	R/W
2	EPF	Error Passive Flag 0: Channel error passive not detected 1: Channel error passive detected	R/W
3	BOEF	Bus-Off Entry Flag 0: Channel bus-off entry not detected 1: Channel bus-off entry detected	R/W

Bit	Symbol	Function	R/W
4	BORF	Bus-Off Recovery Flag 0: Channel bus-off recovery not detected 1: Channel bus-off recovery detected	R/W
5	OVLF	Overload Flag 0: Channel overload not detected 1: Channel overload detected	R/W
6	BLF	Bus Lock Flag 0: Channel bus lock not detected 1: Channel bus lock detected	R/W
7	ALF	Arbitration Lost Flag 0: Channel arbitration lost not detected 1: Channel arbitration lost detected	R/W
8	SERR	Stuff Error 0: Channel stuff error not detected 1: Channel stuff error detected	R/W
9	FERR	Form Error 0: Channel form error not detected 1: Channel form error detected	R/W
10	AERR	Acknowledge Error 0: Channel acknowledge error not detected 1: Channel acknowledge error detected	R/W
11	CERR	CRC Error 0: Channel CRC error not detected 1: Channel CRC error detected	R/W
12	B1ERR	Bit 1 Error 0: Channel bit 1 error not detected 1: Channel bit 1 error detected	R/W
13	B0ERR	Bit 0 Error 0: Channel bit 0 error not detected 1: Channel bit 0 error detected	R/W
14	ADERR	Acknowledge Delimiter Error 0: Channel acknowledge delimiter error not detected 1: Channel acknowledge delimiter error detected	R/W
15	—	This bit is read as 0. The write value should be 0.	R/W
30:16	CRCREG[14:0]	CRC Register value These bits show the CRC value calculated for the CAN2.0 CAN frame.	R
31	—	This bit is read as 0. The write value should be 0.	R/W

Each Channel Error Flag register shows the status of various error conditions detectable regardless of the setting of the related CAN Channel Error Interrupt Enable Register. It also shows the status of the various bus errors detectable by the CAN channel. Refer to the CAN specification (ISO 11898-1) to check when each error condition occurs.

For this register, only a single bit can be cleared by software. Do not use the bit clear instruction to clear the bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

Example in assembler language to clear the CFDCnERFL.BEF bit:

mov.b #0x0FE, CFDCnERFL ;

BEF bit (Bus Error Flag)

The BEF bit indicates a detection of a CAN channel bus error state, flagged by bits [14:8] in this register.

This bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

This bit is set automatically when a bus error is detected, and is cleared automatically when the related CANFD channel is in CH_RESET mode.

If a set from the CAN channel occurs simultaneously with a clear by a write access, then the bit is set.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

EWF bit (Error Warning Flag)

The EWF bit indicates whether an error warning condition has been detected for the CAN channel.

This bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

This bit is set automatically when either TEC or REC exceeds 0x5F.

The setting of this bit only occurs when the TEC or REC initially exceeds 0x5F. Therefore, if the TEC or REC remains > 0x5F and the EWF bit is cleared by software, it is not set again until both the TEC and REC go below 0x60 and either TEC or REC crosses over again from a value 0x5F to a value > 0x5F.

If a set condition occurs simultaneously with a clear condition, then the bit is set. It is cleared automatically when the related CANFD channel is in CH_RESET mode.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

EPF bit (Error Passive Flag)

The EPF bit indicates a detection of a CAN channel error passive state.

This bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

This bit is set automatically when the CAN error state becomes error passive state.

The setting of this bit only occurs when the TEC or REC initially exceeds 0x7F. Therefore, if the TEC or REC remains > 0x7F and the bit is cleared by software, it is not set again until both the TEC and REC go below 0x80 and either TEC or REC crosses over again from a value ≤ 0x7F to a value > 0x7F.

If a set condition occurs simultaneously with a clear condition, then the bit is set. It is cleared automatically when the related CANFD channel is in CH_RESET mode.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

BOEF bit (Bus-Off Entry Flag)

The BOEF bit indicates a detection of a CAN channel bus-off entry state.

This bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

This bit is set automatically when the CAN error state enters the bus-off state.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode. If a set condition occurs simultaneously with a clear condition, then the bit is set.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

BORF bit (Bus-Off Recovery Flag)

The BORF bit indicates a detection of a CAN channel bus-off recovery state.

This bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

This bit is set automatically if CAN channel recovers from bus-off state in the following conditions:

- When CFDCnCTR.BOM is 00b and normal recovery (11 consecutive recessive bits x 128 times detected) occurs
- When CFDCnCTR.BOM is 10b and normal recovery (11 consecutive recessive bits x 128 times detected) occurs
- When CFDCnCTR.BOM is 11b and normal recovery (11 consecutive recessive bits x 128 times detected) occurs.

The bit is not set if CAN channel recovers from bus-off state in the following conditions:

- When CAN Reset mode is requested
- When CFDCnCTR.RTBO is set to 1 (the CAN channel returns to error active)
- When CFDCnCTR.BOM is 01b
- When CFDCnCTR.BOM is 11b and a halt request is asserted before the CAN channel reaches the end of the bus-off state.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode. If a set condition occurs simultaneously with a clear condition, the flag is set.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

OVLF bit (Overload Flag)

The OVLF flag indicates a detection of a CAN channel overload state.

The OVLF bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

This bit is set automatically when an overload condition is detected. If a set condition occurs simultaneously with a clear condition, then the bit is set.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

BLF bit (Bus Lock Flag)

The BLF bit indicates a detection of a CAN channel bus lock condition.

This bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

This bit is set automatically when 32 consecutive dominant bits are detected on the CAN bus while the CAN channel is in Operation mode.

If a set condition occurs simultaneously with a clear condition, then the bit is set. It is cleared automatically when the related CANFD channel is in CH_RESET mode.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

It is cleared automatically when the related CANFD channel is in CH_RESET mode.

ALF bit (Arbitration Lost Flag)

The ALF bit indicates a detection of a CAN channel bus arbitration lost condition.

This bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

The bit is set automatically when an arbitration lost condition is detected on the CAN bus while the CAN channel is in Operation mode.

If a set condition occurs simultaneously with a clear condition, then the bit is set. It is cleared automatically when the related CANFD channel is in CH_RESET mode.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

SERR bit (Stuff Error)

The SERR bit indicates a detection of a CAN stuff error.

This bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

To clear this bit, use the following sequence:

1. Clear the corresponding flag bit.
2. Read if the flag bit is cleared.
3. If yes, continue, else go back to step 1.

This bit is set automatically when a stuff error is detected. If CFDCnCTR.ERRD bit is 1 and if the set and clear conditions occur at the same time for this bit, then this bit is set.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode. If CFDCnCTR.ERRD bit is 0 and the set and clear conditions occur at the same time for this bit, then it is cleared if a bit at CFDCnERFL[14:8] is already set. Otherwise, this bit is set if CFDCnERFL[14:8] is 0000000b.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

FERR bit (Form Error)

The FERR bit indicates a detection of a CAN form error.

This bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

To clear this bit, use the following sequence:

1. Clear the corresponding flag bit.
2. Read if the flag bit is cleared.

3. If yes, continue, else go back to step 1.

This bit is set automatically when a form error is detected. If CFDCnCTR.ERRD bit is 1 and if the set and clear conditions occur at the same time for this bit, then this bit is set.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode. If CFDCnCTR.ERRD bit is 0 and the set and clear conditions occur at the same time for this bit, then it is cleared if a bit at CFDCnERFL[14:8] is already set. Otherwise, this bit is set if CFDCnERFL[14:8] is 0000000b.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

AERR bit (Acknowledge Error)

The AERR bit indicates a detection of a CAN acknowledge error.

This bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

To clear this bit, use the following sequence:

1. Clear the corresponding flag bit.
2. Read if the flag bit is cleared.
3. If yes, continue, else go back to step 1.

This bit is set automatically when an acknowledge error is detected. If CFDCnCTR.ERRD bit is 1 and if the set and clear conditions occur at the same time for this bit, then this bit is set.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode. If CFDCnCTR.ERRD bit is 0 and the set and clear conditions occur at the same time for this bit, then it is cleared if a bit at CFDCnERFL[14:8] is already set. Otherwise, this bit is set if CFDCnERFL[14:8] is 0000000b.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION.

CERR bit (CRC Error)

The CERR bit indicates a detection of a CAN CRC error.

This bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

To clear this bit, use the following sequence:

1. Clear the corresponding flag bit.
2. Read if the flag bit is cleared.
3. If yes, continue, else go back to step 1.

This bit is set automatically when a CRC error is detected. If CFDCnCTR.ERRD bit is 1 and if the set and clear conditions occur at the same time for this bit, then this bit is set.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode. If CFDCnCTR.ERRD bit is 0 and the set and clear conditions occur at the same time for this bit, then it is cleared if a bit at CFDCnERFL[14:8] is already set. Otherwise, this bit is set if CFDCnERFL[14:8] is 0000000b.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

B1ERR bit (Bit 1 Error)

The B1ERR bit indicates a detection of a recessive bit error.

This bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

To clear this bit, use the following sequence:

1. Clear the corresponding flag bit.
2. Read if the flag bit is cleared.
3. If yes, continue, else go back to step 1.

This bit is set automatically when a recessive bit error (expected recessive bit, sampled as dominant bit) is detected. If CFDCnCTR.ERRD bit is 1 and if the set and clear conditions occur at the same time for this bit, then this bit is set.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode. If CFDCnCTR.ERRD bit is 0 and the set and clear conditions occur at the same time for this bit, then it is cleared if a bit at CFDCnERFL[14:8] is already set. Otherwise, this bit is set if CFDCnERFL[14:8] is 0000000b.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

B0ERR bit (Bit 0 Error)

The B0ERR bit indicates a detection of a dominant bit error.

This bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

To clear this bit, use the following sequence:

1. Clear the corresponding flag bit.
2. Read if the flag bit is cleared.
3. If yes, continue, else go back to step 1.

This bit is set automatically when a dominant bit error (expected dominant bit, sampled as recessive bit) is detected. If CFDCnCTR.ERRD bit is 1 and if the set and clear conditions occur at the same time for this bit, then this bit is set.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode. If CFDCnCTR.ERRD bit is 0 and the set and clear conditions occur at the same time for this bit, then it is cleared if a bit at CFDCnERFL[14:8] is already set. Otherwise, this bit is set if CFDCnERFL[14:8] is 0000000b.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

ADERR bit (Acknowledge Delimiter Error)

The ADERR bit indicates a detection of an acknowledge delimiter bit error.

This bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

To clear this bit, use the following sequence:

1. Clear the corresponding flag bit.
2. Read if the flag bit is cleared.
3. If yes, continue, else go back to step 1.

This bit is set automatically when a form error is detected during the acknowledge delimiter state of frame transmission. If CFDCnCTR.ERRD bit is 1 and if the set and clear conditions occur at the same time for this bit, then this bit is set.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode. If CFDCnCTR.ERRD bit is 0 and the set and clear conditions occur at the same time for this bit, then it is cleared if a bit at CFDCnERFL[14:8] is already set. Otherwise, this bit is set if CFDCnERFL[14:8] is 0000000b.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

CRCREG[14:0] bits (CRC Register value)

The CRCREG[14:0] bits read the calculated CRC value when CFDCnCTR.CTME bit is 1 for the channel.

If CFDCnCTR.CTME bit is 0, then these bits are always read as 0.

These bits show the CAN2.0 CRC value calculated by the CANFD channel logic when the CTME bit is enabled.

The CFDCnERFL.CRCREG value is updated in the first bit of the CRC field of the CAN frame (reception and transmission).

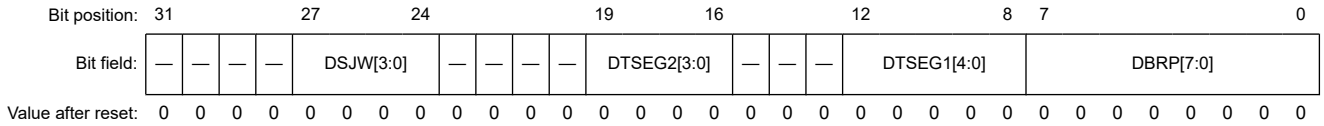
These bits are cleared automatically when the related CANFD channel is in CH_RESET mode.

32.2.7 CFDCnDCFG : Channel n Data Bitrate Configuration Register (n = 0, 1)

This register is not available in the classical CAN function.

Base address: CANFD = 0x400B_0000

Offset address: 0x1400 + 0x20 × n



Bit	Symbol	Function	R/W
7:0	DBRP[7:0]	Channel Data Baud Rate Prescaler Data Baud Rate Prescaler division ratio	R/W
12:8	DTSEG1[4:0]	Timing Segment 1 0x00: Reserved 0x01: 2 Tq 0x02: 3 Tq 0x03: 4 Tq ⋮ 0x1E: 31 Tq 0x1F: 32 Tq	R/W
15:13	—	These bits are read as 0. The write value should be 0.	R/W
19:16	DTSEG2[3:0]	Timing Segment 2 0x0: Reserved 0x1: 2 Tq ⋮ 0xE: 15 Tq 0xF: 16 Tq	R/W
23:20	—	These bits are read as 0. The write value should be 0.	R/W
27:24	DSJW[3:0]	Resynchronization Jump Width 0x0: 1 Tq 0x1: 2 Tq ⋮ 0xF: 16 Tq	R/W
31:28	—	These bits are read as 0. The write value should be 0.	R/W

Note: Tq means time quantum.

The Channel n Data Bitrate Configuration Register (n = 0, 1) configures the transmission/reception data baud rate parameters of the channels.

The channel of Classical CAN mode does not perform configuration of this register.

DBRP[7:0] bits (Channel Data Baud Rate Prescaler)

The DBRP[7:0] bits define the peripheral bus clock periods contained in a time quantum.

Do not write to these bits in CH_OPERATION or CH_SLEEP mode.

Only write to these bits when the related CANFD channel is in CH_RESET or CH_HALT mode.

DTSEG1[4:0] bits (Timing Segment 1)

The DTSEG1[4:0] bits set the segment TSEG1 to compensate for edges on the CAN bus with a positive phase error. A value from 2 to 32 time quanta can be set.

The DTSEG1[4:0] bits are also used to set the propagation segment.

Do not write to these bits in CH_OPERATION or CH_SLEEP mode.

Only write to these bits when the related CANFD channel is in CH_RESET or CH_HALT mode. Do not write any other value to these bits. See section 32.4.1.2. CAN Bit Timing for more details.

DTSEG2[3:0] bits (Timing Segment 2)

The DTSEG2[3:0] bits set the segment TSEG2 to compensate for edges on the CAN bus with a negative phase error. A value from 2 to 16 time quanta can be set.

Do not write to these bits in CH_OPERATION or CH_SLEEP mode.

Only write to these bits when the related CANFD channel is in CH_RESET or CH_HALT mode. Do not write any other value to these bits.

DSJW[3:0] bits (Resynchronization Jump Width)

The DSJW[3:0] bits set the synchronization jump width. A value from 1 to 16 time quanta can be set.

Do not write to these bits in CH_OPERATION or CH_SLEEP mode.

Only write to these bits when the related CANFD channel is in CH_RESET or CH_HALT mode.

32.2.8 CFDCnFDCFG : Channel n CAN-FD Configuration Register (n = 0, 1)

This register is not available in the classical CAN function.

Base address: CANFD = 0x400B_0000

Offset address: 0x1404 + 0x20 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Symbol	Function	R/W
25	GWFDF*1	Gateway FDF Configuration Bit 0: Gateway frame is transmitted as Classical CAN frame 1: Gateway frame is transmitted as CAN-FD frame	R/W
26	GWBRS*1	Gateway BRS Configuration Bit 0: Gateway frame is transmitted with BRS = 0 1: Gateway frame is transmitted with BRS = 1	R/W
27	—	This bit is read as 0. The write value should be 0.	R/W
28	FDOE*1	FD-Only Enable 0: FD-only mode disabled 1: FD-only mode enabled	R/W
29	REFE	RX Edge Filter Enable 0: RX edge filter disabled 1: RX edge filter enabled	R/W
30	CLOE*1	Classical CAN Enable 0: Classical CAN mode disabled 1: Classical CAN mode enabled	R/W
31	CFDTE	CAN-FD Frame Distinction Enable 0: CAN-FD frame distinction disabled 1: CAN-FD frame distinction enabled	R/W

Note 1. These bits are not available in the classical CAN function.

The Channel n CAN-FD Configuration Register (n = 0, 1) configures which communication direction (transmitter/receiver) errors are counted.

EOCCFG[2:0] bits (Error Occurrence Counter Configuration)

The EOCCFG[2:0] bits select which type of CAN frame configuration and direction, including protocol errors are counted.

Do not write to these bits in CH_OPERATION or CH_SLEEP mode.

Only write to these bits when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

TDCOC bit (Transceiver Delay Compensation Offset Configuration)*1

The TDCOC bit selects which offset is used when defining the position of the secondary sample point (SSP) for the CAN-FD channel. If the bit is set to 0, the position of the SSP is the measured transceiver delay plus the fixed offset. If the bit is 1, the position of the SSP is defined only by the offset.

Do not write to this bit in CH_OPERATION or CH_SLEEP mode.

Only write to this bit when the related CAN-FD channel is in CH_RESET or CH_HALT mode. Do not set this bit when in Classical CAN mode.

TDCE bit (Transceiver Delay Compensation Enable)*1

The TDCE bit enables the transceiver delay compensation for the CAN-FD channel.

Do not write to this bit in CH_OPERATION or CH_SLEEP mode.

Only write to this bit when the related CAN-FD channel is in CH_RESET or CH_HALT mode. Do not set this bit when in Classical CAN mode.

ESIC bit (Error State Indication Configuration)*1

Bus controllers that are used as CAN-to-CAN gateway support that in every forwarded CAN-FD message. The ESI flag does not change to reflect the status of the gateway, bridge, or router but instead the flag is sent as it was in the original message.

The ESIC bit controls the transmission of either the ESI flag information or the message of ESI flag information (CFDCFFDCSTSn.CFESI or CFDTMFDCTRn.TMESI).

Do not write to this bit in CH_OPERATION or CH_SLEEP mode.

Only write to this bit when the related CAN-FD channel is in CH_RESET or CH_HALT mode. Do not set this bit when in Classical CAN mode.

TDCO[7:0] bits (Transceiver Delay Compensation Offset)*1

The TDCO[7:0] bits set the secondary sample point offset. How this value is used, depends on the CFDCnFDCFG.TDCOC setting.

If CFDCnFDCFG.TDCOC = 0, the transceiver delay compensation result is equal to the Trv_Delay (measured delay) + the value in CFDCnFDCFG.TDCO, rounded down to the nearest integer number of time quanta. Otherwise, the result is equal to the value in CFDCnFDCFG.TDCO. See section 32.4.1.5. Transmitter Delay Compensation for details on how CFDCnFDCFG.TDCO is used.

The actual offset value is interpreted as TDCO + 1. For example, if 4 is set in TDCO, the offset is 5 clock cycles. Clock cycle is 1 cycle of CAN channel DLL clock.

Do not write to the TDCO[7:0] bits in CH_OPERATION or CH_SLEEP mode.

Only write to these bits when the related CAN-FD channel is in CH_RESET or CH_HALT mode. Do not set this bit when in Classical CAN mode.

GWEN bit (CAN2.0, CAN-FD Multi-Gateway Enable)*1

When the GWEN bit is enabled, a multi-gateway is enabled. Message received on one node can be routed to another node using the COM FIFO when they are configured as gateway FIFO (CFDCFCCn.CFM = 10b). Furthermore, when TX Queue is set as gateway mode, the message received on one node can be stored in TX Queue and can be sent to another node.

The FDF and BRS bits of the routed message can be changed by the configuration value of the CFDCnFDCFG.GWFDF and CFDCnFDCFG.GWBRS bits. By this, the transmitted value of these bits can be replaced.

Example :

CFDCnFDCFG.GWEN = 1 on channel y

CFDCnFDCFG.GWFDF = 1

If a Classical CAN frame is received on channel x and routed to a gateway FIFO or TX Queue of channel y. Then this CAN frame is sent on channel y as a CAN-FD frame because of the CFDCnFDCFG.GWFDF bit.

Table 32.3 shows how the message information is changed depending on the received and configured data.

Table 32.3 Modified message information by received and configured data

Routed CAN frame	Routed received DLC	CAN BRS bit	Configured CFDCnFDCFG.GWFDF bit	Gateway message DLC	Gateway message BRS bit	Gateway message frame type
CAN2.0	≤ 8	N/A	1	≤ 8	Based on configuration of CFDCnFDCFG.GWBRS	FD
CAN2.0	> 8	N/A	1	= 8	Based on configuration of CFDCnFDCFG.GWBRS	FD
FD	≤ 8	None	1	≤ 8	Based on configuration of CFDCnFDCFG.GWBRS	FD
FD	> 8	None	1	> 8	Based on configuration of CFDCnFDCFG.GWBRS	FD
CAN2.0	≤ 8	N/A	0	≤ 8	N/A	CAN2.0
CAN2.0	> 8	N/A	0	> 8	N/A	CAN2.0
FD	≤ 8	None	0	≤ 8	N/A	CAN2.0
FD	> 8	None	0	= 8	N/A	CAN2.0

Note: This gateway is limited to an 8-byte data payload for different frame type. If routing and target frame type is the same, the data length code (DLC) value remains the same. If the source frame is a CAN-FD with more than 8 data

bytes, then on classical destination node, the data payload is reduced to 8 bytes. Only the first 8 bytes of data perform gateway transmission.

Note: Transmission buffers other than the gateway FIFO are not affected by this feature.

Do not route remote frames through the gateway when CFDCnFDCFG.GWEN is set. When a destination node is CFDCnFDCFG.FDOE = 1, set CFDCnFDCFG.GWEN and CFDCnFDCFG.GWFDF to 1. When a destination node is CFDCnFDCFG.CLOE = 1, set CFDCnFDCFG.GWEN=1 and CFDCnFDCFG.GWFDF = 0.

Do not write to this bit in CH_OPERATION or CH_SLEEP mode.

Only write to this bit when the related CAN-FD channel is in CH_RESET mode.

GWFDF bit (Gateway FDF Configuration Bit)*1

When the GWEN bit is set to 1, the FDF bit of the transmitting gateway frame is replaced by the value of the GWFDF bit.

Do not write to this bit in CH_OPERATION or CH_SLEEP mode.

Only write to these bits when the CAN-FD module is in CH_RESET mode. Do not set this bit when in Classical CAN mode.

GWBRS bit (Gateway BRS Configuration Bit)*1

When the GWEN bit is set to 1, the BRS bit of the transmitting gateway frame is replaced by the value of CFDCnFDCFG.GWBRS.

In classical CAN frames, the GWBRS bit is invalid.

Do not write to this bit in CH_OPERATION or CH_SLEEP mode.

Only write to this bit when the related CAN-FD channel is in CH_RESET mode. Do not set this bit when in Classical CAN mode.

FDOE bit (FD-Only Enable)*1

The FDOE bit enables the reception and transmission of CAN-FD-only frames. If enabled, communication in Classical CAN frame format is disabled. Transmission of Classical CAN frames is not possible because the FDF bit of the message buffer is a don’t care (CFDCFFDCSTSn.CFFDF/CFDTMFDCTRn.TMFDF).

If messages with Classical CAN frame format are received, the protocol controller treats them as invalid frames and response with error frames. When a Classical CAN frame is configured for transmitting, the FDF bit is sent as recessive, therefore an FD frame is sent. If the data length code (DLC) is configured of greater than 8 bytes, the remaining data bytes are padded with 0xCC.

The FDOE bit cannot be written in CH_OPERATION, CH_HALT or CH_SLEEP mode.

Do not set CFDCnFDCFG.FDOE and CFDCnFDCFG.CLOE simultaneously.

REFE bit (RX Edge Filter Enable)

The REFE bit enables the RX edge filter during the IDLE detection (bus integration). When the bit is enabled, two consecutive dominant time quanta are required to detect a synchronization edge.

The REFE bit cannot be written in CH_OPERATION, CH_HALT and CH_SLEEP mode. Do not set this bit when in Classical CAN mode and when CFDCnFDCFG.CFDTE = 0 (disabled CAN-FD frame distinction).

CLOE bit (Classical CAN Enable)*1

The CLOE bit enables the Classical CAN mode. If this bit is 1, the protocol controller can only send classical frames and response with a form or CRC error on FD frames.

Do not set CFDCnFDCFG.CLOE and CFDCnFDCFG.FDOE simultaneously.

CFDCnFDCFG.CLOE	CFDCnFDCFG.FDOE	Channel mode
0	0	CAN-FD mode
0	1	FD-only mode
1	0	Classical CAN mode

CFDCnFDCFG.CLOE	CFDCnFDCFG.FDOE	Channel mode
1	1	Reserved

The CANFD mode is available only for CANFD supported product.

Do not write to this bit in CH_OPERATION, CH_HALT or CH_SLEEP mode.

Only write to these bits when the CAN-FD channel is in CH_RESET mode.

CFDTE bit (CAN-FD Frame Distinction Enable)

The CFDTE bit enables the CAN-FD frame distinction function. The CFDTE bit is required for Classical CAN mode (CFDCnFDCFG.CLOE = 1).

If this bit is 0, the protocol controller can only send Classical frames and response with a Form or CRC error on FD frames.

If this bit is 1, the protocol controller behaves according to the ISO 11898-1 (DIS 2015) specification. If the FDF bit is detected recessive, then the protocol controller enters the protocol exception state, and attempts to integrate back to the CAN communication.

Do not write this bit in CH_OPERATION, CH_HALT or CH_SLEEP mode.

Only write to these bits when the related CAN-FD channel is in CH_RESET mode.

Note 1. These bits are not available in the classical CAN function.

32.2.9 CFDCnFDCTR : Channel n CANFD Control Register (n = 0, 1)

Base address: CANFD = 0x400B_0000

Offset address: 0x1408 + 0x20 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SOCCLR	EOCCLR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	EOCCLR	Error Occurrence Counter Clear 0: No error occurrence counter clear 1: Clear error occurrence counter	R/W
1	SOCCLR	Successful Occurrence Counter Clear 0: No successful occurrence counter clear 1: Clear successful occurrence counter	R/W
31:2	—	These bits are read as 0. The write value should be 0.	R/W

The Channel n CANFD Control Register (n = 0, 1) controls the error and successful occurrence counters.

EOCCLR bit (Error Occurrence Counter Clear)

The EOCCLR bit is used to clear the error occurrence counter.

Do not write to this bit in CH_SLEEP or CH_RESET mode. The read value is always 0.

This bit is cleared automatically by the CANFD module logic and when the related CANFD channel is in CH_RESET mode.

SOCCLR bit (Successful Occurrence Counter Clear)

The SOCCLR bit is used to clear the successful occurrence counter.

Do not write to this bit in CH_SLEEP or CH_RESET mode. The read value is always 0.

This bit is cleared automatically by the CANFD module logic and when the related CANFD channel is in CH_RESET mode.

32.2.10 CFDCnFDSTS : Channel n CANFD Status Register (n = 0, 1)

Base address: CANFD = 0x400B_0000

Offset address: 0x140C + 0x20 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	SOC[7:0]								EOC[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	TDCVF	—	—	—	—	—	SOCO	EOCO	TDCR[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	TDCR[7:0]*1	Transceiver Delay Compensation Result	R
8	EOCO	Error Occurrence Counter Overflow 0: Error occurrence counter has not overflowed 1: Error occurrence counter has overflowed	R/W
9	SOCO	Successful Occurrence Counter Overflow 0: Successful occurrence counter has not overflowed 1: Successful occurrence counter has overflowed	R/W
14:10	—	These bits are read as 0. The write value should be 0.	R/W
15	TDCVF*1	Transceiver Delay Compensation Violation Flag 0: Transceiver delay compensation violation has not occurred 1: Transceiver delay compensation violation has occurred	R/W
23:16	EOC[7:0]	Error Occurrence Counter These bits show the error occurrence counter value.	R
31:24	SOC[7:0]	Successful occurrence counter These bits show the successful occurrence counter value.	R

Note 1. These bits are not available in the classical CAN function.

The Channel n CANFD Status Register (n = 0, 1) indicates the transceiver compensation delay result and its related FIFO message lost status.

TDCR[7:0] bits (Transceiver Delay Compensation Result)

The TDCR[7:0] bits are set when the transceiver delay has been measured.

The measured delay is a multiple of the CAN channel DLL clock. The result depends on the CFDCnFDCFG.TDCOC configuration and the offset value in CFDCnFDCFG.TDCO. See section 32.4.1.5. Transmitter Delay Compensation for details on how this value is derived.

The TDCR[7:0] bits are updated at the falling edge between FDF and the RES bit when CFDCnFDCFG.TDCOC = 0 and the transceiver delay compensation is enabled (CFDCnFDCFG.TDCE = 1).

These bits are cleared automatically when the related CANFD channel is in CH_RESET mode.

Note: These bits are not available in the classical CAN function.

EOCO bit (Error Occurrence Counter Overflow)

The EOCO bit indicates whether the related CAN channel error occurrence counter has overflowed. This bit is cleared by writing 0 to it. Writing 1 has no effect.

This bit is set automatically when CFDCnFDSTS.EOC is 0xFF and a CAN bus error is detected based on the configuration defined in CFDCnFDCFG.EOCCFG.

If the set from the CAN channel occurs simultaneously with the clear by the write access, then the bit is set.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

SOCO bit (Successful Occurrence Counter Overflow)

The SOCO bit indicates whether the related CAN channel successful occurrence counter has overflowed. This bit is cleared by writing 0 to it. Writing 1 has no effect.

This bit is set automatically when CFDCnFDSTS.SOC is 0xFF and a successful message reception or successful message transmission occurs.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode.

Write to this bit only when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

TDCVF bit (Transceiver Delay Compensation Violation Flag)

The CANFD module captures internally the transmitted data bit-by-bit. This data is then compared against the received CAN bus level which is delayed by the transceiver loop delay.

The transceiver delay has some variations depending on the physical parameters such as temperature. The result bit CFDCnFDSTS.TDCR is updated by each message. However, temporary maximum delay violation could be missed. Therefore, the TDCVF bit captures this violation.

This bit is cleared by writing 0 to it. Writing 1 has no effect.

This bit is set automatically when the transceiver delay compensation is greater than the maximum delay compensation (6 data bit times - 2 clk_dlc) and the internal bit is overrun.

If the set from the CAN channel occurs simultaneously with the clear by the write access, then the bit is set.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

Note: This bit is not available in the classical CAN function.

EOC[7:0] bits (Error Occurrence Counter)

The EOC[7:0] bits are used together with the SOC[7:0] bits to support an option for host-controlled fall-back to payload bit rate identical to arbitration bit rate when messages utilizing the reduced payload bit length have significant higher error rates compared to other messages.

This higher error rate can be detected depending on the configuration of the CFDCnFDCFG.EOCCFG bits.

The EOC[7:0] bits are set only by CANFD module logic. These bits are cleared by writing 1 to CFDCnFDCTR.EOCCLR. Writing any other value has no effect.

These bits are updated when an error occurs, according to the configuration of the CFDCnFDCFG.EOCCFG bits. When the counter reaches the value of 0xFF, the update stops.

These bits are cleared automatically when the related CANFD channel is in CH_RESET mode.

SOC[7:0] bits (Successful occurrence counter)

The SOC[7:0] bits are used together with the EOC[7:0] bits to support an option for host-controlled fall-back to payload bit rate identical to arbitration bit rate when messages utilizing the reduced payload bit length have significant higher error rates compared to other messages.

The SOC[7:0] bits are set only by CANFD module logic. Writing any other value has no effect.

These bits are updated when the occurrence of any error-free messages on the bus is detected through reception or transmission. When the counter reaches the value of 0xFF, the update stops.

Note: In Loopback mode, the counter is incremented twice.

These bits are cleared by writing 1 to CFDCnFDCTR.SOCCLR.

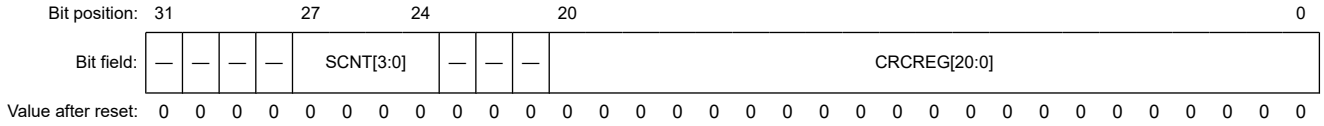
These bits are cleared automatically when the related CANFD channel is in CH_RESET mode.

32.2.11 CFDCnFDCRC : Channel n CANFD CRC Register (n = 0, 1)

This register is not available in the classical CAN function.

Base address: CANFD = 0x400B_0000

Offset address: 0x1410 + 0x20 × n



Bit	Symbol	Function	R/W
20:0	CRCREG[20:0]	CRC Register value These bits show the CRC value calculated for the CANFD frame.	R
23:21	—	These bits are read as 0. The write value should be 0.	R/W
27:24	SCNT[3:0]	Stuff bit count These bits shows the stuff bit count (mod 8) for the CANFD frame.	R
31:28	—	These bits are read as 0. The write value should be 0.	R/W

The Channel n CANFD CRC Register (n = 0, 1) holds the CRC value calculated for the CANFD frame.

CRCREG[20:0] bits (CRC Register value)

The CRCREG[20:0] bits contain the CRC value calculated by the CANFD channel logic when the CFDCnCTR.CTME bit is enabled.

The CFDCnFDCRC.CRCREG value is updated in the first bit of the CRC field of the CANFD frame (reception and transmission).

When the CFDCnCTR.CTME bit is 0, the CRCREG[20:0] bits are always read as 0.

When bit 17th of the CRC field is used, CRCREG[20:17] are always read as 0.

These bits are cleared automatically when the related CANFD channel is in CH_RESET mode.

SCNT[3:0] bits (Stuff bit count)

The SCNT[3:0] bits contain the stuff count value of the CANFD frame. These bits indicate the number of inserted stuff bits (modulo 8, Graycoded) for a CANFD frame when the CFDCnCTR.CTME bit is enabled in CFDCnFDCRC.SCNT[3:1]. SCNT[0] is the parity bit.

When the CFDCnCTR.CTME bit is 0, the SCNT[3:0] bits are always read as 0.

The SCNT value is updated in the first bit of CRC field of the CANFD frame (reception and transmission).

These bits are cleared automatically when the related CANFD channel is in CH_RESET mode.

32.2.12 CFDGCFG : Global Configuration Register

Base address: CANFD = 0x400B_0000

Offset address: 0x0084

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	ITRCP[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	TSBTCS[2:0]			TSSS	TSP[3:0]				—	—	CMPOC	DCS	MME	DRE	DCE	TPRI
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TPRI	Transmission Priority 0: ID priority 1: Message buffer number priority	R/W
1	DCE	DLC Check Enable 0: DLC check disabled 1: DLC check enabled	R/W
2	DRE	DLC Replacement Enable 0: DLC replacement disabled 1: DLC replacement enabled	R/W
3	MME	Mirror Mode Enable 0: Mirror mode disabled 1: Mirror mode enabled	R/W
4	DCS	Data Link Controller Clock Select 0: Internal clean clock 1: External clock source connected to CANMCLK pin	R/W
5	CMPOC*1	CAN-FD Message Payload Overflow Configuration 0: Message is rejected 1: Message payload is cut to fit to configured message size	R/W
7:6	—	These bits are read as 0. The write value should be 0.	R/W
11:8	TSP[3:0]	Timestamp Prescaler 0x0: Timestamp prescaler = 1 0x1: Timestamp prescaler = 2 0x2: Timestamp prescaler = 4 0x3: Timestamp prescaler = 8 ⋮ 0xD: Timestamp prescaler = 8192 0xE: Timestamp prescaler = 16384 0xF: Timestamp prescaler = 32768	R/W
12	TSSS	Timestamp Source Select 0: Source clock for timestamp counter is peripheral clock 1: Source clock for timestamp counter is bit time clock	R/W
15:13	TSBTCS[2:0]	Timestamp Bit Time Channel Select 0 0 0: Select clock from channel 0 0 0 1: Select clock from channel 1 Others: Setting prohibited	R/W
31:16	ITRCP[15:0]	Interval Timer Reference Clock Prescaler FIFO interval timer prescaler value	R/W

Note 1. This bit are not available in the classical CAN function.

The Global Configuration Register is used to select the transmission priority to be used for all the TX message buffers and the clock source for the CAN protocol engine of all CAN channels. The CFDGCFG register is also used to select the source for the timestamp clock and to configure the frequency for the timestamp clock and interval timer reference clock.

TPRI bit (Transmission Priority)

The TPRI bit selects the transmission priority for all CAN channels.

Do not write to this bit in GL_SLEEP mode. Only write to this bit when CAN-FD module is in GL_RESET mode.

Message buffer number priority should not be used together with TX queue transmission.

DCE bit (DLC Check Enable)

The DCE bit enables data length code (DLC) check for all CAN channels.

Do not write to this bit in GL_SLEEP mode. Only write to this bit when CAN-FD module is in GL_RESET mode.

DRE bit (DLC Replacement Enable)

When the DRE bit is 1 and the DCE is 1, the CAN-FD stores the configured value (CFDGAFLP0n.GAFLDLC) of the DLC in the destination RX message buffer or FIFO buffer if the DLC check passes. Otherwise, the DLC value in the destination RX message buffer or FIFO buffer is unchanged.

Do not write to this bit in GL_SLEEP mode. Only write to this bit when CAN-FD module is in GL_RESET mode.

MME bit (Mirror Mode Enable)

The MME bit enables the Mirror mode for all CAN channels.

Do not write to this bit in GL_SLEEP mode. Only write to this bit when CAN-FD module is in GL_RESET mode.

DCS bit (Data Link Controller Clock Select)

The DCS bit selects the clock source for CAN communication. Internal clean clock has a smaller clock jitter than the peripheral clock B (PCLKB).

Do not write to this bit in GL_SLEEP or GL_OPERATION mode. Only write to this bit when CAN-FD module is in GL_RESET mode.

CMPOC bit (CAN-FD Message Payload Overflow Configuration)

The CMPOC bit controls the message payload acceptance mechanism when the received payload is higher than the message buffer payload size CFDRMNB.RMPLS, CFDRFCCn.RFPLS, and CFDCFCCn.CFPLS. The received message payload is always compared with the available message payload size in the message buffer.

Do not write to this bit in GL_SLEEP or GL_OPERATION mode. Only write to this bit when CAN-FD module is in GL_RESET mode.

When this bit is set and payload overflow occurs, the DLC value is stored in the RX message buffer or FIFO buffer unchanged.

Note: This bit is not available in the classical CAN function.

TSP[3:0] bits (Timestamp Prescaler)

The value configured in the TSP[3:0] bits defines the period of the clock source used for the timestamp counter.

Do not write to this bit in GL_SLEEP mode. Only write to this bit when CAN-FD module is in GL_RESET mode.

TSSS bit (Timestamp Source Select)

The TSSS bit allows the selection of the clock source for the timestamp counter.

Do not write to this bit in GL_SLEEP mode. Only write to this bit when CAN-FD module is in GL_RESET mode. Additionally, do not set this bit to 1 when CAN-FD communication is used.*1

Note: The bit time clock varies depending on the nominal and data rate bit configuration.

Note 1. This feature is not available in the classical CAN function.

TSBTCS[2:0] bits (Timestamp Bit Time Channel Select)

The TSBTCS[2:0] bits allow the selection of the bit time clock of a particular channel for the timestamp counter.

Do not write to this bit in GL_SLEEP mode. Only write to this bit when CAN-FD module is in GL_RESET mode.

ITRCP[15:0] bits (Interval Timer Reference Clock Prescaler)

The ITRCP[15:0] bits allow the definition of a reference clock for the FIFO interval timer source clock.

When these bits are 0x0000, the timer is disabled.

Do not write to this bit in GL_SLEEP mode. Only write to this bit when CAN-FD module is in GL_RESET mode.

32.2.13 CFDGCTR : Global Control Register

Base address: CANFD = 0x400B_0000

Offset address: 0x0088

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TSRST
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	MOWEIE	QMEIE	—	—	CMPOFIE	THLEIE	MEIE	DEIE	—	—	—	—	—	GSLPR	GMDC[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	1

Bit	Symbol	Function	R/W
1:0	GMDC[1:0]	Global Mode Control 0 0: Global operation mode request 0 1: Global reset mode request 1 0: Global halt mode request 1 1: Keep current value	R/W
2	GSLPR	Global Sleep Request 0: Global sleep request disabled 1: Global sleep request enabled	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W
8	DEIE	DLC Check Interrupt Enable 0: DLC check interrupt disabled 1: DLC check interrupt enabled	R/W
9	MEIE	Message Lost Error Interrupt Enable 0: Message lost error interrupt disabled 1: Message lost error interrupt enabled	R/W
10	THLEIE	TX History List Entry Lost Interrupt Enable 0: TX history list entry lost interrupt disabled 1: TX history list entry lost interrupt enabled	R/W
11	CMPOFIE*1	CANFD Message Payload Overflow Flag Interrupt Enable 0: CANFD message payload overflow flag interrupt disabled 1: CANFD message payload overflow flag interrupt enabled	R/W
13:12	—	These bits are read as 0. The write value should be 0.	R/W
14	QMEIE	TXQ Message Lost Error Interrupt Enable 0: TXQ message lost error interrupt disabled 1: TXQ message lost error interrupt enabled	R/W
15	MOWEIE	GW FIFO Message Overwrite Error Interrupt Enable 0: GW FIFO message overwrite error interrupt disabled 1: GW FIFO message overwrite error interrupt enabled	R/W
16	TSRST	Timestamp Reset 0: Timestamp not reset 1: Timestamp reset	R/W
31:17	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. This bit is not available in the classical CAN function.

The Global Control Register controls the global mode of the CANFD module and the timestamp function. The register also enables and disables the global error interrupts.

GMDC bits (Global Mode Control)

The GMDC bits can be used to configure the modes for the CANFD module. Additionally, if CFDGCTR.GSLPR bit is 1 when the CANFD module is in Reset mode, the CANFD module enters Global Sleep mode. Additionally, if CFDGCTR.GSLPR is 1 when the CANFD module is in Reset Mode, then the CANFD module enters Global Sleep Mode.

Setting the GMDC bits to 11b has no effect. Mode transition is described in detail in section 32.3.2. Global Modes.

Do not write to this bit when the CANFD module is in GL_SLEEP mode.

GSLPR bit (Global Sleep Request)

The GSLPR bit globally selects the sleep request for CANFD module including all CAN channels. Channel sleep request is set automatically for all channels.

Only write to this bit when the CANFD module is in GL_RESET or GL_SLEEP mode.

DEIE bit (DLC Check Interrupt Enable)

When the DEIE bit is 1, an interrupt is generated if a DLC error is detected in the received frames.

Do not write to this bit when the CANFD module is in GL_SLEEP mode.

MEIE bit (Message Lost Error Interrupt Enable)

When the MEIE bit is 1, an interrupt is generated if a message lost condition occurs.

Do not write to this bit when the CANFD module is in GL_SLEEP mode.

THLEIE bit (TX History List Entry Lost Interrupt Enable)

When the THLEIE bit is 1, an interrupt is generated if a TX history list entry lost condition occurs.

Do not write to this bit when the CANFD module is in GL_SLEEP mode.

CMPOFIE bit (CANFD Message Payload Overflow Flag Interrupt Enable)

When the CMPOFIE bit is 1, an interrupt is generated when a CANFD message payload overflow condition occurs.

Do not write to this bit when the CANFD module is in GL_SLEEP mode.

Note: This bit is not available in the classical CAN function

QMEIE bit (TXQ Message Lost Error Interrupt Enable)

When the QMEIE bit is 1, an interrupt is generated when a TXQ message lost condition occurs.

Do not write to this bit when the CANFD module is in GL_SLEEP mode.

MOWEIE bit (GW FIFO Message Overwrite Error Interrupt Enable)

When the MOWEIE bit is 1, an interrupt is generated in GW mode and a GW FIFO message over write condition occurs.

Do not write to this bit when the CANFD module is in GL_SLEEP mode.

TSRST bit (Timestamp Reset)

When the TSRST bit is 1, the Global Timestamp Register is reset to 0x0000.

Do not write to this bit when the CANFD module is in GL_SLEEP or GL_RESET mode.

Read value is always 0.

This bit is cleared automatically by the CANFD module logic.

32.2.14 CFDGSTS : Global Status Register

Base address: CANFD = 0x400B_0000

Offset address: 0x008C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	GRAMINIT	GSLPSTS	GHLTSTS	GRSTSTS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0	1

Bit	Symbol	Function	R/W
0	GRSTSTS	Global Reset Status 0: Not in Reset mode 1: In Reset mode	R
1	GHLTSTS	Global Halt Status 0: Not in Halt mode 1: In Halt mode	R
2	GSLPSTS	Global Sleep Status 0: Not in Sleep mode 1: In Sleep mode	R
3	GRAMINIT	Global RAM Initialization 0: RAM initialization is complete 1: RAM initialization is ongoing	R
31:4	—	These bits are read as 0.	R

The Global Status Register indicates the global status of the CANFD module.

GRSTSTS bit (Global Reset Status)

The GRSTSTS bit indicates the status of Global CANFD module Reset mode.

This bit is set automatically when the CANFD module enters GL_RESET mode. When the mode changes from GL_RESET mode to GL_SLEEP mode, this bit remains set.

This bit is cleared automatically when the CANFD module exits the GL_RESET mode.

GHLTSTS bit (Global Halt Status)

The GHLTSTS bit indicates the status of Global CANFD module Halt mode.

This bit is set automatically when the CANFD module enters GL_HALT mode.

This bit is cleared automatically when the CANFD module exits the GL_HALT mode.

GSLPSTS bit (Global Sleep Status)

The GSLPSTS bit indicates the status of Global CANFD module Sleep mode.

This bit is set automatically when the CANFD module enters GL_SLEEP mode.

This bit is cleared automatically when the CANFD module exits the GL_SLEEP mode.

GRAMINIT bit (Global RAM Initialization)

The GRAMINIT bit indicates the status of Global CANFD module RAM initialization.

This bit is set automatically when the CANFD module enters GL_SLEEP mode after a hardware reset.

This bit is cleared automatically when the CANFD module completed RAM initialization.

This bit is cleared when the test_mode input port is set to 1.

32.2.15 CFDGERFL : Global Error Flag Register

Base address: CANFD = 0x400B_0000

Offset address: 0x0090

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	EEF1	EEF0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	QMES	—	QOWES	CMPOF	THLES	MES	DEF
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	DEF	DLC Error Flag 0: DLC error not detected 1: DLC error detected	R/W
1	MES	Message Lost Error Status 0: Message lost error not detected 1: Message lost error detected	R
2	THLES	TX History List Entry Lost Error Status 0: TX history list entry lost error not detected 1: TX history list entry lost error detected	R
3	CMPOF*1	CANFD Message Payload Overflow Flag 0: CANFD message payload overflow not detected 1: CANFD message payload overflow detected	R/W
4	QOWES	TXQ Message Overwrite Error Status 0: TXQ message overwrite error not detected 1: TXQ message overwrite error detected	R
5	—	This bit is read as 0. The write value should be 0.	R
6	QMES	TXQ Message Lost Error Status 0: TXQ message lost error not detected 1: TXQ message lost error detected	R
15:7	—	These bits are read as 0. The write value should be 0.	R/W
16	EEF0	ECC Error Flag for Channel 0 0: ECC error not detected during TX-SCAN 1: ECC error detected during TX-SCAN	R/W
17	EEF1	ECC Error Flag for Channel 1 0: ECC error not detected during TX-SCAN 1: ECC error detected during TX-SCAN	R/W
31:18	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. This bit is not available in the classical CAN function.

The Global Error Flag register indicates the detection of global errors.

DEF bit (DLC Error Flag)

The DEF bit indicates the error status of the DLC.

Do not write to this bit when the CANFD module is in GL_SLEEP or GL_RESET mode. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

This bit is set automatically when a DLC error is detected in a received frame.

If the set from the CAN channel occurs simultaneously with the clear by the write access, then the bit is set

The bit is cleared by writing 0 to it.

This bit is cleared automatically in GL_RESET mode.

MES bit (Message Lost Error Status)

The MES bit indicates status of the message lost error.

This bit is set automatically when a FIFO message lost error is detected.

This bit is cleared automatically when:

- All FIFO message lost flags are cleared
- The CANFD module is in GL_RESET mode.

THLES bit (TX History List Entry Lost Error Status)

The THLES bit indicates status of the TX history list entry lost error.

This bit is set automatically when a TX history list entry lost error is detected.

This bit is cleared automatically when:

- All TX history list entry lost flags are cleared
- The CANFD module is in GL_RESET mode.

CMPOF bit (CANFD Message Payload Overflow Flag)

The CMPOF bit is set automatically when a CANFD message payload overflow is detected on at least one channel.

Do not write to this bit when the CANFD module is in GL_SLEEP or GL_RESET mode.

This bit is cleared by writing 0 to it. Writing 1 to this bit has no effect.

If the set from the CAN channel occurs simultaneously with the clear by the write access, then the bit is set.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

This bit is cleared automatically in GL_RESET mode.

Note: This bit is not available in the classical CAN function

QOWES bit (TXQ Message Overwrite Error Status)

The QOWES bit is set automatically when a TXQ message overwrite error is detected.

This bit is cleared automatically when all TXQ message overwrite flags are cleared.

This bit is cleared automatically in GL_RESET mode.

QMES bit (TXQ Message Lost Error Status)

The QMES bit is set automatically when a TXQ message lost error is detected.

This bit is cleared automatically when all TXQ message lost flags are cleared.

This bit is cleared automatically in GL_RESET mode.

EEF0 bit (ECC Error Flag for Channel 0)

The EEF0 bit specifies whether an ECC error has occurred on Channel 0.

Do not write to this bit when the CANFD module is in GL_SLEEP or GL_RESET mode. Writing 1 to this bit has no effect.

If the set from the CAN channel occurs simultaneously with the clear by the write access, then the bit is set.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

The bit is cleared by writing 0 to it. This bit is cleared automatically in GL_RESET mode.

EEF1 bit (ECC Error Flag for Channel 1)

The EEF1 bit specifies whether an ECC error has occurred on Channel 1.

Do not write to this bit when the CANFD module is in GL_SLEEP or GL_RESET mode. Writing 1 to this bit has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

The bit is cleared by writing 0 to it. This bit is cleared automatically in GL_RESET mode.

32.2.16 CFDGTINTSTS0 : Global TX Interrupt Status Register 0

Base address: CANFD = 0x400B_0000

Offset address: 0x1300

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

31:15	—	These bits are read as 0.	R

The Global TX Interrupt Status register indicates the detection of transmit specific interrupts.

TSIF0 bit (TX Successful Interrupt Flag Channel 0)

The TSIF0 bit is set to 1 when the TX Successful Interrupt flag of the related channel is set (when the interrupt is enabled). This bit is cleared automatically:

- When the related TX MB Result Status bits are cleared (when the interrupt enable is disabled)
- When in GL_RESET or CH_RESET mode.

TAI0 bit (TX Abort Interrupt Flag Channel 0)

The TAIF0 bit is set to 1 when the TX Abort Interrupt flag of the related channel is set (when the interrupt is enabled).

This bit is cleared automatically:

- When the related TX MB Result Status bits are cleared (when the interrupt enable is disabled)
- When in GL_RESET or CH_RESET mode.

TQIF0 bit (TX Queue Interrupt Flag Channel 0)

The TQIF0 bit is set to 1 when the TX Queue Interrupt flag of the related channel is set (when the interrupt is enabled). This bit is cleared automatically:

- When the related TX Queue Interrupt flag is cleared (when the interrupt is enable disabled)
- When in GL_RESET or CH_RESET mode.

CFTIF0 bit (COM FIFO TX/GW Mode Interrupt Flag Channel 0)

The CFTIF0 bit is set to 1 when the related COM TX/GW FIFO Mode Interrupt flag (CFDCFSTSn.CFTXIF) is set (when the interrupt is enabled).

This bit is cleared automatically:

- When the related COM TX/GW FIFO Mode Interrupt flag (CFDCFSTSn.CFTXIF) is cleared (when the interrupt enable is disabled)
- When in GL_RESET or CH_RESET mode.

THIF0 bit (TX History List Interrupt Channel 0)

The THIF0 bit is set to 1 when the related TX History List Interrupt flag (CFDTHLSTSn.THLIF) is set (when the interrupt is enabled).

This bit is cleared automatically:

- When the related TX History List Interrupt flag (CFDTHLSTSn.THLIF) is cleared (when the interrupt enable is disabled)
- When in GL_RESET or CH_RESET mode.

CFDGTINTSTS0.TQOFIFn bit (TX Queue One Frame Transmission Interrupt Flag Channel n (n = 0, 1))

The CFDGTINTSTS0.TQOFIFn bit is set to 1 when the TX Queue One Frame Transmission Interrupt flag of the related channel is set (when the interrupt is enabled).

This bit is cleared automatically:

- When the related TX Queue One Frame Transmission Interrupt flag is cleared (when the interrupt enable is disabled)
- When in GL_RESET or CH_RESET mode.

CFDGTINTSTS0.CFOTIFn bit (COM FIFO One Frame Transmission Interrupt Flag Channel n (n = 0, 1))

The CFDGTINTSTS0.CFOTIFn bit is set to 1 when the related COM FIFO One Frame Transmission Interrupt flag (CFDCFSTSn.CFOFTXIF) is set (when the Interrupt is enabled).

This bit is cleared automatically:

- When the related COM FIFO One Frame Transmission Interrupt flag (CFDCFSTSn.CFOFTXIF) is cleared (when the interrupt enable is disabled)
- When in GL_RESET or CH_RESET mode.

TSIF1 bit (TX Successful Interrupt Flag Channel 1)

The TSIF1 bit is set to 1 when the TX Successful Interrupt flag of the related channel is set (when the interrupt is enabled).
This bit is cleared automatically:

- When the related TX MB Result Status bits are cleared (when the interrupt enable is disabled)
- When in GL_RESET or CH_RESET mode.

TAIF1 bit (TX Abort Interrupt Flag Channel 1)

The TAIF1 bit is set to 1 when the TX Abort Interrupt flag of the related channel is set (when the interrupt is enabled).

This bit is cleared automatically:

- When the related TX MB Result Status bits are cleared (when the interrupt enable is disabled)
- When in GL_RESET or CH_RESET mode.

TQIF1 bit (TX Queue Interrupt Flag Channel 1)

The TQIF1 bit is set to 1 when the TX Queue Interrupt flag of the related channel is set (when the interrupt is enabled).
This bit is cleared automatically:

- When the related TX Queue Interrupt flag is cleared (when the interrupt is enable disabled)
- When in GL_RESET or CH_RESET mode.

CFTIF1 bit (COM FIFO TX/GW Mode Interrupt Flag Channel 1)

The CFTIF1 bit is set to 1 when the related COM TX/GW FIFO Mode Interrupt flag (CFDCFSTSn.CFTXIF) is set (when the interrupt is enabled).

This bit is cleared automatically:

- When the related COM TX/GW FIFO Mode Interrupt flag (CFDCFSTSn.CFTXIF) is cleared (when the interrupt enable is disabled)
- When in GL_RESET or CH_RESET mode.

THIF1 bit (TX History List Interrupt Channel 1)

The THIF1 bit is set to 1 when the related TX History List Interrupt flag (CFDTHLSTSn.THLIF) is set (when the interrupt is enabled).

This bit is cleared automatically:

- When the related TX History List Interrupt flag (CFDTHLSTSn.THLIF) is cleared (when the interrupt enable is disabled)
- When in GL_RESET or CH_RESET mode.

32.2.17 CFDGTSC : Global Timestamp Counter Register

Base address: CANFD = 0x400B_0000

Offset address: 0x0094

Bit position:	31															15														0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TS[15:0]														
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	TS[15:0]	Timestamp value	R
31:16	—	These bits are read as 0.	R

The Global Timestamp Counter register stores the timestamp based on the selected configuration.

TS[15:0] bits (Timestamp value)

The Timestamp value is stored in the Global Timestamp Counter register based on the configuration of TSSS, TSBTCS and TSP. The accuracy of the timestamp counter cannot be guaranteed when transitioning to halt state.

The Timestamp value is stored in this register based on the configuration of TSSS, TSBTCS and TSP.

Do not write to bits TS[15:0] when the CANFD module is in GL_RESET or GL_SLEEP mode.

The TS[15:0] bits are cleared automatically in GL_RESET mode.

32.2.18 CFDGAFLECTR : Global Acceptance Filter List Entry Control Register

Base address: CANFD = 0x400B_0000

Offset address: 0x0098

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	AFLDAE	—	—	—	—	AFLPN[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	AFLPN[3:0]	Acceptance Filter List Page Number Select an Acceptance Filter List page	R/W
7:4	—	These bits are read as 0. The write value should be 0.	R/W
8	AFLDAE	Acceptance Filter List Data Access Enable 0: Acceptance Filter List data access disabled 1: Acceptance Filter List data access enabled	R/W
31:9	—	These bits are read as 0. The write value should be 0.	R/W

The Global Acceptance Filter List Entry Control Register is used to select the Global Acceptance Filter List page for reading or writing entries into the Global Acceptance Filter List.

AFLPN[3:0] bits (Acceptance Filter List Page Number)

The AFLPN[3:0] bits select the page number to access the desired RAM area of the Acceptance Filter List. One Acceptance Filter List page consists of 16 Acceptance Filter List entries.

Read/write accesses to the Acceptance Filter List can only be performed through a fixed window.

Do not write to these bits when the CAN-FD module is in GL_SLEEP mode. Enter only the values between 0x00 and 0x07, inclusive.

AFLDAE bit (Acceptance Filter List Data Access Enable)

The AFLDAE bit prevents write access to the Acceptance Filter List when cleared after configuration of the Acceptance Filter List.

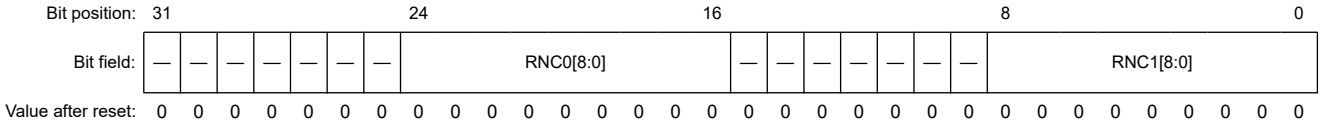
Data can be read from the Acceptance Filter List independent of the status of this bit.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode. Set this bit to enable write access for the Acceptance Filter List.

32.2.19 CFDGAFLCFG0 : Global Acceptance Filter List Configuration Register 0

Base address: CANFD = 0x400B_0000

Offset address: 0x009C



Bit	Symbol	Function	R/W
8:0	RNC1[8:0]	Rule Number for Channel 1 Number of rules dedicated to channel 1	R/W
15:9	—	These bits are read as 0. The write value should be 0.	R/W
24:16	RNC0[8:0]	Rule Number for Channel 0 Number of rules dedicated to channel 0	R/W
31:25	—	These bits are read as 0. The write value should be 0.	R/W

The Global Acceptance Filter List Configuration Register 0 is used to define the number of rules for entries in the Acceptance Filter List, applicable for channels 0 to 1.

The total number of available entries in the Acceptance Filter List is 64 × (n + 1), 128 for 2 CAN channels. However, the filters can be allocated flexibly to the different channels depending on requirements as long as both of the following conditions are satisfied:

- The maximum number of acceptance filter per channel is 384
- The total number of rules defined for all channels is not exceeding the number of available entries in the Acceptance Filter List.

RNC0[8:0] bits (Rule Number for Channel n (n = 0, 1))

The RNC0[8:0] bits define the number of rules in the Acceptance Filter List for channel n.

Only write to these bits when the CAN-FD module is in GL_RESET mode.

32.2.20 CFDGAFLIDn : Global Acceptance Filter List ID Registers (n = 1 to 16)

Base address: CANFD = 0x400B_0000

Offset address: 0x1800 + 0x10 × (n - 1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	GAFLIDE	GAFLRTR	GAFLLB	GAFLID[28:16]												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	GAFLID[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
28:0	GAFLID[28:0]	Global Acceptance Filter List Entry ID Field ID part of the Global Acceptance Filter List entry	R/W
29	GAFLLB	Global Acceptance Filter List Entry Loopback Configuration 0: Global Acceptance Filter List entry ID for acceptance filtering with attribute RX 1: Global Acceptance Filter List entry ID for acceptance filtering with attribute TX	R/W
30	GAFLRTR	Global Acceptance Filter List Entry RTR Field 0: Data frame 1: Remote frame	R/W
31	GAFLIDE	Global Acceptance Filter List Entry IDE Field 0: Standard identifier of rule entry ID is valid for acceptance filtering 1: Extended identifier of rule entry ID is valid for acceptance filtering	R/W

The Global Acceptance Filter List ID Registers (n = 1 to 16) are used to configure the ID field for the rules of entries in the Global Acceptance Filter List.

GAFLID[28:0] bits (Global Acceptance Filter List Entry ID Field)

The GAFLID[28:0] bits represent the CAN identifier (ID) field of each entry in the Global Acceptance Filter List.

Do not write to these bits when CFDGAFLECTR.AFLDAE bit is 0.

Only write to these bits when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

GAFLLB bit (Global Acceptance Filter List Entry Loopback Configuration)

The GAFLLB bit selects whether entry in the Global Acceptance Filter List gets the attribute RX or TX.

This attribute determines the validity of the entry in Mirror mode, Loopback test mode, and during standard (non-loopback) reception. See section 32.5.5. Loopback Modes for detailed description of the validity of the Global Acceptance Filter List entry depending on transmitter/receiver case, the type of loopback mode, and RX/TX attribute.

Do not write to this bit when CFDGAFLECTR.AFLDAE bit is 0.

Only write to this bit when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

GAFLRTR bit (Global Acceptance Filter List Entry RTR Field)

The GAFLRTR bit allows the configuration of the specified frame format (data frame or remote frame) for each entry of the Global Acceptance Filter List. For each rule entry in a CAN channel, the acceptance filter process compares this bit against the RTR bit of the received CAN message.

Do not write to this bit when CFDGAFLECTR.AFLDAE bit is 0.

Only write to this bit when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

GAFLIDE bit (Global Acceptance Filter List Entry IDE Field)

The GAFLIDE bit allows the configuration of the ID format (standard ID or extended ID) for each entry in the Global Acceptance Filter List. For each rule entry in a CAN channel, the acceptance filter process compares this bit against the IDE bit of the received CAN message.

Do not write to this bit when CFDGAFLECTR.AFLDAE bit is 0.

Only write to this bit when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

32.2.21 CFDGAFLMn : Global Acceptance Filter List Mask Registers (n = 1 to 16)

Base address: CANFD = 0x400B_0000

Offset address: 0x1804 + 0x10 × (n - 1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	GAFLIDEM	GAFLRTRM	GAFLIFL1	GAFLIDM[28:16]												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	GAFLIDM[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
28:0	GAFLIDM[28:0]	Global Acceptance Filter List ID Mask Field Global Acceptance Filter List Mask field bits for ID field	R/W
29	GAFLIFL1	Global Acceptance Filter List Information Label 1 Global Acceptance Filter List information label bit 1	R/W
30	GAFLRTRM	Global Acceptance Filter List Entry RTR Mask 0: RTR bit is not used for ID matching 1: RTR bit is used for ID matching	R/W
31	GAFLIDEM	Global Acceptance Filter List IDE Mask 0: IDE bit is not used for ID matching 1: IDE bit is used for ID matching	R/W

The Global Acceptance Filter List Mask Registers are used to configure the Mask field of each rule for entries in the Global Acceptance Filter List.

GAFLIDM[28:0] bits (Global Acceptance Filter List ID Mask Field)

GAFLIDM[28:0] bits are the filter mask bits for the related bits in the CAN Identifier field of each Global Acceptance Filter List entry.

0	Corresponding STD-ID/EXT-ID bit is not used for ID matching
1	Corresponding STD-ID/EXT-ID bit is used for ID matching

Do not write to these bits when CFDGAFLECTR.AFLDAE bit is 0.

Only write to these bits when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

GAFLIFL1 bit (Global Acceptance Filter List Information Label 1)

The GAFLIFL1 bit allows the configuration of a 2-bit information label to be attached to a received message accepted by the associated entry in the Global Acceptance Filter List. This bit is a MSB bit of an information label.

Do not write to this bit when CFDGAFLECTR.AFLDAE bit is 0.

Only write to this bit when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

This bit is stored in the Information Label Field [1] (CFDRMFDSTSn.RMIFL [1], CFDRFFDSTSn.RFIFL [1], CFDCFFDCSTSn.CFIFL [1]) of the storage location of an incoming message.

Note: This bit is stored in CFDTHLACC1n.TIFL [1] when CFDTHLCCn.THLDGE = 1 is set up using Gateway function.

GAFLRTRM bit (Global Acceptance Filter List Entry RTR Mask)

The GAFLRTRM bit allows the configuration of the RTR mask bit for each entry in the Global Acceptance Filter List.

Do not write to this bit when CFDGAFLECTR.AFLDAE bit is 0.

Only write to this bit when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

GAFLIDEM bit (Global Acceptance Filter List IDE Mask)

The GAFLIDEM bit allows the configuration of the IDE mask bit for each entry in the Global Acceptance Filter List.

When the IDE mask bit is 0, the ID comparison depends on the received IDE bit.

If the received IDE bit is 0, the STD-ID comparison takes place.

If the received IDE bit is 1, the EXT-ID comparison takes place.

Do not write to this bit when CFDGAFLECTR.AFLDAE bit is 0.

Only write to this bit when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

32.2.22 CFDGAFLP0n : Global Acceptance Filter List Pointer 0 Registers (n = 1 to 16)

Base address: CANFD = 0x400B_0000

Offset address: 0x1808 + 0x10 × (n - 1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	GAFLPTR[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	GAFL RMV	—	—	GAFLRMDP[4:0]					GAFLI FL0	GAFL SRD2	GAFL SRD1	GAFL SRD0	GAFLDLC[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	GAFLDLC[3:0]	Global Acceptance Filter List DLC Field Minimum number of data bytes in a data frame required for acceptance	R/W
4	GAFLSRD0	Global Acceptance Filter List Select Routing Destination 0 0: Routing target is CFIFO0 1: Routing target is TX Queue 0 instead of CFIFO0	R/W
5	GAFLSRD1	Global Acceptance Filter List Select Routing Destination 1 0: Routing target is CFIFO1 1: Routing target is TX Queue 1 instead of CFIFO1	R/W
6	GAFLSRD2	Global Acceptance Filter List Select Routing Destination 2 0: Routing target is CFIFO2 1: Routing target is TX Queue 2 instead of CFIFO2	R/W
7	GAFLIFL0	Global Acceptance Filter List Information Label 0	R/W
12:8	GAFLRMDP[4:0]	Global Acceptance Filter List RX Message Buffer Direction Pointer RX message buffer number for storage of received messages	R/W
14:13	—	These bits are read as 0. The write value should be 0.	R/W
15	GAFLRMV	Global Acceptance Filter List RX Message Buffer Valid 0: Single message buffer direction pointer is invalid 1: Single message buffer direction pointer is valid	R/W
31:16	GAFLPTR[15:0]	Global Acceptance Filter List Pointer	R/W

The Global Acceptance Filter List Pointer 0 Registers (n = 1 to 16) are used to configure the data length code (DLC), software pointer, single message buffer select, and message buffer direction pointer for each rule entry in the Global Acceptance Filter List.

GAFLDLC[3:0] bits (Global Acceptance Filter List DLC Field)

The GAFLDLC[3:0] bits allow the configuration of a minimum data length code (DLC) value for a message to be accepted by the associated entry in the Global Acceptance Filter List (automatic DLC filter function).

DLC filter process is only passed if the DLC value of the message accepted by an entry in the Global Acceptance Filter List is equal to or higher than the DLC value configured for this associated Global Acceptance Filter List entry. Automatic DLC filter function is disabled for the corresponding rule entry when this field is set to 0.

Table 32.4 shows DLC value that can be configured.

Table 32.4 Configuration of DLC value

Format	DLC[3]	DLC[2]	DLC[1]	DLC[0]	Description
CAN and CAN-FD	0	0	0	0	DLC of received message = 0 or more (DLC filter check is disabled)
CAN and CAN-FD	0	0	0	1	DLC of received message = 1 or more
CAN and CAN-FD	0	0	1	0	DLC of received message = 2 or more
CAN and CAN-FD	0	0	1	1	DLC of received message = 3 or more
CAN and CAN-FD	0	1	0	0	DLC of received message = 4 or more
CAN and CAN-FD	0	1	0	1	DLC of received message = 5 or more
CAN and CAN-FD	0	1	1	0	DLC of received message = 6 or more
CAN and CAN-FD	0	1	1	1	DLC of received message = 7 or more
CAN	1	x	x	x	DLC of received message = 8 or more
CAN-FD	1	0	0	0	DLC of received message = 8 or more*1
CAN-FD	1	0	0	1	DLC of received message = 12 or more*1
CAN-FD	1	0	1	0	DLC of received message = 16 or more*1
CAN-FD	1	0	1	1	DLC of received message = 20 or more*1
CAN-FD	1	1	0	0	DLC of received message = 24 or more*1
CAN-FD	1	1	0	1	DLC of received message = 32 or more*1
CAN-FD	1	1	1	0	DLC of received message = 48 or more*1
CAN-FD	1	1	1	1	DLC of received message = 64*1

Note 1. This setting is not available in the classical CAN function.

Do not write to these bits when CFDGAFLECTR.AFLDAE bit is 0.

Only write to these bits when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

GAFLSRD0 bit (Global Acceptance Filter List Select Routing Destination 0)

The GAFLSRD0 bit changes a copy destination to CFIFO0 or TXQ0 by routing.

If this bit is set as 1, the preset value of CFDGAFLP1n.GAFLFDP selects TX Queue.

If this bit is set to 0, the preset value of CFDGAFLP1n.GAFLFDP selects CFIFO0.

Do not write to this bit when CFDGAFLECTR.AFLDAE bit is 0.

Only write to the bit when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

GAFLSRD1 bit (Global Acceptance Filter List Select Routing Destination 1)

The GAFLSRD1 bit changes a copy destination to CFIFO1 or TXQ1 by routing.

If this bit is set to 1, the preset value of CFDGAFLP1n.GAFLFDP selects TXQ1.

If this bit is set to 0, the preset value of CFDGAFLP1n.GAFLFDP selects CFIFO1.

Do not write to this bit when CFDGAFLECTR.AFLDAE bit is 0.

Only write to the bit when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

GAFLSRD2 bit (Global Acceptance Filter List Select Routing Destination 2)

The GAFLSRD2 bit changes a copy destination to CFIFO2 or TXQ2 by routing.

If this bit is set to 1, the preset value of CFDGAFLP1n.GAFLFDP selects TXQ2.

If this bit is set to 0, the preset value of CFDGAFLP1n.GAFLFDP selects CFIFO2.

Do not write to this bit when CFDGAFLECTR.AFLDAE bit is 0.

Only write to the bit when the CAN-FD module is in CH_RESET or CH_HALT mode.

GAFLIFL0 bit (Global Acceptance Filter List Information Label 0)

The GAFLIFL0 bit allows the configuration of a 2-bit information label that can be attached to a received message accepted by the related Global Acceptance Filter List entry. This bit is a LSB bit of an information label.

You cannot write to this bit when CFDGAFLECTR.AFLDAE bit is 0.

Only write to the bit when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

This bit is stored in Information Label Field[0] (CFDRMFDSTSn.RMIFL[0], CFDRFFDSTSn.RFIFL[0],CFDCFFDCSTSn.CFIFL[0]) of the storage location of an incoming message.

This bit is stored in CFDTHLACC1n.TIFL[0] when CFDTHLCCn.THLDGE = 1 is set up using the gateway function.

GAFLRMDP[4:0] bits (Global Acceptance Filter List RX Message Buffer Direction Pointer)

The GAFLRMDP[4:0] bits allow the configuration of a single reception message buffer as the destination target for a received message that passes the acceptance check of the related Global Acceptance Filter List entry. The value entered is the single destination message buffer number.

Do not write to these bits when CFDGAFLECTR.AFLDAE bit is 0.

Only write to these bits when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

CFDRMNB.NRXMB[7:0] is the value entered in the RX Message Buffer Number Register to configure the number of RX message buffers. The value to be entered in CFDGAFLP0n.GAFLRMDP[6:0] bits should only be between 0x00 and CFDMNB.NMB[7:0] to 1 less.

If CFDRMNB.NRXMB[7:0] = 0x00, the GAFLRMV bit should be configured as 0.

GAFLRMV bit (Global Acceptance Filter List RX Message Buffer Valid)

The GAFLRMV bit allows the enabling or disabling of a single reception message buffer as the target for a received message that passes the acceptance check of the related Global Acceptance Filter List entry.

Do not write to these bits when CFDGAFLECTR.AFLDAE bit is 0.

Only write to these bits when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

GAFLPTR[15:0] bits (Global Acceptance Filter List Pointer)

The GAFLPTR[15:0] bits allow the configuration of a 16-bit pointer to be attached to a received message accepted by the related Global Acceptance Filter List entry. The pointer is added during message storage in the Message Buffer area and can be used by the application as a support function. The pointer information can be used for example, to support PDU Identifier allocation for the received message in AUTOSAR systems.

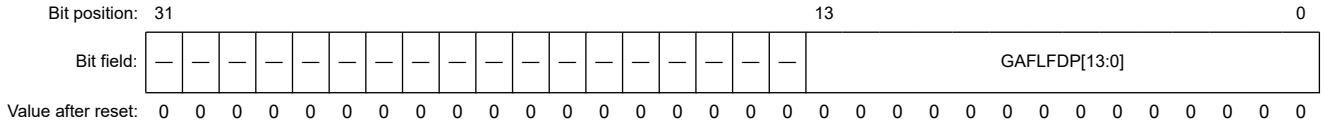
Do not write to these bits when CFDGAFLECTR.AFLDAE bit is 0.

Only write to these bits when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

32.2.23 CFDGAFLP1n : Global Acceptance Filter List Pointer 1 Registers (n = 1 to 16)

Base address: CANFD = 0x400B_0000

Offset address: 0x180C + 0x10 × (n - 1)



Bit	Symbol	Function	R/W
13:0	GAFLFDP[13:0]	Global Acceptance Filter List FIFO Direction Pointer FIFO direction pointer bits for received message storage	R/W
31:14	—	These bits are read as 0. The write value should be 0.	R/W

The Global Acceptance Filter List Pointer 1 registers are used to configure the FIFO direction pointer fields in each Rule Entry of the Global Acceptance Filter List.

GAFLFDP[13:0] bits (Global Acceptance Filter List FIFO Direction Pointer)

The GAFLFDP[13:0] bits allow the configuration of FIFO buffers as the target for a received message that passes the acceptance check of the related Global Acceptance Filter List entry. Each bit of the CFDGAFLP1n.GAFLFDP[13:0] is configured as dedicated FIFO.

Bit	Value (binary)	Function
0	0	Disable RX FIFO 0 as target for reception
	1	Enable RX FIFO 0 as target for reception
1	0	Disable RX FIFO 1 as target for reception
	1	Enable RX FIFO 1 as target for reception
2	0	Disable RX FIFO 2 as target for reception
	1	Enable RX FIFO 2 as target for reception
3	0	Disable RX FIFO 3 as target for reception
	1	Enable RX FIFO 3 as target for reception
4	0	Disable RX FIFO 4 as target for reception
	1	Enable RX FIFO 4 as target for reception
5	0	Disable RX FIFO 5 as target for reception
	1	Enable RX FIFO 5 as target for reception
6	0	Disable RX FIFO 6 as target for reception
	1	Enable RX FIFO 6 as target for reception
7	0	Disable RX FIFO 7 as target for reception
	1	Enable RX FIFO 7 as target for reception
8	0	Disable Common FIFO 0 and Channel 0 TX Queue 0 as target for reception
	1	GAFLSRD0 = 0: Enable Common FIFO 0 as target for reception GAFLSRD0 = 1: Enable Channel 0 TX Queue 0 as target for reception
9	0	Disable Common FIFO 1 and Channel 0 TX Queue 1 as target for reception
	1	GAFLSRD1 = 0: Enable Common FIFO 1 as target for reception GAFLSRD1 = 1: Enable Channel 0 TX Queue 1 as target for reception
10	0	Disable Common FIFO 2 and Channel 0 TX Queue 2 as target for reception
	1	GAFLSRD2 = 0: Enable Common FIFO 2 as target for reception GAFLSRD2 = 1: Enable Channel 0 TX Queue 2 as target for reception

Bit	Value (binary)	Function
11	0	Disable Common FIFO 3 and Channel 1 TX Queue 0 as target for reception
	1	GAFLSRD0 = 0: Enable Common FIFO 3 as target for reception GAFLSRD0 = 1: Enable Channel 1 TX Queue 0 as target for reception
12	0	Disable Common FIFO 4 and Channel 1 TX Queue 1 as target for reception
	1	GAFLSRD1 = 0: Enable Common FIFO 4 as target for reception GAFLSRD1 = 1: Enable Channel 1 TX Queue 1 as target for reception
13	0	Disable Common FIFO 5 and Channel 1 TX Queue 2 as target for reception
	1	GAFLSRD2 = 0: Enable Common FIFO 5 as target for reception GAFLSRD2 = 1: Enable Channel 1 TX Queue 2 as target for reception

Do not write to these bits when CFDGAFLECTR.AFLDAE bit is 0. Only write to these bits when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

For storage in TX queue, TX queue buffers of a target that is in GW mode is possible.

For storage in TX Queue, when these TX Queue buffers of a target are in GW mode, it can do.

Only one of the following configurations is valid:

- Up to 8 destination FIFO buffers
- 7 destination FIFO buffers plus one RX message buffer
- 8 destination TX queue buffers
- 7 destination TX queue buffers plus one RX message buffer
- A maximum of 8 destinations in all at FIFO buffer and TX queue buffer.

32.2.24 CFDRMNB : RX Message Buffer Number Register

Base address: CANFD = 0x400B_0000

Offset address: 0x00AC

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RMPLS[2:0]			NRXMB[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	NRXMB[7:0]	Number of RX Message Buffers	R/W
10:8	RMPLS[2:0]*1	Reception Message Buffer Payload Data Size 0 0 0: 8 bytes 0 0 1: 12 bytes 0 1 0: 16 bytes 0 1 1: 20 bytes 1 0 0: 24 bytes 1 0 1: 32 bytes 1 1 0: 48 bytes 1 1 1: 64 bytes	R/W
31:11	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. These bits are not available in the classical CAN function.

The RX Message Buffer Number register is used to configure the total number of RX message buffers allocated to all channels.

NRXMB[7:0] bits (Number of RX Message Buffers)

The NRXMB[7:0] bits are used to configure the number of RX message buffers.

Only write to these bits when the CAN-FD module is in GL_RESET mode.

Enter only values between 0 and 32 inclusive, with 0x00 indicating that no RX message buffer is allocated.

RMPLS[2:0] bits (Reception Message Buffer Payload Data Size)

The RMPLS[2:0] bits are used to configure the message buffer payload data size.

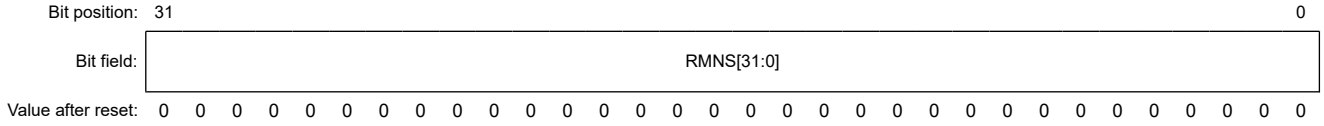
Only write to these bits when the CAN-FD module is in GL_RESET mode.

Note: These bits are not available in the classical CAN function.

32.2.25 CFDRMNDn : RX Message Buffer New Data Register n (n = 0)

Base address: CANFD = 0x400B_0000

Offset address: 0x00B0



Bit	Symbol	Function	R/W
31:0	RMNS[31:0]	RX Message Buffer New Data Status 0: New data not stored in corresponding RX message buffer 1: New data stored in corresponding RX message buffer	R/W

The RX Message Buffer New Data Status Register (n = 0) specifies the new data storage status of the RX message buffers.

RMNS[31:0] bits (RX Message Buffer New Data Status)

The RMNSu[31:0] bits indicate the status of new data for the corresponding RX message buffer. RMNS bit [0] corresponds to RX message buffer [0] and so on.

The bit position of CFDRMND corresponds to the buffer number of RXMB.

Do not write to these bits when the CAN-FD module is in GL_RESET or GL_SLEEP mode. Writing 1 has no effect.

These bits cannot be cleared when message storage in the corresponding RX message buffer is in progress.
Do not use the bit clear instruction to clear these bits. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

These bits are set automatically when storage of new messages are in the corresponding RX message buffer. These bits are cleared by writing 0. These bits are cleared automatically when the CAN-FD module is in GL_RESET mode.

When CFDRMNB.RMPLS = 000b (maximum 8 bytes payload), the duration of message storage is 6 PCLKB cycles.

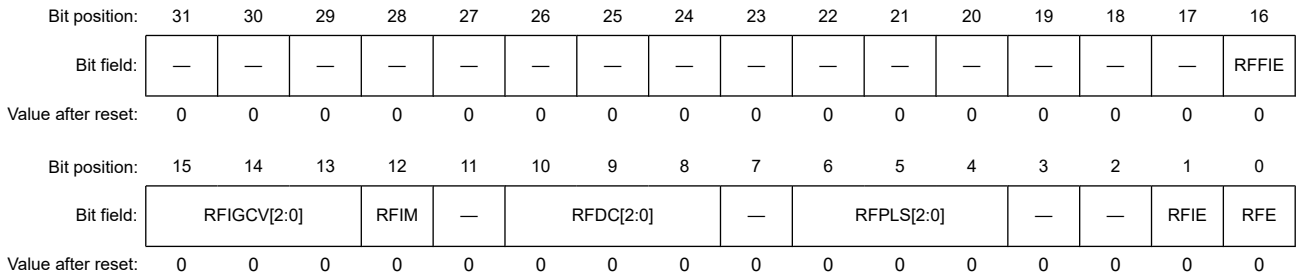
When CFDRMNB.RMPLS > 000b, the duration of message storage is 6 PCLKB cycles + 1 for each 4 bytes (maximum of 20 PCLKB cycles for 64 bytes).

Note: This feature is not available in the classical CAN function.

32.2.26 CFDRFCCn : RX FIFO Configuration/Control Registers n (n = 0 to 7)

Base address: CANFD = 0x400B_0000

Offset address: 0x00C0 + 0x04 × n



Bit	Symbol	Function	R/W
0	RFE	RX FIFO Enable 0: FIFO disabled 1: FIFO enabled	R/W
1	RFIE	RX FIFO Interrupt Enable 0: FIFO interrupt generation disabled 1: FIFO interrupt generation enabled	R/W
3:2	—	These bits are read as 0. The write value should be 0.	R/W
6:4	RFPLS[2:0]*1	Rx FIFO Payload Data Size Configuration 0 0 0: 8 bytes 0 0 1: 12 bytes 0 1 0: 16 bytes 0 1 1: 20 bytes 1 0 0: 24 bytes 1 0 1: 32 bytes 1 1 0: 48 bytes 1 1 1: 64 bytes	R/W
7	—	This bit is read as 0. The write value should be 0.	R/W
10:8	RFDC[2:0]	RX FIFO Depth Configuration 0 0 0: FIFO Depth = 0 message 0 0 1: FIFO Depth = 4 messages 0 1 0: FIFO Depth = 8 messages 0 1 1: FIFO Depth = 16 messages 1 0 0: FIFO Depth = 32 essages 1 0 1: FIFO Depth = 48 messages 1 1 0: FIFO Depth = 64 messages 1 1 1: FIFO Depth = 128 messages	R/W
11	—	This bit is read as 0.	R
12	RFIM	RX FIFO Interrupt Mode 0: Interrupt generated when RX FIFO counter reaches RFIGCV value from values smaller than RFIGCV 1: Interrupt generated at the end of every received message storage	R/W
15:13	RFIGCV[2:0]	RX FIFO Interrupt Generation Counter Value 0 0 0: Interrupt generated when FIFO is 1/8th full 0 0 1: Interrupt generated when FIFO is 1/4th full 0 1 0: Interrupt generated when FIFO is 3/8th full 0 1 1: Interrupt generated when FIFO is 1/2 full 1 0 0: Interrupt generated when FIFO is 5/8th full 1 0 1: Interrupt generated when FIFO is 3/4th full 1 1 0: Interrupt generated when FIFO is 7/8th full 1 1 1: Interrupt generated when FIFO is full	R/W
16	RFFIE	RX FIFO Full Interrupt Enable 0: FIFO interrupt generation disabled 1: FIFO interrupt generation enabled	R/W
31:17	—	These bits are read as 0.	R

Note 1. These bits are not available in the classical CAN function.

The RX FIFO Configuration/Control Registers (n = 0 to 7) are used to configure and control the eight RX FIFOs.

RFE bit (RX FIFO Enable)

The RFE bit enables the FIFO. When this bit is set to 0, the RX FIFO is cleared to empty.

Only write to this bit when the CAN-FD module is in GL_HALT or GL_OPERATION mode.

This bit can only be set if the configured FIFO depth is greater than 0x000 (CFDRFCCn.RFDC > 0x000).

Set the RFE bit with a separate write access to the CFDRFCCn register, after all the other bits in the CFDRFCCn register are set.

This bit is cleared automatically when the CAN-FD module is in GL_RESET mode.

RFIE bit (RX FIFO Interrupt Enable)

The RFIE bit enables generation of the FIFO interrupt.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode.

RFPLS[2:0] bits (Rx FIFO Payload Data Size Configuration)

The RFPLS[2:0] bits define the message data payload allocation in the RAM.

This is the maximum number of bytes which can be received by this FIFO.

Only write to these bits when the CAN-FD module is in GL_RESET mode.

Note: These bits are not available in the classical CAN function.

RFDC[2:0] bits (RX FIFO Depth Configuration)

The RFDC[2:0] bits select the depth of the FIFO in terms of the number of messages. If the FIFO depth is configured to 0 messages, the FIFO cannot be used.

Only write to these bits when the CAN-FD module is in GL_RESET mode.

RFIM bit (RX FIFO Interrupt Mode)

The RFIM bit selects the interrupt generation condition for the FIFO.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode.

Only write to this bit when the CAN-FD module is in GL_RESET mode.

RFIGCV[2:0] bits (RX FIFO Interrupt Generation Counter Value)

The RFIGCV[2:0] bits select the counter value of the FIFO for generation of FIFO interrupts. These values represent fractions of the FIFO depth for which an interrupt is generated.

Do not write to these bits when the CAN-FD module is in GL_SLEEP mode.

The setting of the RFIGCV[2:0] bits should be synchronized with the RFDC[2:0] bits.

Only write to these bits when the CAN-FD module is in GL_RESET mode.

RFFIE bit (RX FIFO Full Interrupt Enable)

The RFFIE bit enables generation of the RXFIFO full interrupt. Do not write to this bit when the CAN-FD module is in GL_SLEEP mode.

The following content shows examples of interruptions:

- Interruption output in number of arbitrary stages (CFDRFCCn.RFIGCV)
- Interruption output in FIFO full state.

Note: Management of the receiving data of FIFO can be performed by these notices of interruption.

32.2.27 CFDRFSTSn : RX FIFO Status Registers n (n = 0 to 7)

Base address: CANFD = 0x400B_0000

Offset address: 0x00E0 + 0x04 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RFFIF
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	RFMC[7:0]								—	—	—	—	RFIF	RFMLT	RFFLL	RFEMP
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Function	R/W
0	RFEMP	RX FIFO Empty 0: FIFO not empty 1: FIFO empty	R
1	RFFLL	RX FIFO Full 0: FIFO not full 1: FIFO full	R
2	RFMLT	RX FIFO Message Lost 0: No message lost in FIFO 1: FIFO message lost	R/W
3	RFIF	RX FIFO Interrupt Flag 0: FIFO interrupt condition not satisfied 1: FIFO interrupt condition satisfied	R/W
7:4	—	These bits are read as 0. The write value should be 0.	R/W
15:8	RFMC[7:0]	RX FIFO Message Count Number of messages stored in FIFO	R
16	RFFIF	RX FIFO Full Interrupt Flag 0: FIFO full interrupt condition not satisfied 1: FIFO full interrupt condition satisfied	R/W
31:17	—	These bits are read as 0. The write value should be 0.	R/W

The RX FIFO Status Registers (n = 0 to 7) show the status of messages stored in the corresponding FIFO buffers.

RFEMP bit (RX FIFO Empty)

The RFEMP bit is set automatically when:

- The RFMC bit is 0
- RX FIFO is disabled by setting the CFDRFCCn.RFE bit to is 0
- The CAN-FD module is in GL_RESET mode.

The RFEMP bit is cleared automatically when the first message is stored in the RX FIFO buffer.

RFFLL bit (RX FIFO Full)

The RFFLL bit is set automatically when the number of CAN messages stored in the FIFO buffer matches the configured FIFO depth.

The RFFLL is cleared automatically when:

- The number of CAN messages stored in the FIFO buffer is less than the configured FIFO depth
- RX FIFO is disabled by setting the CFDRFCCn.RFE bit to 0
- The CAN-FD module is in GL_RESET mode.

RFMLT bit (RX FIFO Message Lost)

Only write to the RFMLT bit when CAN-FD module is in GL_HALT or GL_OPERATION mode. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

This bit is set automatically whenever a message is lost due to attempted storage when the FIFO buffer is already full. If a set from the CAN channel occurs simultaneously with a clear by a write access, then the bit is set.

The bit is cleared:

- By writing 0 to it
- When the CAN-FD module is in GL_RESET mode.

RFIF bit (RX FIFO Interrupt Flag)

The RFIF bit is set automatically when the configured interrupt condition is satisfied. This bit is not automatically cleared when the RX FIFO buffer is disabled.

Only write to this bit when the CAN-FD module is in GL_HALT or GL_OPERATION mode. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

If a set from the CAN channel occurs simultaneously with a clear by a write access, then this bit is set.

The bit is cleared by writing 0 to it. The bit is also cleared when CAN-FD module is in GL_RESET mode.

RFMC[7:0] bits (RX FIFO Message Count)

The RFMC[7:0] bits indicate the number of CAN messages stored in the RX FIFO buffer that can be read by the CPU.

These bits are cleared automatically when the FIFO is disabled and when the CAN-FD module is in GL_RESET mode.

RFFIF bit (RX FIFO Full Interrupt Flag)

The RFFIF bit is not cleared automatically when the RX FIFO buffer is disabled.

Only write to this bit when the CAN-FD module is in GL_HALT or GL_OPERATION mode. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

This bit is set automatically when the FIFO full interrupt condition is satisfied. If a set from the CAN channel occurs simultaneously with a clear by a write access, then the bit is set.

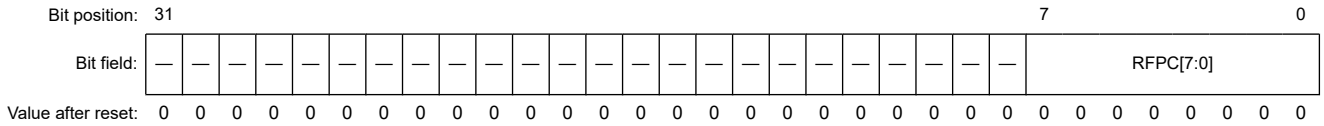
The bit is cleared by writing 0 to it.

The bit is also cleared when the CAN-FD module is in GL_RESET mode.

32.2.28 CFDRFPCTRn : RX FIFO Pointer Control Registers n (n = 0 to 7)

Base address: CANFD = 0x400B_0000

Offset address: 0x0100 + 0x04 × n



Bit	Symbol	Function	R/W
7:0	RFPC[7:0]	RX FIFO Pointer Control Increments read pointer of the corresponding RX FIFO buffers	W
31:8	—	These bits are read as 0. The write value should be 0.	R/W

The RX FIFO Pointer Control Registers (n = 0 to 7) can be used to increment the read pointer of the corresponding RX FIFO buffers.

RFPC bits (RX FIFO Pointer Control)

When the value 0xFF is written to the RFPC bits, the pointer of the corresponding RX FIFO buffer is moved to the next FIFO entry. Only write 0xFF to these registers when the corresponding RX FIFO buffer is enabled and not empty.

The read value from these bits is always 0x00.

Only write to these bits when the CAN-FD module is in GL_HALT or GL_OPERATION mode.

Do not write to the RX FIFO Pointer Control registers when DMA is enabled.

32.2.29 CFDCFCCn : Common FIFO Configuration/Control Registers n (n = 0 to 5)

Base address: CANFD = 0x400B_0000

Offset address: 0x0120 + 0x04 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	CFITT[7:0]								CFDC[2:0]			CFTML[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CFIGCV[2:0]			CFIM	CFITR	CFITSS	CFM[1:0]		—	CFPLS[2:0]			—	CFTXIE	CFRXIE	CFE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CFE	Common FIFO Enable 0: FIFO disabled 1: FIFO enabled	R/W
1	CFRXIE	Common FIFO RX Interrupt Enable 0: FIFO interrupt generation disabled for Frame RX 1: FIFO interrupt generation enabled for Frame RX	R/W
2	CFTXIE	Common FIFO TX Interrupt Enable 0: FIFO interrupt generation disabled for Frame TX 1: FIFO interrupt generation enabled for Frame TX	R/W
3	—	This bit is read as 0. The write value should be 0.	R/W

7	—	This bit is read as 0. The write value should be 0.	R/W
9:8	CFM[1:0]	Common FIFO Mode 0 0: RX FIFO mode 0 1: TX FIFO mode 1 0: CAN – CAN GW FIFO mode 1 1: Reserved	R/W
10	CFITSS	Common FIFO Interval Timer Source Select 0: Reference clock (× 1 / × 10 period) 1: Bit time clock of related channel (FIFO is linked to fixed channel)	R/W
11	CFITR	Common FIFO Interval Timer Resolution 0: Reference clock period × 1 1: Reference clock period × 10	R/W

Bit	Symbol	Function	R/W
12	CFIM	Common FIFO Interrupt Mode 0: RX FIFO mode: RX interrupt generated when Common FIFO counter reaches CFIGCV value from a lower value TX FIFO mode: TX interrupt generated when Common FIFO transmits the last message successfully GW FIFO mode: For RX interrupt flag: Interrupt generated when FIFO counter increments and reaches the value configured in CFIGCV For TX interrupt flag: Interrupt generated when FIFO transmits the last message successfully 1: RX FIFO mode: RX interrupt generated at the end of every received message storage TX FIFO mode: interrupt generated for every successfully transmitted message GW FIFO mode: For RX interrupt flag: Interrupt generated when a message is stored in the FIFO For TX interrupt flag: Interrupt generated when a message is successfully transmitted from the FIFO	R/W
15:13	CFIGCV[2:0]	Common FIFO Interrupt Generation Counter Value 0 0 0: Interrupt generated when FIFO is 1/8th full 0 0 1: Interrupt generated when FIFO is 1/4th full 0 1 0: Interrupt generated when FIFO is 3/8th full 0 1 1: Interrupt generated when FIFO is 1/2 full 1 0 0: Interrupt generated when FIFO is 5/8th full 1 0 1: Interrupt generated when FIFO is 3/4th full 1 1 0: Interrupt generated when FIFO is 7/8th full 1 1 1: Interrupt generated when FIFO is full	R/W
20:16	CFTML[4:0]	Common FIFO TX Message Buffer Link Transmission scan link position of the corresponding channel	R/W
23:21	CFDC[2:0]	Common FIFO Depth Configuration 0 0 0: FIFO Depth = 0 messages 0 0 1: FIFO Depth = 4 messages 0 1 0: FIFO Depth = 8 messages 0 1 1: FIFO Depth = 16 messages 1 0 0: FIFO Depth = 32 messages 1 0 1: FIFO Depth = 48 messages 1 1 0: FIFO Depth = 64 messages 1 1 1: FIFO Depth = 128 messages	R/W
31:24	CFITT[7:0]	Common FIFO Interval Transmission Time Delay the start of transmission from the FIFO if configured in TX or GW mode, delay is a multiple of basic Interval Timer Clock Source unit	R/W

Note 1. These bits are not available in the classical CAN function.

CFE bit (Common FIFO Enable)

The CFE bit enables the FIFO when set. FIFO is disabled when this bit is cleared.

This bit can also be used, by clearing it, to abort transmission from Common FIFO when configured in TX mode or GW mode, or to stop reception into the Common FIFO in RX mode.

Only write to this bit when the CAN-FD module is in GL_HALT or GL_OPERATION mode and the related CAN-FD channel is not in CH_RESET mode for FIFOs configured as TX or GW FIFO.

This bit can only be set if the configured FIFO depth is greater than 0 (CFDC bit > 0).

Set the CFE bit with a separate write access to the CFDCFCCn register, after all the other bits in this register are set.

This bit is cleared automatically when the CAN-FD module is in GL_RESET mode.

This bit is also cleared automatically when the related channel is in CH_RESET mode if the FIFO is configured in TX or GW mode.

CFRXIE bit (Common FIFO RX Interrupt Enable)

The CFRXIE bit enables generation of FIFO interrupts when the interrupt flag is set after reception of a frame in the corresponding FIFO buffer.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode.

CFTXIE bit (Common FIFO TX Interrupt Enable)

The CFTXIE bit enables generation of common FIFO interrupts when the interrupt flag is set after transmission of a frame from the corresponding FIFO buffer.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode.

CFPLS[2:0] bits (Common FIFO Payload Data Size Configuration)

The CFPLS[2:0] bits define the message data payload allocation in the RAM. This is the maximum number of bytes which can be received or transmitted by the FIFO buffer.

For details, see section 32.6. FIFO Buffers and Normal Message Buffer Configuration.

Only write to this bit when the CAN-FD module is in GL_RESET mode.

Note: These bits are not available in the classical CAN function.

CFM[1:0] bits (Common FIFO Mode)

The CFM[1:0] bits select the mode of the FIFO. When a hardware reset is applied, all the Common FIFO buffers are configured in RX FIFO mode. Do not configure these bits to 11b.

Do not write to these bits in GL_OPERATION or GL_SLEEP mode.

Only write to these bits when the CAN-FD module is in GL_RESET mode.

CFITSS bit (Common FIFO Interval Timer Source Select)

The CFITSS bit selects the basic clock source for the Interval Transmission Timer.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode. In addition, do not write to this bit when the CFE bit is set to 1.

Do not write 1 to this bit when CAN-FD communication is used.*1

Note: The bit time clock can vary depending on the nominal and data rate bit configuration.

Note 1. This feature is not available in the classical CAN function.

CFITR bit (Common FIFO Interval Timer Resolution)

The CFITR bit selects the resolution of the reference clock for the Interval Transmission Timer (peripheral clock is the source for the reference clock).

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode. Also, do not write to this bit when the CFE bit is set to 1.

CFIM bit (Common FIFO Interrupt Mode)

The CFIM bit selects the interrupt generation condition for the FIFO buffer.

Do not write to this bit in GL_SLEEP mode.

Only write to this bit when the CAN-FD module is in GL_RESET mode.

CFIGCV[2:0] bits (Common FIFO Interrupt Generation Counter Value)

The CFIGCV[2:0] bits select the message counter value for the generation of FIFO interrupts. These values represent fractions of the FIFO depth at which the interrupt is to be generated.

Do not write to these bits when the CAN-FD module is in GL_SLEEP mode.

The setting of these bits should be synchronized with the CFDC[2:0] bits.

Only write to these bits when the CAN-FD module is in GL_RESET mode.

CFTML[4:0] bits (Common FIFO TX Message Buffer Link)

The CFTML[4:0] bits select the normal transmit message buffer position where the TX or GW FIFO is linked to, for transmission scanning.

Do not write to these bits in GL_OPERATION or GL_SLEEP mode.

Only write to this bit when the CAN-FD module is in GL_RESET mode.

CFDC[2:0] bits (Common FIFO Depth Configuration)

The CFDC[2:0] bits select the depth of the common FIFO in terms of the number of messages. If the FIFO depth is configured to 0 message, the FIFO cannot be used.

Only write to these bits when the CAN-FD module is in GL_RESET mode.

CFITT[7:0] bits (Common FIFO Interval Transmission Time)

The CFITT[7:0] bits select the delay in the start of transmission for all messages transmitted from this FIFO buffer when configured in TX or GW mode. The delay is a multiple of the basic interval timer clock source period (reference clock × 1, reference clock × 10, or bit time clock of the related CAN channel).

Do not write to these bits when the CAN-FD module is in GL_SLEEP mode.

Do not write to these bits when the CFE bit is set to 1.

When CFDGCFG.ITRCP[15:0] = 0x0000, set the CFITT[7:0] bits to 0x0000.

32.2.30 CFDCFCCEn : Common FIFO Configuration/Control Enhancement Registers n (n = 0 to 5)

Base address: CANFD = 0x400B_0000

Offset address: 0x0180 + 0x04 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CFBME
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	CFMOWM	—	—	—	—	—	CFOFTXIE	CFOFRXIE	CFFIE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CFFIE	Common FIFO Full Interrupt Enable 0: FIFO Interrupt generation disabled 1: FIFO Interrupt generation enabled	R/W
1	CFOFRXIE	Common FIFO One Frame Reception Interrupt Enable 0: One Frame RX interrupt generation disabled 1: One Frame RX interrupt generation enabled	R/W
2	CFOFTXIE	Common FIFO One Frame Transmission Interrupt Enable 0: One Frame TX interrupt generation disabled 1: One Frame TX interrupt generation enabled	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W
8	CFMOWM	Common FIFO Message Overwrite Mode 0: Message discarded mode 1: Message overwrite mode	R/W
15:9	—	These bits are read as 0. The write value should be 0.	R/W
16	CFBME	Common FIFO Buffering Mode Enable 0: Transmission from Common FIFO 1: Transmission halt from Common FIFO	R/W
31:17	—	These bits are read as 0. The write value should be 0.	R/W

The Common FIFO Configuration/Control Enhancement Registers (n = 0 to 5) are used to configure the Common FIFOs.

no_of_channels = 2

no_of_CFIFOs_per_channel = Number of Common FIFOs per channel = 3

Where the total number of CFIFOs = no_of_CFIFOs_per_channel × no_of_channels = 3 × 2 = 6 as shown in Figure 32.28.

n = Common FIFO index = [0 .. no_of_CFIFOs - 1]

CFFIE bit (Common FIFO Full Interrupt Enable)

The CFFIE bit enables generation of the FIFO full interrupt when the interrupt flag is set after reception of a frame in the corresponding FIFO buffer.

Do not write to this bit when the CANFD module is in GL_SLEEP mode.

The following content shows examples of interruptions:

1. Interruption output in number of arbitrary stages (CFDCFCCn.CFIGCV)
2. Interruption output in FIFO full state.

Management of the receiving data of FIFO can be performed by these notices of interruption.

CFOFRXIE bit (Common FIFO One Frame Reception Interrupt Enable)

The CFOFRXIE bit enables generation of the one frame reception interrupt when the interrupt flag is set after reception of a frame in the corresponding FIFO buffer.

Do not write to this bit when the CANFD module is in GL_SLEEP mode.

CFOFTXIE bit (Common FIFO One Frame Transmission Interrupt Enable)

The CFOFTXIE bit enables generation of the one frame transmission interrupt when the interrupt flag is set after transmission of a frame in the corresponding FIFO buffer.

Do not write to this bit when the CANFD module is in GL_SLEEP mode.

CFMOWM bit (Common FIFO Message Overwrite Mode)

When the CFMOWM bit is 0, a receiving message is discarded and FIFO is full. When the CFMOWM bit is 1, a receiving message is overwritten and FIFO is full.

Do not write to this bit when the CANFD module is in GL_SLEEP mode.

Only write 1 to this bit when the common FIFO is in GW mode.

Do not write 1 to this bit when the CFE bit is 1.

CFBME bit (Common FIFO Buffering Mode Enable)

When the CFBME bit is 0, messages are transmitted from FIFO. When the CFBME bit is 1, messages are not transmitted from FIFO.

Do not write to this bit when the CANFD module is in GL_SLEEP mode. Additionally, do not write 1 to this bit when the CFE bit is 1.

32.2.31 CFDCFSTSn : Common FIFO Status Registers n (n = 0 to 5)

Base address: CANFD = 0x400B_0000

Offset address: 0x01E0 + 0x04 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	CFMOW	—	—	—	—	—	CFOFTXIF	CFOFRXIF	CFFIF
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CFMC[7:0]								—	—	—	CFTXIF	CFRXIF	CFMLT	CFFLL	CFEMP
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Function	R/W
0	CFEMP	Common FIFO Empty 0: FIFO not empty 1: FIFO empty	R
1	CFFLL	Common FIFO Full 0: FIFO not full 1: FIFO full	R
2	CFMLT	Common FIFO Message Lost 0: Number of message lost in FIFO 1: FIFO message lost	R/W
3	CFRXIF	Common RX FIFO Interrupt Flag 0: FIFO interrupt condition not satisfied after frame reception 1: FIFO interrupt condition satisfied after frame reception	R/W
4	CFTXIF	Common TX FIFO Interrupt Flag 0: FIFO interrupt condition not satisfied after frame transmission 1: FIFO Interrupt condition satisfied after frame transmission	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W
15:8	CFMC[7:0]	Common FIFO Message Count Number of messages stored in FIFO	R
16	CFFIF	Common FIFO Full Interrupt Flag 0: Interrupt condition not satisfied for FIFO full interrupt 1: Interrupt condition satisfied for FIFO full interrupt	R/W
17	CFOFRXIF	Common FIFO One Frame Reception Interrupt Flag For each FIFO that receives a frame, a corresponding interrupt is set.	R/W
18	CFOFTXIF	Common FIFO One Frame Transmission Interrupt Flag For each FIFO that transmits a frame, a corresponding interrupt is set.	R/W
23:19	—	These bits are read as 0. The write value should be 0.	R/W
24	CFMOW	Common FIFO Message Overwrite 0: No message overwrite occurred in FIFO 1: Message overwrite occurred in FIFO	R/W
31:25	—	These bits are read as 0. The write value should be 0.	R/W

CFEMP bit (Common FIFO Empty)

The CFEMP bit is set automatically when:

- The CPU has read all messages from the FIFO configured in RX mode
- All messages have been transmitted from the FIFO configured in TX or GW mode
- The FIFO is disabled by setting the CFE bit to 0
- The CAN-FD module is in GL_RESET mode
- The related CAN-FD channel is in CH_RESET when FIFO configured in TX or GW mode.

The CFEMP bit is cleared automatically when:

- The first reception message is stored in the FIFO buffer when configured in RX mode
- The first message to be transmitted is stored in the FIFO buffer when configured in TX or GW mode.

CFFLL bit (Common FIFO Full)

The CFFLL bit is set automatically when the number of CAN messages stored in the FIFO matches the configured FIFO depth.

The CFFLL bit is cleared automatically when:

- The number of CAN messages stored in the FIFO is less than the configured FIFO depth
- The FIFO is disabled by setting the CFE bit to 0
- The CAN-FD module is in GL_RESET mode

- The related CAN-FD channel is in CH_RESET mode when FIFO buffer is configured in TX or GW mode.

CFMLT bit (Common FIFO Message Lost)

The CFMLT bit is set automatically whenever a message is lost due to attempted storage of a new message when FIFO is already full in RX or GW mode.

If a set from the CAN channel occurs simultaneously with a clear by a write access, then this bit is set.

Only write to this bit when the CAN-FD module is in GL_HALT or GL_OPERATION mode and the related CAN-FD channel is not in CH_RESET mode for FIFO configured as TX or GW FIFO. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

The CFMLT bit is cleared:

- By writing 0 to it
- When the CAN-FD module is in GL_RESET mode
- When the related CAN-FD channel is in CH_RESET mode if the FIFO buffer is configured in TX or GW mode.

CFRXIF bit (Common RX FIFO Interrupt Flag)

The CFRXIF bit is not cleared automatically if the Common FIFO buffer is disabled.

Only write to this bit when the CAN-FD module is in GL_HALT or GL_OPERATION mode and the related CAN-FD channel is not in CH_RESET mode for FIFO configured as TX or GW FIFO. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

This bit is set automatically when the configured interrupt condition is satisfied for Common FIFO buffers when configured in GW mode or RX mode.

The CFRXIF bit is cleared:

- By writing 0 to it
- When the CAN-FD module is in GL_RESET mode
- When the related CAN-FD channel is in CH_RESET mode if the FIFO buffer is configured in GW mode.

CFTXIF bit (Common TX FIFO Interrupt Flag)

The CFTXIF bit is not cleared automatically if the Common FIFO buffer is disabled.

Only write to this bit when the CAN-FD module is in GL_HALT or GL_OPERATION mode and the related CAN-FD channel is not in CH_RESET mode for FIFO buffer configured as TX or GW FIFO. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

This bit is set automatically when the configured interrupt condition is satisfied for Common FIFO buffers configured in GW or TX mode.

The CFTXIF bit is cleared:

- By writing 0 to it
- When the CAN-FD module is in GL_RESET mode
- When the related CAN-FD channel is in CH_RESET mode if the FIFO buffer is configured in TX or GW mode.

CFMC[7:0] bits (Common FIFO Message Count)

The CFMC[7:0] bits indicate the following:

- Number of CAN messages stored by the CPU in the FIFO buffer configured in TX mode pending for transmission
- Number of CAN messages stored in the FIFO buffer configured in RX mode by RS-CAN-FD to be read by the CPU
- Number of CAN messages stored by the RS-CAN-FD in the GW FIFO pending for transmission.

The CFMC[7:0] bits are cleared automatically when:

- The FIFO is disabled
- The CAN-FD module is in GL_RESET mode
- The related CAN-FD channel is in CH_RESET mode if the FIFO buffer is configured in TX or GW mode.

CFFIF bit (Common FIFO Full Interrupt Flag)

The CFFIF bit is not cleared automatically if the Common FIFO buffer is disabled.

Only write to this bit when the CAN-FD module is in GL_HALT or GL_OPERATION mode and the related CAN-FD channel is not in CH_RESET mode for FIFO configured as TX or GW FIFO. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

This bit is set automatically when the FIFO Full Interrupt condition is satisfied for Common FIFO buffers when configured in GW or RX mode.

If a set from the CAN channel occurs simultaneously with a clear by a write access, then the bit is set.

The CFFIF bit is cleared:

- By writing 0 to it
- When the CAN-FD module is in GL_RESET mode
- When the related CAN-FD channel is in CH_RESET mode if the FIFO buffer is configured in TX or GW mode.

CFOFRXIF bit (Common FIFO One Frame Reception Interrupt Flag)

The CFOFRXIF bit is not cleared automatically if the Common FIFO buffer is disabled.

Only write to this bit when the CAN-FD module is in GL_HALT or GL_OPERATION mode and the related CAN-FD channel is not in CH_RESET mode for the FIFO buffer configured as TX or GW FIFO. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

This bit is set automatically when the One Frame Reception Interrupt condition is satisfied for the Common FIFO buffers when configured in GW or RX mode.

If a set from the CAN channel occurs simultaneously with a clear by a write access, then the bit is set.

The CFOFRXIF bit is cleared:

- By writing 0 to it
- When the CAN-FD module is in GL_RESET mode
- When the related CAN-FD channel is in CH_RESET mode if the FIFO buffer is configured in TX or GW mode.

CFOFTXIF bit (Common FIFO One Frame Transmission Interrupt Flag)

The CFOFTXIF bit is not cleared automatically if the Common FIFO buffer is disabled.

Only write to this bit when the CAN-FD module is in GL_HALT or GL_OPERATION mode and the related CAN-FD channel is not in CH_RESET mode for FIFOs configured as TX or GW FIFO. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

This bit is set automatically when the One Frame Transmission Interrupt condition is satisfied for Common FIFO buffers configured in GW mode or TX mode.

If a set from the CAN channel occurs simultaneously with a clear by a write access, then the bit is set.

The bit is cleared:

- By writing 0 to it
- When the CAN-FD module is in GL_RESET mode
- When the related CAN-FD channel is in CH_RESET mode if the FIFO is configured in TX or GW mode.

CFMOW bit (Common FIFO Message Overwrite)

The CFMOW bit is set automatically whenever a message is an overwrite storage of a new message when CFDCFCCEn.CFMOWM = 1 and FIFO is already full in GW mode.

If the set from the CAN channel occurs simultaneously with the clear by a write access, the bit is set.

Only write to this bit when the CAN-FD module is in GL_HALT or GL_OPERATION mode and the related CAN-FD channel is not in CH_RESET mode for FIFO buffer configured as TX or GW FIFO. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

The CFMOW bit is cleared:

- By writing 0 to it
- When the CAN-FD module is in GL_RESET mode
- When the related CAN-FD channel is in CH_RESET mode if the FIFO buffer is configured in TX or GW mode.

32.2.32 CFDCFPCTRn : Common FIFO Pointer Control Registers n (n = 0 to 5)

Base address: CANFD = 0x400B_0000

Offset address: 0x0240 + 0x04 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CFPC[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	CFPC[7:0]	Common FIFO Pointer Control Increments read or write pointer of the corresponding Common FIFO buffers depending on the mode configuration.	W
31:8	—	These bits are read as 0. The write value should be 0.	R/W

The Common FIFO Pointer Control Registers (n = 0 to 5) can be used to increment the read or write pointer of the corresponding Common FIFO buffer.

CFPC[7:0] bits (Common FIFO Pointer Control)

When the value 0xFF is written into the CFPC[7:0] bits, the read pointer of the corresponding Common FIFO buffer (when configured in RX mode), or the write pointer of the corresponding Common FIFO buffer (when configured in TX mode) moves to the next FIFO entry.

The read value from these bits is always 0x00.

Only write to these bits when the CAN-FD module is in GL_HALT or GL_OPERATION mode.

Only write 0xFF to this register when:

- The Common FIFO buffer is enabled and is not empty if configured in RX mode
- The Common FIFO buffer is enabled and is not full if configured in TX mode
- The Common FIFO buffer is enabled and is not configured in GW mode.

Do not write to the Common FIFO Pointer Control registers when DMA is enabled.

32.2.33 CFDFESTS : FIFO Empty Status Register

Base address: CANFD = 0x400B_0000

Offset address: 0x02A0

Bit position:	31														13		8	7		0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CFXEMP[5:0]		RFXEMP[7:0]
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
7:0	RFXEMP[7:0]	RX FIFO Empty Status 0: Corresponding FIFO not empty 1: Corresponding FIFO empty	R
13:8	CFXEMP[5:0]	Common FIFO Empty Status 0: Corresponding FIFO not empty 1: Corresponding FIFO empty	R
31:14	—	These bits are read as 0. The write value should be 0.	R

The FIFO Empty Status register shows status of the empty bits of the FIFO buffers.

RFXEMP[7:0] bits (RX FIFO Empty Status)

Bit 7 (RFXEMP[7]) is associated with FIFO index 7 and bit 0 (RFXEMP[0]) is associated with FIFO index 0.

The RFXEMP[7:0] bits are set when the CAN-FD module is in GL_RESET mode.

Each bit is set automatically when the corresponding bit is set in the RX FIFO Status Registers.

Each bit is cleared automatically when the corresponding bit is cleared in the RX FIFO Status Registers.

CFXEMP[5:0] bits (Common FIFO Empty Status)

Bit 13 (CFXEMP[5]) is associated with common FIFO index 5 and bit 8 (CFXEMP[0]) is associated with common FIFO index 0.

The CFXEMP[5:0] bits are set when the CAN-FD module is in GL_RESET mode.

Each bit is set automatically when the corresponding bit is set in the Common FIFO Status Registers.

Each bit is cleared automatically when the corresponding bit is cleared in the Common FIFO Status Registers.

32.2.34 CFDFFSTS : FIFO Full Status Register

Base address: CANFD = 0x400B_0000

Offset address: 0x02A4

Bit position:	31														13		8	7		0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CFXFLL[5:0]		RFXFLL[7:0]
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	RFXFLL[7:0]	RX FIFO Full Status 0: Corresponding FIFO not full 1: Corresponding FIFO full	R
13:8	CFXFLL[5:0]	Common FIFO Full Status 0: Corresponding FIFO not full 1: Corresponding FIFO full	R
31:14	—	These bits are read as 0. The write value should be 0.	R

The FIFO Full Status Register shows status of the full bits of the FIFO buffers.

RFXFLL[7:0] bits (RX FIFO Full Status)

The RFXFLL[7:0] bits are cleared when CAN-FD module is in GL_RESET mode.

Each bit is set automatically when the corresponding bit is set in the RX FIFO Status Registers.

Each bit is cleared automatically when the corresponding bit is cleared in the RX FIFO Status Registers.

CFXFLL[5:0] bits (Common FIFO Full Status)

The CFXFLL[5:0] bits are cleared when the CAN-FD module is in GL_RESET mode.

Each bit is set automatically when the corresponding bit is set in the Common FIFO Status Registers.

Each bit is cleared automatically when the corresponding bit is cleared in the Common FIFO Status Registers.

32.2.35 CFDFMSTS : FIFO Message Lost Status Register

Base address: CANFD = 0x400B_0000

Offset address: 0x02A8

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CFXMLT[5:0]						RFXMLT[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	RFXMLT[7:0]	RX FIFO Message Lost Status 0: Corresponding FIFO Message Lost flag not set 1: Corresponding FIFO Message Lost flag set	R
13:8	CFXMLT[5:0]	Common FIFO Message Lost Status 0: Corresponding FIFO Message Lost flag not set 1: Corresponding FIFO Message Lost flag set	R
31:14	—	These bits are read as 0. The write value should be 0.	R

The FIFO Message Lost Status Register shows status of the Msg Lost bits of the FIFO buffers.

RFXMLT[7:0] bits (RX FIFO Message Lost Status)

The RFXMLT[7:0] bits are cleared when the CAN-FD module is in GL_RESET mode.

Each bit is set automatically when the corresponding bit is set in the RX FIFO Status Registers.

Each bit is cleared automatically when the corresponding bit is cleared in the RX FIFO Status Registers.

CFXMLT[5:0] bits (Common FIFO Message Lost Status)

The CFXMLT[5:0] bits are cleared when the CAN-FD module is in GL_RESET mode.

Each bit is set automatically when the corresponding bit is set in the Common FIFO Status Registers.

Each bit is cleared automatically when the corresponding bit is cleared in the Common FIFO Status Registers.

32.2.36 CFDRFISTS : RX FIFO Interrupt Flag Status Register

Base address: CANFD = 0x400B_0000

Offset address: 0x02AC

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	RFXFFLL[7:0]								—	—	—	—	—	—	—	—	RFXIF[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	RFXIF[7:0]	RX FIFO[x] Interrupt Flag Status 0: Corresponding RX FIFO Interrupt flag not set 1: Corresponding RX FIFO Interrupt flag set	R
15:8	—	These bits are read as 0. The write value should be 0.	R/W
23:16	RFXFFLL[7:0]	RX FIFO[x] Interrupt Full Flag Status 0: Corresponding RX FIFO Interrupt Full flag not set 1: Corresponding RX FIFO Interrupt Full flag set	R
31:24	—	These bits are read as 0. The write value should be 0.	R/W

The FIFO Interrupt Flag Status Register shows status of the interrupt flag bits of the RX FIFO buffers.

RFXIF[7:0] bits (RX FIFO[x] Interrupt Flag Status)

Each bit is set automatically when the corresponding interrupt flag bit is set in the RX FIFO Status Registers.

The RFXIF[7:0] bits are cleared when the CAN-FD module is in GL_RESET mode.

Each bit is cleared automatically when the corresponding interrupt flag bit is cleared in the RX FIFO Status Registers.

RFXFFLL[7:0] bits (RX FIFO[x] Interrupt Full Flag Status)

Each bit is set automatically when the corresponding interrupt full flag bit is set in the RX FIFO Status Registers.

The RFXFFLL[7:0] bits are cleared when the CAN-FD module is in GL_RESET mode.

Each bit is cleared automatically when the corresponding interrupt full flag bit is cleared in the RX FIFO Status Registers.

32.2.37 CFDCFRISTS : Common FIFO RX Interrupt Flag Status Register

Base address: CANFD = 0x400B_0000

Offset address: 0x02B0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CFXRXIF[5:0]					
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	CFXRXIF[5:0]	Common FIFO RX Interrupt Flag Status 0: Corresponding Common FIFO RX Interrupt flag is not set 1: Corresponding Common FIFO RX Interrupt flag is set	R
31:6	—	These bits are read as 0. The write value should be 0.	R/W

The Common FIFO RX Interrupt Flag Status Register shows status of the interrupt flag bits of the Common FIFO buffers.

CFXRXIF[5:0] bits (Common FIFO RX Interrupt Flag Status)

Each bit is set automatically when the corresponding RX interrupt flag bit is set in the Common FIFO Status Registers.

The CFXRXIF[5:0] bits are cleared when the CANFD module is in GL_RESET mode.

Each bit is cleared automatically when the corresponding RX interrupt flag bit is cleared in the Common FIFO Status Registers.

32.2.38 CFDCFTISTS : Common FIFO TX Interrupt Flag Status Register

Base address: CANFD = 0x400B_0000

Offset address: 0x02B4

Bit position:	31																								6	5						0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CFXTXIF[5:0]						
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	CFXTXIF[5:0]	Common FIFO [x] TX Interrupt Flag Status 0: Corresponding Common FIFO TX Interrupt flag is not set 1: Corresponding Common FIFO TX Interrupt flag is set	R
31:6	—	These bits are read as 0. The write value should be 0.	R/W

The Common FIFO TX Interrupt Flag Status Register shows status of the interrupt flag bits of the Common FIFO buffers.

CFXTXIF[5:0] bits (Common FIFO [x] TX Interrupt Flag Status)

Each bit is set automatically when the corresponding TX interrupt flag bit is set in the Common FIFO Status Registers.

The CFXTXIF[5:0] bits are cleared when the CANFD module is in GL_RESET mode.

Each bit is cleared automatically when the corresponding TX interrupt flag bit is cleared in the Common FIFO Status Registers.

32.2.39 CFDFFFSTS : FIFO FDC Full Status Register

Base address: CANFD = 0x400B_0000

Offset address: 0x02C4

Bit position:	31																		13					8	7							0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CFXFFLL[5:0]						RFXFFLL[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	RFXFFLL[7:0]	RX FIFO FDC Level Full Status 0: Corresponding FIFO full interrupt not set 1: Corresponding FIFO full interrupt is set	R
13:8	CFXFFLL[5:0]	COMMON FIFO FDC Level Full Status 0: Corresponding FIFO full interrupt not set 1: Corresponding FIFO full interrupt is set	R
31:14	—	These bits are read as 0. The write value should be 0.	R

The FIFO FDC Full Status Register shows status of the full interrupt flag bits of the FIFO buffers.

RFXFFLL[7:0] bits (RX FIFO FDC Level Full Status)

Each bit is set automatically when the corresponding bit is set in the RX FIFO Status Registers.

Each bit is cleared automatically when the corresponding bit is cleared in the RX FIFO Status Registers.

The RFXFFLL[7:0] bits are cleared when the CANFD module is in GL_RESET mode.

CFXFFLL[5:0] bits (COMMON FIFO FDC Level Full Status)

Each bit is set automatically when the corresponding bit is set in the Common FIFO Status Registers.

Each bit is cleared automatically when the corresponding bit is cleared in the Common FIFO Status Registers.

The CFXFFLL[5:0] bits are cleared when the CANFD module is in GL_RESET mode.

32.2.40 CFDCFMOWSTS : Common FIFO Message Over Write Status Register

Base address: CANFD = 0x400B_0000

Offset address: 0x02C0

Bit position:	31																								5	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CFXMOW[5:0]
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	CFXMOW[5:0]	Common FIFO Massage Overwrite Status 0: Corresponding FIFO Overwrite flag is not set 1: Corresponding FIFO Overwrite flag is set	R
31:6	—	These bits are read as 0. The write value should be 0.	R

CFXMOW[5:0] bits (Common FIFO Massage Overwrite Status)

The CFXMOW[5:0] bits are cleared when the CANFD module is in GL_RESET mode. This register is only valid in GW mode.

Each bit is set automatically when the corresponding bit is set in the Common FIFO Status Registers.

Each bit is cleared automatically when the corresponding bit is cleared in the Common FIFO Status Registers.

32.2.41 CFDCFOFRISTS : Common FIFO One Frame RX Interrupt Flag Status Register

Base address: CANFD = 0x400B_0000

Offset address: 0x02B8

Bit position:	31																								5	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CFXOFRXIF[5:0]
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	CFXOFRXIF[5:0]	Common FIFO One Frame RX Interrupt Flag Status 0: Corresponding Common FIFO One Frame RX Interrupt flag is not set 1: Corresponding Common FIFO One Frame RX Interrupt flag is set	R
31:6	—	These bits are read as 0. The write value should be 0.	R

The Common FIFO One Frame RX Interrupt Flag Status register shows status of the interrupt flag bits of the Common FIFO buffers.

CFXOFRXIF[5:0] bits (Common FIFO One Frame RX Interrupt Flag Status)

Each bit is set automatically when the corresponding One Frame RX Interrupt flag bit is set in the Common FIFO Status Registers.

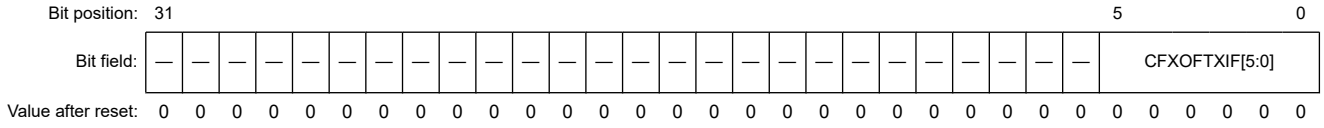
The CFXOFRXIF[5:0] bits are cleared when the CANFD module is in GL_RESET mode.

Each bit is cleared automatically when the corresponding One Frame RX Interrupt flag bit is cleared in the Common FIFO Status Registers.

32.2.42 CFDCFOFTISTS : Common FIFO One Frame TX Interrupt Flag Status Register

Base address: CANFD = 0x400B_0000

Offset address: 0x02BC



Bit	Symbol	Function	R/W
5:0	CFXOFTXIF[5:0]	Common FIFO One Frame TX Interrupt Flag Status 0: Corresponding Common FIFO One Frame TX Interrupt flag is not set 1: Corresponding Common FIFO One Frame TX Interrupt flag is set	R
31:6	—	These bits are read as 0. The write value should be 0.	R

The Common FIFO One Frame TX Interrupt Flag Status Register shows status of the interrupt flag bits of the Common FIFO buffers.

CFXOFTXIF[5:0] bits (Common FIFO One Frame TX Interrupt Flag Status)

Each bit is set automatically when the corresponding One Frame TX Interrupt flag bit is set in the Common FIFO Status Registers.

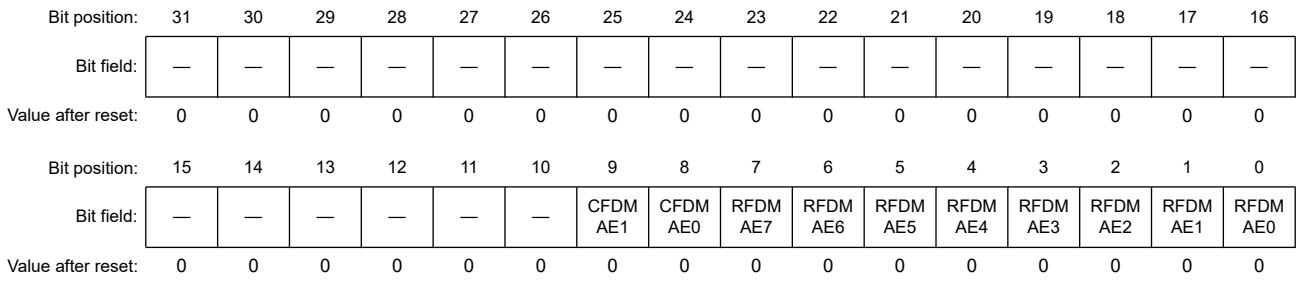
The CFXOFTXIF[5:0] bits are cleared when the CANFD module is in GL_RESET mode.

Each bit is cleared automatically when the corresponding One Frame TX Interrupt flag bit is cleared in the Common FIFO Status Registers.

32.2.43 CFDCDTCT : DMA Transfer Control Register

Base address: CANFD = 0x400B_0000

Offset address: 0x1330



Bit	Symbol	Function	R/W
0	RFDMAE0	DMA Transfer Enable for RXFIFO 0 0: DMA transfer request disabled 1: DMA transfer request enabled	R/W
1	RFDMAE1	DMA Transfer Enable for RXFIFO 1 0: DMA transfer request disabled 1: DMA transfer request enabled	R/W
2	RFDMAE2	DMA Transfer Enable for RXFIFO 2 0: DMA transfer request disabled 1: DMA transfer request enabled	R/W
3	RFDMAE3	DMA Transfer Enable for RXFIFO 3 0: DMA transfer request disabled 1: DMA transfer request enabled	R/W

Bit	Symbol	Function	R/W
4	RFDMAE4	DMA Transfer Enable for RXFIFO 4 0: DMA transfer request disabled 1: DMA transfer request enabled	R/W
5	RFDMAE5	DMA Transfer Enable for RXFIFO 5 0: DMA transfer request disabled 1: DMA transfer request enabled	R/W
6	RFDMAE6	DMA Transfer Enable for RXFIFO 6 0: DMA transfer request disabled 1: DMA transfer request enabled	R/W
7	RFDMAE7	DMA Transfer Enable for RXFIFO 7 0: DMA transfer request disabled 1: DMA transfer request enabled	R/W
8	CFDMAE0	DMA Transfer Enable for Common FIFO 0 of Channel 0 0: DMA transfer request disabled 1: DMA transfer request enabled	R/W
9	CFDMAE1	DMA Transfer Enable for Common FIFO 0 of Channel 1 0: DMA transfer request disabled 1: DMA transfer request enabled	R/W
31:10	—	These bits are read as 0. The write value should be 0.	R/W

The DMA Transfer Control Register controls the start and stop of DMA transfer operation.

RFDMAEn (n = 0 to 7) bit (DMA Transfer Enable for RXFIFOn)

The RFDMAEn bit cannot be set in GL_SLEEP or GL_RESET mode.

This bit is cleared when the CAN-FD module is in GL_RESET mode.

CFDMAEn (n = 0, 1) bit (DMA Transfer Enable for Common FIFO 0 of Channel 0, 1)

The CFDMAEn bit enables or disables DMA transfer request for common FIFO 0 of channel 0 or 1. Only Common FIFO 0 can be linked to a DMA channel with this bit. Common FIFO 1 cannot be linked to a DMA channel.

To link Common FIFO 2, see bit CFDCDTTCT.CFDMAEn in section 32.2.45. CFDCDTTCT : DMA TX Transfer Control Register.

The CFDMAEn bit cannot be set in GL_SLEEP or GL_RESET mode.

Do not enable a DMA transfer for a Common FIFO that is configured as TX or GW FIFO.

This bit is cleared when the CAN-FD module is in GL_RESET mode.

32.2.44 CFDCDTSTS : DMA Transfer Status Register

Base address: CANFD = 0x400B_0000

Offset address: 0x1334

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	CFDMASTS1	CFDMASTS0	RFDMASTS7	RFDMASTS6	RFDMASTS5	RFDMASTS4	RFDMASTS3	RFDMASTS2	RFDMASTS1	RFDMASTS0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	RFDMASTS0	DMA Transfer Status for RX FIFO 0 0: DMA transfer stopped 1: DMA transfer on going	R
1	RFDMASTS1	DMA Transfer Status for RX FIFO 1 0: DMA transfer stopped 1: DMA transfer on going	R
2	RFDMASTS2	DMA Transfer Status for RX FIFO 2 0: DMA transfer stopped 1: DMA transfer on going	R
3	RFDMASTS3	DMA Transfer Status for RX FIFO 3 0: DMA transfer stopped 1: DMA transfer on going	R
4	RFDMASTS4	DMA Transfer Status for RX FIFO 4 0: DMA transfer stopped 1: DMA transfer on going	R
5	RFDMASTS5	DMA Transfer Status for RX FIFO 5 0: DMA transfer stopped 1: DMA transfer on going	R
6	RFDMASTS6	DMA Transfer Status for RX FIFO 6 0: DMA transfer stopped 1: DMA transfer on going	R
7	RFDMASTS7	DMA Transfer Status for RX FIFO 7 0: DMA transfer stopped 1: DMA transfer on going	R
8	CFDMASTS0	DMA Transfer Status only for Common FIFO 0 of Channel 0 0: DMA transfer stopped 1: DMA transfer on going	R
9	CFDMASTS1	DMA Transfer Status only for Common FIFO 0 of Channel 1 0: DMA transfer stopped 1: DMA transfer on going	R
31:10	—	These bits are read as 0.	R

The DMA Transfer Status Register shows the status of the DMA transfer.

RFDMASTSn (n = 0 to 7) bit (DMA Transfer Status for RX FIFO n)

Each bit is set automatically when the corresponding DMA enable bit is set and the corresponding DMA FIFO is not empty.

Each bit is cleared automatically when the DMA transfer stops either because the DMA is disabled or the DMA FIFO is empty.

When CFDCDTCT.RFDMAEn (see CFDCDTCT.RFDMAEn bit in section 32.2.43. CFDCDTCT : DMA Transfer Control Register) is set to 0 while DMA transfer for the corresponding FIFO is on going, the RFDMASTSn bit becomes 0 when the DMA transfer is complete.

This bit is cleared when the CAN-FD module is in GL_RESET mode.

CFDMASTSn bit (DMA Transfer Status only for Common FIFO 0 of Channel 0, 1)

Each bit is set automatically when the corresponding DMA enable bit is set and the corresponding DMA FIFO is not empty.

Each bit is cleared automatically when the DMA transfer stops either because the DMA is disabled or the DMA FIFO is empty.

When CFDCDTCT.CFDMAEn (see CFDCDTCT.CFDMAEn bit in section 32.2.43. CFDCDTCT : DMA Transfer Control Register) is set to 0 while DMA transfer for the corresponding FIFO is on going, the CFDMASTSn bit becomes 0 when the DMA transfer is complete.

This bit is cleared when the CAN-FD module is in GL_RESET mode.

32.2.45 CFDCDTTCT : DMA TX Transfer Control Register

Base address: CANFD = 0x400B_0000

Offset address: 0x1340

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CFDMAE1	CFDMAE0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	TQ3DMAE1	TQ3DMAE0	—	—	—	—	—	—	TQ0DMAE1	TQ0DMAE0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TQ0DMAE0	DMA TX Transfer Enable for TXQ 0 of Channel 0 0: DMA TX transfer request disabled 1: DMA TX transfer request enabled	R/W
1	TQ0DMAE1	DMA TX Transfer Enable for TXQ 0 of Channel 1 0: DMA TX transfer request disabled 1: DMA TX transfer request enabled	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W
8	TQ3DMAE0	DMA TX Transfer Enable for TXQ 3 of Channel 0 0: DMA TX transfer request disabled 1: DMA TX transfer request enabled	R/W
9	TQ3DMAE1	DMA TX Transfer Enable for TXQ 3 of Channel 1 0: DMA TX transfer request disabled 1: DMA TX transfer request enabled	R/W
15:10	—	These bits are read as 0. The write value should be 0.	R/W
16	CFDMAE0	DMA TX Transfer Enable for Common FIFO 2 of Channel 0 0: DMA TX transfer request disabled 1: DMA TX transfer request enabled	R/W
17	CFDMAE1	DMA TX Transfer Enable for Common FIFO 2 of Channel 1 0: DMA TX transfer request disabled 1: DMA TX transfer request enabled	R/W
31:18	—	These bits are read as 0. The write value should be 0.	R/W

The DMA TX Transfer Control Register controls the start and stop of DMA transfer operation.

TQ0DMAEn (n = 0, 1) bit (DMA TX Transfer Enable for TXQ 0 of Channel n)

The TQ0DMAEn bit cannot be set in GL_SLEEP or GL_RESET mode.

This bit is cleared when the CANFD module is in GL_RESET mode.

TQ3DMAEn (n = 0, 1) bit (DMA TX Transfer Enable for TXQ 3 of Channel n)

The TQ3DMAEn bit cannot be set in GL_SLEEP or GL_RESET mode.

This bit is cleared when the CANFD module is in GL_RESET mode.

CFDMAEn (n = 0, 1) bit (DMA TX Transfer Enable for Common FIFO 2 of Channel n)

The CFDMAEn bit cannot be set in GL_SLEEP or GL_RESET mode.

Only common FIFO 2 can be linked to a DMA channel with this bit. Common FIFO 1 cannot be linked to a DMA channel.

To link Common FIFO 0, see CFDCDTCT.CFDMAEn bit in section 32.2.43. CFDCDTCT : DMA Transfer Control Register.

Do not enable a DMA transfer for a Common FIFO that is configured as RX or GW FIFO.

The CFDMAEn bit is cleared when the CANFD module is in GL_RESET mode.

32.2.46 CFDCDTTSTS : DMA TX Transfer Status Register

Base address: CANFD = 0x400B_0000

Offset address: 0x1344

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CFDMASTS1	CFDMASTS0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	TQ3DMASTS1	TQ3DMASTS0	—	—	—	—	—	—	TQ0DMASTS1	TQ0DMASTS0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TQ0DMASTS0	DMA TX Transfer Status for TXQ0 of Channel 0 0: DMA transfer stopped 1: DMA transfer enabled	R
1	TQ0DMASTS1	DMA TX Transfer Status for TXQ0 of Channel 1 0: DMA transfer stopped 1: DMA transfer enabled	R
7:2	—	These bits are read as 0. The write value should be 0.	R
8	TQ3DMASTS0	DMA TX Transfer Status for TXQ3 of Channel 0 0: DMA transfer stopped 1: DMA transfer enabled	R
9	TQ3DMASTS1	DMA TX Transfer Status for TXQ3 of Channel 1 0: DMA transfer stopped 1: DMA transfer enabled	R
15:10	—	These bits are read as 0. The write value should be 0.	R
16	CFDMASTS0	DMA TX Transfer Status only for Common FIFO 2 of Channel 0 0: DMA transfer stopped 1: DMA transfer enabled	R
17	CFDMASTS1	DMA TX Transfer Status only for Common FIFO 2 of Channel 1 0: DMA transfer stopped 1: DMA transfer enabled	R
31:18	—	These bits are read as 0. The write value should be 0.	R/W

The DMA TX Transfer Status Register shows the status of the DMA transfer.

TQ0DMASTSn (n = 0, 1) bit (DMA TX Transfer Status for TXQ 0 of Channel n)

The TQ0DMASTSn bit is set when the CFDCDTTCT.TQ0DMAEn bit in the corresponding CFDCDTTCT register is set (see section 32.2.45. CFDCDTTCT : DMA TX Transfer Control Register).

This bit is cleared when:

- The CFDCDTTCT.TQ0DMAEn bit in the corresponding CFDCDTTCT register is cleared
- The CANFD module is in GL_RESET mode.

TQ3DMASTSn (n = 0, 1) bit (DMA TX Transfer Status for TXQ 3 of Channel n)

The TQ3DMASTSn bit is set when the CFDCDTTCT.TQ3DMAEn bit in the corresponding CFDCDTTCT register is set (see section 32.2.45. CFDCDTTCT : DMA TX Transfer Control Register).

This bit is cleared when:

- The CFDCDTTCT.TQ3DMAEn bit in the corresponding CFDCDTTCT register is cleared

- The CANFD module is in GL_RESET mode.

CFDMASTSn (n = 0, 1) bit (DMA TX Transfer Status only for Common FIFO 2 of Channel n)

The CFDMASTSn bit is set when the CFDCDTTCT.CFDMAEn bit in the corresponding CFDCDTTCT register is set (see section 32.2.45. CFDCDTTCT : DMA TX Transfer Control Register).

This bit is cleared when:

- The CFDCDTTCT.CFDMAEn bit in the corresponding CFDCDTTCT register is cleared
- The CANFD module is in GL_RESET mode.

32.2.47 CFDGRINTSTSn : Global RX Interrupt Status Register n (n = 0, 1)

Base address: CANFD = 0x400B_0000

Offset address: 0x1350 + 0x04 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	QFIF[2:0]	TXQ Full Interrupt Flag Channel n (n = 0, 1) 0: Corresponding TXQ Full Interrupt flag is not set 1: Corresponding TXQ Full Interrupt flag is set	R
7:3	—	These bits are read as 0. The write value should be 0.	R/W
10:8	QOFRIF[2:0]	TXQ One Frame RX Interrupt Flag Channel n (n = 0, 1) 0: Corresponding TXQ One Frame RX Interrupt flag is not set 1: Corresponding TXQ One Frame RX Interrupt flag is set	R
15:11	—	These bits are read as 0. The write value should be 0.	R/W
18:16	CFRIF[2:0]	Common FIFO RX Interrupt Flag Channel n (n = 0, 1) 0: Corresponding Common FIFO RX Interrupt flag is not set 1: Corresponding Common FIFO RX Interrupt flag is set	R
23:19	—	These bits are read as 0. The write value should be 0.	R/W
26:24	CFRFIF[2:0]	Common FIFO FDC Level Full Interrupt Flag Channel n (n = 0, 1) 0: Corresponding Common FIFO Full Interrupt flag is not set 1: Corresponding Common FIFO Full Interrupt flag is set	R
27	—	This bit is read as 0. The write value should be 0.	R/W
30:28	CFOFRIF[2:0]	Common FIFO One Frame RX Interrupt Flag Channel n (n = 0, 1) 0: Corresponding Common FIFO One Frame RX Interrupt flag is not set 1: Corresponding Common FIFO One Frame RX Interrupt flag is set	R
31	—	This bit is read as 0. The write value should be 0.	R/W

QFIF[2:0] bits (TXQ Full Interrupt Flag Channel n (n = 0, 1))

The QFIF[2:0] bits are set automatically when the TXQ Full Interrupt flag of the related channel is set when the interrupt is enabled.

The QFIF[2:0] bits are cleared automatically when:

- The related TXQ result status bits are cleared or the interrupt enable is disabled
- The CANFD module is in GL_RESET mode
- The related CANFD channel is in CH_RESET mode.

QOFRIF[2:0] bits (TXQ One Frame RX Interrupt Flag Channel n (n = 0, 1))

The QOFRIF[2:0] bits are set automatically when the TXQ One Frame RX Interrupt flag of the related channel is set when the interrupt is enabled.

The QOFRIF[2:0] bits are cleared automatically when:

- The related TXQ result status bits are cleared or the interrupt enable is disabled
- The CANFD module is in GL_RESET or CH_RESET mode.

CFRIF[2:0] bits (Common FIFO RX Interrupt Flag Channel n (n = 0, 1))

The CFRIF[2:0] bits are set automatically when the Common FIFO RX Interrupt flag of the related channel is set when the interrupt is enabled.

The CFRIF[2:0] bits are cleared automatically when:

- The related Common FIFO RX result status bits are cleared or the interrupt enable is disabled
- The CANFD module is in GL_RESET or CH_RESET mode.

CFRFIF[2:0] bits (Common FIFO FDC Level Full Interrupt Flag Channel n (n = 0, 1))

The CFRFIF[2:0] bits are set automatically when the Common FIFO Full Interrupt flag of the related channel is set when the interrupt is enabled.

The CFRFIF[2:0] bits are cleared automatically when:

- The related Common FIFO RX result status bits are cleared or the interrupt enable is disabled
- The CANFD module is in GL_RESET mode
- The related CANFD channel is in CH_RESET mode.

CFOFRIF[2:0] bits (Common FIFO One Frame RX Interrupt Flag Channel n (n = 0, 1))

The CFOFRIF[2:0] bits are set automatically when the Common FIFO One Frame RX Interrupt flag of the related channel is set when the interrupt is enabled.

The CFOFRIF[2:0] bits are cleared automatically when:

- The related Common FIFO RX result status bits are cleared or the interrupt enable is disabled
- The CANFD module is in GL_RESET mode
- The related CANFD channel is in CH_RESET mode.

32.2.48 CFDTMCn : TX Message Buffer Control Registers n (n = 0 to 7, 32 to 39, 64 to 71, 96 to 103)

Base address: CANFD = 0x400B_0000

Offset address: 0x02D0 + 0x01 × n

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	TMOM	TMTAR	TMTR
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TMTR	TX Message Buffer Transmission Request 0: TX Message buffer transmission not requested 1: TX message buffer transmission requested	R/W
1	TMTAR	TX Message Buffer Transmission Abort Request 0: TX message buffer transmission request abort not requested 1: TX message buffer transmission request abort requested	R/W
2	TMOM	TX Message Buffer One-shot Mode 0: TX message buffer not configured in one-shot mode 1: TX message buffer configured in one-shot mode	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W

The TX Message Buffer Control Registers configure the TX message buffer functions.

TMTR bit (TX Message Buffer Transmission Request)

When the TMTR bit is set, the CAN-FD module logic tries to transmit the message stored in the corresponding message buffer.

Only write to this bit when the related CAN-FD module is in CH_HALT or CH_OPERATION mode.

Do not set this bit if the corresponding TX message buffer is linked to a COM FIFO in TX or GW mode or is a part of TX Queue.

This bit cannot be directly cleared by a CPU write access.

This bit can only be set when the Transmission Result flag bits (CFDTMSTSn.TMTRF) in the CFDTMSTSn register corresponding to the message buffer are cleared to 00b.

The TMTR bit is automatically cleared by the:

- CAN-FD module logic at the end of a successful transmission
- CAN-FD module logic at the end of a transmission abort, requested by the corresponding CFDTMCn.TMTAR bit
- CAN-FD module logic when there is a detection of a CAN bus error or arbitration loss if CFDTMCn.TMOM bit is set for the message buffer
- CAN-FD module logic when the CAN-FD module is in GL_RESET mode or the related channel is in CH_RESET mode.

TMTAR bit (TX Message Buffer Transmission Abort Request)

When the TMTAR bit is set, the CAN-FD module logic tries to abort the transmission of the frame stored in the corresponding message buffer.

In most cases, transmission cannot be aborted if the internal scan for transmission is complete and the message buffer has already been selected for transmission. In this case, frame may be transmitted successfully from the message buffer. The message buffer selection is released by entering CH_HALT mode.

However, message buffer selected for transmission can be aborted by an abort request when the CAN node detects a new message on the bus (RX pin) before it starts transmission from the selected message buffer.

Only write to the TMTAR bit when the related CAN-FD channel is in CH_HALT or CH_OPERATION mode. This bit can only be set when the related transmit request TMTR bit is set.

The TMTAR bit cannot be cleared by a CPU write access. Clearing of this bit by CAN-FD has priority over setting by a CPU write access.

The TMTAR bit is automatically cleared by:

- The CAN-FD module logic at the end of a successful transmission
- The CAN-FD module logic at the end of a transmission abort
- The CAN-FD module logic when there is detection of a CAN bus error or arbitration loss
- The CAN-FD module logic when the CAN-FD module is in GL_RESET mode or the related channel enters CH_RESET mode.

TMOM bit (TX Message Buffer One-shot Mode)

When the TMOM bit is set, the CAN-FD module logic tries to transmit the message only once.

If the transmission is successful, the CFDTMSTSn.TMTRF bits are set to 10b or 11b. Otherwise, the transmission is automatically aborted and CFDTMSTSn.TMTRF bits are set to 01b due to a bus error or a bus arbitration lost.

The TMOM bit remains set if the transmission has completed successfully or aborted due to an error or a loss of arbitration.

Only write to this bit when the related CAN-FD channel is in CH_HALT or CH_OPERATION mode.

Set this bit at the same time as the TMTR bit. Clear this bit with a write access.

If a message has already been requested for transmission, do not write to this bit until the message has been successfully transmitted or transmission has been aborted.

The TMOM bit is automatically cleared by the CAN-FD module logic when the CAN-FD module is in GL_RESET mode or the related channel is in CH_RESET mode.

32.2.49 CFDTMSTSn : TX Message Buffer Status Registers n (n = 0 to 7, 32 to 39, 64 to 71, 96 to 103)

Base address: CANFD = 0x400B_0000

Offset address: 0x07D0 + 0x01 × n

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	TMTARM	TMTRM	TMTRF[1:0]		TMTSTS
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TMTSTS	TX Message Buffer Transmission Status 0: No on-going transmission 1: On-going transmission	R
2:1	TMTRF[1:0]	TX Message Buffer Transmission Result Flag 0 0: No result 0 1: Transmission aborted from the TX message buffer 1 0: Transmission successful from the TX message buffer and transmission abort was not requested 1 1: Transmission successful from the TX message buffer and transmission abort was requested	R/W
3	TMTRM	TX Message Buffer Transmission Request Mirrored 0: TX message buffer transmission not requested 1: TX message buffer transmission requested	R
4	TMTARM	TX Message Buffer Transmission Abort Request Mirrored 0: TX message buffer transmission request abort not requested 1: TX message buffer transmission request abort requested	R
7:5	—	These bits are read as 0. The write value should be 0.	R/W

The TX Message Buffer Status Registers show status of the transmission and transmission abort for the corresponding message buffers.

TMTSTS bit (TX Message Buffer Transmission Status)

The TMTSTS bit is set automatically at the start of the transmission from the corresponding TX message buffer.

This bit is cleared automatically when:

- Transmission stops
- The CAN-FD module is in GL_RESET mode
- The related CAN-FD channel is in CH_RESET mode.

TMTRF[1:0] bits (TX Message Buffer Transmission Result Flag)

The TMTRF[1:0] bits show the result for the corresponding TX message buffer. The status is as follows:

- 00: Transmission in progress or has not been requested
- 01: Transmission has been aborted from the corresponding TX message buffer
- 10: Transmission was successful from the corresponding TX message buffer and the CFDTMCn.TMTAR bit was not set for this TX message buffer
- 11: Transmission was successful from the corresponding TX message buffer, but the CFDTMCn.TMTAR bit was set for this TX message buffer.

Only write to these bits when the related CAN-FD channel is in CH_HALT or CH_OPERATION mode.

The TMTRF[1:0] bits are cleared automatically when the CAN-FD module is in GL_RESET mode or the related channel is in CH_RESET mode.

TMTRM bit (TX Message Buffer Transmission Request Mirrored)

The TMTRM bit is set when the CFDTMCn.TMTR bit in the corresponding CFDTMCn register is set.

This bit is cleared when the CFDTMCn.TMTR bit in the corresponding CFDTMCn register is cleared.

TMTARM bit (TX Message Buffer Transmission Abort Request Mirrored)

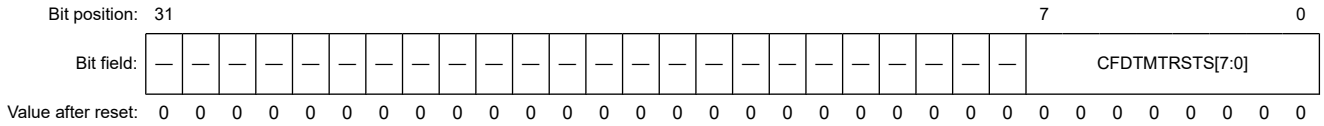
The TMTARM bit is set when the CFDTMCn.TMTAR bit in the corresponding CFDTMCn register is set.

This bit is cleared when the CFDTMCn.TMTAR bit in the corresponding CFDTMCn register is cleared.

32.2.50 CFDTMTRSTSf : TX Message Buffer Transmission Request Status Register f (f = 0 to 3)

Base address: CANFD = 0x400B_0000

Offset address: 0x0CD0 + 0x04 × f



Bit	Symbol	Function	R/W
7:0	CFDTMTRSTS[7:0]	TX Message Buffer Transmission Request Status 0: Transmission not requested for corresponding TX message buffer 1: Transmission requested for corresponding TX message buffer	R
31:8	—	These bits are read as 0. The write value should be 0.	R

CFDTMTRSTS[7:0] bits (TX Message Buffer Transmission Request Status)

The CFDTMTRSTS[7:0] bits show status of the CFDTMCn.TMTR bits of the TX Message Buffer Control Registers.

Each bit is set automatically when the corresponding bit is set in the TX Message Buffer Control Registers (CFDTMCn), and only when the message buffer does not belong to a TX Queue.

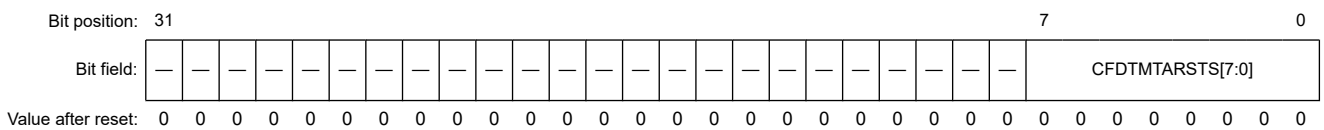
Each bit is cleared automatically when:

- The corresponding bit is cleared in the TX Message Buffer Control Registers
- The CAN-FD module is in GL_RESET mode
- The related CAN-FD channel is in CH_RESET mode.

32.2.51 CFDTMTARSTSf : TX Message Buffer Transmission Abort Request Status Register f (f = 0 to 3)

Base address: CANFD = 0x400B_0000

Offset address: 0x0D70 + 0x04 × f



Bit	Symbol	Function	R/W
7:0	CFDTMTARSTS[7:0]	TX Message Buffer Transmission Abort Request Status 0: Transmission abort not requested for corresponding TX message buffer 1: Transmission abort requested for corresponding TX message buffer	R
31:8	—	These bits are read as 0. The write value should be 0.	R

CFDTMTARSTS[7:0] bits (TX Message Buffer Transmission Abort Request Status)

The CFDTMTARSTS[7:0] bits show status of the CFDTMCn.TMTAR bits of the TX Message Buffer Control Registers.

Alignment of the CFDTMTARSTS[7:0] bits is shown in Table 32.5.

Table 32.5 Alignment of CFDTMTARSTS[7:0] mirror bits

Bit position	g = TX message buffer number
n*64-fmin*32	n*64+0
n*64+1-fmin*32	n*64+1
⋮	⋮
n*64+31-fmin*32	n*64+31
n*64+32-fmax*32	n*64+32
n*64+33-fmax*32	n*64+33
⋮	⋮
n*64+62-fmax*32	n*64+62
n*64+63-fmax*32	n*64+63

Note: When n = 0, fmin = 0, fmax = 1
When n = 1, fmin = 2, fmax = 3

Each bit is set automatically when the corresponding bit is set in the TX Message Buffer Control Registers, and when the message buffer belongs to a TX Queue.

Each bit is cleared automatically when:

- The corresponding bit is cleared in the TX Message Buffer Control Registers
- The CAN-FD module is in GL_RESET mode
- The related CAN-FD channel is in CH_RESET mode.

32.2.52 CFDTMTCSTSf : TX Message Buffer Transmission Completion Status Register f (f = 0 to 3)

Base address: CANFD = 0x400B_0000

Offset address: 0x0E10 + 0x04 × f

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CFDTMTCSTS[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	CFDTMTCSTS[7:0]	TX Message Buffer Transmission Completion Status 0: Transmission not complete for corresponding TX message buffer 1: Transmission completed for corresponding TX message buffer	R
31:8	—	These bits are read as 0. The write value should be 0.	R

CFDTMTCSTS[7:0] bits (TX Message Buffer Transmission Completion Status)

The CFDTMTCSTS[7:0] bits show status of successful completion of the TX Message Buffer Status Registers.

Each bit is set automatically when the corresponding bit is set in the TX Message Buffer Status Registers.

Each bit is cleared automatically when:

- The corresponding bit is cleared in the TX Message Buffer Status Registers
- The CANFD module is in GL_RESET mode
- The related CANFD channel is in CH_RESET mode.

If a CAN channel enters CH_RESET mode, then the bits related to that channel are cleared.

32.2.53 CFDTMTASTSf : TX Message Buffer Transmission Abort Status Register f (f = 0 to 3)

Base address: CANFD = 0x400B_0000

Offset address: 0x0EB0 + 0x04 × f

Bit position:	31																								7							0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CFDTMTASTS[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	CFDTMTASTS[7:0]	TX Message Buffer Transmission Abort Status 0: Transmission not aborted for corresponding TX message buffer 1: Transmission aborted for corresponding TX message buffer	R
31:8	—	These bits are read as 0. The write value should be 0.	R

CFDTMTASTS[7:0] bits (TX Message Buffer Transmission Abort Status)

The CFDTMTASTS[7:0] bits show status of the successful transmission abort of the corresponding TX message buffer.

Alignment of the CFDTMTASTS[7:0] bits is shown in Table 32.6.

Table 32.6 Alignment of CFDTMTASTS[7:0] mirror bits

Bit position	g = TX message buffer number
n*64-fmin*32	n*64+0
n*64+1-fmin*32	n*64+1
⋮	⋮
n*64+31-fmin*32	n*64+31
n*64+32-fmax*32	n*64+32
n*64+33-fmax*32	n*64+33
⋮	⋮
n*64+62-fmax*32	n*64+62
n*64+63-fmax*32	n*64+63

Note: When n = 0, fmin = 0, fmax = 1
When n = 1, fmin = 2, fmax = 3

Each bit is set automatically when the CFDTMSTSn.TMTRF bits are set to 01b in the corresponding TX Message Buffer Status Register.

Each bit is cleared automatically when:

- The CFDTMSTSn.TMTRF bits are cleared in the corresponding TX Message Buffer Status Register
- The CAN-FD module is in GL_RESET mode
- The related CAN-FD channel is in CH_RESET mode.

32.2.54 CFDTMIECf : TX Message Buffer Interrupt Enable Configuration Register f (f = 0 to 3)

Base address: CANFD = 0x400B_0000

Offset address: 0x0F50 + 0x04 × f

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TMIE[7:0]
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	TMIE[7:0]	TX Message Buffer Interrupt Enable 0: TX message buffer interrupt disabled for corresponding TX message buffer 1: TX message buffer interrupt enabled for corresponding TX message buffer	R/W
31:8	—	These bits are read as 0. The write value should be 0.	R

TMIE[7:0] bits (TX Message Buffer Interrupt Enable)

If the TMIE[7:0] bits are set, an interrupt is generated at the end of a successful transmission from the corresponding message buffer.

See section 32.7. Interrupts and DMA for TX Message Buffer Interrupt specification.

Do not write to the TMIE[7:0] bits when:

- The CAN-FD module is in GL_SLEEP mode
- The related CAN-FD channel is in CH_SLEEP mode
- The corresponding TX message buffer is part of a TX Queue
- The corresponding TX message buffer is linked to a Common FIFO with the CFDCFCCn.CFTML bits.

32.2.55 CFDTXQCC0n : TX Queue Configuration/Control Registers 0n (n = 0, 1)

Base address: CANFD = 0x400B_0000

Offset address: 0x1000 + 0x04 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	TXQOFTXIE	TXQOFRXIE	TXQFIE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	TXQDC[12:8]					TXQIM	—	TXQTXIE	—	—	—	TXQGWE	TXQE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

15:13	—	These bits are read as 0. The write value should be 0.	R/W
16	TXQFIE	TXQ Full Interrupt Enable 0: TX Queue full interrupt generation disabled 1: TX Queue full interrupt generation enabled	R/W
17	TXQOFRXIE	TXQ One Frame Reception Interrupt Enable 0: One Frame RX interrupt generation disabled 1: One Frame RX interrupt generation enabled	R/W
18	TXQOFTXIE	TXQ One Frame Transmission Interrupt Enable 0: One Frame TX interrupt generation disabled 1: One Frame TX interrupt generation enabled	R/W
31:19	—	These bits are read as 0. The write value should be 0.	R/W

The TX Queue Configuration/Control Registers 0n (n = 0, 1) are used to configure the TX Queue transmission.

TXQ0 is composed of TXMB0 to TXMB31 (at the maximum) when TXQE is enabled.

TXQE bit (TX Queue Enable)

The TXQE bit cannot be set if the configured TX Queue depth is 0x00 (CFDTXQCC0n.TXQDC == 0x00).

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in CH_RESET or CH_SLEEP mode.

The TXQE bit is cleared automatically when the related CAN-FD channel is in CH_RESET mode.

TXQGWE bit (TX Queue Gateway Mode Enable)

When the TXQGWE bit is set, the TX Queue is in TX Queue GW mode.

When this bit is set, CPU must not access the TX Queue.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in any of the following modes:

- CH_SLEEP
- CH_HALT
- CH_OPERATION.

TXQTXIE bit (TX Queue TX Interrupt Enable)

When the TXQTXIE bit is set, an interrupt is generated based on the setting of the TXQIM bit.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in CH_SLEEP mode.

TXQIM bit (TX Queue Interrupt Mode)

The TXQIM bit selects the interrupt generation condition for the TX Queue.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in any of the following modes:

- CH_SLEEP
- CH_HALT
- CH_OPERATION.

TXQDC[12:8] bits (TX Queue Depth Configuration)

The TXQDC[12:8] bits select the depth of the transmission queue. The message buffer selection starts from MB[0] up to MB[7] depending on the configured depth.

When using TXQ1 and TXQ0 simultaneously, the total depth of TXQ1 and TXQ0 should be 8 or less.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in any of the following modes:

- CH_SLEEP
- CH_HALT
- CH_OPERATION.

TXQFIE bit (TXQ Full Interrupt Enable)

When the TXQFIE bit is set, an interrupt is generated based on the setting of the CFDTXQSTS0n.TXQFIF bit.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in CH_SLEEP mode.

Only write 1 to this bit in Gateway mode (CFDTXQCC0n.TXQGWE = 1).

TXQOFRXIE bit (TXQ One Frame Reception Interrupt Enable)

When the TXQOFRXIE bit is set, an interrupt is generated based on the setting of the CFDTXQSTS0n.TXQOFRXIF bit.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in CH_SLEEP mode.

Only write 1 to this bit in GW mode (CFDTXQCC0n.TXQGWE = 1).

TXQOFTXIE bit (TXQ One Frame Transmission Interrupt Enable)

When the TXQOFTXIE bit is set, an interrupt is generated based on the setting of the CFDTXQSTS0n.TXQOFTXIF bit.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in CH_SLEEP mode.

32.2.56 CFDTXQCC1n : TX Queue Configuration/Control Registers 1n (n = 0, 1)

Base address: CANFD = 0x400B_0000

Offset address: 0x1060 + 0x04 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

31:19	—	These bits are read as 0. The write value should be 0.	R/W

The TX Queue Configuration/Control Registers 1n (n = 0, 1) are used to configure the TX Queue transmission.

TXQ1 is composed of TXMB31 to TXMB0 (at the maximum) when TXQE is enabled.

TXQE bit (TX Queue Enable)

The TXQE bit cannot be set if the configured TX Queue depth is 0x00 (CFDTXQCC1n.TXQDC == 0x00).

You cannot write to this bit when the CANFD module is in GL_SLEEP mode.

Do write to this bit when the related CANFD channel is in CH_RESET or CH_SLEEP mode.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode.

TXQGWE bit (TX Queue Gateway Mode Enable)

When the TXQGWE bit is set, the TX Queue is in TX Queue Gateway mode.

When this bit is set, CPU must not access the TX Queue.

You cannot write to this bit when the CANFD module is in GL_SLEEP mode.

Do not write to this bit when the related CANFD channel is in any of the following modes:

- CH_SLEEP
- CH_HALT
- CH_OPERATION.

TXQTXIE bit (TX Queue TX Interrupt Enable)

When the TXQTXIE bit is set, an interrupt is generated based on the setting of the TXQIM bit.

You cannot write to this bit when the CANFD module is in GL_SLEEP mode.

Do not write to this bit when the related CANFD channel is in CH_SLEEP mode.

TXQIM bit (TX Queue Interrupt Mode)

The TXQIM bit selects the interrupt generation condition for the TX Queue.

You cannot write to this bit when the CANFD module is in GL_SLEEP mode.

Do not write to this bit when the related CANFD channel is in any of the following modes:

- CH_SLEEP
- CH_SLEEP
- CH_OPERATION.

TXQDC[12:8] bits (TX Queue Depth Configuration)

The TXQDC[12:8] bits select the depth of the transmission queue. The message buffer selection starts from MB[7] down to MB[0] depending on the configured depth.

When using TXQ1 and TXQ0 simultaneously, the total depth of TXQ1 and TXQ0 should be 8 or less.

You cannot write to this bit when the CANFD module is in GL_SLEEP mode.

Do not write to this bit when the related CANFD channel is in any of the following modes:

- CH_SLEEP
- CH_HALT
- CH_OPERATION.

TXQFIE bit (TXQ Full Interrupt Enable)

When the TXQFIE bit is set, an interrupt is generated based on the setting of the CFDTXQSTS1n.TXQFIF bit.

You cannot write to this bit when the CANFD module is in GL_SLEEP mode.

Do not write to this bit when the related CANFD channel is in CH_SLEEP mode.

Only write 1 to this bit when in Gateway mode (CFDTXQCC1n.TXQGWE = 1)..

TXQOFRXIE bit (TXQ One Frame Reception Interrupt Enable)

When the TXQOFRXIE bit is set, an interrupt is generated based on the setting of the CFDTXQSTS1n.TXQOFRXIF bit.

You cannot write to this bit when the CANFD module is in GL_SLEEP mode.

Do not write to this bit when the related CANFD channel is in CH_SLEEP mode.

Only write 1 to this bit when in Gateway mode (CFDTXQCC1n.TXQGWE = 1).

TXQOFTXIE bit (TXQ One Frame Transmission Interrupt Enable)

When the TXQOFTXIE bit is set, an interrupt is generated based on the setting of the CFDTXQSTS1n.TXQOFTXIF bit.

You cannot write to this bit when the CANFD module is in GL_SLEEP mode.

Do not write to this bit when the related CANFD channel is in CH_SLEEP mode.

32.2.57 CFDTXQCC2n : TX Queue Configuration/Control Registers 2n (n = 0, 1)

31:19	—	These bits are read as 0. The write value should be 0.	R/W

The TX Queue Configuration/Control Registers 2n (n = 0, 1) are used to configure the TX Queue transmission.

TXQ2 is composed of TXMB32 to TXMB63 (at the maximum) when TXQE is enabled.

TXQE bit (TX Queue Enable)

The TXQE bit cannot be set if the configured TX Queue depth is 0x00 (CFDTXQCC2n.TXQDC == 0x00).

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode.

You cannot write to this bit when the CANFD module is in GL_SLEEP mode.

Do not write to this bit when the related CANFD channel is in CH_RESET or CH_SLEEP mode.

TXQGWE bit (TX Queue Gateway Mode Enable)

When the TXQGWE bit is set, the TX Queue is in TX Queue Gateway mode. When this bit is set, CPU must not access the TX Queue.

You cannot write to this bit when the CANFD module is in GL_SLEEP mode.

Do not write to this bit when the related CANFD channel is in any of the following modes:

- CH_SLEEP
- CH_HALT
- CH_OPERATION.

TXQTXIE bit (TX Queue TX Interrupt Enable)

When the TXQTXIE bit is set, an interrupt is generated based on the setting of the TXQIM bit.

You cannot write to this bit when the CANFD module is in GL_SLEEP mode.

Do not write to this bit when the related CANFD channel is in CH_SLEEP mode.

TXQIM bit (TX Queue Interrupt Mode)

The TXQIM bit selects the interrupt generation condition for the TX Queue.

You cannot write to this bit when the CANFD module is in GL_SLEEP mode.

Do not write to this bit when the related CANFD channel is in any of the following modes:

- CH_SLEEP
- CH_HALT
- CH_OPERATION.

TXQDC[12:8] bits (TX Queue Depth Configuration)

The TXQDC[12:8] bits select the depth of the transmission queue. The message buffer selection starts from MB[32] up to MB[39] depending on the configured depth.

When using TXQ3 and TXQ2 simultaneously, the total depth of TXQ3 and TXQ2 should be 8 or less.

You cannot write to this bit when the CANFD module is in GL_SLEEP mode.

Do not write to this bit when the related CANFD channel is in any of the following modes:

- CH_HALT
- CH_OPERATION
- CH_SLEEP.

TXQFIE bit (TXQ Full Interrupt Enable)

When the TXQFIE bit is set, an interrupt is generated based on the setting of the CFDTXQSTS2n.TXQFIF bit.

You cannot write to this bit when the CANFD module is in GL_SLEEP mode.

Do not write to this bit when the related CANFD channel is in CH_SLEEP mode.

Only write 1 to this bit when in GW mode (CFDTXQCC2n.TXQGWE = 1).

TXQOFRXIE bit (TXQ One Frame Reception Interrupt Enable)

When the TXQOFRXIE bit is set, an interrupt is generated based on the setting of the CFDTXQSTS2n.TXQOFRXIF bit.

You cannot write to this bit when the CANFD module is in GL_SLEEP mode.

Do not write to this bit when the related CANFD channel is in CH_SLEEP mode.

Only write 1 to this bit when in GW mode (CFDTXQCC2n.TXQGWE = 1).

TXQOFTXIE bit (TXQ One Frame Transmission Interrupt Enable)

When the TXQOFTXIE bit is set, an interrupt is generated based on the setting of the CFDTXQSTS2n.TXQOFTXIF bit.

You cannot write to this bit when the CANFD module is in GL_SLEEP mode.

Do not write to this bit when the related CANFD channel is in CH_SLEEP mode.

32.2.58 CFDTXQCC3n : TX Queue Configuration/Control Registers 3n (n = 0, 1)

Base address: CANFD = 0x400B_0000

Offset address: 0x1120 + 0x04 × n

31:19	—	These bits are read as 0. The write value should be 0.	R/W

The TX QueueConfiguration/Control Registers 3n (n = 0, 1) are used to configure the TX Queue transmission.

TXQ3 is composed of TXMB63 to TXMB32 (at the maximum) when TXQE is enabled.

TXQE bit (TX Queue Enable)

The TXQE bit cannot be set if the configured TX Queue depth is 0x00 (CFDTXQCC3n.TXQDC == 0x00).

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode.

You cannot write to this bit when the CANFD module is in GL_SLEEP mode.

Do not write to this bit when the related CANFD channel is in CH_RESET or CH_SLEEP mode.

TXQTXIE bit (TX Queue TX Interrupt Enable)

When the TXQTXIE bit is set, an interrupt is generated based on the setting of the TXQIM bit.

You cannot write to this bit when the CANFD module is in GL_SLEEP mode.

Do not write to this bit when the related CANFD channel is in CH_SLEEP mode.

TXQIM bit (TX Queue Interrupt Mode)

The TXQIM bit selects the interrupt generation condition for the TX Queue.

You cannot write to this bit when the CANFD module is in GL_SLEEP mode.

Do not write to this bit when the related CANFD channel is in any of the following modes:

- CH_SLEEP
- CH_HALT
- CH_OPERATION mode.

TXQDC[12:8] bits (TX Queue Depth Configuration)

The TXQDC[12:8] bits select the depth of the transmission queue. The message buffer selection starts from MB[39] down to MB[32] depending on the configured depth.

When using TXQ3 and TXQ2 simultaneously, the total depth of TXQ3 and TXQ2 should be 8 or less.

You cannot write to this bit when the CANFD module is in GL_SLEEP mode.

Do not write to this bit when the related CANFD channel is in any of the following modes:

- CH_SLEEP
- CH_HALT
- CH_OPERATION mode.

TXQOFTXIE bit (TXQ One Frame Transmission Interrupt Enable)

When the TXQOFTXIE bit is set, an interrupt is generated based on the setting of the CFDTXQSTS3n.TXQOFTXIF bit.

You cannot write to this bit when the CANFD module is in GL_SLEEP mode.

Do not write to this bit when the related CANFD channel is in CH_SLEEP mode.

32.2.59 CFDTXQSTS0n : TX Queue Status Registers 0n (n = 0, 1)

Base address: CANFD = 0x400B_0000

Offset address: 0x1020 + 0x04 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15:14	—	These bits are read as 0. The write value should be 0.	R/W
16	TXQFIF	TXQ Full Interrupt Flag When TXQ is in full status, an interrupt is set.	R/W
17	TXQOFRXIF	TXQ One Frame Reception Interrupt Flag When TXQ receives one frame, an interrupt is set.	R/W
18	TXQOFTXIF	TXQ One Frame Transmission Interrupt Flag When one frame transmits from TXQ, an interrupt is set.	R/W
19	TXQMLT	TXQ Message Lost 0: No message lost in TXQ 1: TXQ message lost	R/W
31:20	—	These bits are read as 0. The write value should be 0.	R/W

The TX Queue Status Registers 0n (n = 0, 1) show the status of the TX Queue of corresponding CAN channel.

TXQEMP bit (TX Queue Empty)

The TXQEMP bit is set automatically when the TX Queue is disabled or no messages are stored in the TX Queue.

This bit is set automatically when:

- The last message is transmitted from the TX Queue
- The related CAN-FD channel is in CH_RESET mode.

The bit is cleared automatically when the first message to be transmitted is stored in the TX Queue.

TXQFLL bit (TX Queue Full)

The TXQFLL bit is set automatically when the number of CAN messages stored in the TX Queue matches the configured TX Queue depth.

This bit is cleared automatically when:

- The number of CAN messages stored in the TX Queue is less than the configured TX Queue depth
- The related CAN-FD channel is in CH_RESET mode.

TXQTXIF bit (TX Queue TX Interrupt Flag)

The TXQTXIF bit is not cleared automatically if the TX Queue is disabled.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1. Writing 1 has no effect.

This bit is set automatically when the configured interrupt condition is satisfied for the TX Queue.

You cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

The bit is cleared:

- By writing 0 to it
- When the related CAN-FD channel is in CH_RESET mode.

TXQMC[13:8] bits (TX Queue Message Count)

The TXQMC[13:8] bits show the number of CAN messages in the TX Queue.

These bits are cleared automatically when the related CAN-FD channel is in CH_RESET mode.

TXQFIF bit (TXQ Full Interrupt Flag)

The TXQFIF bit is not cleared automatically if the TX Queue is disabled.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of the TX Queue.

Only in GW mode (CFDTXQCC0n.TXQGWE = 1) that this bit is set automatically when the TX Queue enters a buffer full status.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1. Writing 1 has no effect.

You cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

The bit is cleared:

- By writing 0 to it
- When the related CAN-FD channel is in CH_RESET mode.

TXQOFRXIF bit (TXQ One Frame Reception Interrupt Flag)

The TXQOFRXIF bit is not cleared automatically if the TX Queue is disabled.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue. When receiving data is stored in the TX Queue in Gateway mode, this bit is set automatically.

This function can only be used in GW mode of the TX Queue.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1. Writing 1 has no effect.

You cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

The bit is cleared:

- By writing 0 to it
- When the related CAN-FD channel is in CH_RESET mode.

TXQOFTXIF bit (TXQ One Frame Transmission Interrupt Flag)

The TXQOFTXIF bit is not cleared automatically if the TX Queue is disabled.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue. When transmission is successful in the TX Queue, this bit is set automatically.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1. Writing 1 has no effect.

You cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

The bit is cleared:

- By writing 0 to it
- When the related CAN-FD channel is in CH_RESET mode.

TXQMLT bit (TXQ Message Lost)

The TXQMLT bit is not cleared automatically if the TX Queue is disabled.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue. When a message lost occurs in GW mode of the TX Queue, this bit is set automatically.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1. Writing 1 has no effect.

You cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

The bit is cleared:

- By writing 0 to it
- When the related CAN-FD channel is in CH_RESET mode.

32.2.60 CFDTXQSTS1n : TX Queue Status Registers 1n (n = 0, 1)

Base address: CANFD = 0x400B_0000

Offset address: 0x1080 + 0x04 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

31:20	—	These bits are read as 0. The write value should be 0.	R/W

The TX Queue Status Registers 1n (n = 0, 1) show the status of the TX Queue of corresponding CAN channel.

TXQEMP bit (TX Queue Empty)

The TXQEMP bit is set automatically when the TX Queue is disabled or no messages are stored in the TX Queue.

The bit is cleared automatically when the first message to be transmitted is stored in the TX Queue.

This bit is set automatically when:

- The last message is transmitted from the TX Queue
- The related CANFD channel is in CH_RESET mode.

TXQFLL bit (TX Queue Full)

The TXQFLL bit is set automatically when the number of CAN messages stored in the TX Queue matches the configured TX Queue depth.

This bit is cleared automatically when:

- The number of CAN messages stored in the TX Queue is less than the configured TX Queue depth

- The related CANFD channel is in CH_RESET mode.

TXQTXIF bit (TX Queue TX Interrupt Flag)

The TXQTXIF bit is not cleared automatically if the TX Queue is disabled.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue.

This bit is set automatically when the configured interrupt condition is satisfied for the TX Queue.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1. Writing 1 has no effect.

You cannot write to this bit when the related CANFD channel is in CH_SLEEP or CH_RESET mode.

The bit is cleared:

- By writing 0 to it
- When the related CANFD channel is in CH_RESET mode.

TXQMC[13:8] bits (TX Queue Message Count)

The TXQMC[13:8] bits show the number of CAN messages in the TX Queue.

These bits are cleared automatically when the related CANFD channel is in CH_RESET mode.

TXQFIF bit (TXQ Full Interrupt Flag)

The TXQFIF bit is not cleared automatically if the TX Queue is disabled.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue.

Only in Gateway mode (CFDTXQCC1n.TXQGWE = 1) that this bit is set automatically when TX Queue enters a buffer full status.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1. Writing 1 has no effect.

You cannot write to this bit when the related CANFD channel is in CH_SLEEP or CH_RESET mode.

The bit is cleared:

- By writing 0 to it
- When the related CANFD channel is in CH_RESET mode.

TXQOFRXIF bit (TXQ One Frame Reception Interrupt Flag)

The TXQOFRXIF bit is not cleared automatically if the TX Queue is disabled.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue. When receiving data is stored in the TX Queue in Gateway mode, this bit is set automatically.

This function can only be used in GW mode of the TX Queue.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1. Writing 1 has no effect.

You cannot write to this bit when the related CANFD channel is in CH_SLEEP or CH_RESET mode.

The bit is cleared:

- By writing 0 to it
- When the related CANFD channel is in CH_RESET mode.

TXQOFTXIF bit (TXQ One Frame Transmission Interrupt Flag)

The TXQOFTXIF bit is not cleared automatically if the TX Queue is disabled.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue. When transmission is successful in the TX Queue, this bit is set automatically.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1. Writing 1 has no effect.

You cannot write to this bit when the related CANFD channel is in CH_SLEEP or CH_RESET mode.

The bit is cleared:

- By writing 0 to it
- When the related CANFD channel is in CH_RESET mode.

TXQMLT bit (TXQ Message Lost)

The TXQMLT bit is not cleared automatically if the TX Queue is disabled.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue. When a message lost occurs in GW mode of the TX Queue, this bit is set automatically.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1. Writing 1 has no effect.

You cannot write to this bit when the related CANFD channel is in CH_SLEEP or CH_RESET mode.

The bit is cleared:

- By writing 0 to it
- When the related CANFD channel is in CH_RESET mode.

32.2.61 CFDTXQSTS2n : TX Queue Status Registers 2n (n = 0, 1)

Base address: CANFD = 0x400B_0000

Offset address: 0x10E0 + 0x04 × n

The TX Queue Status Registers 2n (n = 0, 1) show the status of the TX Queue of corresponding CAN Channel.

TXQEMP bit (TX Queue Empty)

The TXQEMP bit is set automatically when the TX Queue is disabled or no messages are stored in the TX Queue.

This bit is cleared automatically when the first message to be transmitted is stored in the TX Queue.

This bit is set automatically when:

- The last message is transmitted from the TX Queue
- The related CANFD channel is in CH_RESET mode.

TXQFLL bit (TX Queue Full)

The TXQFLL bit is set automatically when the number of CAN messages stored in the TX Queue matches the configured TX Queue depth

This bit is cleared automatically when:

- The number of CAN messages stored in the TX Queue is less than the configured TX Queue depth
- The related CANFD channel is in CH_RESET mode.

TXQTXIF bit (TX Queue TX Interrupt Flag)

The TXQTXIF bit is not cleared automatically if the TX Queue is disabled.

This bit is set automatically when the configured interrupt condition is satisfied for the TX Queue.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of the TX Queue.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1. Writing 1 has no effect.

You cannot write to this bit when the related CANFD channel is in CH_SLEEP or CH_RESET mode.

The bit is cleared:

- By writing 0 to it
- When the related CANFD channel is in CH_RESET mode.

TXQMC[13:8] bits (TX Queue Message Count)

The TXQMC[13:8] bits show the number of CAN messages in the TX Queue.

These bits are cleared automatically when the related CANFD channel is in CH_RESET mode.

TXQFIF bit (TXQ Full Interrupt Flag)

The TXQFIF bit is not cleared automatically if the TX Queue is disabled.

You cannot write to this bit when the related CANFD channel is in CH_SLEEP or CH_RESET mode.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of the TX Queue.

Only in Gateway mode (CFDTXQCC2n.TXQGWE = 1) that this bit is set automatically when the TX Queue enters a buffer full status.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1. Writing 1 has no effect.

The bit is cleared:

- By writing 0 to it
- When the related CANFD channel is in CH_RESET mode.

TXQOFRXIF bit (TXQ One Frame Reception Interrupt Flag)

The TXQOFRXIF bit is not cleared automatically if the TX Queue is disabled.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue. When receiving data is stored in the TX Queue in Gateway mode, this bit is set automatically.

This function can only be used in Gateway mode of the TX queue.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1. Writing 1 has no effect.

The bit is cleared:

- By writing 0 to it
- When the related CANFD channel is in CH_RESET mode.

TXQOFTXIF bit (TXQ One Frame Transmission Interrupt Flag)

The TXQOFTXIF bit is not cleared automatically if the TX Queue is disabled.

You cannot write to this bit when the related CANFD channel is in CH_SLEEP or CH_RESET mode.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue. When transmission is successful in the TX Queue, this bit is set automatically.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1. Writing 1 has no effect.

The bit is cleared:

- By writing 0 to it
- When the related CANFD channel is in CH_RESET mode.

TXQMLT bit (TXQ Message Lost)

The TXQMLT bit is not cleared automatically if the TX Queue is disabled.

You cannot write to this bit when the related CANFD channel is in CH_SLEEP or CH_RESET mode.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue. When a message lost occurs in Gateway mode of the TX Queue, this bit is set automatically.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1. Writing 1 has no effect.

The bit is cleared:

- By writing 0 to it
- When the related CANFD channel is in CH_RESET mode.

32.2.62 CFDTXQSTS3n : TX Queue Status Registers 3n (n = 0, 1)

Base address: CANFD = 0x400B_0000

18	TXQOFTXIF	TXQ One Frame Transmission Interrupt Flag When one frame transmits from TXQ, an interrupt is set.	R/W
31:19	—	These bits are read as 0. The write value should be 0.	R/W

The TX Queue Status Registers 3n (n = 0, 1) show the status of the TX Queue of corresponding CAN Channel.

TXQEMP bit (TX Queue Empty)

The TXQEMP bit is cleared automatically when the first message to be transmitted is stored in the TX Queue.

This bit is set automatically when:

- The TX Queue is disabled or no messages are stored in the TX Queue
- The last message is transmitted from the TX Queue
- The related CANFD channel is in CH_RESET mode.

TXQFLL bit (TX Queue Full)

The TXQFLL bit is set automatically when the number of CAN messages stored in the TX Queue matches the configured TX Queue depth.

This bit is cleared automatically when:

- The number of CAN messages stored in the TX Queue is less than the configured TX Queue depth
- The related CANFD channel is in CH_RESET mode.

TXQTXIF bit (TX Queue TX Interrupt Flag)

The TXQTXIF bit is not cleared automatically if the TX Queue is disabled.

This bit is set automatically when the configured interrupt condition is satisfied for the TX Queue.

When stopping TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue.

You cannot write to this bit when the related CANFD channel is in CH_SLEEP or CH_RESET mode.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1. Writing 1 has no effect.

The bit is cleared:

- By writing 0 to it
- When the related CANFD channel is in CH_RESET mode.

TXQMC[13:8] bits (TX Queue Message Count)

The TXQMC[13:8] bits show the number of CAN messages in the TX Queue.

These bits are cleared automatically when the related CANFD channel is in CH_RESET mode.

TXQOFTXIF bit (TXQ One Frame Transmission Interrupt Flag)

The TXQOFTXIF bit is not cleared automatically if the TX Queue is disabled. When transmission is successful in the TX Queue, this bit is set automatically.

You cannot write to this bit when the related CANFD channel is in CH_SLEEP or CH_RESET mode. When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of the TX Queue.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1. Writing 1 has no effect.

The bit is cleared:

- By writing 0 to it
- When the related CANFD channel is in CH_RESET mode.

32.2.63 CFDTXQPCTR0n : TX Queue Pointer Control Registers 0n (n = 0, 1)

Base address: CANFD = 0x400B_0000

Offset address: 0x1040 + 0x04 × n

Bit position:	31																							7							0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TXQPC[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	TXQPC[7:0]	TX Queue Pointer Control Increments the write pointer to the TX Queue buffer in the corresponding channel	W
31:8	—	These bits are read as 0. The write value should be 0.	R/W

The TX Queue Pointer Control Registers 0n (n = 0, 1) are used to confirm storage of a full message in the corresponding TX Queue buffers.

TXQPC[7:0] bits (TX Queue Pointer Control)

When the value 0xFF is written to the TXQPC[7:0] bits, the write pointer of the corresponding TX Queue buffer is updated and a transmit request is initiated for this message.

The read value from these bits is always 0x00. Do not write to the FIFO control registers when DMA is enabled.

You cannot write to these bits when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

Only write 0xFF to this register when:

- The corresponding TX Queue is enabled and not full
- The Common FIFO is enabled and is not configured in GW mode.

32.2.64 CFDTXQPCTR1n : TX Queue Pointer Control Registers 1n (n = 0, 1)

Base address: CANFD = 0x400B_0000

Offset address: 0x10A0 + 0x04 × n

Bit position:	31																							7							0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TXQPC[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	TXQPC[7:0]	TX Queue Pointer Control Increments the write pointer to the TX Queue buffer in the corresponding channel	W

Bit	Symbol	Function	R/W
31:8	—	These bits are read as 0. The write value should be 0.	R/W

The TX Queue Pointer Control Registers 1n (n = 0, 1) are used to confirm storage of a full message in the corresponding TX Queue buffers.

TXQPC[7:0] bits (TX Queue Pointer Control)

When the value 0xFF is written to the TXQPC[7:0] bits, the write pointer of the corresponding TX Queue buffer is updated and a transmit request is initiated for this message.

The read value from these bits is always 0x00.

Only write 0xFF to this register when:

- The corresponding TX Queue is enabled and not full
- The Common FIFO is enabled and is not configured in GW mode.

32.2.65 CFDTXQPCTR2n : TX Queue Pointer Control Registers 2n (n = 0, 1)

Base address: CANFD = 0x400B_0000

Offset address: 0x1100 + 0x04 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TXQPC[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	TXQPC[7:0]	TX Queue Pointer Control Increments the write pointer to the TX Queue buffer in the corresponding channel	W
31:8	—	These bits are read as 0. The write value should be 0.	R/W

The TX Queue Pointer Control Registers 2n (n = 0, 1) are used to confirm storage of a full message in the corresponding TX Queue buffers.

TXQPC[7:0] bits (TX Queue Pointer Control)

When the value 0xFF is written to the TXQPC[7:0] bits, the write pointer of the corresponding TX Queue buffer is updated and a transmit request is initiated for this message.

The read value from these bits is always 0x00.

You cannot write to these bits when the related CANFD channel is in CH_SLEEP or CH_RESET mode.

Only write 0xFF to this register when:

- The corresponding TX Queue is enabled and not full
- The Common FIFO is enabled and is not configured in GW mode.

32.2.66 CFDTXQPCTR3n : TX Queue Pointer Control Registers 3n (n = 0, 1)

Base address: CANFD = 0x400B_0000

Offset address: 0x1160 + 0x04 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TXQPC[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	TXQPC[7:0]	TX Queue Pointer Control Increments the write pointer to the TX Queue buffer in the corresponding channel	W
31:8	—	These bits are read as 0. The write value should be 0.	R/W

The TX Queue Pointer Control Registers 3n (n = 0, 1) are used to confirm storage of a full message in the corresponding TX Queue buffers.

TXQPC[7:0] bits (TX Queue Pointer Control)

When the value 0xFF is written to the TXQPC[7:0] bits, the write pointer of the corresponding TX Queue buffer is updated and a transmit request is initiated for this message.

The read value from these bits is always 0x00. Do not write to the FIFO control registers when DMA is enabled.

You cannot write to these bits when the related CANFD channel is in CH_SLEEP or CH_RESET mode.

Only write 0xFF to this register when the corresponding TX Queue is enabled and not full.

32.2.67 CFDTXQESTS : TX Queue Empty Status Register

Base address: CANFD = 0x400B_0000

Offset address: 0x1180

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bit	Symbol	Function	R/W
2:0	TXQ0OFRISF[2:0]	TXQ One Frame RX Interrupt Status Flag 0: TXQ One Frame RX Interrupt flag is not set 1: TXQ One Frame RX Interrupt flag is set	R
3	—	This bit is read as 0. The write value should be 0.	R/W
6:4	TXQ1OFRISF[2:0]	TXQ One Frame RX Interrupt Status Flag 0: TXQ One Frame RX Interrupt flag is not set 1: TXQ One Frame RX Interrupt flag is set	R
31:7	—	These bits are read as 0. The write value should be 0.	R/W

The TX Queue One Frame RX Interrupt Status Register shows the status of the One Frame RX Interrupt flag of the TXQ buffers.

TXQxOFRISF[2:0] (x = 0, 1) bits (TXQ One Frame RX Interrupt Status Flag)

Each bit is set automatically when the corresponding bit is set in the TX Queue One Frame RX Interrupt Status Register.

Each bit is cleared automatically when the corresponding bit is cleared in the TX Queue One Frame RX Interrupt Status Register.

This bit is cleared when the CANFD module is in GL_RESET mode.

Bit position	Corresponding TX Queue
0	Channel 0 TX Queue0
1	Channel 0 TX Queue1
2	Channel 0 TX Queue2
3	Reserved
4	Channel 1 TX Queue0
5	Channel 1 TX Queue1
6	Channel 1 TX Queue2
7	Reserved

32.2.73 CFDTXQFSTS : TX Queue Full Status Register

Base address: CANFD = 0x400B_0000

Offset address: 0x119C

Bit position:	31																							8	7	4	3	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TXQ1FSF[3:0]		TXQ0FSF[3:0]

Bit field:	—	—	—	—	THLDGE	THLDTE	THLIM	THLIE	—	—	—	—	—	—	—	THLE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	THLE	TX History List Enable 0: TX History List disabled 1: TX History List enabled	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W
8	THLIE	TX History List Interrupt Enable 0: TX History List Interrupt disabled 1: TX History List Interrupt enabled	R/W
9	THLIM	TX History List Interrupt Mode 0: Interrupt generated if TX History List level reaches ¾ of the TX History List depth 1: Interrupt generated for every successfully stored entry	R/W

Bit	Symbol	Function	R/W
10	THLDTE	TX History List Dedicated TX Enable 0: TX FIFO + TX Queue 1: Flat TX MB + TX FIFO + TX Queue	R/W
11	THLDGE	TX History List Dedicated Gateway Enable 0: Not dedicated Gateway FIFO + Gateway TX Queue 1: Dedicated Gateway FIFO + Gateway TX Queue	R/W
31:12	—	These bits are read as 0. The write value should be 0.	R/W

The TX History List Configuration/Control Register n (n = 0, 1) configures the TX History List functions.

THLE bit (TX History List Enable)

The THLE bit enables the TX History List buffer when it is set.

You cannot write to this bit when the related CAN-FD channel is in CH_RESET or CH_SLEEP mode.

This bit is cleared automatically when the related CAN-FD channel is in CH_RESET mode.

THLIE bit (TX History List Interrupt Enable)

The THLIE bit enables the generation of the TX History List interrupt when it is set.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

THLIM bit (TX History List Interrupt Mode)

The THLIM bit selects the interrupt generation condition for the FIFO.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the CAN-FD module is in GL_HALT or GL_OPERATION mode.

THLDTE bit (TX History List Dedicated TX Enable)

The THLDTE bit selects the condition for storing an entry in the TX History List after successful transmission.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the CAN-FD module is in GL_HALT or GL_OPERATION mode.

THLDGE bit (TX History List Dedicated Gateway Enable)

The THLDGE bit selects the condition for storing an entry in the TX History List after successful transmission.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the CAN-FD module is in GL_HALT or GL_OPERATION mode.

32.2.75 CFDTHLSTSn : TX History List Status Register n (n = 0, 1)

Base address: CANFD = 0x400B_0000

Offset address: 0x1220 + 0x04 × n (n = 0, 1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	THLMC[5:0]						—	—	—	—	THLIF	THLELT	THLFLL	THLEMP
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Function	R/W
0	THLEMP	TX History List Empty 0: TX History List not empty 1: TX History List empty	R
1	THLFLL	TX History List Full 0: TX History List not full 1: TX History List full	R
2	THLELT	TX History List Entry Lost 0: No entry lost in TX History List 1: TX History List entry Lost	R/W
3	THLIF	TX History List Interrupt Flag 0: TX History List interrupt condition not satisfied 1: TX History List interrupt condition satisfied	R/W
7:4	—	These bits are read as 0. The write value should be 0.	R/W
13:8	THLMC[5:0]	TX History List Message Count Number of messages stored in TX History List	R
31:14	—	These bits are read as 0. The write value should be 0.	R/W

The TX History List Status register shows the status of data stored in the TX History List buffer.

THLEMP bit (TX History List Empty)

The THLEMP bit is set automatically when the CPU has read all the entries from the TX History List buffer.

This bit is cleared automatically when the first entry is stored to the TX History List.

This bit is set automatically when:

- TX History List is disabled
- The related CAN-FD channel is in CH_RESET mode.

THLFLL bit (TX History List Full)

The THLFLL bit is set automatically when the number of entries in the TX History List buffer matches the TX History List depth.

Each TX History List can store up to 32 entries (each channel has a dedicated TX History List).

This bit is cleared automatically when:

- The number of entries in the TX History List buffer is less than the TX History List depth
- The TX History List is disabled
- The related CAN-FD channel is in CH_RESET mode.

THLELT bit (TX History List Entry Lost)

The THLELT bit is set when a new entry cannot be stored because the related TX History List buffer is already full.

Only write to this bit when the related CAN-FD channel is in CH_HALT or CH_OPERATION mode. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

This bit is cleared:

- By writing 0 to it
- When the related CAN-FD channel is in CH_RESET mode.

THLIF bit (TX History List Interrupt Flag)

The THLIF bit is set when the configured interrupt condition is satisfied.

Only write to this bit when the related CAN-FD channel is in CH_HALT or CH_OPERATION mode. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

This bit is cleared:

- By writing 0 to it
- When the related CAN-FD channel is in CH_RESET mode.

The bit is cleared by writing 0 to it.

This bit is automatically cleared in CH_RESET mode.

THLMC[5:0] bits (TX History List Message Count)

The THLMC[5:0] bits show the number of transmitted messages stored in the TX History List.

These bits are cleared automatically when the related CAN-FD channel is in CH_RESET mode.

32.2.76 CFDTHLACC0n : TX History List Access Registers 0 (n = 0, 1)

Base address: CANFD = 0x400B_0000

Offset address: 0x8000 + 0x08 × n (n = 0, 1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	TMTS[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	TGW	—	—	—	—	—	BN[6:0]							BT[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	BT[2:0]	Buffer Type 0 0 1: Flat TX message buffer 0 1 0: TX FIFO message buffer number and gateway FIFO message number 1 0 0: TX Queue message buffer number	R
9:3	BN[6:0]	Buffer Number Number of the message buffer	R
14:10	—	These bits are read as 0. The write value should be 0.	R
15	TGW	Transmit Gateway Buffer Indication 0: No transmission from gateway 1: Transmission from gateway	R
31:16	TMTS[15:0]	Transmit Timestamp Transmit timestamp value for software drivers	R

The TX History List Access Registers 0 (n = 0, 1) provide access to the entry in the TX History List based on the read timestamp value.

BT[2:0] bits (Buffer Type)

The BT[2:0] bits indicate whether data has been stored following a transmission from a FIFO buffer, a TX Queue or a TX message buffer.

BN[6:0] bits (Buffer Number)

The BN[6:0] bits show the message buffer from which transmission was successfully completed. If a message from a Common FIFO is transmitted, then these bits show the message buffer that is linked to the Common FIFO for transmission.

TGW bit (Transmit Gateway Buffer Indication)

The TGW bit is automatically set to 1 when transmission is completed in GW mode.

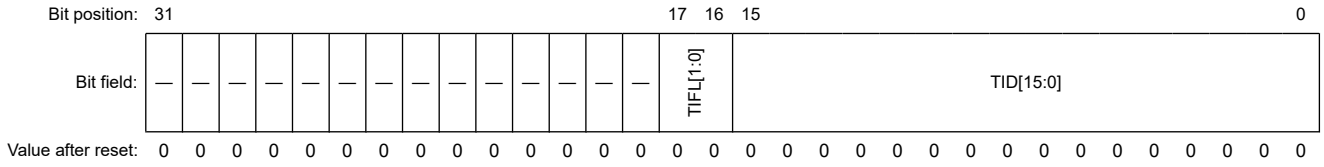
TMTS[15:0] bits (Transmit Timestamp)

The TMTS[15:0] bits indicate the timestamp for use by software drivers.

32.2.77 CFDTHLACC1n : TX History List Access Registers 1 (n = 0, 1)

Base address: CANFD = 0x400B_0000

Offset address: 0x8004 + 0x08 × n (n = 0, 1)



Bit	Symbol	Function	R/W
15:0	TID[15:0]	Transmit ID These bits indicate that message buffer reference ID, TX FIFO reference ID, or AFL pointer field is stored for software drivers.	R
17:16	TIFL[1:0]	Transmit Information Label These bits indicate that message buffer information label, TX FIFO information label, or AFL information label is stored for software drivers.	R
31:18	—	These bits are read as 0. The write value should be 0.	R/W

The TX History List Access Registers 1 provide access to entry in the TX History List based on the read pointer value.

TID[15:0] bits (Transmit ID)

The TID[15:0] bits indicate whether the message buffer reference ID (CFDTMFDCTRn.TMPTR) or the TX FIFO reference ID (CFDCFFDCSTSn.CFPTR) is for use by software drivers.

When transmission in GW mode, these bits indicate the AFL pointer field (CFDGAFLP0n.GAFLPTR) instead of the message buffer reference ID (CFDTMFDCTRn.TMPTR).

TIFL[1:0] bits (Transmit Information Label)

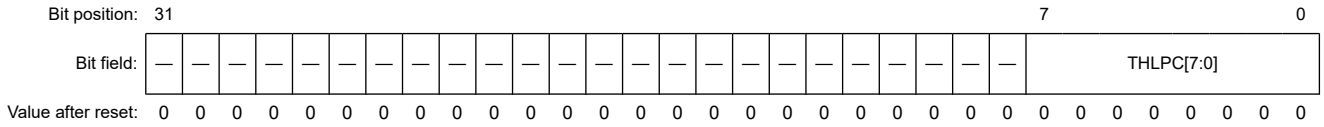
The TIFL[1:0] bits indicate whether the message buffer information label (CFDTMFDCTRn.TMIFL) or the TX FIFO information label (CFDCFFDCSTSn.CFIFL) is for use by software drivers.

When transmission in GW mode, these bits indicate the AFL pointer field (CFDGAFLMn.GAFLIFL1 and CFDGAFLP0n.GAFLIFL0) instead of the MB information label (CFDTMFDCTRn.TMIFL).

32.2.78 CFDTHLPCTRn : TX History List Pointer Control Registers n (n = 0, 1)

Base address: CANFD = 0x400B_0000

Offset address: 0x1240 + 0x04 × n (n = 0, 1)



Bit	Symbol	Function	R/W
7:0	THLPC[7:0]	TX History List Pointer Control Increments the write pointer to the TX History List in the corresponding channel	W
31:8	—	These bits are read as 0. The write value should be 0.	R/W

The TX History List Pointer Control Registers n (n = 0, 1) are used to increment the read pointer of the TX History List.

THLPC[7:0] bits (TX History List Pointer Control)

When 0xFF is written to the THLPC[7:0] bits, the read pointer of the TX History List is moved to the next TX History List entry address.

The read value from these bits is always 0x00. Only write to these bits when the related CAN-FD channel is in CH_HALT or CH_OPERATION mode.

Only write 0xFF to these registers when the corresponding TX History List is enabled and not empty.

32.2.79 CFDGRSTC : Global SW reset Register

Base address: CANFD = 0x400B_0000

Offset address: 0x1380

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	KEY[7:0]								—	—	—	—	—	—	—	SRST
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SRST	SW Reset 0: Normal state 1: SW reset state	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W
15:8	KEY[7:0]	Key Code These bits control the validity of rewriting of a SRST bit.	W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

SRST bit (SW Reset)

When the SRST bit is set, the CANFD module is in the same state as hardware reset. When a reset is required, write 1 then write 0 to this bit.

This bit is cleared when the CANFD module is in GL_SLEEP mode.

When this bit is cleared, the RAM initialization sequence does not operate. The configuration of RAM is performed by software.

The RAM is not initialized when software reset is performed during the initialization of RAM. Software must perform the initialization of RAM.

KEY[7:0] bits (Key Code)

When 0xC4 is written in the KEY[15:8] bits, a write to the SRST bit is valid.

The read value from these bits is always 0x00.

CFDGRSTC.SRST bit and the CFDGRSTC.KEY bit should be written simultaneously.

32.2.80 CFDGTSTCFG : Global Test Configuration Register

Base address: CANFD = 0x400B_0000

Offset address: 0x1308

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	RTMPS[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ICBCE[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	ICBCE[1:0]	Channel n Internal CAN Bus Communication Test Mode Enable 0: Channel n internal CAN bus communication disabled 1: Channel n internal CAN bus communication enabled	R/W
15:2	—	These bits are read as 0. The write value should be 0.	R/W
25:16	RTMPS[9:0]	RAM Test Mode Page Select Select a RAM test mode page	R/W
31:26	—	These bits are read as 0. The write value should be 0.	R/W

The Global Test Configuration Register is used to configure the CAN channels joining the internal CAN bus communication test mode and the RAM test mode page.

ICBCE[1:0] bits (Channel n Internal CAN Bus Communication Test Mode Enable)

When the ICBCE[1:0] bits are set and CAN-FD module is configured in the internal CAN bus communication test mode, then CAN channel n joins the internal CAN bus communication test mode operation.

Do not write to these bits when the CAN-FD module is in GL_RESET or GL_SLEEP mode.

Only write to these bits when the CAN-FD module is in GL_HALT mode.

These bits are cleared automatically when the CAN-FD module is in GL_RESET mode.

RTMPS[9:0] bits (RAM Test Mode Page Select)

The RTMPS[9:0] bits select the RAM page mode for CPU read/write access when the CAN-FD module is configured in RAM test mode.

See section 32.9.2.1. RAM Test Mode for the RAM test mode specification.

Do not write to these bits when the CAN-FD module is in GL_RESET or GL_SLEEP mode.

Only enter values from 0 to 7 (0x007) for the AFL RAM and 8 to 39 (0x027) for the message buffer RAM.

Only write to these bits when the CAN-FD module is in GL_HALT mode.

These bits are cleared automatically when the related CAN-FD channel is in GL_RESET mode.

32.2.81 CFDGTSTCTR : Global Test Control Register

Base address: CANFD = 0x400B_0000

Offset address: 0x130C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	RTME	—	ICBCTME
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	ICBCTME	Internal CAN Bus Communication Test Mode Enable 0: Internal CAN Bus Communication test mode disabled 1: Internal CAN Bus Communication test mode enabled	R/W
1	—	This bit is read as 0. The write value should be 0.	R/W
2	RTME	RAM Test Mode Enable 0: RAM test mode disabled 1: RAM test mode enabled	R/W
31:3	—	These bits are read as 0. The write value should be 0.	R/W

The Global Test Control register is used to control the global test modes of the CANFD module.

ICBCTME bit (Internal CAN Bus Communication Test Mode Enable)

When the ICBCTME bit is set, internal CAN bus communication is enabled for the CAN channels that are configured for internal CAN bus communication participation. See section 32.9.2.2. Internal CAN Bus Communication Test Mode for the specification of internal CAN bus communication test mode.

Only write to this bit when the CANFD module is in GL_HALT mode.

Clear this bit when the CANFD module is in GL_HALT mode.

This bit is cleared automatically when the CANFD module is in GL_RESET mode.

RTME bit (RAM Test Mode Enable)

When the RTME bit is set, the CANFD module is configured in RAM test mode. See section 32.9.2.1. RAM Test Mode for RAM test mode specification.

Only write to this bit when the CANFD module is in GL_HALT mode.

Clear this bit when the CANFD module is in GL_HALT mode.

This bit is cleared automatically when the CANFD module is in GL_RESET mode.

32.2.82 CFDGFDCFG : Global FD Configuration Register

Base address: CANFD = 0x400B_0000

Offset address: 0x1314

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	TSCCFG[1:0]		—	—	—	—	—	—	—	RPED
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	RPED	RES Bit Protocol Exception Disable 0: Protocol exception event detection enabled 1: Protocol exception event detection disabled	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W
9:8	TSCCFG[1:0]	Timestamp Capture Configuration 0 0: Timestamp capture at the sample point of SOF (start of frame) 0 1: Timestamp capture at frame valid indication 1 0: Timestamp capture at the sample point of RES bit 1 1: Reserved	R/W
31:10	—	These bits are read as 0. The write value should be 0.	R/W

RPED bit (RES Bit Protocol Exception Disable)

The RPED bit configures the protocol exception event handling according to ISO 11898-1.

When this bit is enabled, the protocol exception event detection is disabled, and the protocol controller transmits an error frame when the protocol exception event is detected (RES bit is sampled recessive).

Only write to this bit when the CANFD module is in GL_RESET mode.

TSCCFG[1:0] bits (Timestamp Capture Configuration)

The TSCCFG[1:0] bits configure the different capture points of the timestamp for transmission and reception.

When CFDGFDCFG.TSCCFG[1:0] = 10b, the timestamp capture is performed for CANFD frames at RES bit and for Classical frames at the start of frame.

Only write to these bits when the CANFD module is in GL_RESET mode.

32.2.83 CFDGLOCKK : Global Lock Key Register

Base address: CANFD = 0x400B_0000

Offset address: 0x131C

Bit position:	31															15															0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	LOCK[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	LOCK[15:0]	Lock Key Key bits for unlocking the protection of test modes	W
31:16	—	The write value should be 0.	W

The Global Lock Key register is a write-only register that is used to unlock the protection for special test bits.

See section 32.9.2. Global Test Modes for Lock key specification.

LOCK[15:0] bits (Lock Key)

The unlock key sequence must be written in the LOCK[15:0] bits to configure the CANFD module in FIFO OTB disable and RAM test modes.

The read value from these bits is always 0x0000.

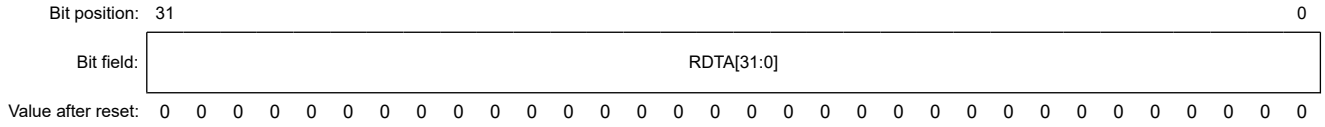
You cannot write to these bits when the CANFD module is in GL_SLEEP or GL_RESET mode.

Do not write to these bits when the CANFD module is in GL_OPERATION mode.

32.2.84 CFDRPGACCn : RAM Test Page Access Registers n (n = 0 to 63)

Base address: CANFD = 0x400B_0000

Offset address: 0x8400 + 0x04 × n (n = 0 to 63)



Bit	Symbol	Function	R/W
31:0	RDTA[31:0]	RAM Data Test Access RAM data bytes	R/W

RDTA[31:0] bits (RAM Data Test Access)

Data can be read from or written into the RDTA[31:0] bits when the CAN-FD module is configured in RAM test mode.

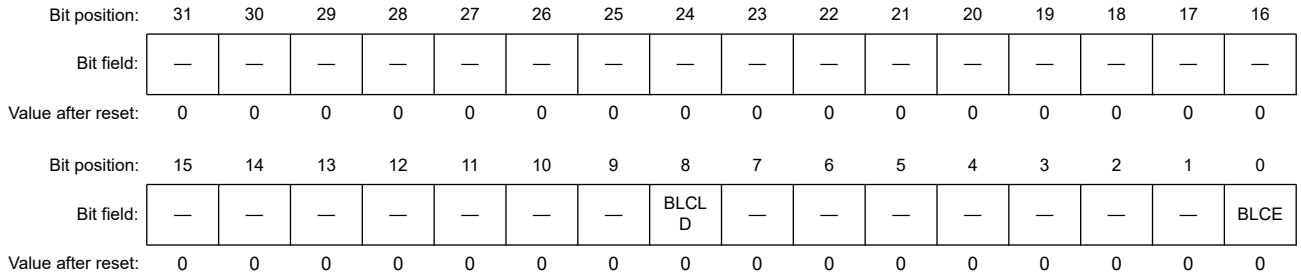
Only write to this bit when the CAN-FD module is in GL_HALT mode and RAM test mode is enabled.

Software data should be read/written in the RAM Test Page Access registers during RAM test mode.

32.2.85 CFDCnBLCT : Channel n Bus Load Control Register (n = 0, 1)

Base address: CANFD = 0x400B_0000

Offset address: 0x1418 + 0x20 × n (n = 0, 1)



Bit	Symbol	Function	R/W
0	BLCE	Bus Load Counter Enable 0: Bus load counter disable 1: Bus load counter enable	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W
8	BLCLD	BUS Load Counter Load When CFDCnBLCT.BLCLD is set, it is reset after a Bus load counter value is loaded.	W
31:9	—	These bits are read as 0. The write value should be 0.	R/W

BLCE bit (Bus Load Counter Enable)

The BLCE bit indicates the enabling signal of a bus load counter. Write to this bit after setting up the CFDCnNCFG register.

When this bit is 0, the bus load counter stops but the counter is not clear.

The bit is cleared when the related CANFD channel is in CH_RESET mode.

You cannot write to this bit in CH_SLEEP mode.

BLCLD bit (BUS Load Counter Load)

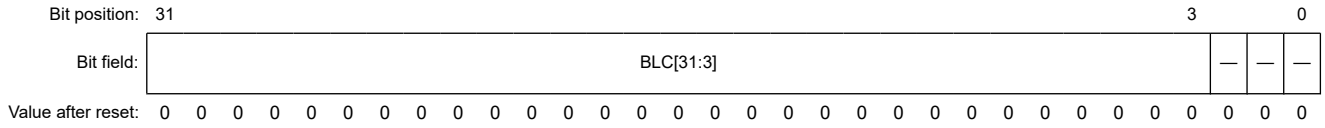
When the BLCLD bit is set, the bus load counter value is loaded into CFDCnBLSTS.BLC and the bus load counter is reset.

The read value is always 0.

32.2.86 CFDCnBLSTS : Channel n Bus Load Status Register (n = 0, 1)

Base address: CANFD = 0x400B_0000

Offset address: 0x141C + 0x20 × n (n = 0, 1)



Bit	Symbol	Function	R/W
2:0	—	These bits are read as 0. The write value should be 0.	R/W
31:3	BLC[31:3]	Bus Load Counter These bits indicate the bus load counter value.	R

BLC[31:3] bits (Bus Load Counter)

When the CFDCnBLCT.BLCLD bit is set, the bus load counter value is loaded to BLC bit and the bus load counter is reset.

Bits [2:0] are fixed to 000b.

The bus load counter increases by CANFDCLK period while the CAN bus is in an idle state.

These bits are set only by the CANFD module. Writing any value has no effect.

32.2.87 Message Buffer Component Structure

32.2.87.1 Start Addresses

The start address for each of the Message Buffer component is calculated using the number of related Message Buffer components and the number of channels.

no_of_channels	2
no_of_RMBCPs_per_channel	16
no_of_RFMBCPs	8
no_of_CFMBCPs_per_channel	3
no_of_TMBCPs_per_channel	16

The start addresses for each register in the Message Buffer component are depicted in Table 32.7.

Table 32.7 Message Buffer Component Register Start Addresses (1 of 2)

b = Message buffer component index	MBCP	Register	p	Regular Start Address n = [0…no_of_channels-1]
[0…no_of_RMBCPs_per_channel-1]	RMBCPb[i]	RMID	x	0x2000 + b*0x0080 + n*0x800
		RMPTR	x	0x2004 + b*0x0080 + n*0x800
		RMFDSTS	x	0x2008 + b*0x0080 + n*0x800
		RMDFp	[0…15]	0x200C + p*0x0004 + b*0x0080 + n*0x800

Table 32.7 Message Buffer Component Register Start Addresses (2 of 2)

b = Message buffer component index	MBCP	Register	p	Regular Start Address n = [0…no_of_channels-1]
[0…no_of_RFMBCPs-1]	RFMBCPb[i]	RFIDE	x	0x6000 + b*0x0080
		RFPTRE	x	0x6004 + b*0x0080
		RFFDSTSE	x	0x6008 + b*0x0080
		RFDFpE	[0…15]	0x600C + p*0x0004 + b*0x0080
[0…no_of_CFMBCPs_per_channel-1]	CFMBCPb[i]	CFIDE	x	0x6400 + b*0x0080 + n*0x180
		CFPTRE	x	0x6404 + b*0x0080 + n*0x180
		CFFDCSTSE	x	0x6408 + b*0x0080 + n*0x180
		CFDFpE	[0…15]	0x640C + p*0x0004 + b*0x0080 + n*0x180
[0…no_of_TMBCPs_per_channel-1]	TMBCPb[i]	TMID	x	0x10000 + b*0x0080 + n*0x2000
		TMPTR	x	0x10004 + b*0x0080 + n*0x2000
		TMFDCTR	x	0x10008 + b*0x0080 + n*0x2000
		TMDFp	[0…15]	0x1000C + p*0x0004 + b*0x0080 + n*0x2000

Note: '-' means Not Applicable

The message buffer configuration consists of four types of Message Buffer components:

- RX Message Buffer Component (CFDRMBCPb[i])
- RX FIFO Access Message Buffer Component (CFDRFMBCPb[i])
- Common FIFO Access Message Buffer Component (CFDCFMBCPb[i])
- TX Message Buffer Component (CFDTMBCPb[i]).

Where b = the Message Buffer component index that has a range that varies based on the type of Message Buffer component and i = channel index that has a range from 0 to n.

For a summary of this configuration, see Figure 32.28. For a detailed description of the number of and the different types of message buffers, see section 32.6. FIFO Buffers and Normal Message Buffer Configuration.

As described in section 32.2. Register Descriptions, each Message Buffer component consists of the following registers:

- Identifier (ID)
- Pointer (PTR)
- Data Field (DFp).

Rc is the Message Buffer Component register where c = Message Buffer Component register index that has a range that varies based on the type of Message Buffer component.

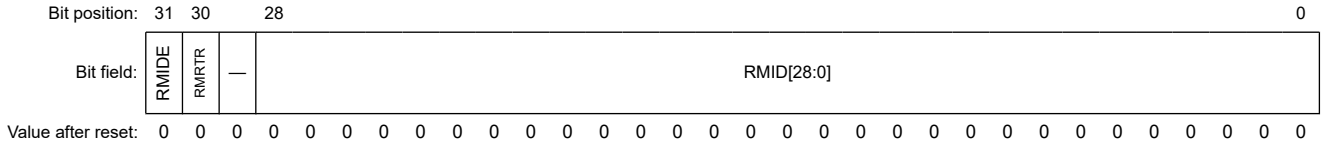
A description of the registers, their associated bits and their accessibility are shown below the summary and detailed figures of each component.

In each of the figures, a cell that contains '-' means reserved and has the same behavio as reserved bits for registers in section 32.2.87. Message Buffer Component Structure.

32.2.87.2 CFDRMIDn_i : RX Message Buffer ID Register n Channel i (n = 0 to 15, i = 0, 1)

Base address: CANFD = 0x400B_0000

Offset address: 0x2000 + 0x080 × n + 0x800 × i



Bit	Symbol	Function	R/W
28:0	RMID[28:0]	RX Message Buffer ID Field STD-ID/EXT-ID fields	R
29	—	This bit is read as 0. The write value should be 0.	R
30	RMRTR	RX Message Buffer RTR Bit 0: Data frame 1: Remote frame	R
31	RMIDE	RX Message Buffer IDE Bit 0: STD-ID is stored 1: EXT-ID is stored	R

The RX Message Buffer ID Registers n (n = 0 to 15) store the ID field, IDE bit, and RTR bit of the received message.

RMID[28:0] bits (RX Message Buffer ID Field)

The RMID[28:0] are the bits of the STD-ID/EXT-ID fields of the message stored in the RX message buffer.

See section 32.2.87.1. Start Addresses for details on how to interpret the structure of this buffer component.

RMRTR bit (RX Message Buffer RTR Bit)

The RMRTR bit shows whether a data frame or a remote frame was stored in the RX message buffer.

Note: There are no remote frames in CAN-FD format. When a CAN-FD frame is received, the register reflects the state of the received value (the RRS bit in FD frame format).

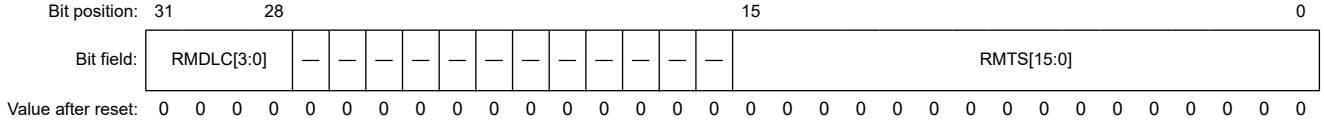
RMIDE bit (RX Message Buffer IDE Bit)

The RMIDE bit shows whether message with Standard Identifier or Extended Identifier was stored in the RX message buffer.

32.2.87.3 CFDRMPTRn_i : RX Message Buffer Pointer Register n Channel i (n = 0 to 15, i = 0, 1)

Base address: CANFD = 0x400B_0000

Offset address: 0x2004 + 0x080 × n + 0x800 × i



Bit	Symbol	Function	R/W
15:0	RMTS[15:0]	RX Message Buffer Timestamp Field Timestamp value stored for the message in the RX message buffer	R
27:16	—	These bits are read as 0. The write value should be 0.	R
31:28	RMDLC[3:0]	RX Message Buffer DLC Field Number of data bytes received in a CAN frame.	R

The RX Message Buffer Pointer Registers n (n = 0 to 15) store the DLC and Timestamp fields for the received message.

RMTS[15:0] bits (RX Message Buffer Timestamp Field)

The RMTS[15:0] bits store the timestamp value taken at the capture point as configured by CFDGFDCFG.TSCCFG of the received message.

RMDLC[3:0] bits (RX Message Buffer DLC Field)

The RMDLC[3:0] bits store the number of data bytes that were received in the RX message buffer.

See Table 5 in ISO 11898-1 (2015) Specification for details in defining the number of data bytes that were received.

Note: The maximum capacity of the buffer belongs to CFDRMNB.RMPLS and this is not available in the classical CAN function.

32.2.87.4 CFDRMFDSTSn_i : RX Message Buffer CAN-FD Status Register n Channel i (n = 0 to 15, i = 0, 1)

Base address: CANFD = 0x400B_0000

Offset address: 0x2008 + 0x080 × n + 0x800 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	RMPTR[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	RMIFL[1:0]		—	—	—	—	—	RMFDF	RMBRS	RMESI
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	RMESI*1	Error State Indicator bit 0: CAN-FD frame received from error active node 1: CAN-FD frame received from error passive node	R
1	RMBRS*1	Bit Rate Switch bit 0: CAN-FD frame received with no bit rate switch 1: CAN-FD frame received with bit rate switch	R
2	RMFDF*1	CAN FD Format bit 0: Non CAN-FD frame received 1: CAN-FD frame received	R
7:3	—	These bits are read as 0. The write value should be 0.	R
9:8	RMIFL[1:0]	RX Message Buffer Information Label Field	R
15:10	—	These bits are read as 0. The write value should be 0.	R
31:16	RMPTR[15:0]	RX Message Buffer Pointer Field	R

Note 1. This bit is not available in the classical CAN function.

The RX Message Buffer CAN-FD Status Registers n (n = 0 to 2) show the status of the FDF, BRS and ESI bits, and pointer of the received CAN-FD frame.

RMESI bit (Error State Indicator bit)

The RMESI bit has the same value as the ESI bit of the received CAN-FD frame.

When the received FDF bit is 0, this means a CAN2.0 frame is received and 0 is stored to this bit.

Note: This bit is not available in the classical CAN function.

RMBRS bit (Bit Rate Switch bit)

The RMBRS bit has the same value as the BRS bit of the received CAN-FD frame.

When the received FDF bit is 0, this means a CAN2.0 frame is received and 0 is stored to this bit.

Note: This bit is not available in the classical CAN function.

RMFDF bit (CAN FD Format bit)

The RMFDF bit has the same value as the FDF bit of the received CAN-FD frame.

Note: This bit is not available in the classical CAN function.

RMIFL[1:0] bits (RX Message Buffer Information Label Field)

The RMIFL[1:0] bits store the information label value from the related Global Acceptance Filter List entry.

RMPTR[15:0] bits (RX Message Buffer Pointer Field)

The RMPTR[15:0] bits store the pointer value from the related Global Acceptance Filter List entry.

32.2.87.5 CFDRMDFp_n_i : RX Message Buffer Data Field p Register n Channel i (p = 0 to 15, n = 0 to 15, i = 0, 1)

Base address: CANFD = 0x400B_0000

Offset address: 0x200C + 0x004 × p + 0x080 × n + 0x800 × i

Bit position:	31							24	23							16	15							8	7							0
Bit field:	RMDB_HH[7:0]								RMDB_HL[7:0]								RMDB_LH[7:0]								RMDB_LL[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	RMDB_LL[7:0]	RX Message Buffer Data Byte (p * 4)	R
15:8	RMDB_LH[7:0]	RX Message Buffer Data Byte ((p * 4) + 1)	R
23:16	RMDB_HL[7:0]	RX Message Buffer Data Byte ((p * 4) + 2)	R
31:24	RMDB_HH[7:0]*1	RX Message Buffer Data Byte ((p * 4) + 3)	R

Note 1. These bits are not available in the classical CAN function.

The RX Message Buffer Data Field p Registers n (p = 0 to 15, n = 0 to 15) store the data bytes (p * 4) to data bytes ((p * 4) + 3) of the received message.

RMDB_LL[7:0] bits (RX Message Buffer Data Byte (p * 4))

The RMDB(p * 4) [7:0] bits store data bytes (p*4) of the message in the RX message buffer.

Unused data bytes are filled with 0x00.

RMDB_LH[7:0] bits (RX Message Buffer Data Byte ((p * 4) + 1))

The RMDB((p * 4) + 1)[7:0] bits store data bytes ((p * 4) + 1) of the message in the RX message buffer.

Unused Data Bytes will be filled with 0x00.

RMDB_HL[7:0] bits (RX Message Buffer Data Byte ((p * 4) + 2))

The RMDB((p * q) +2)[7:0] bits store data bytes ((p * 4 + 2) of the message in the RX message buffer.

Unused data bytes are filled with 0x00.

RMDB_HH[7:0] bits (RX Message Buffer Data Byte ((p * 4) + 3))

The RMDB((p * 4) +3)[7:0] bits store data bytes ((p * 4) + 3) of the message in the RX message buffer.

Unused data bytes are filled with 0x00.

32.2.87.6 CFDRFIDn : RX FIFO Access ID Register n (n = 0 to 7)

Base address: CANFD = 0x400B_0000

Offset address: 0x6000 + 0x080 × n

Bit position:	31	30	28	0
Bit field:	RFIDE	RFRTR	—	RFID[28:0]
Value after reset:	0	0	0	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
28:0	RFID[28:0]	RX FIFO Buffer ID Field STD-ID/EXT-ID fields	R
29	—	This bit is read as 0.	R
30	RFRTR	RX FIFO Buffer RTR bit 0: Data frame 1: Remote frame	R
31	RFIDE	RX FIFO Buffer IDE bit 0: STD-ID has been received 1: EXT-ID has been received	R

The RX FIFO Access ID Registers n (n = 0 to 7) store the ID field, IDE bit and RTR bit of the message.

RFID[28:0] bits (RX FIFO Buffer ID Field)

The RFID[28:0] bits are the bits of the STD-ID/EXT-ID fields of the message in the FIFO buffer.

For alignment of these bits in standard and extended frame format, see Identifier Bits Alignment.

RFRTR bit (RX FIFO Buffer RTR bit)

The RFRTR bit shows whether a data frame or a remote frame was stored in the FIFO buffer.

Note: There are no remote frames in CAN-FD format. When a CAN-FD frame was received, the register reflects the state of the received value (RRS bit in FD frame format).

RFIDE bit (RX FIFO Buffer IDE bit)

The RFIDE bit shows whether message with the Standard Identifier or Extended Identifier was received in the FIFO buffer.

32.2.87.7 CFDRFPTRn : RX FIFO Access Pointer Register n (n = 0 to 7)

Base address: CANFD = 0x400B_0000

Offset address: 0x6004 + 0x080 × n

Bit position:	31	28	15	0
Bit field:	RFDLC[3:0]	— — — — — — — — — — — —		RFTS[15:0]
Value after reset:	0	0 0 0 0 0 0 0 0 0 0 0 0		0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
15:0	RFTS[15:0]	RX FIFO Timestamp Value Timestamp value of the received CAN frame	R
27:16	—	These bits are read as 0. The write value should be 0.	R
31:28	RFDLC[3:0]	RX FIFO Buffer DLC Field Number of data bytes received in a CAN frame	R

The FIFO Access Pointer Registers n (n = 0 to 7) store the DLC and Timestamp fields for the received message.

RFTS[15:0] bits (RX FIFO Timestamp Value)

The RFTS[15:0] bits store the timestamp value taken at the capture point as configured by the CFDGFDCFG.TSCCFG bit of the received message.

RFDLC[3:0] bits (RX FIFO Buffer DLC Field)

The RFDLC[3:0] bits store the number of data bytes that were received in the RX FIFO buffer.

See Table 5 in ISO 11898-1 (2015) Specification for details in defining the number of data bytes that were received.

32.2.87.8 CFDRFFDSTSn : RX FIFO Access CAN-FD Status Register n (n = 0 to 7)

Base address: CANFD = 0x400B_0000

Offset address: 0x6008 + 0x080 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	CFDRFPTR[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	RFIFL[1:0]		—	—	—	—	—	RFFDF	RFBRS	RFESI
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	RFESI*1	Error State Indicator bit 0: CAN-FD frame received from error active node 1: CAN-FD frame received from error passive node	R
1	RFBRS*1	Bit Rate Switch bit 0: CAN-FD frame received with no bit rate switch 1: CAN-FD frame received with bit rate switch	R
2	RFFDF*1	CAN FD Format bit 0: Non CAN-FD frame received 1: CAN-FD frame received	R
7:3	—	These bits are read as 0. The write value should be 0.	R
9:8	RFIFL[1:0]	RX FIFO Buffer Information Label Field	R
15:10	—	These bits are read as 0. The write value should be 0.	R
31:16	CFDRFPTR[15:0]	RX FIFO Buffer Pointer Field	R

Note 1. This bit is not available in the classical CAN function.

The RX FIFO Access CAN-FD Status Registers n (n = 0 to 7) show the status of the FDF, BRS, and ESI bits, including the pointer of the received CAN-FD frame.

RFESI bit (Error State Indicator bit)

The RFESI bit has the same value as the ESI bit of the received CAN-FD frame.

When the received FDF bit is 0, this means a CAN2.0 frame is received and 0 is stored to this bit.

Note: This bit is not available in the classical CAN function.

RFBRS bit (Bit Rate Switch bit)

The RFBRS bit has the same value as the BRS bit of the received CAN-FD frame.

When the received FDF bit is 0, this means a CAN2.0 frame is received and 0 is stored to this bit.

Note: This bit is not available in the classical CAN function.

RFFDF bit (CAN FD Format bit)

The RFFDF bit has the same value as the FDF bit of the received CAN-FD frame.

Note: This bit is not available in the classical CAN function.

RFIFL[1:0] bits (RX FIFO Buffer Information Label Field)

The RFIFL[1:0] bits store the information label value from the related Global Acceptance Filter List entry.

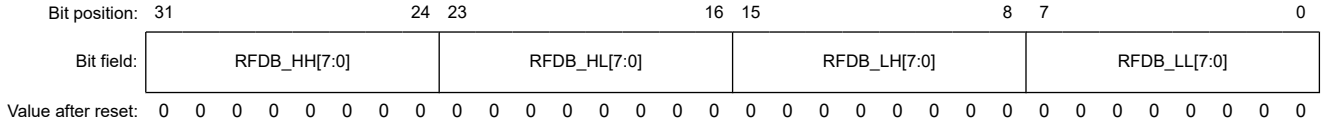
CFDRFPTR[15:0] bits (RX FIFO Buffer Pointer Field)

The CFDRFPTR[15:0] bits store the pointer value from the related Global Acceptance Filter List entry.

32.2.87.9 CFDRFDFpn : RX FIFO Access Data Field p Register n (p = 0 to 15, n = 0 to 7)

Base address: CANFD = 0x400B_0000

Offset address: 0x600C + 0x004 × p + 0x080 × n



Bit	Symbol	Function	R/W
7:0	RFDB_LL[7:0]	RX FIFO Buffer Data Byte (p * 4)	R
15:8	RFDB_LH[7:0]	RX FIFO Buffer Data Byte ((p * 4) + 1)	R
23:16	RFDB_HL[7:0]	RX FIFO Buffer Data Byte ((p * 4) + 2)	R
31:24	RFDB_HH[7:0]	RX FIFO Buffer Data Byte ((p * 4) + 3)	R

The RX FIFO Access Data Field p Registers n (p = 0 to 15, n = 0 to 7) store data bytes ((p * 4) to data byte ((p * 4) + 3) of the received message.

RFDB_LL[7:0] bits (RX FIFO Buffer Data Byte (p * 4))

The RFDB(p * 4)[7:0] bits store data bytes (p * 4) of the message present in the FIFO buffer.

Unused data bytes are filled with 0x00 according to the configured data payload size CFDRFCCn.RFPLS.

RFDB_LH[7:0] bits (RX FIFO Buffer Data Byte ((p * 4) + 1))

The RFDB((p * 4) + 1))[7:0] bits store data bytes ((p * 4) + 1)) of the message present in the FIFO buffer.

Unused data bytes are filled with 0x00.

RFDB_HL[7:0] bits (RX FIFO Buffer Data Byte ((p * 4) + 2))

The RFDB((p * 4) + 2)[7:0] bits store data bytes ((p * 4) + 2) of the message present in the FIFO buffer.

Unused data bytes are filled with 0x00.

RFDB_HH[7:0] bits (RX FIFO Buffer Data Byte ((p * 4) + 3))

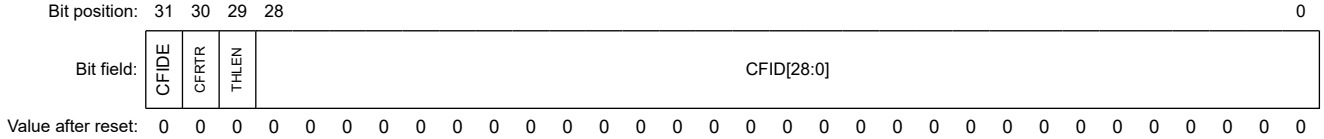
The RFDB((p * 4) + 3)[7:0] bits store data bytes ((p * 4) + 3) of the message present in the FIFO buffer.

Unused data bytes are filled with 0x00.

32.2.87.10 CFDCFIDn_i : Common FIFO Access ID Register n Channel i (n = 0 to 2, i = 0, 1)

Base address: CANFD = 0x400B_0000

Offset address: 0x6400 + 0x080 × n + 0x180 × i



Bit	Symbol	Function	R/W
28:0	CFID[28:0]	Common FIFO Buffer ID Field STD-ID/EXT-ID fields	R/W
29	THLEN	THL Entry Enable TX FIFO mode: 0: Entry is not to be stored in THL after successful TX 1: Entry is to be stored in THL after successful TX RX FIFO mode: Reserved, this bit is read as 0.	R/W
30	CFRTR	Common FIFO Buffer RTR bit 0: Data frame 1: Remote frame	R/W
31	CFIDE	Common FIFO Buffer IDE bit 0: STD-ID is to be transmitted or has been received 1: EXT-ID is to be transmitted or has been received	R/W

The Common FIFO Access ID Registers n (n = 0 to 5) store the ID field, IDE bit and RTR bit of the message.

In TX mode, you can read data from the FIFO, only for the current entry based on the write pointer value, and not for the other entries.

CFID[28:0] bits (Common FIFO Buffer ID Field)

The CFID[28:0] bits are the bits of the STD-ID/EXT-ID fields of the message in the FIFO buffer.

In TX mode, you can write and read from FIFO buffers.

In RX mode, you can only read data from FIFO buffers.

In GW mode, you cannot write data to the FIFO buffers.

THLEN bit (THL Entry Enable)

The THLEN bit controls the storage of an entry corresponding to the transmitted message in the TX History list at the end of a successful transmission.

In TX mode, you can write and read from FIFO buffers.

In RX mode, you can only read data from FIFO buffers.

In GW mode, you cannot write data to the FIFO buffers.

CFRTR bit (Common FIFO Buffer RTR bit)

The CFRTR bit selects whether a data frame or a remote frame is to be transmitted from or was received in the FIFO buffer.

Note: There are no remote frames in CAN FD format. When a CANFD frame is received (RX mode), the register reflects the state of the received value (RRS bit in FD frame format). When CANFD transmission (TX or GW mode CFDCFID.CFFDF = 1), the bit is always transmitted dominant (data frame).

In TX mode, you can write and read from FIFO buffers.

In RX mode, you can only read data from FIFO buffers.

In GW mode, you cannot write data to the FIFO buffers.

CFIDE bit (Common FIFO Buffer IDE bit)

The CFIDE bit selects whether a message with EXT-ID or STD-ID is to be transmitted from or was received in the FIFO buffer.

In TX mode, you can write and read from FIFO buffers.

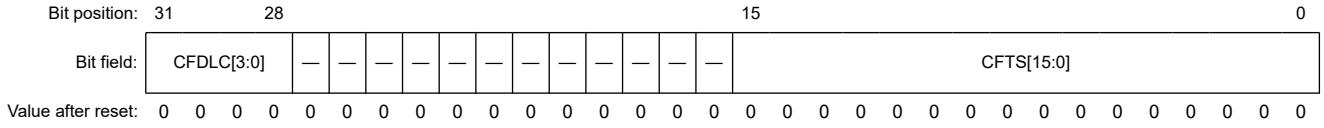
In RX mode, you can only read data from FIFO buffers.

In GW mode, you cannot write data to the FIFO buffers.

32.2.87.11 CFDCFPTRn_i : Common FIFO Access Pointer Register n Channel i (n = 0 to 2, i = 0, 1)

Base address: CANFD = 0x400B_0000

Offset address: 0x6404 + 0x080 × n + 0x180 × i



Bit	Symbol	Function	R/W
15:0	CFTS[15:0]	Common FIFO Timestamp Value Timestamp value of the received CAN frame (FIFO in RX mode).	R/W
27:16	—	These bits are read as 0. The write value should be 0.	R/W
31:28	CFDLC[3:0]	Common FIFO Buffer DLC Field Number of data bytes received in a CAN frame, or to be transmitted in a CAN frame.	R/W

The Common FIFO Access Pointer Registers n (n = 0 to 2) store the DLC and Timestamp fields.

In TX mode, you can read data from the FIFO buffer, only for the current entry based on the write pointer value, and not for the other entries.

CFTS[15:0] bits (Common FIFO Timestamp Value)

The CFTS[15:0] bits store the timestamp value taken at the capture point as configured by the CFDGFDCFG.TSCCFG bit of the received message (if FIFO is configured in RX mode).

In TX mode, you can read and write from FIFO buffers.

In RX mode, you can only read data from FIFO buffers.

In GW mode, you cannot write data to the FIFO buffers.

CFDLC[3:0] bits (Common FIFO Buffer DLC Field)

The CFDLC[3:0] bits store the number of data bytes that were received in the FIFO buffer or are to be transmitted.

See Table 5 in ISO 11898-1 (2015) Specification for details in defining the number of data bytes.

In TX mode, you can read and write from the FIFO buffers. Do not read data for the other entries in the FIFO when configured in TX mode.

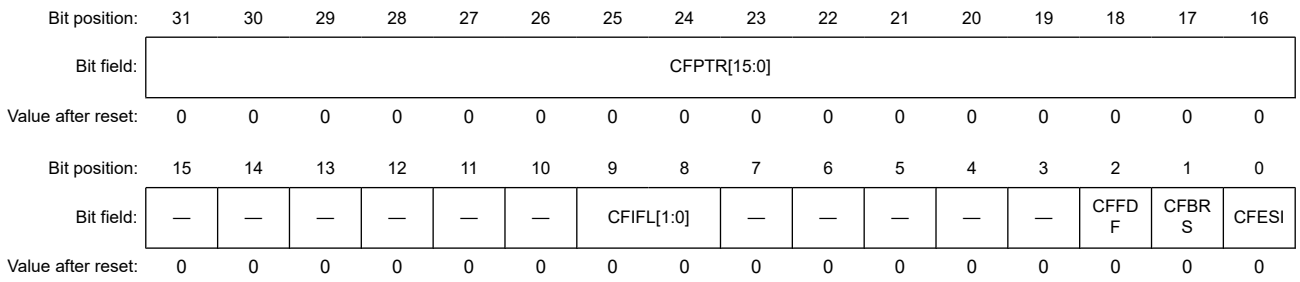
In RX mode, you can only read data from the FIFO buffers.

In GW mode, you cannot write data to the FIFO buffers.

32.2.87.12 CFDCFFDCSTSn_i : Common FIFO Access CAN-FD Control/Status Register n Channel i (n = 0 to 2, i = 0, 1)

Base address: CANFD = 0x400B_0000

Offset address: 0x6408 + 0x080 × n + 0x180 × i



Bit	Symbol	Function	R/W
0	CFESI*1	Error State Indicator bit 0: CAN-FD frame received or to transmit by error active node 1: CAN-FD frame received or to transmit by error passive node	R/W
1	CFBRS*1	Bit Rate Switch bit 0: CAN-FD frame received or to transmit with no bit rate switch 1: CAN-FD frame received or to transmit with bit rate switch	R/W
2	CFFDF*1	CAN FD Format bit 0: Non CAN-FD frame received or to transmit 1: CAN-FD frame received or to transmit	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W
9:8	CFIFL[1:0]	COMMON FIFO Buffer Information Label Field	R/W
15:10	—	These bits are read as 0. The write value should be 0.	R/W
31:16	CFPTR[15:0]	Common FIFO Buffer Pointer Field	R/W

Note 1. This bit is not available in the classical CAN function.

The Common FIFO Access CAN-FD Control/Status Registers n (n = 0 to 2) show the status of the FDF, BRS and ESI bits, including the pointer of the received CAN-FD frame or the CAN-FD frame to transmit.

In TX mode, you can read data from the FIFO, only for the current entry based on the write pointer value, and not for the other entries.

CFESI bit (Error State Indicator bit)

In TX mode, you can read and write from FIFO buffers. In this mode, when the CAN-FD module is not in error passive, the CFESI bit equals the write value. Otherwise, it is a don’t care and the bit is transmitted as 1 on the CAN bus, indicating this is an error passive node.

In RX mode, you can only read data from FIFO buffers.

In GW mode, you cannot write data to the FIFO buffers.

In RX or GW mode, the CFESI bit is updated with the ESI bit value of the CAN-FD frame when it has been received, indicating the error state of the transmitting node. In RX or GW mode, 0 is stored to this bit when the received FDF bit is 0, this means a CAN 2.0 frame is received.

Note: This bit is not available in the classical CAN function.

CFBRS bit (Bit Rate Switch bit)

In TX mode, you can read and write from FIFO buffers. In this mode, the CAN-FD module either transmits a 0 to indicate no bit rate switch in the frame to be transmitted or a 1 to indicate a bit rate switch in the frame to be transmitted.

In RX mode, you can only read data from FIFO buffers.

In GW mode, you cannot write data to the FIFO buffers.

In RX or GW mode, the CFBRS bit is updated with the BRS bit value of the CAN-FD frame when it has been received, indicating whether there is a bit rate switch (1) or (0) on the CAN-FD frame.

In RX or GW mode, 0 is stored to the CFBRS bit when the received FDF bit is 0, this means a CAN 2.0 frame is received.

Note: This bit is not available in the classical CAN function.

CFFDF bit (CAN FD Format bit)

In TX mode, you can read and write from FIFO buffers. In this mode, the CAN-FD module either transmits a 0 to indicate a CAN 2.0 frame is to be transmitted or a 1 to indicate a CAN-FD frame is to be transmitted.

In RX mode, you can only read data from FIFO buffers.

In GW mode, you cannot write data to the FIFO buffers.

In RX or GW mode, the CFFDF bit is updated with the FDF bit value of the CAN frame when it has been received, indicating whether it is a CAN 2.0 frame (0) or a CAN-FD frame (1).

Note: This bit is not available in the classical CAN function.

CFIFL[1:0] bits (COMMON FIFO Buffer Information Label Field)

If the Common FIFO is configured in TX mode, the value programmed in CFDCFFDCSTSn.CFIFL[1:0] is stored together with additional message information, to the TX History List after successful transmission of the message.

The information label value from the related Global Acceptance Filter List entry is stored in these bits (if FIFO is configured in either RX or GW mode).

In TX mode, you can read and write from FIFO buffers.

In RX mode, you can only read data from FIFO buffers.

In GW mode, you cannot write data to the FIFO buffers.

CFPTR[15:0] bits (Common FIFO Buffer Pointer Field)

If the Common FIFO is configured in TX mode, the value programmed in CFDCFFDCSTSn.CFPTR[15:0] is stored together with additional message information, to the TX History List after successful transmission of the message.

The pointer value from the related Global Acceptance Filter List entry is stored in these bits (if FIFO is configured in either RX or GW mode).

In TX mode, you can read and write from FIFO buffers.

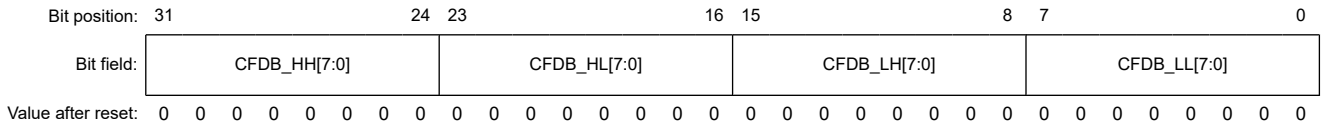
In RX mode, you can only read data from FIFO buffers.

In GW mode, you cannot write data to the FIFO buffers.

32.2.87.13 CFDCFDFpn_i : Common FIFO Access Data Field p Register n Channel i (p = 0 to 15, n = 0 to 2, i = 0, 1)

Base address: CANFD = 0x400B_0000

Offset address: 0x640C + 0x004 × p + 0x080 × n + 0x180 × i



Bit	Symbol	Function	R/W
7:0	CFDB_LL[7:0]	Common FIFO Buffer Data Bytes ((p * 4)	R/W
15:8	CFDB_LH[7:0]	Common FIFO Buffer Data Bytes ((p * 4) + 1)	R/W
23:16	CFDB_HL[7:0]	Common FIFO Buffer Data Bytes ((p * 4) + 2)	R/W
31:24	CFDB_HH[7:0]	Common FIFO Buffer Data Bytes ((p * 4) + 3)	R/W

i = Channel number

The FIFO Access Data Field p Registers n (p = 0 to 15, n = 0 to 2) store data bytes (p * 4) to data bytes ((p * q) + 3) of the message.

In TX mode, you can read data from the FIFO, only for the current entry based on the write pointer value, and not for the other entries.

CFDB_LL[7:0] bits (Common FIFO Buffer Data Bytes ((p * 4))

The CFDB((p * 4)[7:0] bits store data bytes ((p * 4) of the message present in the FIFO buffer.

In TX mode, you can read and write from the FIFO buffers.

In RX mode, you can only read data from the FIFO buffers.

In GW mode, you cannot write data to the FIFO buffers.

In RX or GW mode, unused data bytes are filled with 0x00, according to their configured data payload size CFDCFCCn.CFPLS.*1

CFDB_LH[7:0] bits (Common FIFO Buffer Data Bytes ((p * 4) + 1))

The CFDB((p * 4) + 1)[7:0] bits store data bytes ((p * 4) + 1) of the message present in the FIFO buffer.

In TX mode, you can read and write from the FIFO buffers.

In RX mode, you can only read data from the FIFO buffers.

In GW mode, you cannot write data to the FIFO buffers.

In RX or GW mode, unused data bytes are filled with 0x00, according to their configured data payload size CFDCFCCn.CFPLS.*1

CFDB_HL[7:0] bits (Common FIFO Buffer Data Bytes ((p * 4) + 2))

The CFDB((p * 4) + 2)[7:0] bits store data bytes ((p * 4) + 2) of the message present in the FIFO buffer.

In TX mode, you can read and write from the FIFO buffers.

In RX mode, you can only read data from the FIFO buffers.

In GW mode, you cannot write data to the FIFO buffers.

In RX or GW mode, unused data bytes are filled with 0x00, according to their configured data payload size CFDCFCCn.CFPLS.*1

CFDB_HH[7:0] bits (Common FIFO Buffer Data Bytes ((p * 4) + 3))

The CFDB((p * 4) + 3)[7:0] bits store data bytes ((p * 4) + 3) of the message present in the FIFO buffer.

In TX mode, you can read and write from the FIFO buffers.

In RX mode, you can only read data from the FIFO buffers.

In GW mode, you cannot write data to the FIFO buffers.

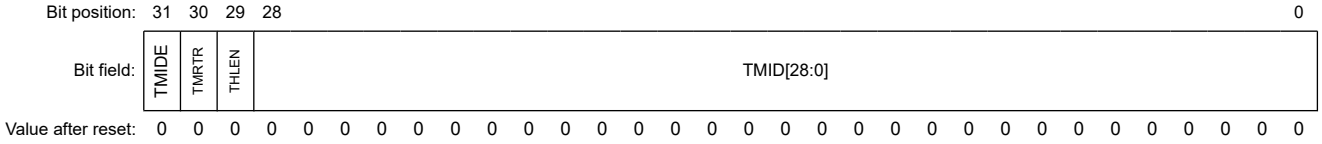
In RX or GW mode, unused data bytes are filled with 0x00, according to their configured data payload size CFDCFCCn.CFPLS.*1

Note 1. In RX or GW mode, unused data bytes are filled with 0x00 according to the configured data payload size CFDCFCCn.CFPLS, which is a CAN-FD feature not found in classical CAN.

32.2.87.14 CFDTMIDn_i : TX Message Buffer ID Register n Channel i (n = 0 to 7, 32 to 39, i = 0, 1)

Base address: CANFD = 0x400B_0000

Offset address: 0x1_0000 + 0x080 × n + 0x2000 × i



Bit	Symbol	Function	R/W
28:0	TMID[28:0]	TX Message Buffer ID Field STD-ID/EXT-ID fields	R/W
29	THLEN	Tx History List Entry 0: Entry not stored in THL after successful TX 1: Entry stored in THL after successful TX	R/W
30	TMRTR	TX Message Buffer RTR bit 0: Data frame 1: Remote frame	R/W
31	TMIDE	TX Message Buffer IDE bit 0: STD-ID is transmitted 1: EXT-ID is transmitted	R/W

Each TX Message Buffer ID Registers n (n = 0 to 7, 32 to 39) are used to store the ID, IDE, RTR fields and history configuration of the message to be transmitted from the associated buffer.

TMID[28:0] bits (TX Message Buffer ID Field)

The TMID[28:0] bits are bits of the STD-ID/EXT-ID fields of the message stored in this TX message buffer.

Do not write to these bits when the related CAN-FD channel is in CH_SLEEP mode.

THLEN bit (Tx History List Entry)

The THLEN bit controls the storage of an entry corresponding to the transmitted message in the TX History list at the end of a successful transmission.

Do not write to these bits when the related CAN-FD channel is in CH_SLEEP mode.

TMRTR bit (TX Message Buffer RTR bit)

The TMRTR bit selects whether a data frame or remote frame is to be transmitted from this TX message buffer.

Note: There are no remote frames in CAN-FD format. For a CAN-FD transmission (CFDTMFDCTRn.CFFDF = 1), this bit is always transmitted dominant (data frame).

Do not write to these bits when the related CAN-FD channel is in CH_SLEEP mode.

TMIDE bit (TX Message Buffer IDE bit)

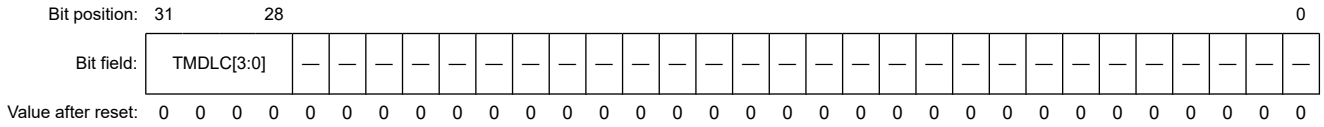
The TMIDE bit selects whether a message with EXT-ID or STD-ID is to be transmitted from this TX message buffer.

Do not write to these bits when the related CAN-FD channel is in CH_SLEEP mode.

32.2.87.15 CFDTMPTRn_i : TX Message Buffer Pointer Register n Channel i (n = 0 to 7, 32 to 39, i = 0, 1)

Base address: CANFD = 0x400B_0000

Offset address: 0x1_0004 + 0x080 × n + 0x2000 × i



Bit	Symbol	Function	R/W
27:0	—	The read values are undefined. The write value should be 0.	R/W
31:28	TMDLC[3:0]	TX Message Buffer DLC Field Number of data bytes to be transmitted in a CAN frame.	R/W

Each TX Message Buffer Pointer Register n (n = 0 to 7, 32 to 39) is used to store the DLC fields of the message to transmit from the associated buffer.

TMDLC[3:0] bits (TX Message Buffer DLC Field)

The TMDLC[3:0] bits select the number of data bytes to be transmitted from this TX message buffer when the corresponding TMRTR bit is configured as 0.

See Table 5 in ISO 11898-1 (2015) Specification for details in defining the number of data bytes to be transmitted.

Do not write to these bits when the related CANFD channel is in CH_SLEEP mode.

32.2.87.16 CFDTMFDCTRn_i : TX Message Buffer CANFD Control Register n Channel i (n = 0 to 7, 32 to 39, i = 0, 1)

Base address: CANFD = 0x400B_0000

Offset address: 0x1_0008 + 0x080 × n + 0x2000 × i

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	TMPTR[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	TMIFL[1:0]		—	—	—	—	—	TMFDF	TMBRS	TMESI
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TMESI*1	Error State Indicator bit 0: CANFD frame to transmit by error active node 1: CANFD frame to transmit by error passive node	R/W
1	TMBRS*1	Bit Rate Switch bit 0: CANFD frame to transmit with no bit rate switch 1: CANFD frame to transmit with bit rate switch	R/W
2	TMFDF*1	CAN FD Format bit 0: Non CANFD frame to transmit 1: CANFD frame to transmit	R/W
7:3	—	The read values are undefined. The write value should be 0.	R/W
9:8	TMIFL[1:0]	TX Message Buffer Information Label Field	R/W
15:10	—	The read values are undefined. The write value should be 0.	R/W
31:16	TMPTR[15:0]	TX Message Buffer Pointer Field	R/W

Note 1. This bit is not available in the classical CAN function.

The TX Message Buffer CANFD Control Registers n (n = 0 to 7, 32 to 39) show the status of the FDF, BRS and ESI bits, including the pointer fields of the CANFD frame to be transmitted.

TMESI bit (Error State Indicator bit)

If the channel is not in error passive, then the TMESI bit equals the write value, otherwise it is a don't care and the bit is transmitted as 1 on the CAN bus, indicating this is an error passive node.

Do not write to the TMESI bit when the related CANFD channel is in CH_SLEEP mode.

Note: This bit is not available in the classical CAN function.

TMBRS bit (Bit Rate Switch bit)

Do not write to the TMBRS bit when the related CANFD channel is in CH_SLEEP mode.

Note: This bit is not available in the classical CAN function.

TMFDF bit (CAN FD Format bit)

Do not write to the TMFDF bit when the related CANFD channel is in CH_SLEEP mode.

Note: This bit is not available in the classical CAN function.

TMIFL[1:0] bits (TX Message Buffer Information Label Field)

The TMIFL[1:0] bits store the information label value to be copied, together with additional message information, in the TX History List after successful transmission of the message.

Do not write to these bits when the related CANFD channel is in CH_SLEEP mode.

TMPTR[15:0] bits (TX Message Buffer Pointer Field)

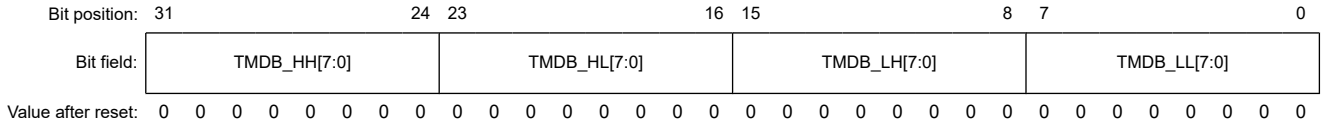
The TMPTR[15:0] bits store the pointer value to be copied, together with additional message information in the TX History List after successful transmission of the message.

Do not write to these bits when the related CANFD channel is in CH_SLEEP mode.

32.2.87.17 CFDTMDFp_n_i : TX Message Buffer Data Field p Register n Channel i (p = 0 to 15, n = 0 to 7, 32 to 39, i = 0, 1)

Base address: CANFD = 0x400B_0000

Offset address: 0x1_000C + 0x004 × p + 0x080 × n + 0x2000 × i



Bit	Symbol	Function	R/W
7:0	TMDB_LL[7:0]	TX Message Buffer Data Byte ((p * 4)	R/W
15:8	TMDB_LH[7:0]	TX Message Buffer Data Byte ((p * 4) + 1)	R/W
23:16	TMDB_HL[7:0]	TX Message Buffer Data Byte ((p * 4) + 2)	R/W
31:24	TMDB_HH[7:0]	TX Message Buffer Data Byte ((p * 4) + 3)	R/W

i = Channel number

Each TX Message Buffer Data Field p Register n (p = 0 to 15, n = 0 to 7, 32 to 39) is used to store data bytes ((p * q) + (q - 4)) to data bytes ((p * 4) + (q - 1)) of the message to transmit from the associated buffer.

TMDB_LL[7:0] bits (TX Message Buffer Data Byte ((p * 4))

Data bytes ((p * 4)[7:0] of the message stored in the TX message buffer.

Do not write to these bits when the related CAN-FD channel is in CH_SLEEP mode.

TMDB_LH[7:0] bits (TX Message Buffer Data Byte ((p * 4) + 1))

Data bytes ((p * 4) + 1)[7:0] of the message stored in the TX message buffer.

Do not write to these bits when the related CAN-FD channel is in CH_SLEEP mode.

TMDB_HL[7:0] bits (TX Message Buffer Data Byte ((p * 4) + 2))

Data bytes ((p * 4) + 2)[7:0] of the message stored in the TX message buffer.

Do not write to these bits when the related CAN-FD channel is in CH_SLEEP mode.

TMDB_HH[7:0] bits (TX Message Buffer Data Byte ((p * 4) + 3))

Data bytes ((p * 4) + 3)[7:0] of the message stored in the TX message buffer.

Do not write to these bits when the related CAN-FD hannel is in CH_SLEEP mode.

32.3 Modes of Operation

32.3.1 Overview

The modes of the CANFD module can be classified into 2 groups:

- Global modes
- Channel modes

32.3.2 Global Modes

These modes are applicable for the complete CANFD module and therefore are called Global modes. The global modes of the CANFD module are:

- Global Sleep
- Global Reset
- Global Halt
- Global Operation.

Figure 32.2 shows the possible transitions between the Global modes.

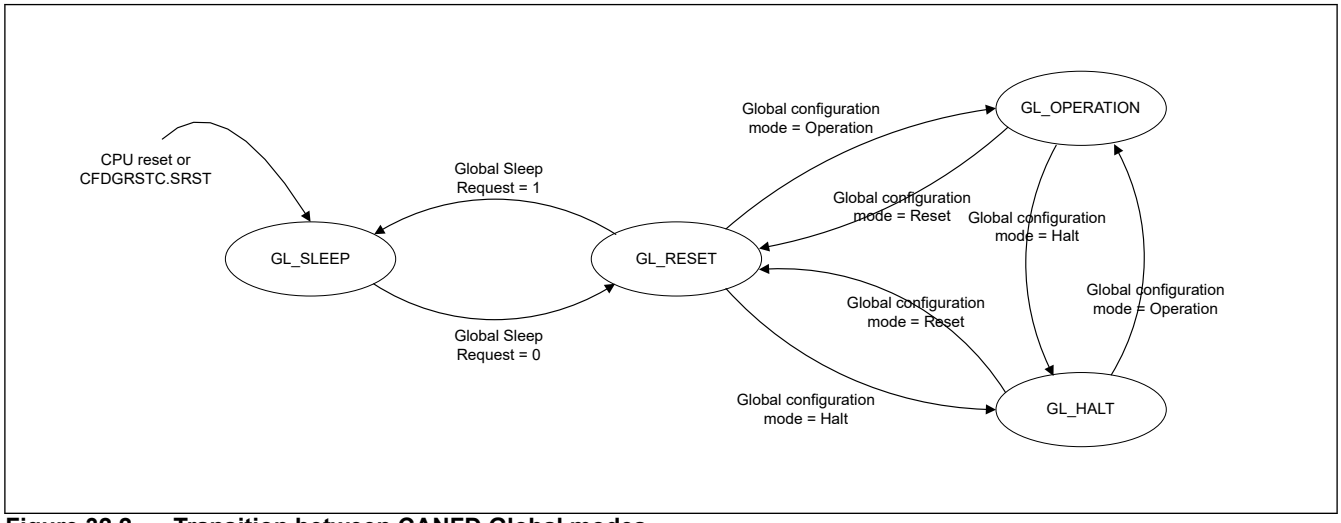


Figure 32.2 Transition between CANFD Global modes

Change in the Global mode can affect the Channel mode. Table 32.8 shows the effect of a Global mode transition on a Channel mode.

Table 32.8 Possible CANFD Channel modes and Global modes

Current Global mode	Target Global mode			
	Sleep	**Reset**	**Halt**	**Operation**
Sleep		Ch-Sleep: Keep Ch-Reset: N/A Ch-Halt: N/A Ch-Oper: N/A		
Reset	Ch-Sleep: Keep Ch-Reset: → Ch-Sleep Ch-Halt: N/A Ch-Oper: N/A		Ch-Sleep: Keep Ch-Reset: Keep Ch-Halt: N/A Ch-Oper: N/A	Ch-Sleep: Keep Ch-Reset: Keep Ch-Halt: N/A Ch-Oper: N/A
Halt		Ch-Sleep: Keep Ch-Reset: Keep Ch-Halt: → Ch-Reset Ch-Oper: N/A		Ch-Sleep:Keep Ch-Reset: Keep Ch-Halt: Keep Ch-Oper: N/A
Operation		Ch-Sleep: Keep Ch-Reset: Keep Ch-Halt: → Ch-Reset Ch-Oper: → Ch-Reset	Ch-Sleep: Keep Ch-Reset: Keep Ch-Halt: Keep Ch-Oper: → Ch-Halt	

32.3.2.1 Global Sleep Mode

After the release of a hardware reset or after setting and clearing a CFDGRSTC.SRST bit, the CANFD module automatically enters Global Sleep mode.

The CANFD module also enters the Global Sleep mode when the Global Sleep Request bit is set while it is in Global Reset mode. This control bit cannot be set in Global Halt mode or Global Operation mode.

Setting the Global Sleep Request bit sets all Channel Sleep Request bits and forces all channels into the Channel Sleep mode.

Sleep mode is used for power saving purpose. When CANFD module is in Global Sleep mode, only the clock for CPU write access to the Global Sleep Mode Request bit is active. All other clocks are stopped and all other functions of the CANFD module are suspended.

Read access from all registers is still possible and all register values are preserved.

After setting the Global Sleep Request bit, it is necessary to confirm that the Global Sleep status has been updated, indicating successful transition to Global Sleep mode before the Global Sleep Request bit can be cleared again.

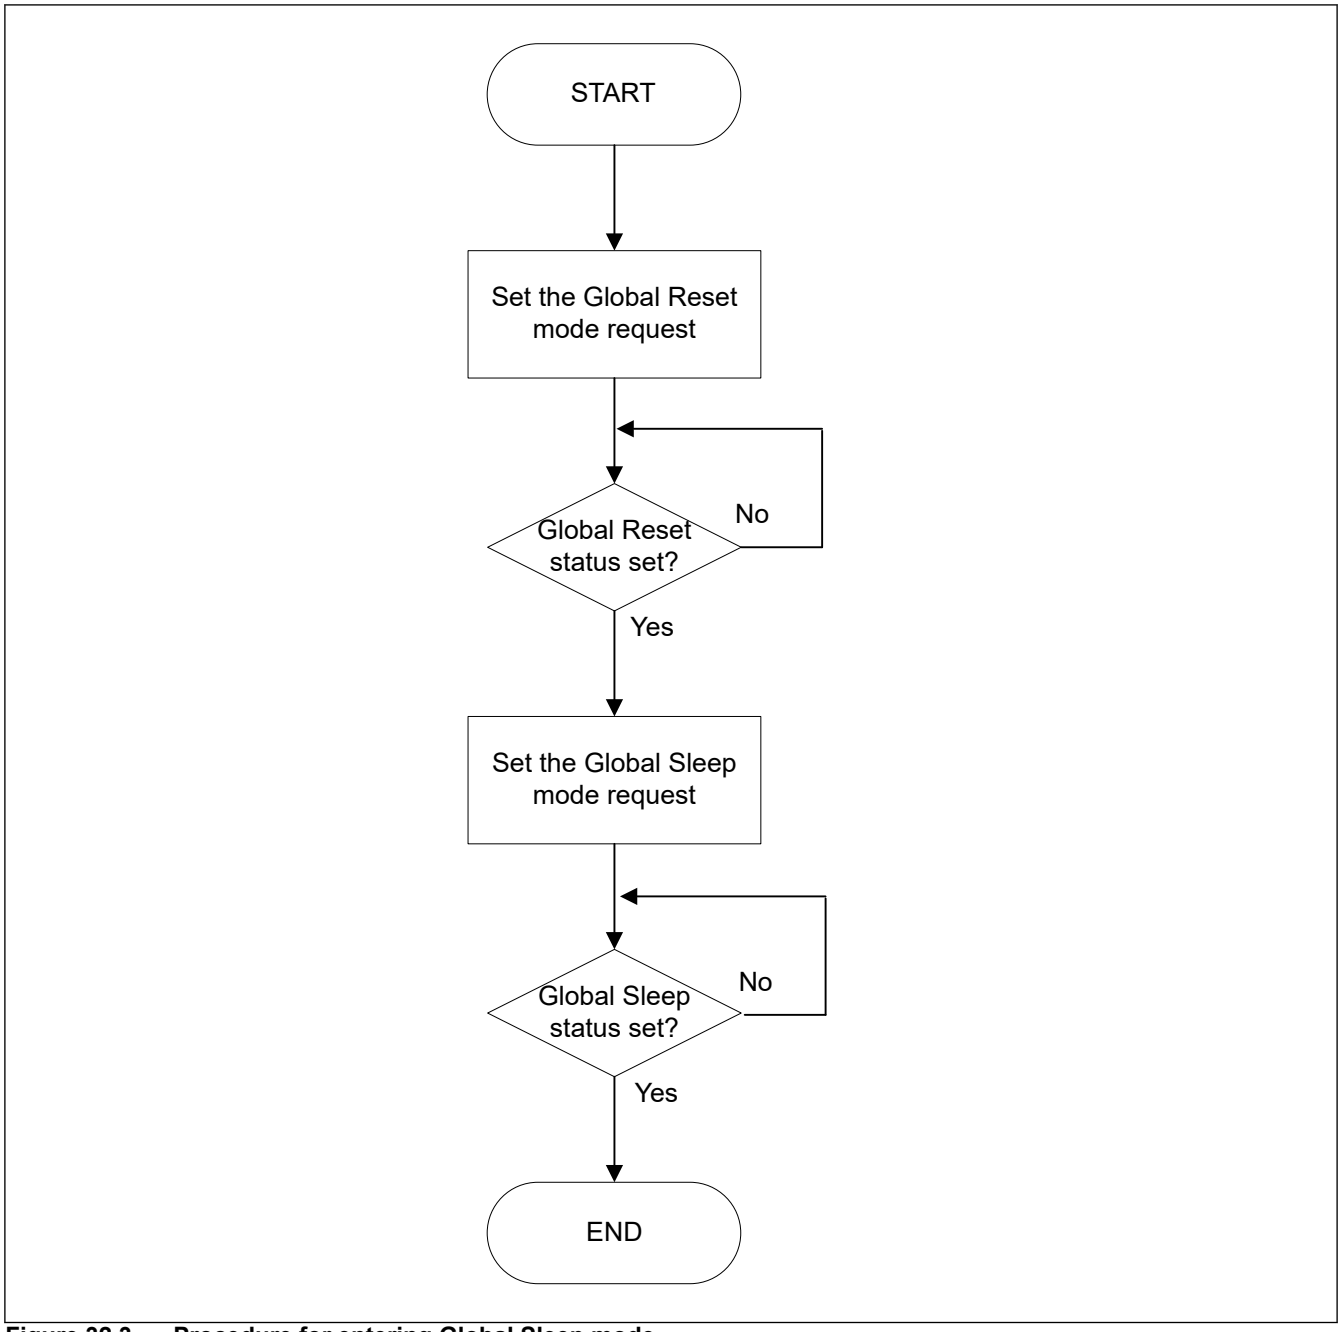

Figure 32.3 Procedure for entering Global Sleep mode

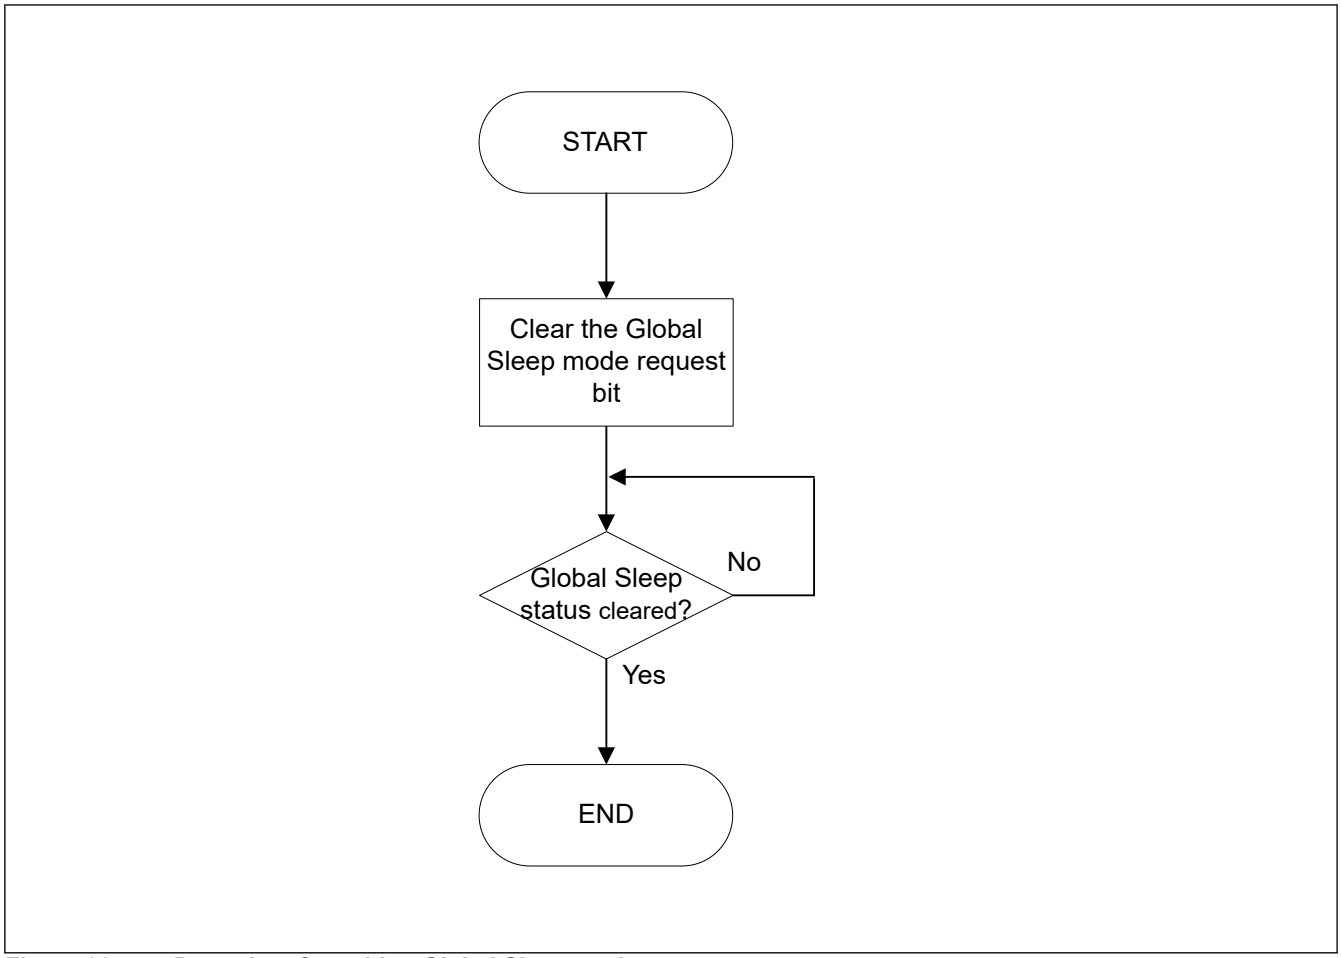

Figure 32.4 Procedure for exiting Global Sleep mode

32.3.2.2 Global Reset Mode

The CANFD module enters this mode in the following ways:

- Global Mode Control bit CFDGCTR.GMDC in the Global Control Register is configured for Global Reset mode while the CANFD module is in Global Halt or Global Operation mode
- Global Sleep Mode Request bit is cleared while CANFD module is in Global Sleep mode.

In Global Reset mode, all CANFD module functions are suspended and all status and flag registers are initialized.

Additionally all FIFOs and all channel TX Queues are disabled and transmission control bits are cleared.

Configuration registers (except the test mode registers) are not initialized in this mode to their MCU reset values and the CANFD module can be configured.

See section 32.3.4. Global Mode and Channel Mode Transition Interactions for a detailed description of the behavior of all registers when transition to Global Reset mode is performed.

Setting the Global mode to Reset by setting the Global Mode Control bits CFDGCTR.GMDC in the Global Control Register to 01b sets all Channel Mode Control bits CFDCnCTR.CHMDC in the Channel Control Registers to 01b and forces all channels into the Channel Reset mode.

For channels that are already in Channel Reset mode or Channel Sleep mode, this automatic transition is not performed (CFDCnCTR.CHMDC of related channel already set to 01b).

After setting Global Mode Control bit CFDGCTR.GMDC to Reset mode, it is necessary to confirm that the Reset Mode Status bit CFDGSTS.GRSTSTS in the Global Status Register has been updated, indicating successful transition to Global Reset mode before CFDGCTR.GMDC can be changed again.

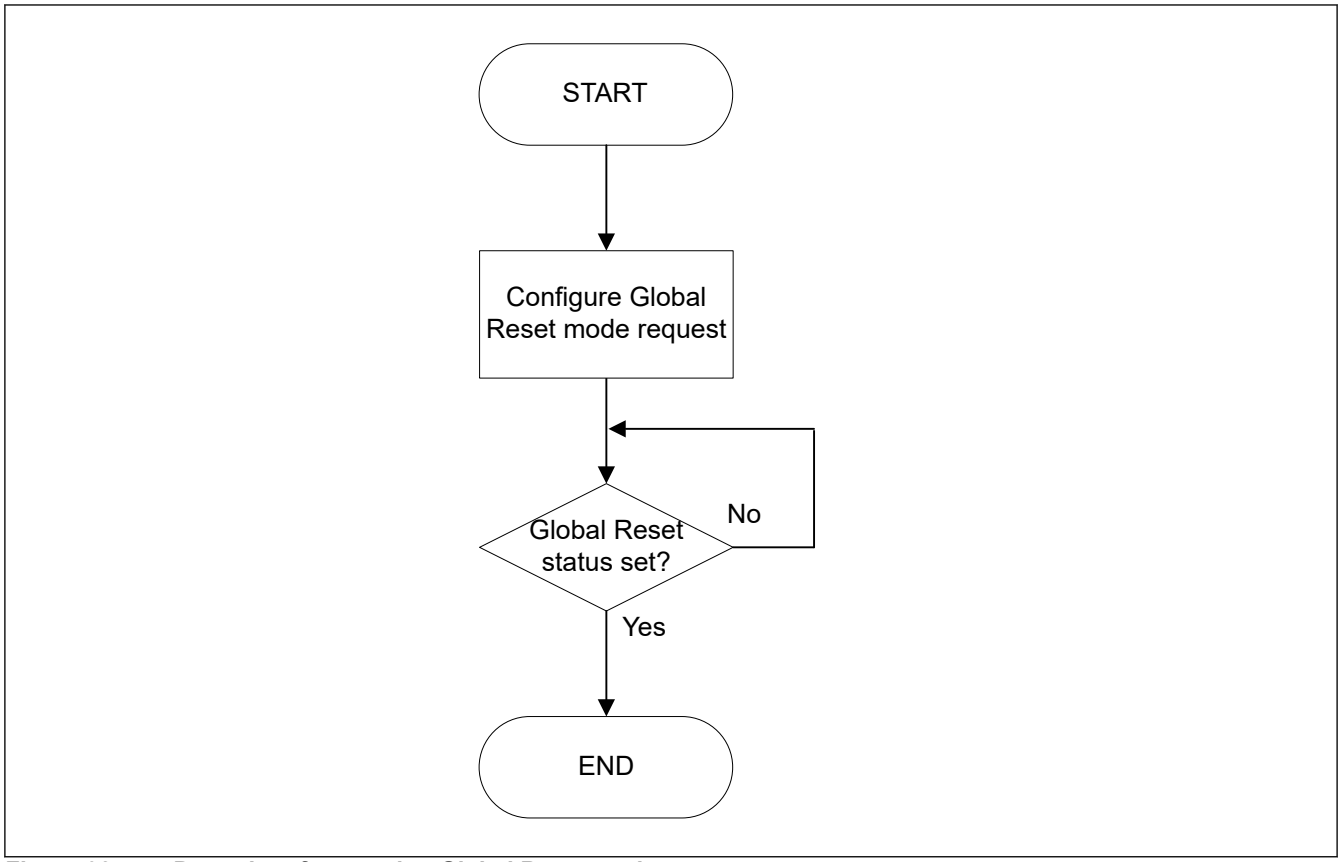

Figure 32.5 Procedure for entering Global Reset mode

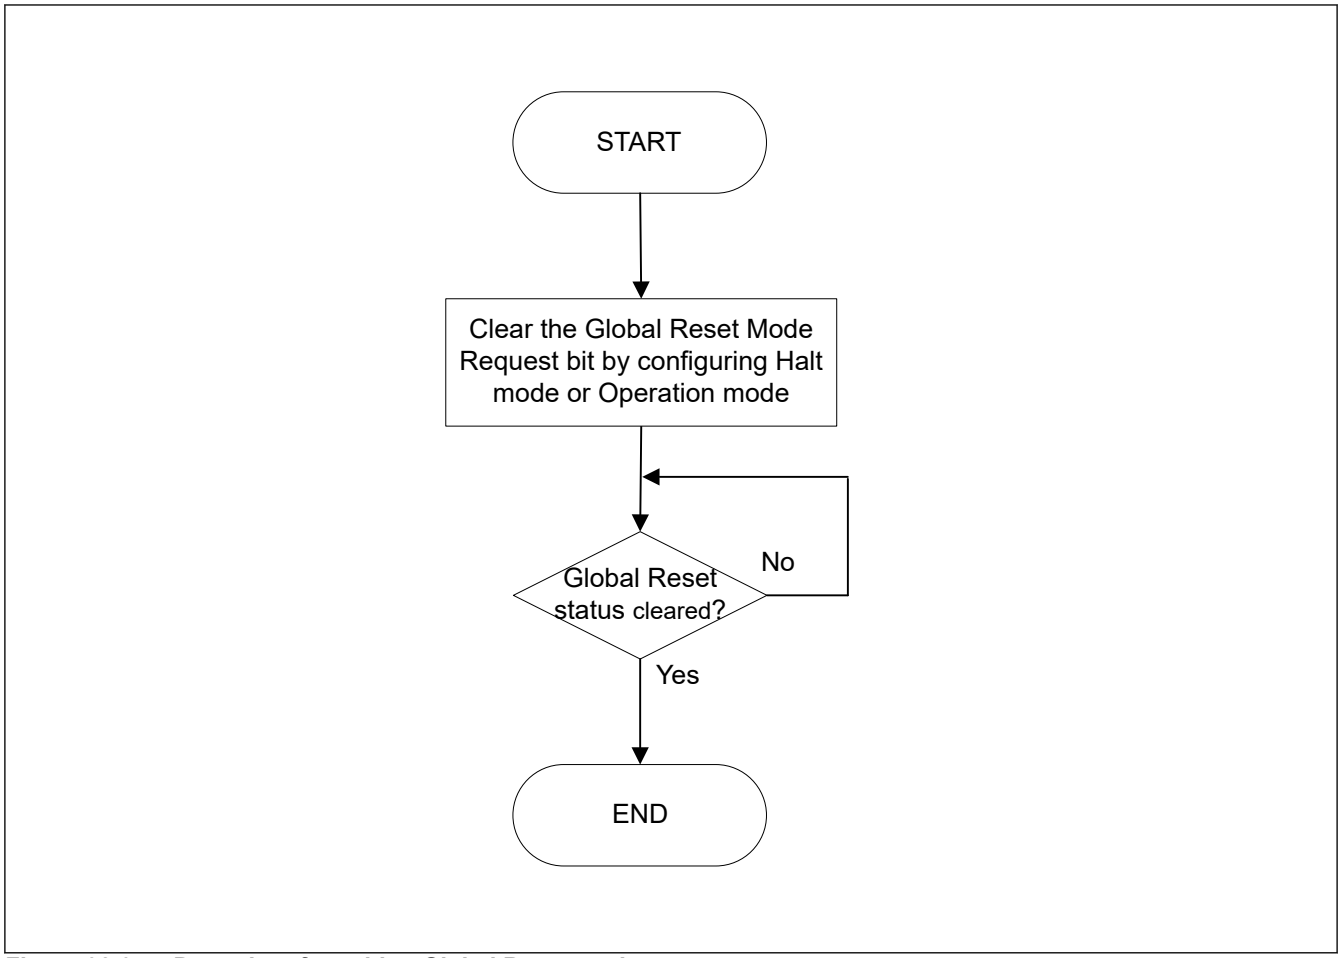

Figure 32.6 Procedure for exiting Global Reset mode

32.3.2.3 Global Halt Mode

The CANFD module enters this mode in the following ways:

- Global Mode Control bit CFDGCTR.GMDC in the Global Control Register is configured for Global Halt mode while the CANFD module is in Global Reset mode:
  - the channels in either Channel Reset or Channel Sleep mode remain in this mode
- Global Mode Control bit CFDGCTR.GMDC in the Global Control Register is configured for Global Halt mode while the CANFD module is in Global Operation mode:
  - all channels in Channel Reset, Channel Halt, or Channel Sleep mode remain in this mode
  - all channels in Channel Operation mode transition to Channel Halt mode
  - Global Halt Mode Status bit is set when all channels have left Channel Operation mode.

If a transmission or reception is ongoing for a channel, the transition to Channel Halt mode is delayed until completion of the communication.

Similarly, if a channel is in bus-off, the full bus-off recovery sequence may be delayed depending on the channel configuration.

In Global Halt mode, all communications are suspended and CANFD logic does not cause any change to the Status and Flag registers (only when a channel is in the bus-off that its REC and TEC values are cleared). Additionally, the test mode configuration and control registers are not initialized in this mode.

The Global Halt mode should be used to configure global module test modes.

See section 32.3.4. Global Mode and Channel Mode Transition Interactions for a detailed description of the behavior of all registers when transition to Global Halt mode is performed.

Setting the Global mode to Halt by setting the Global Mode Control bit CFDGCTR.GMDC in the Global Control Register to 10b sets all Channel Mode Control bits CFDCnCTR.CHMDC in the Channel Control Registers to 10b for the channels that are in Channel Operation mode and forces these channels into the Channel Halt mode.

For channels that are already in Channel Reset, Channel Halt, or Channel Sleep mode, this automatic transition is not performed.

Therefore, the Global Halt mode request can be used to shut down all CANFD channel communications without loss of messages and disruption on the related CAN bus (no interruption of reception/transmission processes on the channels).

After setting the Global Mode Control bit CFDGCTR.GMDC to Halt mode, it is necessary to confirm that the Halt Mode Status bit CFDGSTS.GHLTSTS in the Global Status Register has been updated to indicate a successful transition to Global Halt mode. Do not specify any other SFR setting until confirming CFDGSTS.GHLTSTS is set.

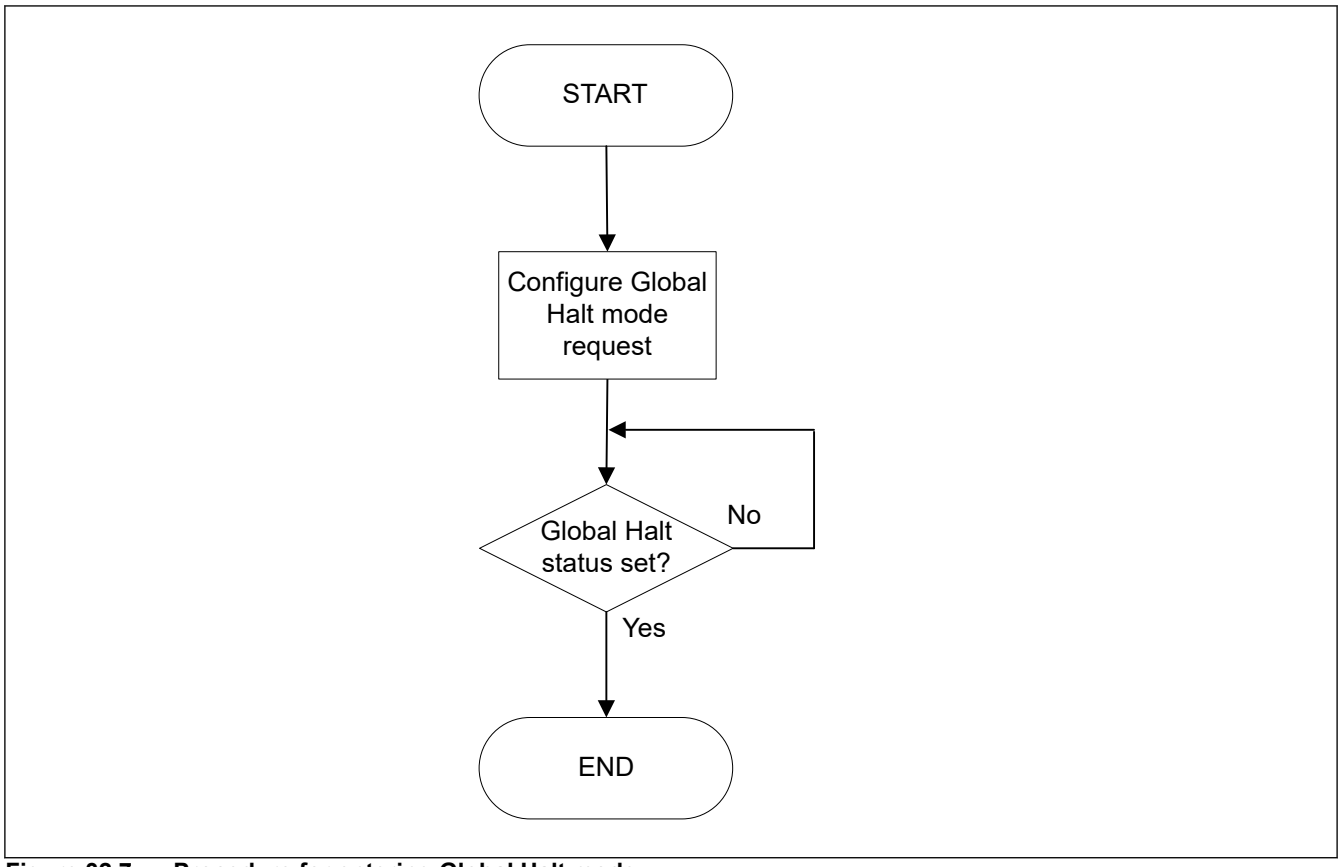

Figure 32.7 Procedure for entering Global Halt mode

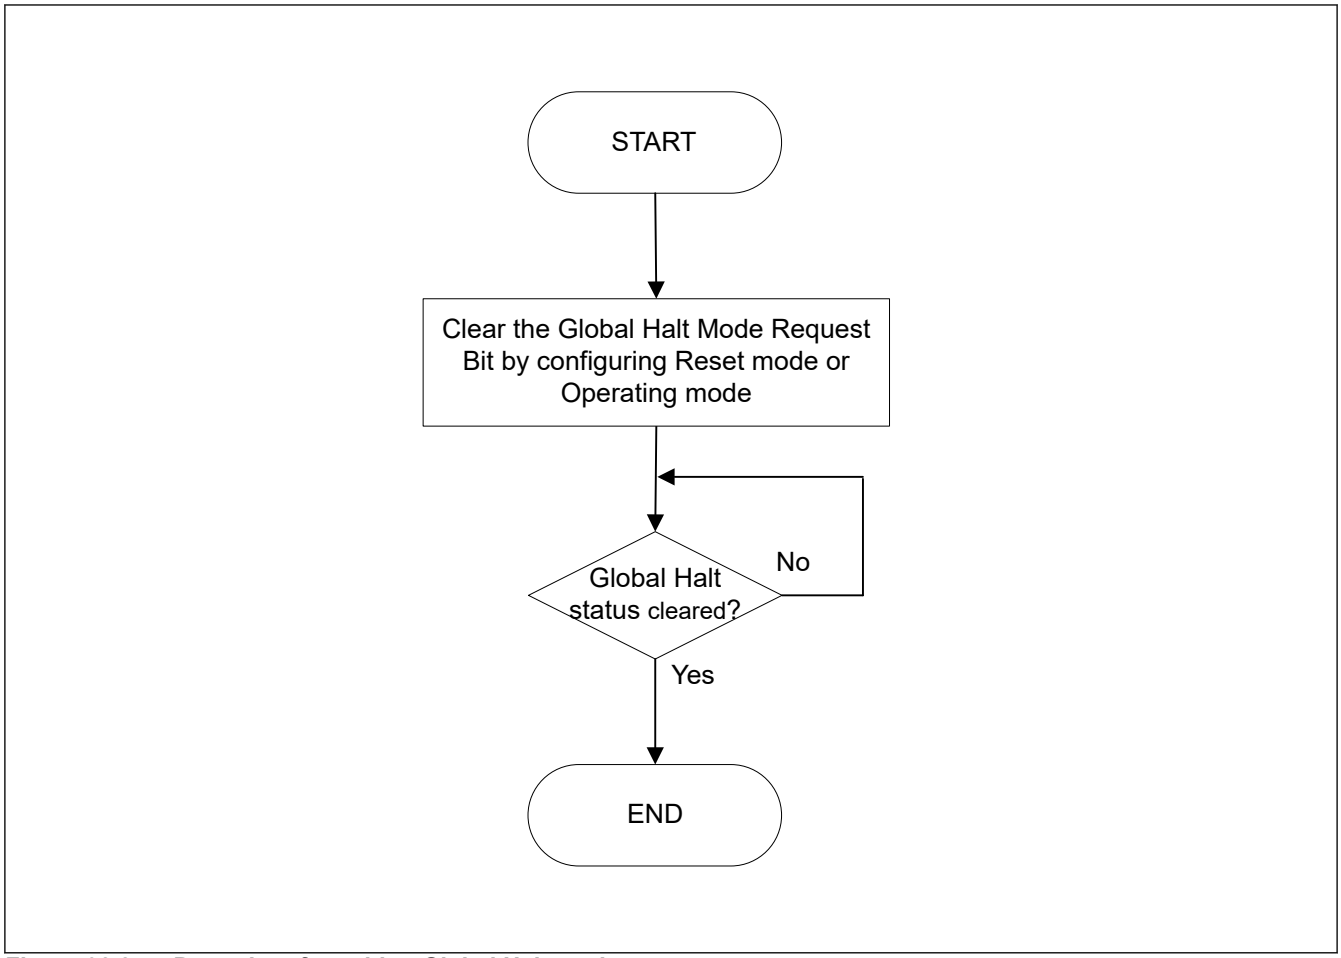

Figure 32.8 Procedure for exiting Global Halt mode

32.3.2.4 Global Operation Mode

The CANFD module enters this mode when the Global Mode Configuration bits are set to Global Operation mode.

The CANFD channels can only be set to Channel Operation mode and start CAN communication when CANFD is in Global Operation mode.

After setting the Global Mode Control bit CFDGCTR.GMDC to Global Operation mode, it is necessary to confirm that the Global Reset Mode Status bit CFDGSTS.GRSTSTS and the Global Halt Mode Status bit CFDGSTS.GHLTSTS in the Global Status Register have been cleared to indicate a successful transition to Global Operation mode before CFDGCTR.GMDC can be modified again.

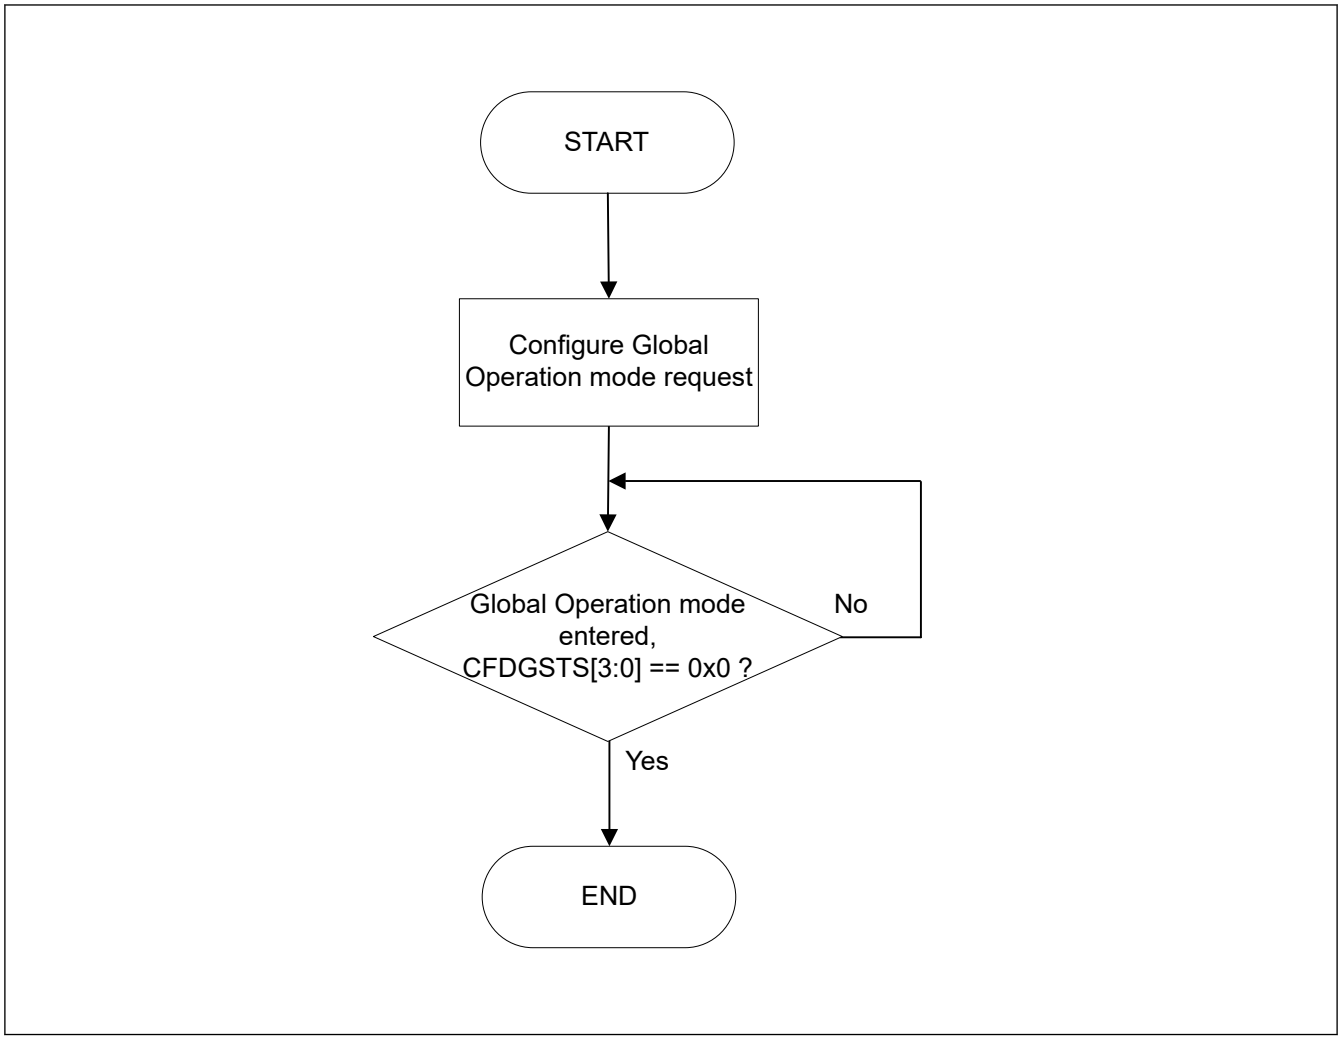

Figure 32.9 Procedure for entering Global Operation mode

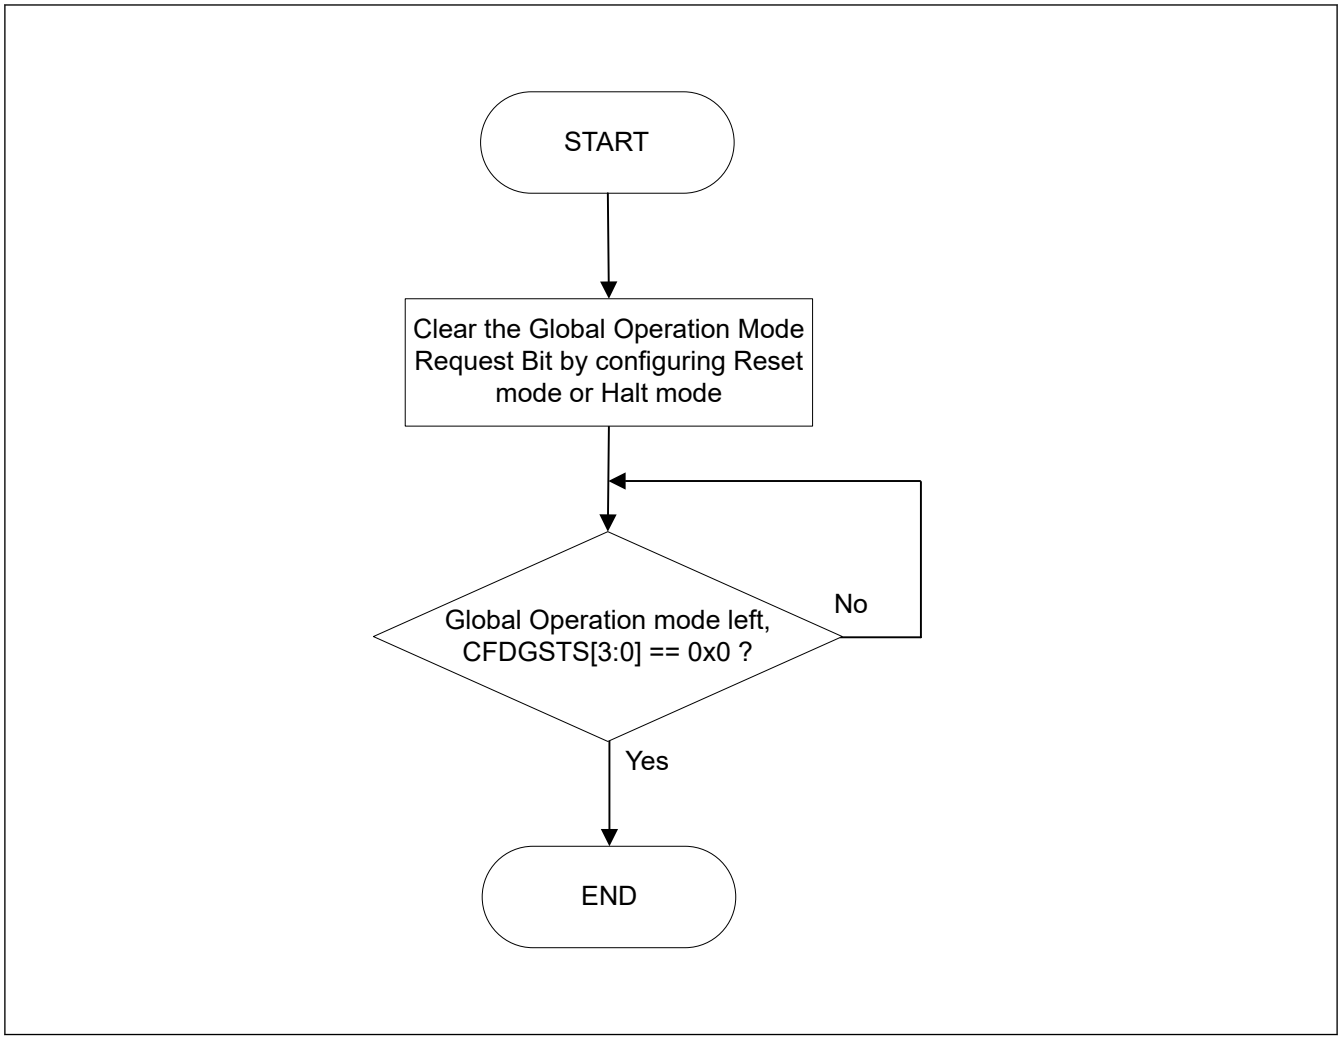

Figure 32.10 Procedure for exiting Global Operation mode

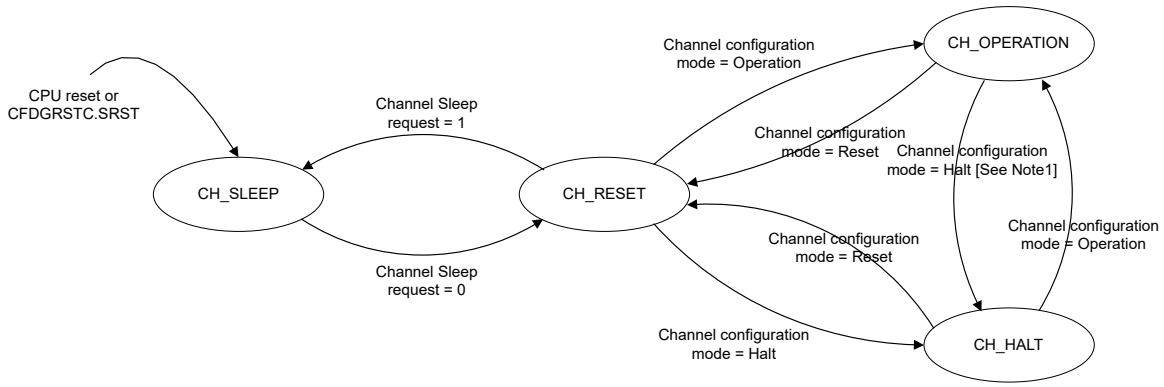
32.3.3 Channel Modes

Each CAN channel can be in one of the following four channel modes:

- Reset
- Halt
- Operation
- Sleep.

Figure 32.11 shows the possible transitions between the channel modes.



Note 1. The transition timing depends on BOM setting in the Channel Configuration Register:
- when BOM = 01b, the state transition timing is immediate after entering bus-off state
- when BOM = 10b, the state transition timing is at the end of bus-off state
- when BOM = 11b, the state transition timing is matching with the setting of CHMDC to Halt mode.

Figure 32.11 Transition between CAN channel modes

32.3.3.1 CAN Channel Sleep Mode

After the release of a hardware reset or after setting and clearing the CFDGRSTC.SRST bit, each CAN channel of the CANFD module automatically enters Channel Sleep mode.

Each CAN channel also enters Channel Sleep mode when the related Channel Sleep Mode Request bit is set while the CAN channel is in Channel Reset mode. Do not set this control bit in Channel Halt mode or Channel Operation mode.

Entering the CAN Channel Sleep mode instantly stops the clock supplied to the CAN channel unit and therefore reduces power consumption.

After setting the Channel Sleep Mode Request bit, it is necessary to confirm that the Channel Sleep mode status has been updated to indicate a successful transition to Channel Sleep mode before the Channel Sleep Mode Request bit can be cleared again.

During Channel Sleep mode, do not write to channel related registers. Read operation is still possible.

32.3.3.2 CAN Channel Reset Mode

A CANFD CAN channel enters this mode in the following ways:

- Channel Mode Control bit CFDCnCTR.CHMDC in the Channel Control Registers is configured for Channel Reset mode while the related CAN channel is in Channel Halt mode or Channel Operation mode
- Channel Sleep Mode Request bit is cleared while the related CAN channel is in Channel Sleep mode
- Global Mode Control bit CFDGCTR.GMDC is set to Global Reset mode and CAN channel is not in Channel Sleep mode or Channel Reset mode.

In Channel Reset mode, all CAN channel status and flag registers are initialized.

Additionally all channel related transmission control bits are cleared and the channel related TX Queue is disabled.

Configuration registers (except the Channel Test Mode registers) are not initialized in this mode and the CAN channel can be configured for communication.

See section 32.3.4. Global Mode and Channel Mode Transition Interactions for a detailed description of the behavior of all registers when transition to Channel Reset mode is performed.

After setting the Channel Mode Control bit CFDCnCTR.CHMDC to Channel Reset mode, it is necessary to confirm that the Reset Mode Status bit CFDCnSTS.CRSTSTS in the related Channel Status Registers has been updated to indicate a successful transition to Channel Reset mode before the related CFDCnCTR.CHMDC bit can be modified again.

See Table 32.9 for the behavior of transitioning to Channel Reset mode while CAN communication is ongoing.

32.3.3.3 CAN Channel Halt Mode

An CANFD CAN channel enters this mode in the following ways:

- Channel Mode Control bit CFDCnCTR.CHMDC in the Channel Control Registers is configured for Channel Halt mode while the related CAN channel is in Channel Reset mode or Channel Operation mode
- Global Mode Control bit CFDGCTR.GMDC is set to Global Halt mode and CAN channel is in Channel Operation mode.

In Channel Halt mode, all channel CAN communication is suspended but all status and flag registers remain unchanged during Channel Halt mode entry (except for the bus-off case where REC and TEC values are cleared for this channel).

In addition, the Channel Test Mode Configuration and Control registers are not initialized in this mode.

The Channel Halt mode should be used to configure channel test modes.

See section 32.3.4. Global Mode and Channel Mode Transition Interactions for a detailed description of the behavior of all registers when transition to Channel Halt mode is performed.

After setting the Channel Mode Control bit CFDCnCTR.CHMDC to Channel Halt mode, it is necessary to confirm that the Halt Mode Status bit CFDCnSTS.CHLTSTS in the related Channel Status Register has been updated to indicate a successful transition to Channel Halt mode before the related CFDCnCTR.CHMDC can be modified again.

See Table 32.9 for the transition behavior to Channel Halt mode while CAN communication is ongoing.

Table 32.9 Transition behavior in CAN Reset mode and Halt mode

Mode	State		
	Receiver	**Transmitter**	**Bus-Off**
CAN Channel Reset mode (CFDCnCTR.CHMDC = 01b)	The CAN channel enters Channel Reset mode without waiting for the completion of the ongoing reception.*1	The CAN channel enters Channel Reset mode without waiting for the completion of the ongoing transmission.*1	The CAN channel enters Channel Reset mode without waiting for the completion of the bus-off recovery.
CAN Channel Halt mode (CFDCnCTR.CHMDC = 10b)	CAN channel enters Channel Halt mode at the end of the ongoing reception or error.*2	CAN channel enters Channel Halt mode after completion of the ongoing transmission.	When CFDCnCTR.BOM is set to 00b, a Channel Halt mode request is accepted only after the completion of the full bus-off recovery sequence. When CFDCnCTR.BOM is set to 10b, the CAN channel transits automatically to Channel Halt mode after waiting for the completion of the bus-off recovery. When CFDCnCTR.BOM is set to 01b, the CAN channel transits automatically to Channel Halt mode without waiting for the completion of the bus-off recovery. When CFDCnCTR.BOM is set to 11b, the CAN channel enters Channel Halt mode as soon as Channel Halt mode is requested (without waiting for the completion of the bus-off recovery).

Note 1. If the entry to Channel Reset mode is required only at the end of an ongoing communication, then Channel Halt mode can be requested first to prevent interruption of CAN communication by direct transition to Channel Reset mode. After the CAN channel enters Channel Halt mode, the Channel Reset mode can be requested.

Note 2. If CAN communication is locked at dominant level after an error flag, software can detect this situation by monitoring the channel related BusLock flag and resolve lock condition by setting the CAN channel to Channel Reset mode.

32.3.3.4 CAN Channel Operation Mode

The Channel Operation mode is activated by setting the CFDCnCTR.CHMDC bits to 00b. If 11 consecutive recessive bits are detected after entering the CAN Operation mode, the CFDCnSTS.COMSTS bit is set and the CAN channel:

- Enables the functions of the channel communication by allowing the channel to become an active node on the CAN network
- Releases the internal fault confinement logic including receive and transmit error counters

At this point, the CAN channel can start transmission and reception of CAN messages.

Within the CAN Channel Operation mode, the channel may be in four different sub-modes, depending on which type of communication functions are performed (see Figure 32.12):

- Channel idle: The CAN channel is neither receiving nor transmitting
- Channel receives: The channel is receiving a CAN message sent by another CAN node
- Channel transmits: The channel is transmitting a CAN message

  Note: The channel may receive its own message simultaneously when Self-test mode is enabled.
- Channel is in bus-off state: The CAN channel is cut-off from CAN bus communication.

After setting the Channel Mode Control bit CFDCnCTR.CHMDC to Channel Operation mode, it is necessary to confirm that the Channel Reset Mode Status bit CFDCnSTS.CRSTSTS and the Channel Halt Mode Status bit CFDCnSTS.CHLTSTS in the Channel Status Register have been updated to indicate a successful transition to Channel Operation mode before the related CFDCnCTR.CHMDC bit can be changed again.

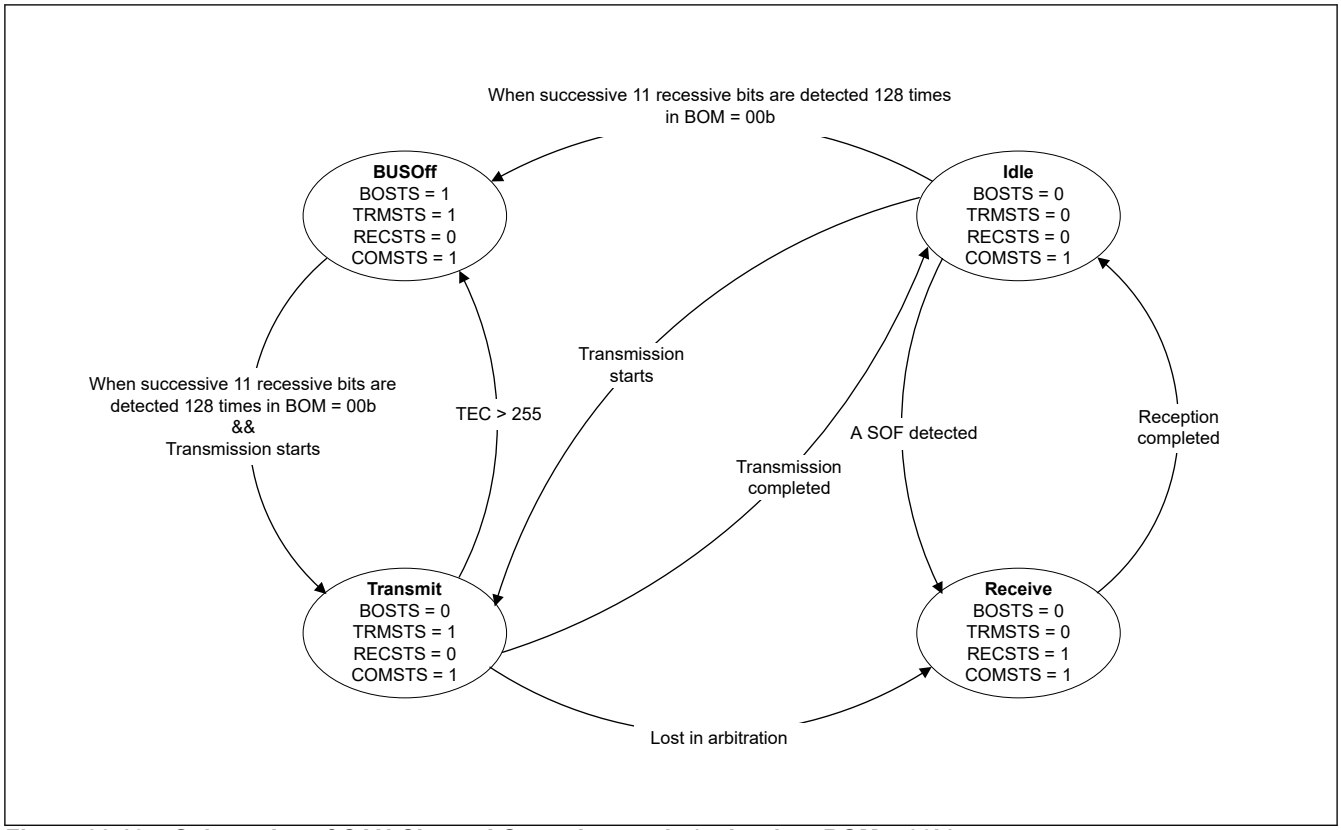


Figure 32.12 Sub-modes of CAN Channel Operation mode (only when BOM = 00b)

32.3.3.5 CAN Channel Bus-Off State

The CAN channel bus-off state is entered according to the fault confinement rules of the CAN specification. The following modes can be configured for returning to the CAN Channel Operation mode from the bus-off state:

- CFDCnCTR.BOM = 00b:
  Bus-Off recovery is compliant to ISO 11898-1, namely the CAN channel re-enters CAN communication (error active state) after 11 consecutive recessive bits are detected 128 times. TEC and REC counters are initialized to 0. The Bus-Off Recovery Flag CFDCnERFL.BORF is set in this case.
- CFDCnCTR.BOM = 01b:

The CAN channel changes the value of the CFDCnCTR.CHMDC bits within the CAN Channel Control Register to 10b and switches immediately to Channel Halt mode automatically after entering bus-off state. TEC and REC counters are initialized to 0 and the Bus-Off Recovery Flag CFDCnERFL.BORF is not set in this case.

- CFDCnCTR.BOM = 10b:
  The CAN channel changes the value of the CFDCnCTR.CHMDC bits within the CAN Channel Control Register to 10b as soon as it reaches bus-off state and enters Channel Halt mode automatically after the CAN channel has completed the bus-off recovery sequence (after 11 consecutive recessive bits are detected 128 times). TEC and REC counters are initialized to 0 and the Bus-Off Recovery Flag CFDCnERFL.BORF is set in this case.
- CFDCnCTR.BOM = 11b:
  Bus-off recovery is initiated but CAN channel can immediately enter Channel Halt mode when still in bus-off state if a request is made to enter Channel Halt mode.
  TEC and REC counters are initialized to 0 and the Bus-Off Recovery Flag CFDCnERFL.BORF is not set.
  Without setting CFDCnCTR.CHMDC [1:0] = 10b and when 11 recessive bits is detected 128 times continuously, transition conditions become the same as CFDCnCTR.BOM = 00b.

Note: If the recovery from bus-off occurs normally in this mode (after waiting for 128 sequences of 11 consecutive recessive bits), and no halt request has been generated during this period, then the Bus-Off Recovery flag CFDCnERFL.BORF is set.

When software writes to the CFDCnCTR.CHMDC bit at the same time as the CAN channel enters Halt mode (at the start of bus-off when CFDCnCTR.BOM = 01b, or at the end of bus-off when CFDCnCTR.BOM = 10b), the software request has the highest priority.

Note: In the above case, the automatic setting of the CFDCnCTR.CHMDC bit to Channel Halt mode request is performed when the CFDCnCTR.CHMDC bit value is previously 00b (Channel Operation mode).

Additionally, it is possible to force the CAN channel to recover from the bus-off state by setting CFDCnCTR.RTBO to 1. The error state changes from bus-off state to integrating state with a maximum delay of 1 CAN bit time, and the CAN communication becomes possible again after 11 consecutive recessive bits are detected. The Bus-Off Recovery Flag is not set in this case, and the TEC and REC counters are initialized to 0.

Before setting CFDCnCTR.RTBO to 1, all pending transmissions from the TX message buffers, TX Queues and/or Common FIFO in TX or GW mode should be disabled.

The disable of the pending transmission message buffer, TX Queue or FIFO must be confirmed by the corresponding acknowledge flags.

For the TX message buffer, the acknowledge flags are the Transmission Result Flags (CFDTMSTSn.TMTRF). For the TX Queue, it is the TX Queue Empty flag (CFDTXQSTSn.TXQEMP). For the FIFO, it is the FIFO Empty flag (CFDCFSTSn.CFEMP).

The CFDCnCTR.RTBO bit should be used for bus-off recovery only when CFDCnCTR.BOM is set to 00b.

Setting this bit in any state other than bus-off has no effect and the bit is cleared immediately.

Table 32.10 shows the settings for the Bus-Off Entry flag CFDCnERFL.BOEF and the Bus-Off Recovery flag CFDCnERFL.BORF for the different configurations of CFDCnCTR.BOM.

Table 32.10 Behavior of Bus-off Entry and Recovery flags

BOM	BOEF bit set	BORF bit set
00b	Always (on entry to bus-off)	Always (on exit from bus-off)
00b CFDCnCTR.RTBO set to 1	Always (on entry to bus-off)	Only if normal bus-off recovery occurs before software sets CFDCnCTR.RTBO to 1'
01b	Always (on entry to bus-off)	Never
10b	Always (on entry to bus-off)	Always (on exit from bus-off)
11b	Always (on entry to bus-off)	Only if normal bus-off recovery occurs before software issues a Halt request

For an efficient software procedure, it is not necessary to wait for the bus-off recovery sequence to end.

It is possible to perform a transmission re-initialization during bus-off recovery. To do this, follow the recommended software flow in Figure 32.13.

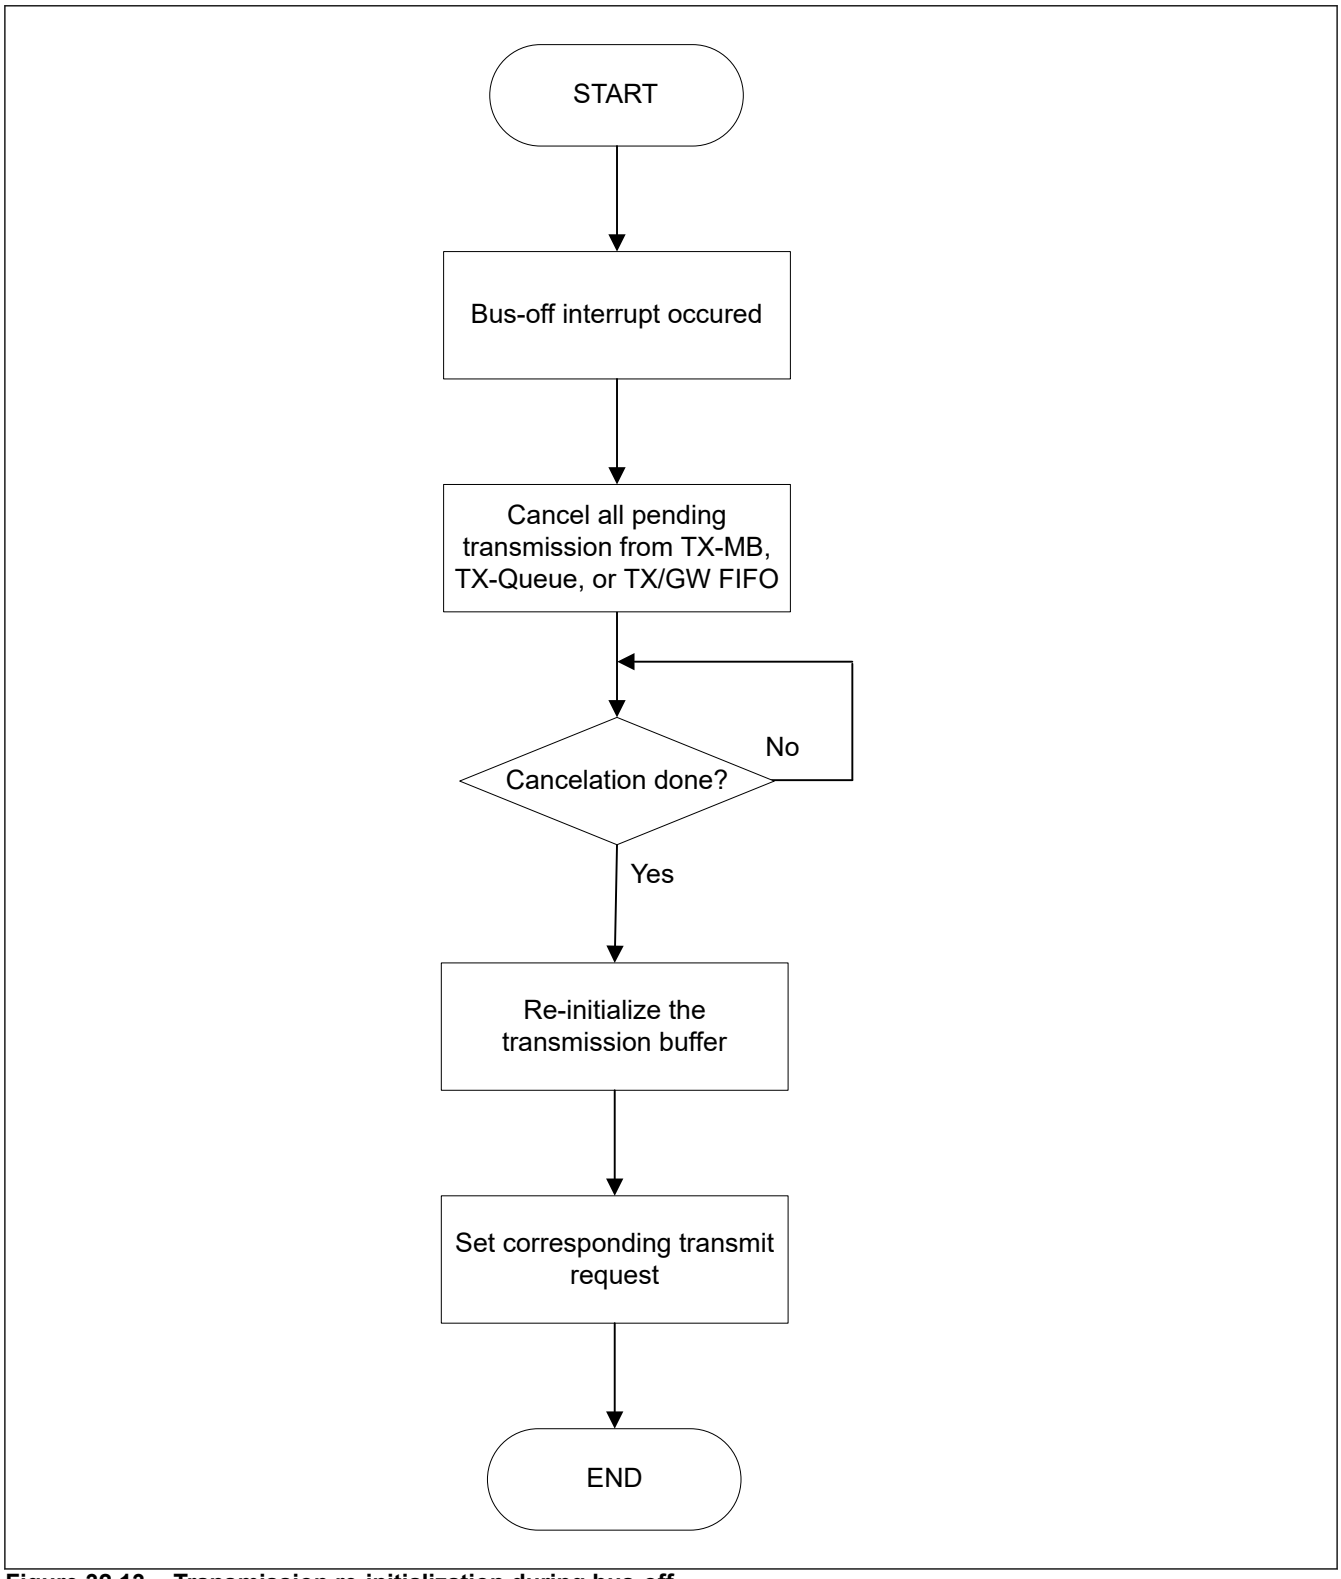

Figure 32.13 Transmission re-initialization during bus-off

32.3.4 Global Mode and Channel Mode Transition Interactions

The interaction between Global mode setting and Channel mode setting is as follows:

- Changing the Channel Mode Control bit CFDCnCTR.CHMDC in the Channel Control Registers does not affect the Global Mode Control bit CFDGCTR.GMDC.
- Changing the Global Mode Control bit CFDGCTR.GMDC affects the channel mode control as described in Table 32.11.

Table 32.11 Interaction between Global and Channel mode transition

Global mode change	Channel mode	Channel mode transition action
Sleep → Reset	Sleep	Channel remains in Sleep mode
Sleep → Halt	— (Global mode change not possible)	
Sleep → Operation	— (Global mode change not possible)	
Reset → Sleep	Sleep	Channels remains in Sleep mode
	Reset	Channel Sleep request bit is set automatically, channel enters Sleep Mode
Reset → Halt	Sleep	Channel remains in Sleep mode
	Reset	Channel remains in Reset mode
Reset → Operation	Sleep	Channel remains in Sleep mode
	Reset	Channel remains in Reset mode
Halt → Sleep	— (Global mode change not possible)	
Halt → Reset	Sleep	Channel remains in Sleep mode
	Reset	Channel remains in Reset mode
	Halt	Channel mode control is set to Reset mode, channel enters Reset mode
Halt → Operation	Sleep	Channel remains in Sleep mode
	Reset	Channel remains in Reset mode
	Halt	Channel remains in Halt mode
Operation → Sleep	— (Global mode change not possible)	
Operation → Reset	Sleep	Channel remains in Sleep mode
	Reset	Channel remains in Reset mode
	Halt	Channel mode control is set to Reset mode, channel enters Reset mode
	Operation	Channel mode control is set to Reset mode, channel enters Reset mode
Operation → Halt	Sleep	Channel remains in Sleep mode
	Reset	Channel remains in Reset mode
	Halt	Channel remains in Halt mode
	Operation	Channel mode control is set to Halt mode, channel enters Halt mode after communication finished

32.3.4.1 Timing of Global Mode Change

The transition time for the Global mode changes are shown in the following table.

Table 32.12 Maximum transition time for the global mode (1 of 2)

From	To	Maximum transition time
GL_SLEEP	GL_RESET	3 peripheral clock cycles*2
GL_RESET	GL_SLEEP	3 peripheral clock cycles
GL_RESET	GL_HALT	10 peripheral clock cycles
GL_RESET	GL_OPERATION	10 peripheral clock cycles

Table 32.12 Maximum transition time for the global mode (2 of 2)

From	To	Maximum transition time
GL_HALT	GL_RESET	2 CAN bit times
GL_HALT	GL_OPERATION	3 peripheral clock cycles
GL_OPERATION	GL_RESET	2 CAN bit times
GL_OPERATION	GL_HALT	3 CAN frames*1 *3

Note 1. The given transition time is the time without any errors on the bus. In case of an error condition, the transition time can lengthen to an uncalculated result. The transition time can also come to a stuck condition for locked RX lines or continued error conditions.
Note 2. Exit GL_SLEEP mode only when CFDGSTS.GRAMINIT is cleared.
Note 3. TQ, CAN frame and CAN bits are related to the individual channels. For the maximum transition time, the channel with the lowest baud rate must be used.

32.3.4.2 Timing of Channel Mode Change

The transition time for the Channel mode changes are shown in the following table.

Table 32.13 Maximum transition time for the channel mode

From	To	max. transition time
CH_SLEEP	CH_RESET	3 peripheral clock cycles
CH_RESET	CH_SLEEP	3 peripheral clock cycles
CH_RESET	CH_HALT	3 CAN bit times
CH_RESET	CH_OPERATION	4 CAN bit times
CH_HALT	CH_RESET	2 CAN bit times
CH_HALT	CH_OPERATION	4 CAN bit times*3
CH_OPERATION	CH_RESET	2 CAN bit times
CH_OPERATION	CH_HALT	2 CAN frames*1 *2

Note 1. The time specified for this transition does not include the case where channel enters bus-off state. For bus-off, the timing depends on the configuration of the CFDCnCTR.BOM[1:0] bits.
Note 2. The given transition time is the time without any errors on the bus. In case of an error condition, the transition time can lengthen to an uncalculated result. The transition time can also come to a stuck condition for locked RX lines or continued error conditions.
Note 3. In general, if the baudrate prescaler value CFDCnNCFG.NBRP is changed in CH_HALT mode, the transition time can deviate. The internal prescaler is a free running down counter that creates the TQ clock, and new BRP value is captured when the counter reaches the value 0.

32.4 Initialization

Before joining CAN communications, configure the following settings:

- Clock setting
- Bit timing setting (nominal and data rate)
- Baud Rate setting (nominal and data rate)
- CANFD setting
- Acceptance Filter setting (configuration of Global Acceptance Filter List)
- Reception, Transmission and GW-FIFO setting
- CAN Operation mode setting

32.4.1 Initialization of CAN Clock, Bit Timing and Baud Rate

32.4.1.1 Bit Timing Conditions

The following lines describe the composition of each segment and the restriction that apply to the segment setting.

1. Each segment setting
   SS = Fixed to 1 TQ

TSEG1 = See to (CFDCnNCFG) and (CFDCnDCFG)*1
TSEG2 = See to (CFDCnNCFG) and (CFDCnDCFG)*1
SJW = See to (CFDCnNCFG) and (CFDCnDCFG)*1
SS + TSEG1 + TSEG2 = 5 to 49 TQs for Data Bit Rate and 8 to 385 for Nominal Bit Rate

2. Restriction on TSEG1, TSEG2 and SJW
TSEG1(N) > TSEG2(N) ≥ SJW(N)
TSEG1(D) ≥ TSEG2(D) ≥ SJW(D)*1
When only classical frames are used, configure the bit fields TSEG1 and TSEG2 of CFDCnDCFG to valid values.

Note 1. This feature is not available in the classical CAN function.

Table 32.14 shows an example of how to set the bit timing to achieve the required Sample Point settings.

Table 32.14 Bit timing examples

1 bit	Set value (TQ)				Sample point*1(%)
	SS	TSEG1	TSEG2	SJW	
5TQ	1	2	2	1	60.00
8TQ	1	4	3	1	62.50
	1	5	2	1	75.00
10TQ	1	6	3	1	70.00
	1	7	2	1	80.00
12TQ	1	8	3	1	75.00
	1	9	2	1	83.33
15TQ	1	10	4	1	73.33
	1	11	3	1	80.00
16TQ	1	10	5	1	68.75
	1	11	4	1	75.00
20TQ	1	12	7	1	65.00
	1	13	6	1	70.00
24TQ	1	15	8	1	66.66
	1	16	7	1	70.83
50TQ	1	39	10	4	80.00

Note 1. Sample point (in case of 75%)

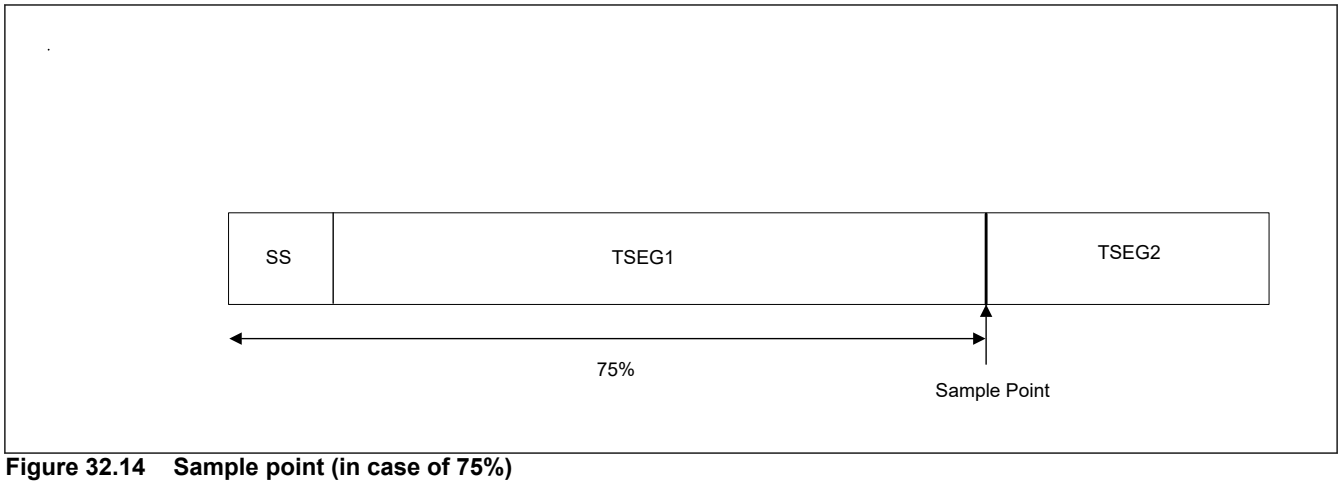

Figure 32.14 Sample point (in case of 75%)

32.4.1.2 CAN Bit Timing

In the CAN protocol, each bit in a communication frame is composed of three segments that can be configured individually for each channel using the related CFDCnNCFG and CFDCnDCFG*1 registers.

Note 1. This register is not available in the classical CAN function.

Figure 32.15 shows the segment composition of a bit and the sample point in it.

Of these segments, the Time Segment 1 (TSEG1) and Time Segment 2 (TSEG2) are used to specify the position of the sample point, so that the timing at which each bit on the CAN bus is sampled can be altered by changing the values of these segments.

The minimum resolution for this timing is referred to as Time Quantum (TQ), which is determined by the clock frequency supplied to the CAN channel and the divide-by-N value of the baud rate prescaler (nominal and data rate).

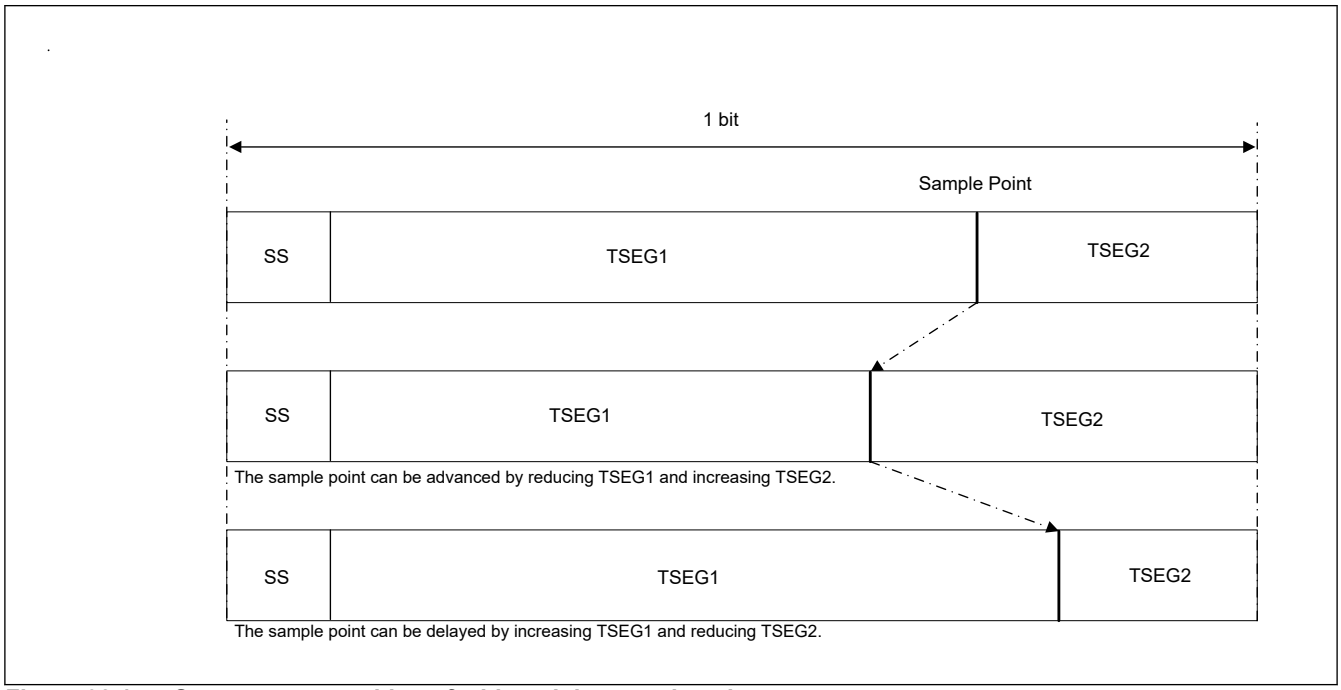

Figure 32.15 Segment composition of a bit and the sample point

1. SS: Synchronization Segment
   This segment is used to synchronize bits by monitoring a recessive-to-dominant edge during the interframe space. This comprises of intermission, suspend transmission, bus idle, during bus idle, and all nodes that can start transmission.
2. TSEG1: Time Segment 1
   This segment absorbs physical delays on the CAN network. A physical delay on the network is two times the total sum of a bus delay, input comparator delay, and output driver delay. It can be lengthened by SJW.
3. TSEG2: Time Segment 2
   This segment is used to correct a phase error by performing resynchronization. It can be shortened by SJW. While sending or receiving a message, communication frames between some nodes may get out of sync due to a drift in the oscillator frequency or a delay in the transmission path. This is referred to as a phase error.
4. SJW: Resynchronization Jump Width
   This is the maximum width by which bits that have become out of sync due to a phase error may be corrected.

Figure 32.15 shows only one symbolic sample point.

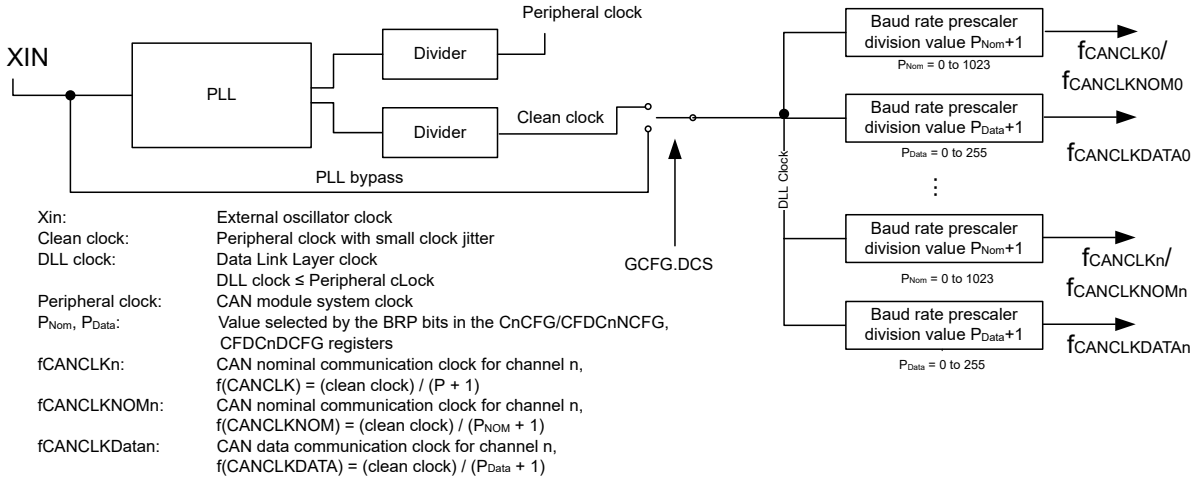
32.4.1.3 Baud Rate

Either the CAN channel system clock (clean clock) or the external oscillator clock can be selected globally for all CAN channels as CAN communication clock.

The transfer speed is determined by the DLL clock, the divide-by-N value of the baud rate prescaler, and the number of TQs in one bit.

$$\text{baudrate} = \frac{\text{DLL\_Clock}}{(\text{number\_of\_time\_quanta\_per\_bit}) \times (\text{BRP} + 1)}$$

Figure 32.16 shows a block diagram of the circuit that generates the CAN channel system clock and Table 32.15 shows a baud rate examples.



Note: CFDCnDCFG register is not available in the classical CAN function.

Figure 32.16 Block diagram of the circuit that generates the CAN channel communication clock

Table 32.15 Nominal baud rate calculation formula and example CAN communication configurations

Baud rate calculation formula	(DLL clock) (baud rate prescaler divide-by-N value*1) × (number of TQs in one bit)								
	80 MHz	40 MHz	32 MHz	30 MHz	24 MHz	20 MHz	16 MHz	10 MHz	8 MHz*2
1 Mbps	8TQ (10) 20TQ (4)	8TQ (5) 20TQ (2)	8TQ (4) 16TQ (2)	10TQ (3) 15TQ (2)	8TQ (3) 12TQ (2) 24TQ (1)	10TQ (2) 20TQ (1)	8TQ (2) 16TQ (1)	10TQ (1)	8TQ (1)
500 Kbps	8TQ (20) 20TQ (8)	8TQ (10) 20TQ (4)	8TQ (8) 16TQ (4)	10TQ (6) 15TQ (4) 20TQ (3)	8TQ (6) 12TQ (4) 24TQ (2)	10TQ (4) 20TQ (2)	8TQ (4) 16TQ (2)	10TQ (2) 20TQ (1)	8TQ (2) 16TQ (1)
250 Kbps	8TQ (40) 20TQ (16)	8TQ (20) 20TQ (8)	8TQ (16) 16TQ (8)	10TQ (12) 15TQ (8) 20TQ (6)	8TQ (12) 12TQ (8) 24TQ (4)	10TQ (8) 20TQ (4)	8TQ (8) 16TQ (4)	10TQ (4) 20TQ (2)	8TQ (4) 16TQ (2)
125 Kbps	8TQ (80) 20TQ (32)	8TQ (40) 20TQ (16)	8TQ (32) 16TQ (16)	10TQ (24) 15TQ (16) 20TQ (12)	8TQ (24) 12TQ (16) 24TQ (8)	10TQ (16) 20TQ (8)	8TQ (16) 16TQ (8)	10TQ (8) 20TQ (4)	8TQ (8) 16TQ (4)
83.3 Kbps	8TQ (120) 12TQ (80) 16TQ (60) 24TQ (40)	8TQ (60) 12TQ (40) 16TQ (30) 24TQ (20)	8TQ (48) 12TQ (32) 16TQ (24) 24TQ (16)	8TQ (45) 10TQ (36) 12TQ (30) 15TQ (24) 20TQ (18) 24TQ (15)	8TQ (36) 12TQ (24) 16TQ (18) 24TQ (12)	8TQ (30) 10TQ (24) 12TQ (20) 15TQ (16) 16TQ (15) 20TQ (12) 24TQ (10)	8TQ (24) 12TQ (16) 16TQ (12) 24TQ (8)	8TQ (15) 10TQ (12) 12TQ (10) 15TQ (8) 20TQ (6) 24TQ (5)	8TQ (12)
33.3 Kbps	8TQ (300) 12TQ (200) 16TQ (150) 20TQ (120) 24TQ (100)	8TQ (150) 12TQ (100) 16TQ (75) 20TQ (60) 24TQ (50)	8TQ (120) 10TQ (96) 12TQ (80) 15TQ (64) 16TQ (60) 20TQ (48) 24TQ (40)	10TQ (90) 12TQ (75) 15TQ (60) 20TQ (45)	8TQ (90) 10TQ (72) 12TQ (60) 15TQ (48) 16TQ (45) 20TQ (36) 24TQ (30)	8TQ (75) 10TQ (60) 12TQ (50) 15TQ (40) 20TQ (30) 24TQ (25)	8TQ (60) 10TQ (48) 12TQ (40) 15TQ (32) 16TQ (30) 20TQ (24) 24TQ (20)	10TQ (30) 12TQ (25) 15TQ (20) 20TQ (15)	8TQ (30)

Note: Shown in ( ) are the baud rate prescaler divide-by-N value.
Note 1. Baud rate prescaler divide-by-N value = P + 1 (P = 0 - 1023) P: value selected by the BRP bits in the Channel Configuration Registers.
Note 2. Minimum frequency to achieve maximum nominal baud rate of 1 Mbps.

Table 32.16 Baud rate calculation example for nominal and data bit rate CAN communication configurations

Baud rate calculation formula	(DLL clock) (baud rate prescaler divide-by-N value*1) × (number of TQs in one bit)		
	80 MHz	40 MHz	20 MHz
Nominal 1 Mbps Data 8 Mbps	80TQ (1)	40TQ (1)	20TQ (1)
	10TQ (1)	5TQ (1)	Not possible
Nominal 1 Mbps Data 5 Mbps	80TQ (1)	40TQ (1)	20TQ (1)
	16TQ (1)	8TQ (1)	Not possible
Nominal 500 Kbps Data 2 Mbps	160TQ (1)	80TQ (1)	40TQ (1)
	40TQ (1)	20TQ (1)	10TQ (1)

Note: Shown in ( ) are the baud rate prescaler divide-by-N values and this table is not available in the classical CAN function.
Note 1. Baud rate prescaler divide-by-N value = P + 1 (P = 0 - 1023) P: value selected by the BRP bits in the Channel Configuration Registers.

For optimum clock tolerance in networks using the FD frame format, the length of the time quantum should be the same in nominal bit time and in data bit time. This means CFDCnNCFG.NBRP = CFDCnDCFG.DBRP.

Additionally, if transceiver delay compensation is used, do not program the CFDCnDCFG.DBRP bit to be greater than 1, as 1 means divide by 2.

32.4.1.4 Setting of CAN Clock, Bit Timing and Baud Rate

Figure 32.17 shows the procedure for setting the CAN clock and the baud rate for each channel.

These settings should be performed during Channel Reset mode (Configuration mode) for the CAN channels.

Before going to channel communication state, the baud rate must be configured, otherwise the mode does not switch correctly.

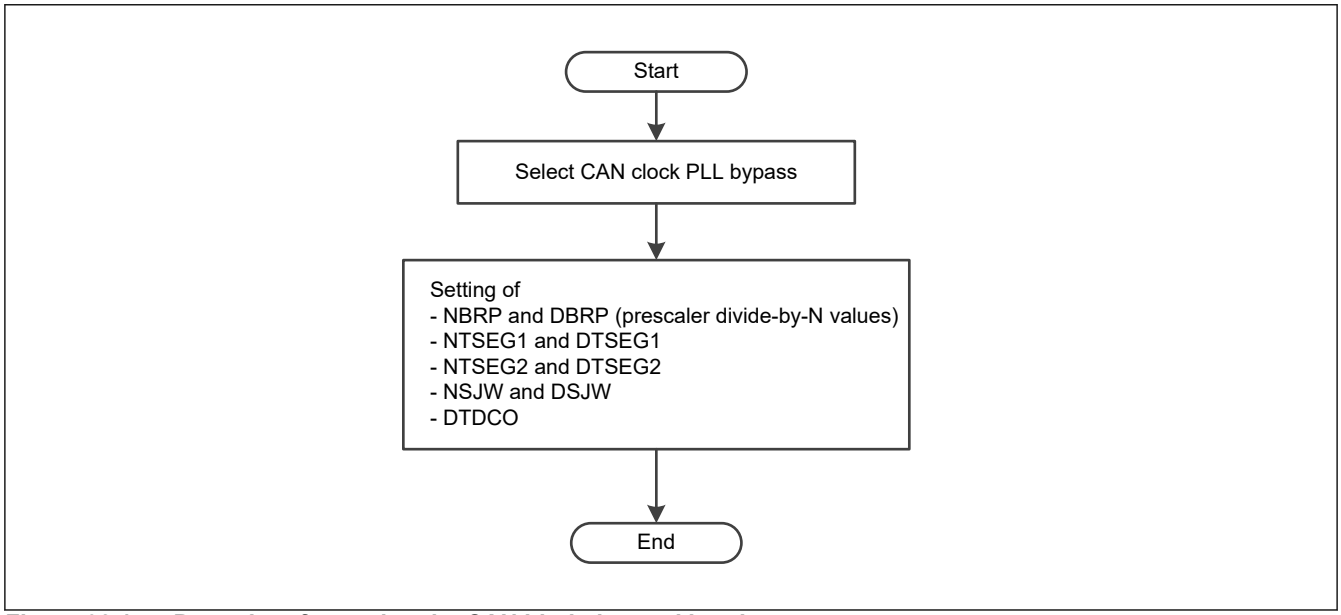


Figure 32.17 Procedure for setting the CAN bit timing and baud rate

32.4.1.5 Transmitter Delay Compensation

This chapter is not valid for classical CAN.

When a high baud rate is used such as 5 to 8 Mbps for the data phase, the transmitter delay can become greater than TSEG1. In this case, the transmitter always detects a bit-error in the data phase of the CANFD frame. The TDC compensates for the inability of the transmitter to receive its own transmitted bit at the sample point of that bit.

There is another symbolic sample point known as the Secondary Sample Point (SSP) that is used only during the data phase of CANFD frames. This is derived from the Transceiver Delay Compensation Result bit (CFDCnFDSTS.TDCR) as shown in Figure 32.18.

The resolution of the configuration, measured and offset values is based on the CAN channel DLL clock.

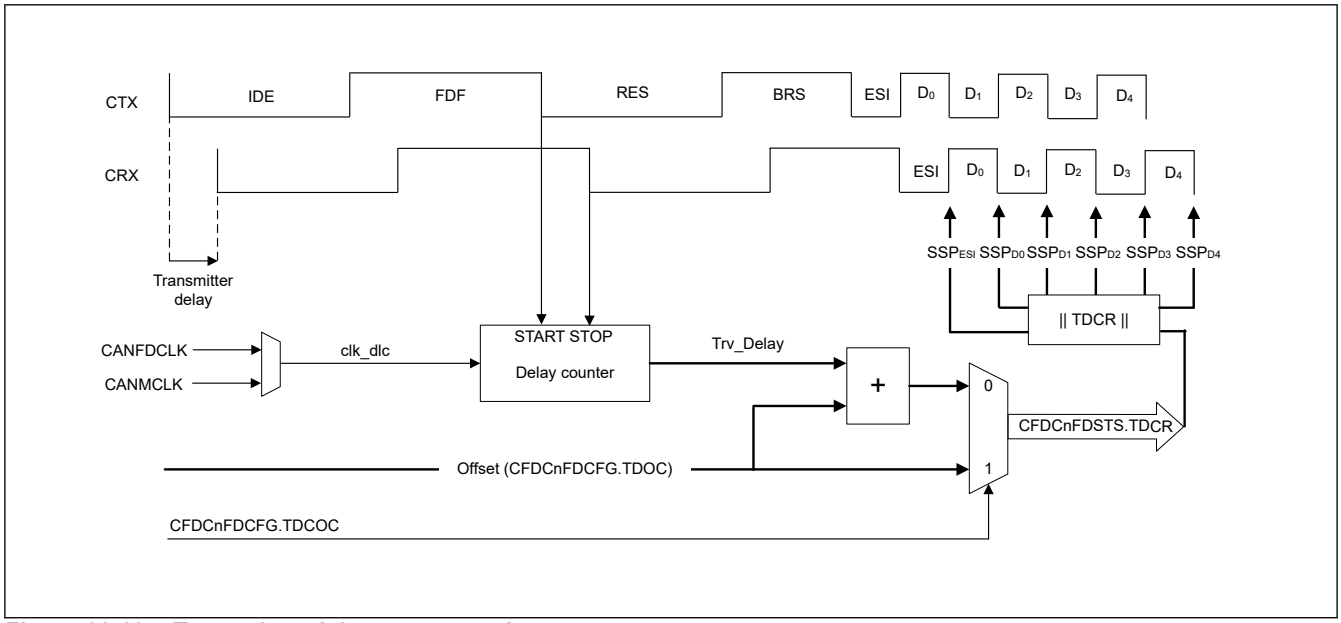

Figure 32.18 Transmitter delay compensation

The measured Trv_Delay is based on the number of clk_dlc clock cycles.The delay is counted up by one for each started clock until the dominant value is seen on CAN_RX. Figure 32.19 shows the measured result. Trv_Delay counted to maximum 127 with a clk_dlc clock.

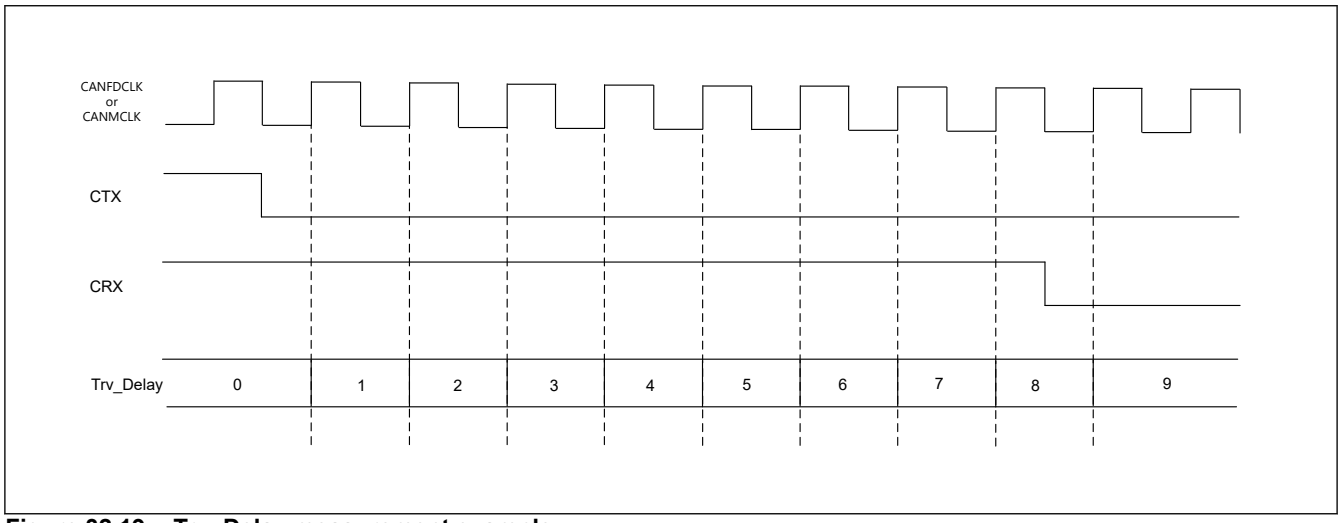

Figure 32.19 Trv_Delay measurement example

The SSP is calculated by taking the result from CFDCnFDSTS.TDCR and rounding the value down to the nearest integer number of data time quanta.

Figure 32.20 shows the positioning of the secondary sample point. When CFDCnFDCFG.TDCOC is equal to 0, the SSP is equal to the Trv_Delay (measured delay) + CFDCnFDCFG.TDCO, rounded down to the nearest integer number of time quanta. Usually, the TDCO value should have the size of (SyncSegmentdata + TSEG1data) to position the SSP to a theoretical location of the sample point.

If the CFDCnFDCFG.TDCOC is equal to 1, the SSP is defined by CFDCnFDCFG.TDCO. If CFDCnDCFG.DBRP is greater than 0, the value is also rounded down to the nearest integer number of time quanta.

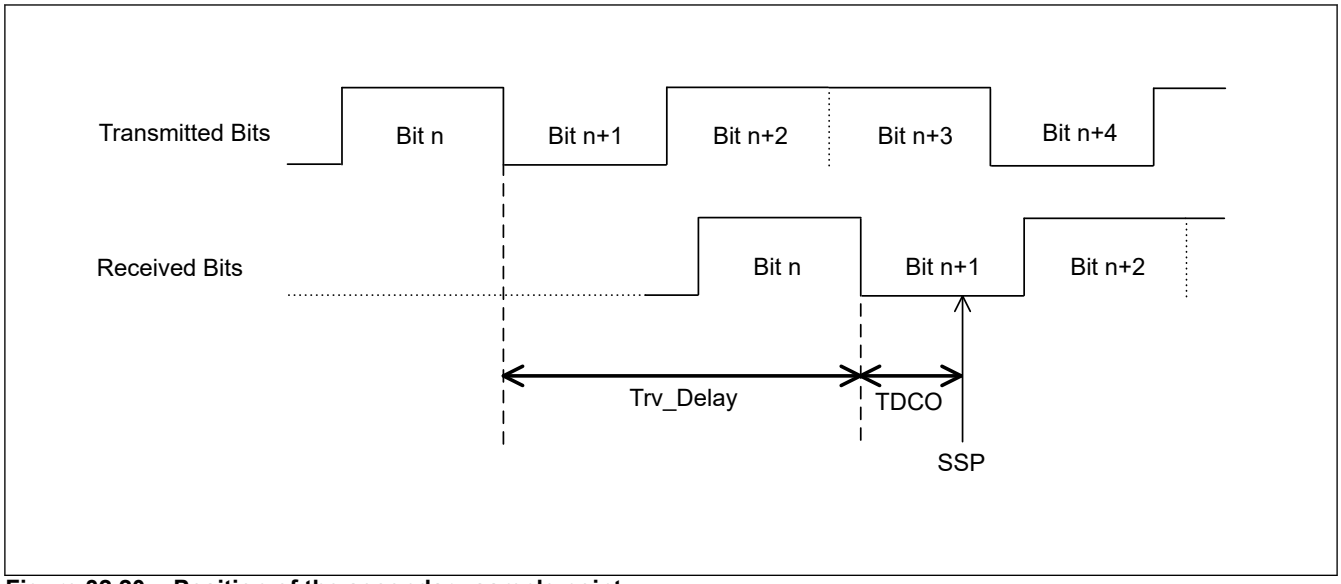

Figure 32.20 Position of the secondary sample point

The maximum delay (Trv_Delay + TDCO) which can be compensated by the CANFD module is (6 data bits - 2clk_dlc).

The ISO 11898-1 allows you to set different values for BRP_data and BRP_nom.

If different values are used for CFDCnNCFG.NBRP and CFDCnDCFG.DBRP, then two CAN nodes may be out of synchronization at the point when the bit rate changes from nominal bit rate to data bit rate after sample point of the BRS bit. This condition is shown in Figure 32.21.

The length of the time quantum should be the same in the nominal bit time and in the data bit time. This means CFDCnNCFG.NBRP = CFDCnDCFG.DBRP.

Different bit rates can be achieved by selecting different configuration values for the Time Segments. The nominal bit rate can be configured from 8 to 385 TQs and the data bit rate from 5 to 49 TQs.

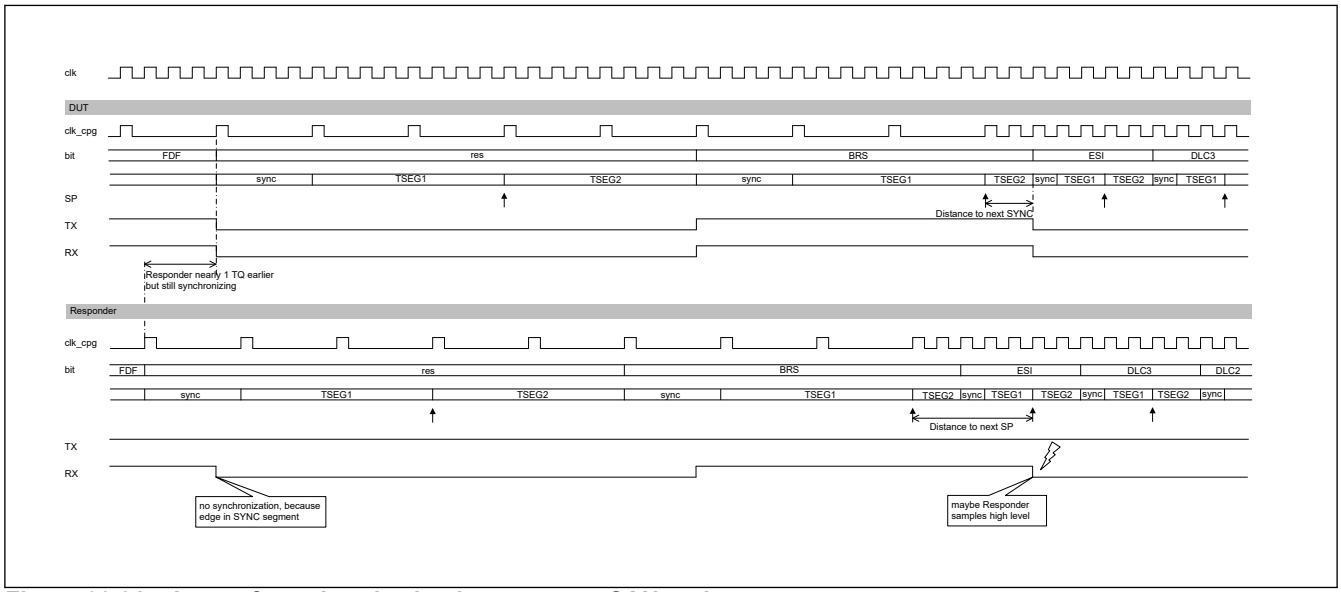

Figure 32.21 Loss of synchronization between two CAN nodes

The transmitter delay compensation measurement result is updated at the falling edge from FDF bit to RES bit when configured accordingly (CFDCnFDCFG.TDCE = 1, CFDCnFDCFG.TDCOC = 0).

Figure 32.22 shows the read flow to get the measured transmitter delay compensation result.

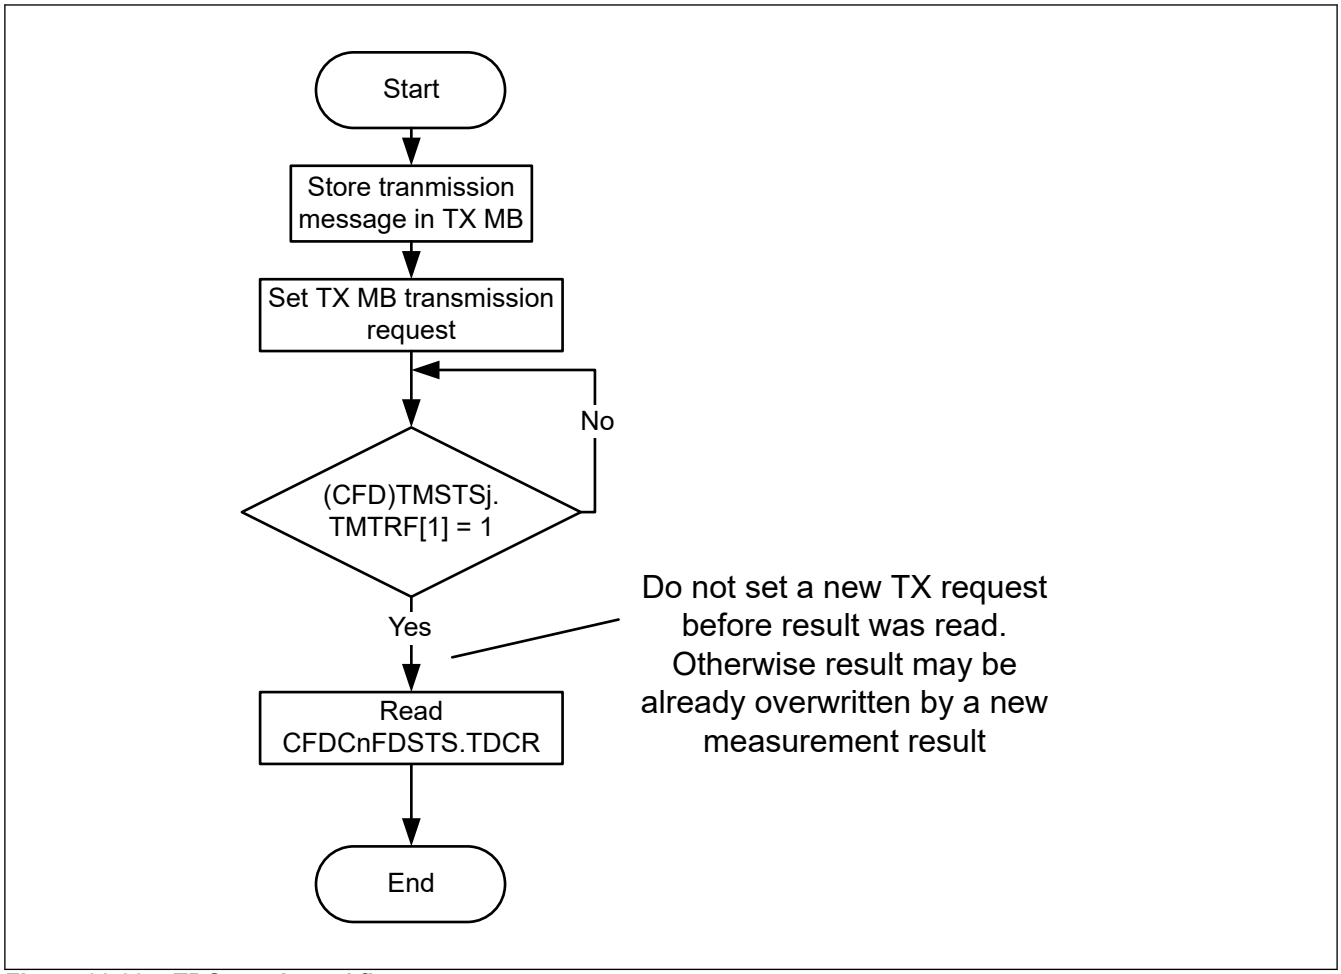

Figure 32.22 TDC result read flow

32.4.2 CAN Module Configuration after Hardware Reset

After a hardware reset (power on reset) or after setting and clearing a CFDGRSTC.SRST bit, the CANFD module enters Global Sleep mode automatically.

To enable configuration of the CANFD module, you must exit Sleep mode by clearing the Global Sleep Request bit CFDGCTR.GSLPR to 0.

After a hardware reset, the module starts RAM initialization, the CFDGSTS.GRAMINIT bit in the Global Status Register is set automatically to indicate that the CANFD logic is initializing the RAM.

After RAM initialization is complete, this bit is cleared automatically.

RAM initialization is necessary to avoid setting of false ECC error flag after HW reset the random data presented in the RAM.

Do not access registers of CANFD in either read or write until RAM initialization is complete and the CFDGSTS.GRAMINIT bit is cleared.

Before going to communication mode, the Global Acceptance Filter List and message FIFO buffers must be configured. In addition, each required CAN channel must be configured such as CAN bit timing. For this configuration, all required CAN channels must be released from Channel Sleep mode and must be configured for communication in Channel Reset mode (Configuration mode).

Figure 32.23 shows the configuration procedure. For details about each step, seesection 32.5. Acceptance Filtering Function using Global Acceptance Filter List (AFL), section 32.6. FIFO Buffers and Normal Message Buffer Configuration, section 32.7. Interrupts and DMA and section 32.4.1.3. Baud Rate.

The CANFD module does not perform the RAM initialization sequence after executing a software reset by setting CFDGRSTC.SRST.

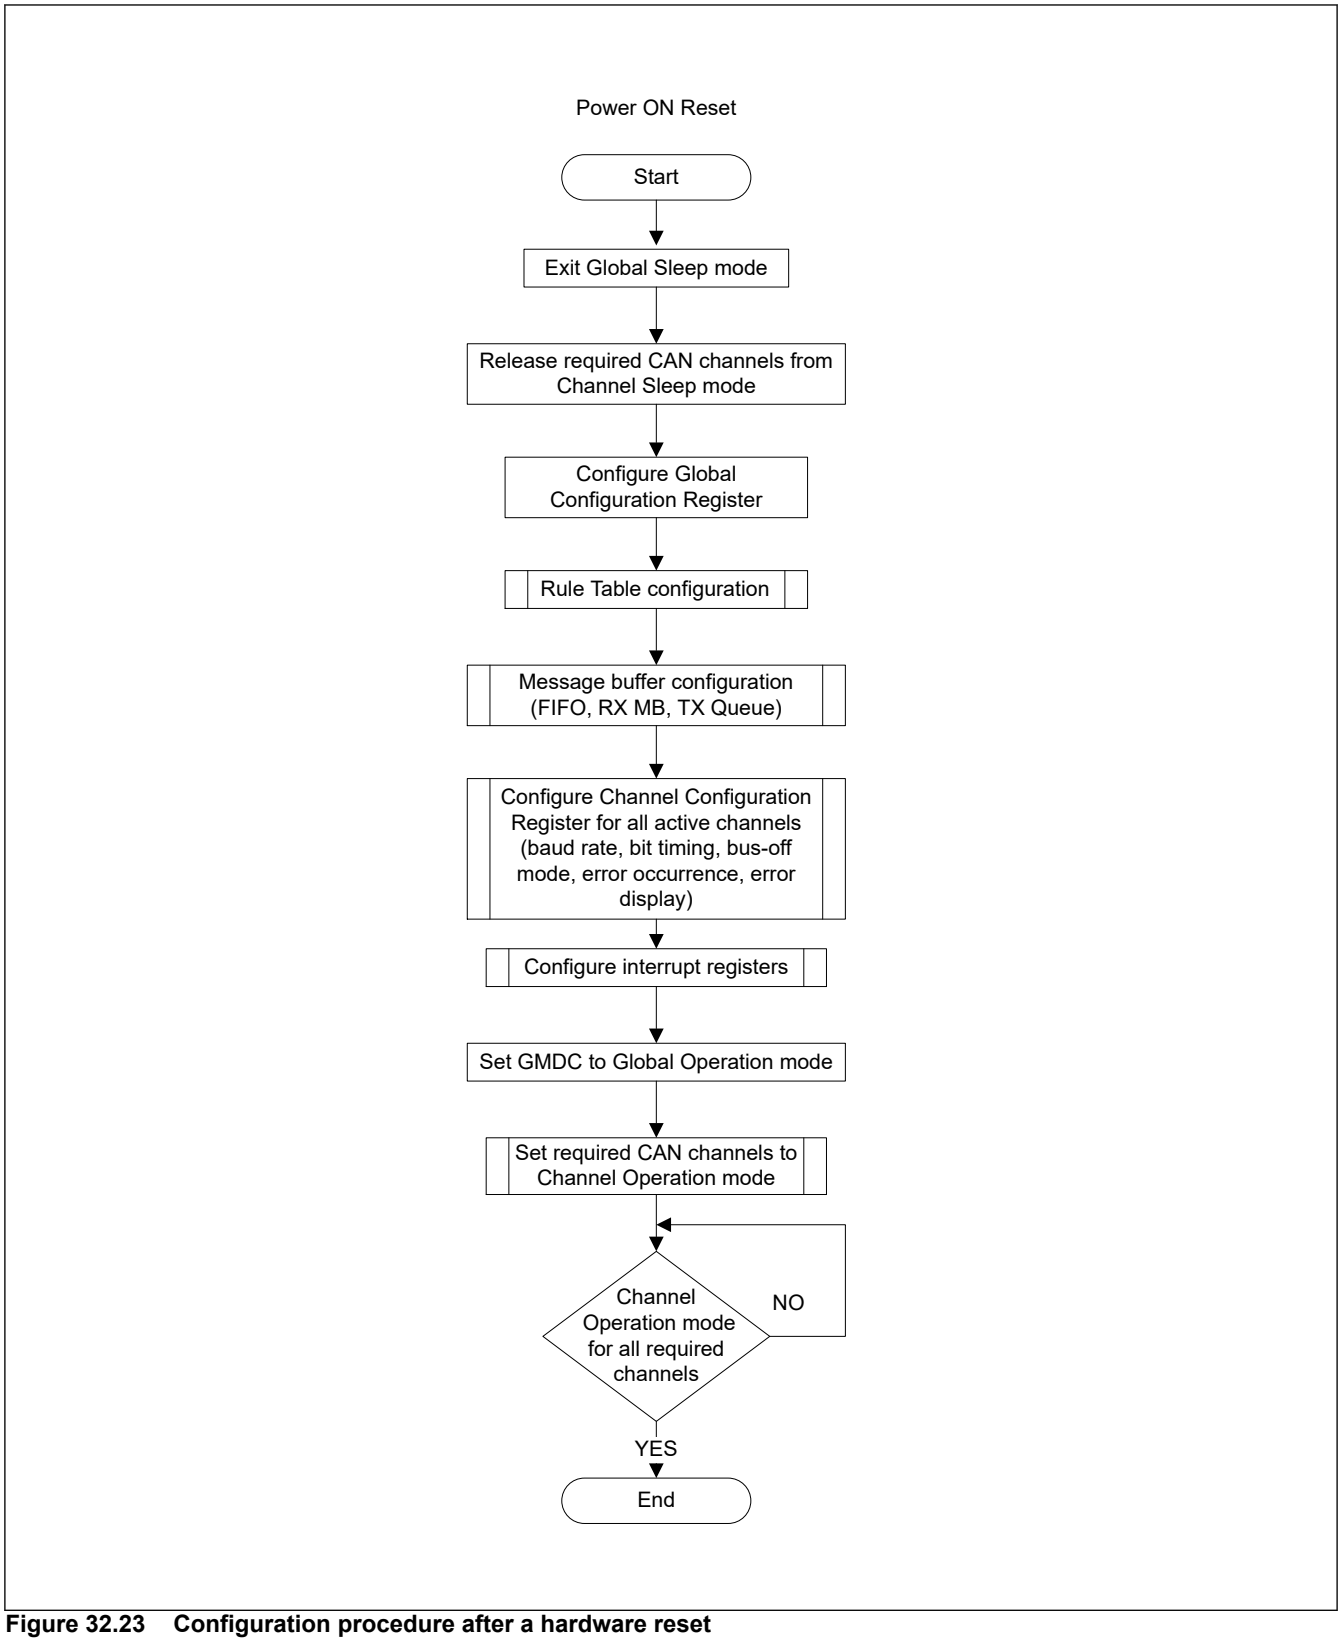

Figure 32.23 Configuration procedure after a hardware reset

32.5 Acceptance Filtering Function using Global Acceptance Filter List (AFL)

32.5.1 Overview

The CANFD module can handle message acceptance filtering for all channels with a global Acceptance Filter List (called AFL). Each element of the AFL defines a filter rule for messages received on a specific channel.

The following actions are performed based on the AFL entries:

- Acceptance filtering based on received CAN Identifier and masking
- DLC filtering based on received DLC value
- Message data payload according to the CFDGCFG.CMPOC bit*1
- Storage of accepted messages in the message buffer objects defined in the related AFL entry
- Attaching a 16-bit pointer to the stored messages defined in the related AFL entry, for example to support AUTOSAR applications
- Attaching a 2-bit information label to the stored messages defined in the related AFL entry

Note 1. This feature is not available in the classical CAN function.

The 2-channel CANFD module allows a maximum of 128 AFL entries across all channels with a maximum of 64 AFL entries per channel.

During acceptance filtering process, each AFL entry in a channel is checked against the received message by the acceptance filter unit. The check starts from the lowest AFL entry number for this channel.

AFL search stops when a match of the received identifier with a configured identifier/mask combination occurs or when the received identifier has been compared against all AFL entries defined for the related channel. If no match occurs, then the received message is rejected. No notification is given to the application in this case.

Additionally, an automatic DLC filtering is performed for each accepted message if DLC check is globally enabled. If the DLC value of the received message is equal to or higher than the configured DLC value in the matching AFL entry, the DLC check is passed.

If DLC replacement (CFDGCFG.DRE bit) is enabled, DLC value configured in the matching AFL entry is greater than 0x0 and DLC check passes, then the configured value of DLC in the matching AFL entry is stored in the destination RXMB or FIFO Buffer.

If the received value of DLC is greater than the configured DLC value in the matching AFL entry, then the additional data bytes received on the CAN Bus are not stored in the destination RXMB or FIFO Buffer. These additional data bytes are stored as 0x00 in the destination RXMB or FIFO Buffer.

If DLC replacement is enabled and DLC value of matching AFL entry is 0x0, then the received value of DLC is stored in the destination RX MB or FIFO Buffer.

If DLC replacement (the CFDGCFG.DRE bit) is disabled and DLC check passes, then the received value of DLC on the CAN bus is stored in the destination RXMB or FIFO buffer.

If the received value of DLC is greater than the configured DLC value in the matching AFL entry, then the additional data bytes received from the CAN bus are also stored in the destination RXMB or FIFO buffer.

If DLC value of the received message is less than the configured DLC value in the matching AFL entry, then DLC check fails. In this case, the received message is rejected and is not stored in any RXMB or FIFO buffer.

Additionally, DLC check failure is flagged by the DLC Error Flag in the Global Error Flag Register. If configured, an error interrupt is also generated. The DLC replacement configuration has no impact if the DLC check fails.

If a message has passed both acceptance filtering and DLC filtering, it is stored in a single reception message buffer and/or in FIFO buffers configured for reception or gateway function.

This message storage target information is also defined in the same AFL entry. Do not set a target at the AFL entry which is not configured.

Each accepted received message can be stored into a maximum of 8 different target destinations (single reception message buffer and/or FIFO buffers).

The programming of more than eight target destinations is not allowed. If more destinations are programmed, then the internal timing might lead to a race condition that prevents the storage of received messages in the message RAM.. Correct configuration of the numbers of target destination is the responsibility of the application.

Additional protection mechanism is made for the case when a received message contains more data payload Bytes than possible to store in the target destination (CFDRMNB.RMPLS, CFDRFCCn.RFPLS or CFDCFCCn.CFPLS).

If CFDGCFG.CMPOC = 0, the message is completely rejected and is stored in the target destination. When CFDGCFG.CMPOC = 0 and RX or Common FIFO full including the received message contains more data payload bytes

than possible to store in the target destination (CFDRMNB.RMPLS, CFDRFCCn.RFPLS or CFDCFCCn.CFPLS), the corresponding CFDFMSTS.RFxMLT or CFDFMSTS.CFxMLT bit is not set to 1, respectively.

When CFDGCFG.CMPOC = 1, the received data bytes greater than CFDRMNB.RMPLS is rejected. When CFDGCFG.CMPOC = 1 and RX or Common FIFO full including the received message contains more data payload bytes than possible to store in the target destination (CFDRMNB.RMPLS, CFDRFCCn.RFPLS or CFDCFCCn.CFPLS), the corresponding CFDFMSTS.RFxMLT or CFDFMSTS.CFxMLT bit is set to 1, respectively.

Depending on the CFDGCFG.DRE bit, the original received DLC or the DLC value configured at the AFL entry is stored.

Regardless of the CFDGCFG.CMPOC bit setting, CFDGERFL.CMPOF is set to 1 if a payload overflow condition is detected.

The DLC filtering is performed before the payload overflow function. So for one reception frame, only one flag can be set at the same time with CFDGERFL.DEF or CFDGERFL.CMPOF[*1].

Note 1. This bit is not available in the classical CAN function.

32.5.2 Allocation of AFL Entries to each CAN Channel

The number of AFL entries per channel can be configured using the dedicated field in the related Global Acceptance Filter Configuration Registers (see Figure 32.24).

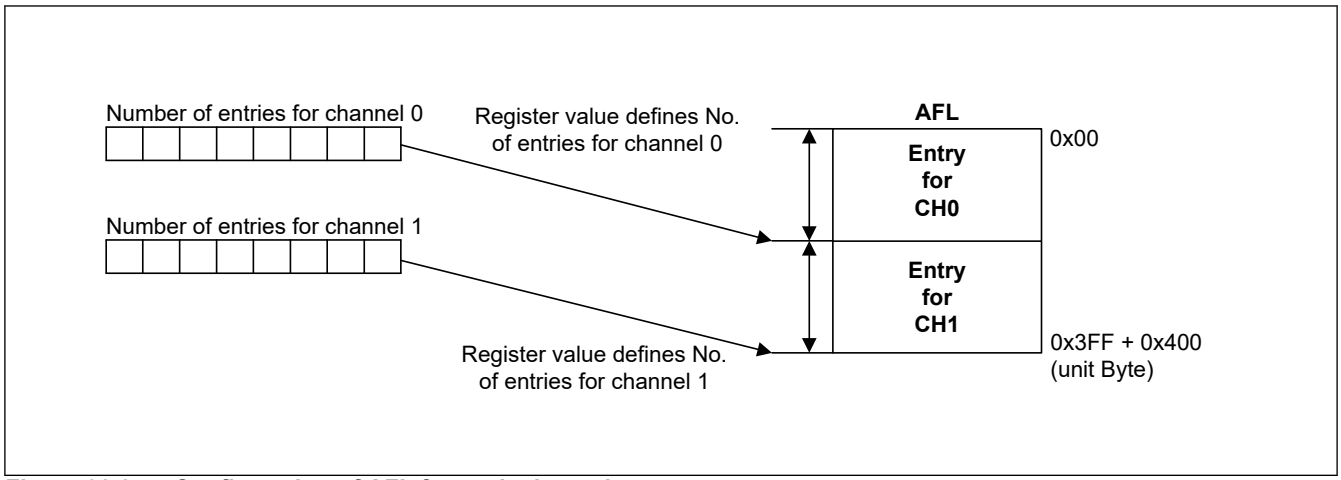

Figure 32.24 Configuration of AFL for each channel

The minimum number of entries for one channel is 0 (no entries defined for the channel) and the maximum number of entries for one channel is 64. The total number of entries for all channels should not exceed the maximum limit of (n + 1) × 64.

All entries are unique for a channel and overlapping or sharing of entries is not supported. Correct configuration of the AFL is the responsibility of the application.

The CANFD module does not flag errors related to the configuration of the AFL.

32.5.3 AFL Entry Description

Each AFL entry consists of 16 bytes. The fields in all entries are identical.

Each entry contains the following information for acceptance filtering and DLC filtering:

- Identifier (11 bits for Standard Frame format, 29 bits for Extended Frame format):
  Acceptance filter unit checks the identifier field of the received message against the identifier field of each AFL entry (full 29 bits masking of identifier bits is possible, see information that follows).

- IDE bit:
  Acceptance filter unit checks the IDE bit of the received message against this bit and selects the relevant part of the identifier field for acceptance filtering (masking of IDE bit is possible, see the information that follows).

- RTR bit:

Acceptance filter unit only accepts data frames (RTR = 0) or remote frames (RTR = 1) according to the setting of this bit (masking of RTR bit is possible, see the information that follows).

- Loopback Configuration bit:
  This bit can enable or disable the AFL entry depending on the Loopback Configuration or Mirror mode condition.
- Mask for Identifier bits (29 bits):
  Each bit in the identifier mask can mask the corresponding identifier bit in the AFL entry during acceptance filtering, see Figure 32.25.
- Mask for IDE bit:
  If this Mask bit masks the IDE bit of the AFL entry in both Standard Identifier and Extended Identifier format, messages can be accepted by this AFL entry. The identifier of the received message is compared against the Standard Identifier part of the AFL entry for Standard Identifier format messages and against the Extended Identifier part of the AFL entry for Extended Identifier format messages.
- Mask for RTR bit:
  If this Mask bit masks the RTR bit of the AFL entry in both frame formats, data frame and remote frame formats are accepted by this AFL entry.
- Pointer information (16 bits):
  This 16-bit pointer is attached to a received message accepted by the related AFL entry. The pointer is added during message storage in the message buffer area and can be used by application as support function. The pointer information can be used for example to support PDU identifier allocation for the received message in AUTOSAR systems.
- Information label (2 bits):
  This 2-bit label is attached to a received message accepted by the related AFL entry. The label is added during message storage in the message buffer area and can be used by application as support function.
- DLC value for automatic DLC filtering:
  If the DLC value of the received message is equal or higher than the configured DLC value, the DLC check is passed.

If the DLC value in this AFL entry is configured to 0, DLC filtering is effectively disabled for this entry (all accepted messages pass DLC filtering).

Each AFL entry contains the following information for the handling of received messages:

- Message buffer number of one single reception message buffer as target for received message storage
- Single reception message buffer enable bit to configure the single reception message buffer number to be valid or invalid, as target for received message storage
- FIFO direction pointer - each bit of the FIFO direction pointer configures a dedicated FIFO as possible target for a received message

Note: A message received on channel A can be routed to Common FIFO buffer of another channel. If this Common FIFO buffer is configured in Gateway mode, then the message stored in this Common FIFO Buffer is transmitted on that channel because Common FIFO buffer is associated with channel.

There is no hardware protection against such storage of message. Therefore, the FIFO direction pointer must be configured carefully.

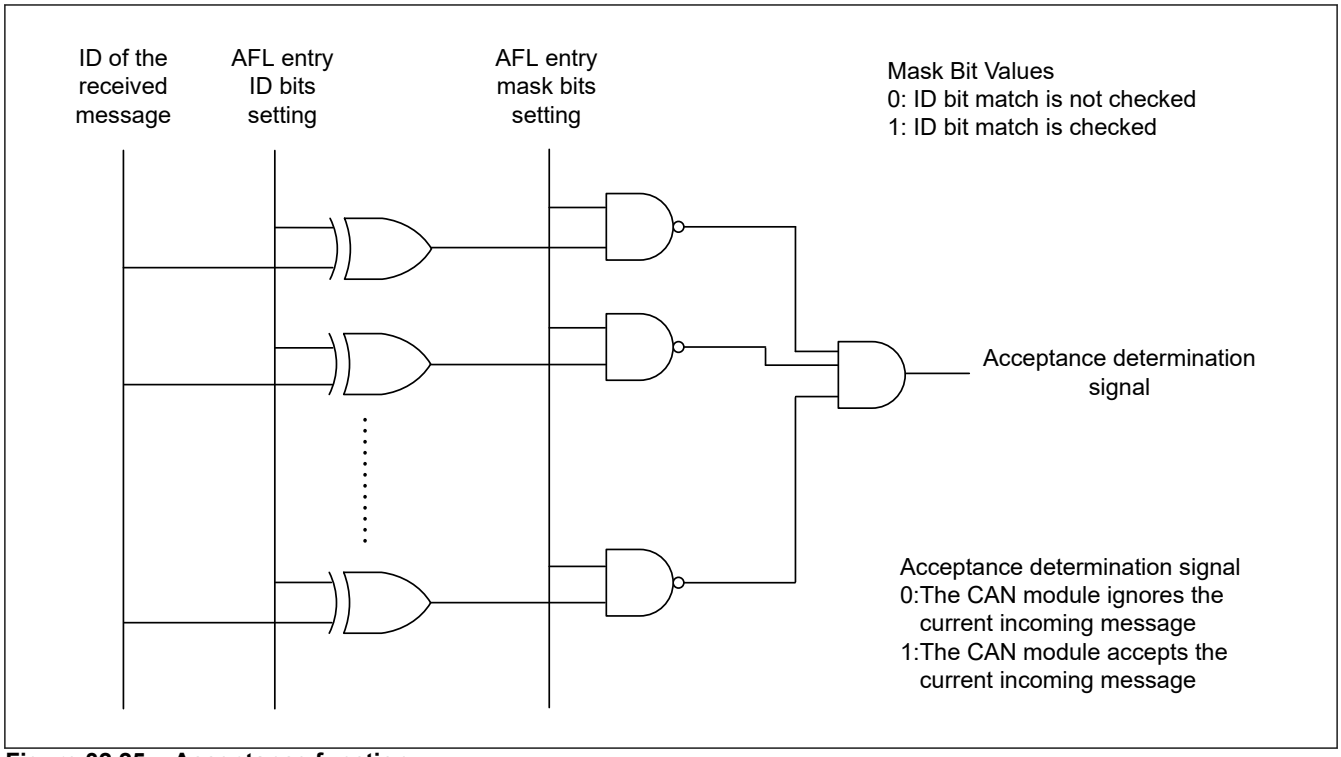

Figure 32.25 Acceptance function

32.5.4 Entering Entries in the AFL

Application software can enter one full entry into the AFL using the following registers:

- Global AFL ID Entry Register: Part 1 of the AFL entry
- Global AFL Mask Entry Register: Part 2 of the AFL entry
- Global AFL Pointer 0 Entry Register: Part 3 of the AFL entry
- Global AFL Pointer 1 Entry Register: Part 4 of the AFL entry.

16 sets of these registers form a group of AFL entries. Each group can be accessed through a page mechanism. For the CANFD module, 2-channel version, 8 of these pages exist to allow access to the whole AFL range. The AFL should only be configured in CH_RESET or CH_HALT mode. Pages are linked to the AFL entries in the following way:

Page 0	Entry 0 — 15
Page 1	Entry 16 — 31
Page 2	Entry 32 — 47
Page 3	Entry 48 — 63
Page 4	Entry 64 — 79
Page 5	Entry 80 — 95
Page 6	Entry 96 — 111
Page 7	Entry 112 — 127

The selection of the AFL access page is done using the Global Acceptance Filter List Entry Control Register (CFDGAFLECTR) (Figure 32.26). This register has the following fields:

- 7 bits to select the AFL page number
- 1 bit to enable or disable the AFL data access to prevent unwanted write access to the AFL.

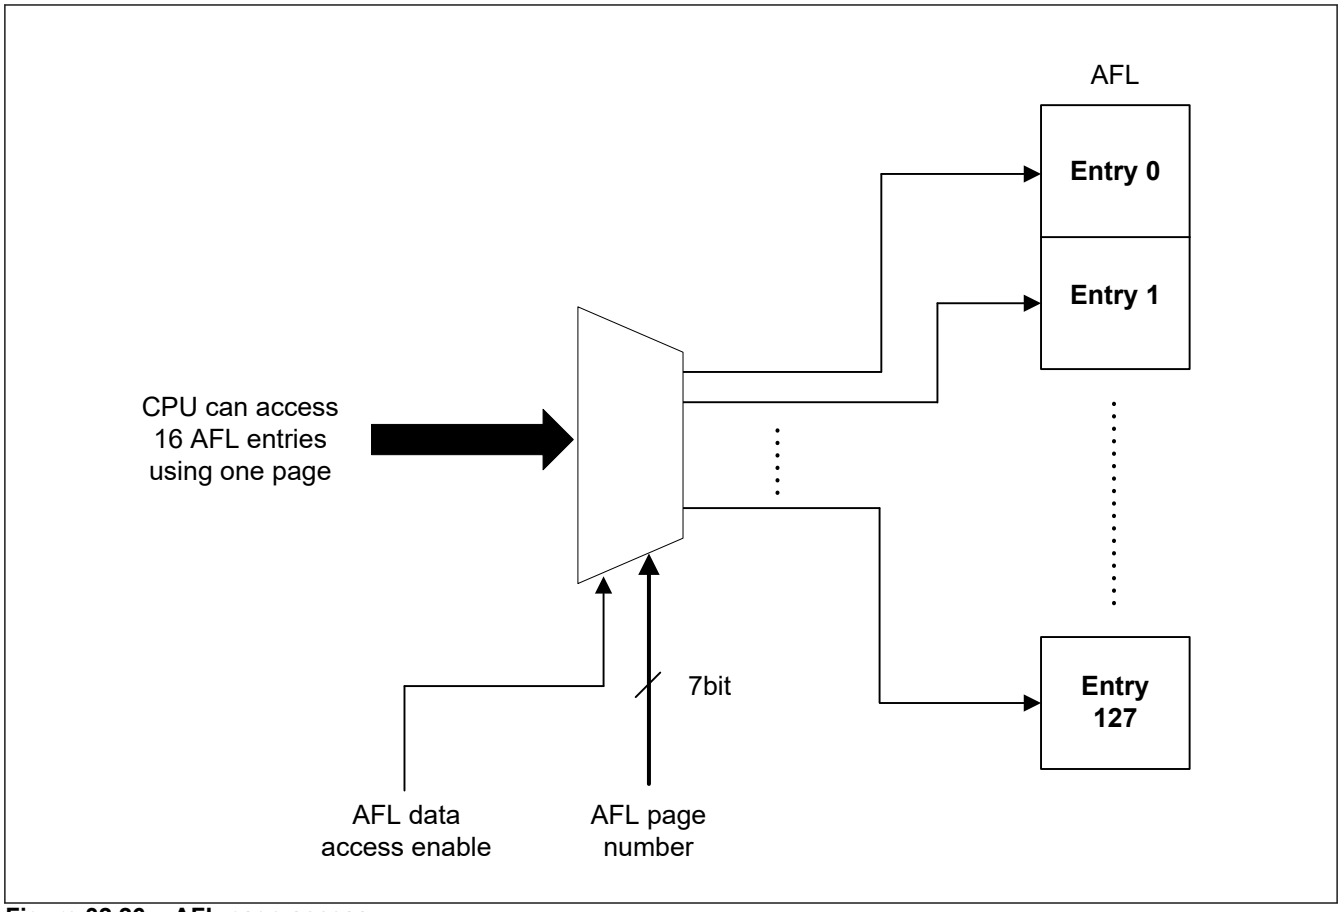

Figure 32.26 AFL page access

Application software should not write numbers higher than 0x5F for the AFL page number.

Follow the configuration shown in Figure 32.27 to program the AFL.

After entering all entries in Configuration mode, locking of the AFL access should be performed to protect unwanted write access to the AFL.

Write protection is active during all Global modes (GL_RESET, GL_HALT, and GL_OPERATION) if the lock bit is set.

Read access to AFL is still possible during all Global modes even when AFL data access is disabled (consistency check of AFL contents is possible during run time).

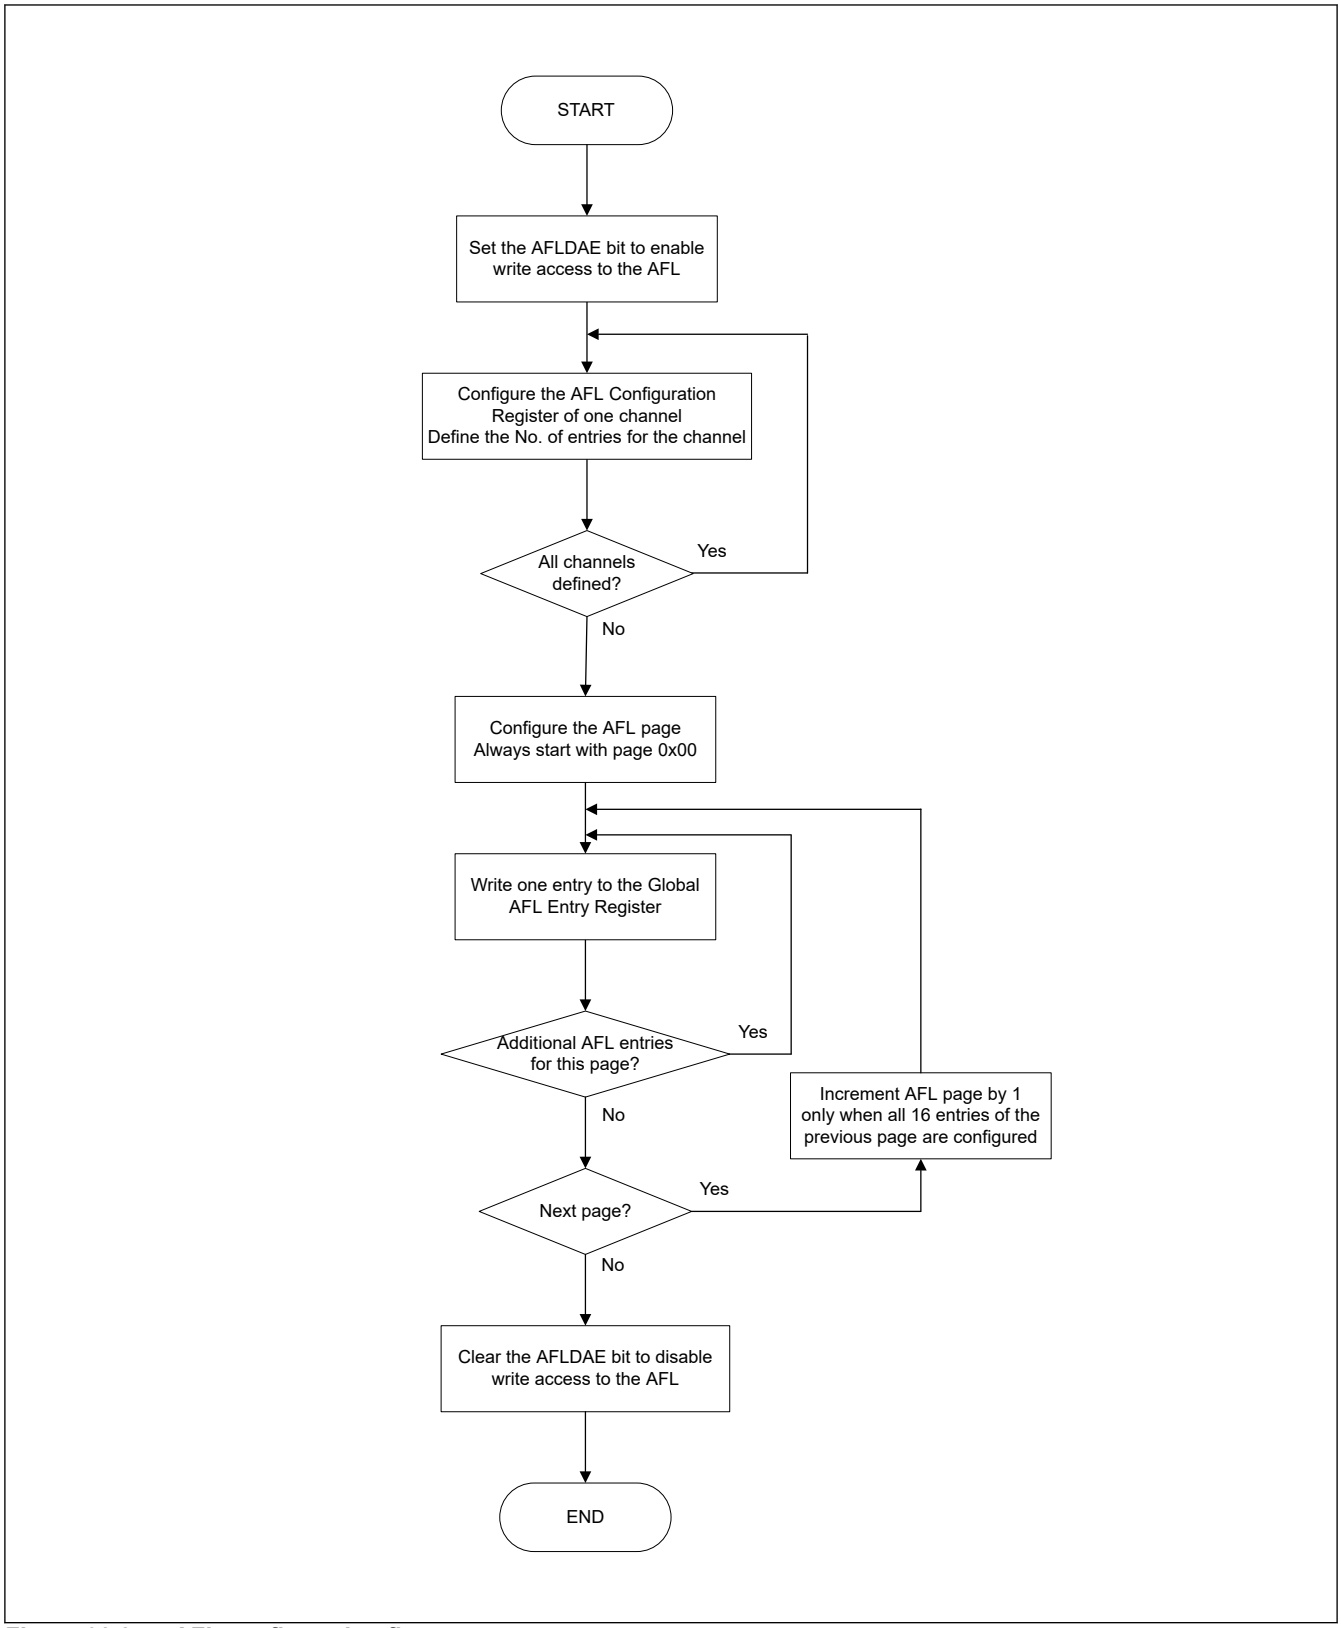

Figure 32.27 AFL configuration flow

32.5.5 Loopback Modes

If the Loopback Configuration bit is set, the AFL entry is only valid in Loopback test mode (Self-test mode 0 or Self-test mode 1) or in mirror mode when receiving messages that were transmitted by the respective CAN channel itself.

The AFL entry is not valid for received messages in loopback mode transmitted by other CAN nodes on the bus. The expression valid or invalid for the related entry means that this AFL entry is or is not compared against the received message ID respectively.

If the Loopback Configuration bit is 0, the AFL entry is only valid for:

- Received messages transmitted by other CAN nodes on the bus in normal (non-loopback mode) and mirror modes
- Received messages transmitted by other CAN nodes or the CAN channel itself in Loopback test mode.

The mirror mode can be enabled with the CFDGCFG.MME bit in the Global Configuration Register. If CFDGCFG.MME bit is set, then a successfully transmitted message can be stored back in an RX message buffer or FIFO buffer if a matching entry is configured in the AFL for that channel.

The Loopback Configuration bit in the matching AFL entry must be set to store this frame.

If Mirror mode and Loopback test mode are configured at the same time, the Loopback test mode behavior applies.

Table 32.17 shows the behavior of the acceptance filter unit depending on the setting of the related input signals.

Table 32.17 Behavior of acceptance filter based on the loopback configuration setting in AFL entry

Mirror Mode Enable (MME Configuration bit)	Loopback in test mode (Self-test mode 0 or Self-test mode 1)	Channel mode	Loopback Configuration bit in AFL entry	AFL entry
0	0	Receiver	0	Valid
			1	Invalid
		Transmitter	0	Invalid
			1	Invalid
	1	Receiver	0	Valid
			1	Invalid
		Transmitter	0	Valid
			1	Valid
1	0	Receiver	0	Valid
			1	Invalid
		Transmitter	0	Invalid
			1	Valid
	1	Receiver	0	Valid
			1	Invalid
		Transmitter	0	Valid
			1	Valid

Note: The expression valid or invalid for the related entry means that this AFL entry is or is not compared against the received message ID, respectively.

32.5.6 IDE Masking

When the GAFLIDEM bit is 0 in an AFL entry, the IDE bit configured in the AFL entry is not used for ID matching. In this case, the use of ID[10:0] or ID[28:0] matching is based on the received IDE bit.

Consider the following example:

- The ID and Mask fields of an AFL entry x is configured as follows:
  - CFDGAFLID [x] = 0xC0553A20 → IDE = 1, RTR = 1, LLB = 0, ID[10:0] = 0x220 / ID[28:0] = 0x00553A20
  - CFDGAFLMn = 0x0000FFFF → IDEM = 0. RTRM = 0, IDM[10:0] = 0x7FF / IDM[28:0] = 0x0000FFFF
- The comparison result for the four different received IDs with AFL entry x is described as follows:
  - If a frame with IDE = 0 and ID = 0x220 is received, this is considered as a match
  - If a frame with IDE = 0 and ID = 0x320 is received, this is not a match

- If a frame with IDE = 1 and ID = 0x1FFF3A20 is received, this is considered as a match
- If a frame with IDE = 1 and ID = 0x08803220 is received, this is not a match.

32.6 FIFO Buffers and Normal Message Buffer Configuration

This section describes the process for configuring the number of RX message buffers, the FIFO buffers, and the flat TX message buffers in the CANFD module. The message buffers are mapped as shown in Figure 32.28.

The RX message buffers can be accessed with the RX Message Buffer Registers.

The RX FIFO buffers and the common FIFO buffers configured in RX mode, TX mode, or GW mode can only be accessed with the FIFO Access Registers.

If the common FIFO is configured in TX mode, you can only write data into the FIFO buffer using the FIFO Access registers.

If the common FIFO is configured in GW mode or RX mode, you can only read data from the FIFO Access Registers.

The TX message buffers can be accessed with the TX Message Buffer Registers.

If unused message buffer locations are read, the message buffer locations are read as unknown values.

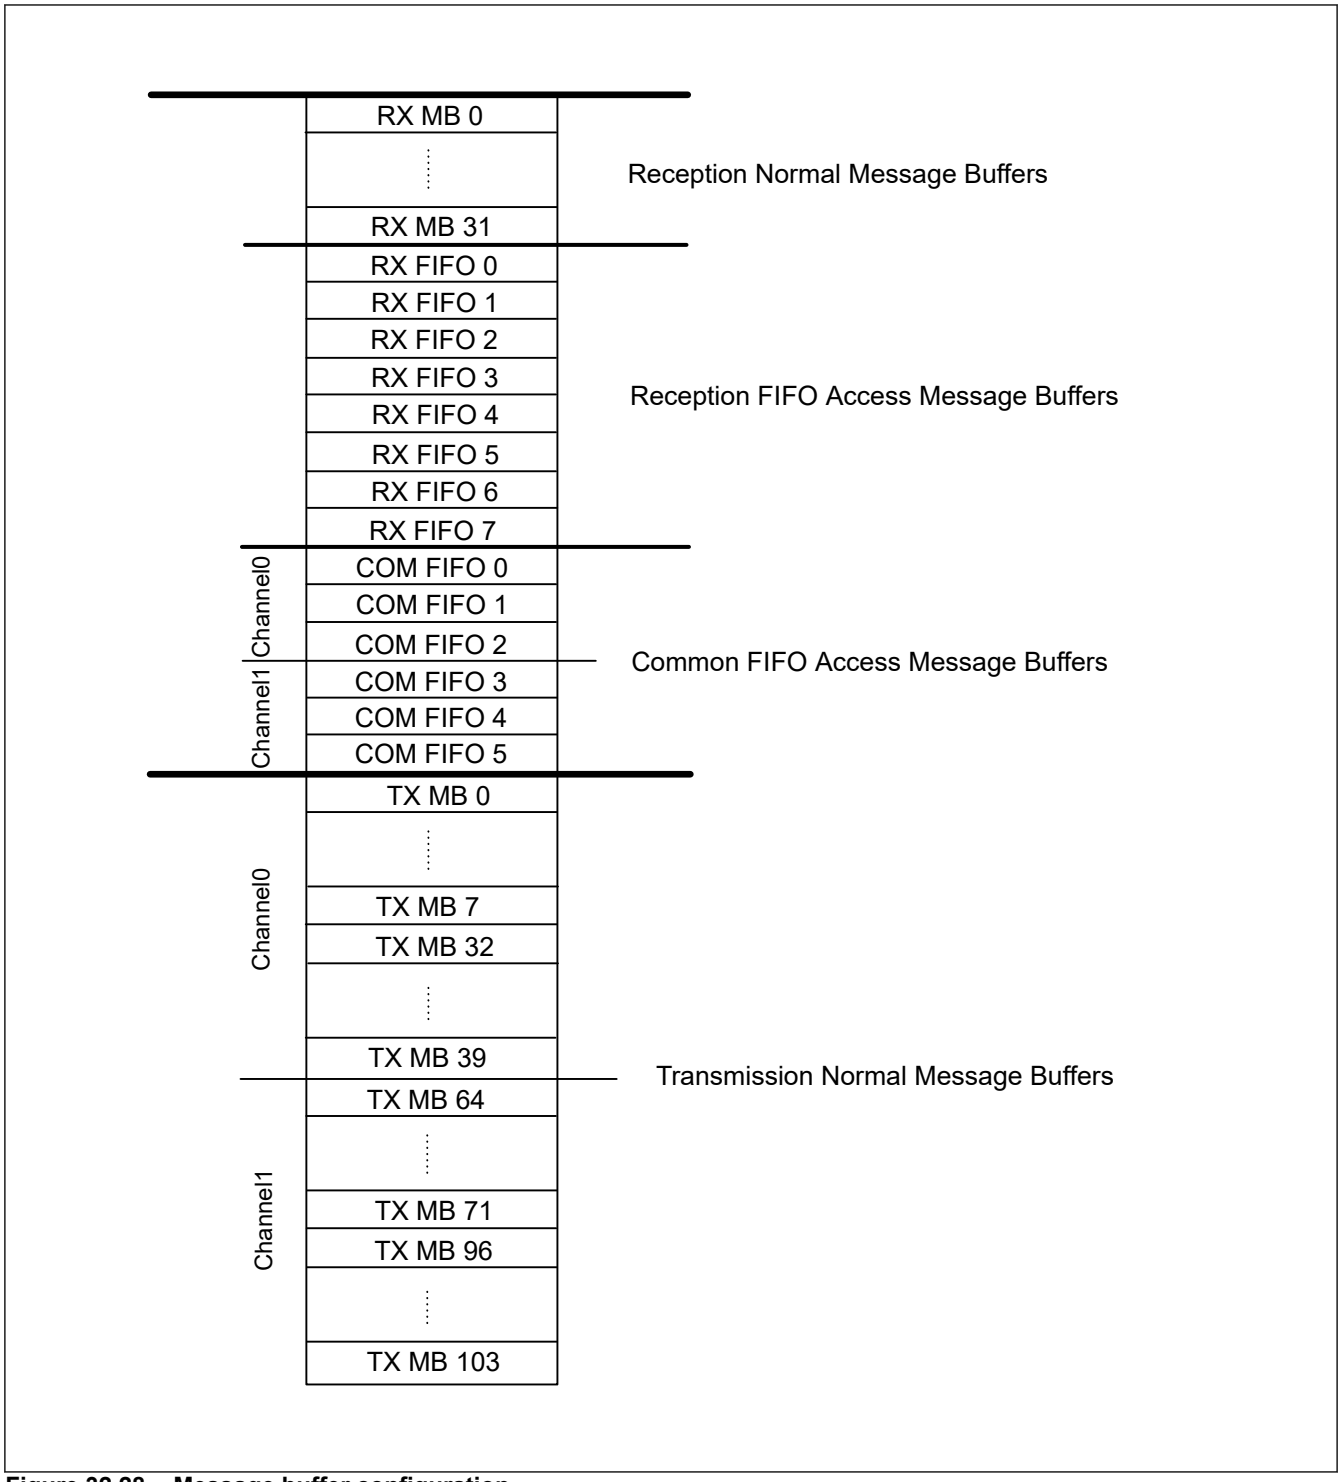

Figure 32.28 Message buffer configuration

32.6.1 Normal RX Message Buffers

In CANFD module, the frames received by various channels can be stored in normal RX message buffers based on the configuration of the AFL entries.

Additionally, the number of normal RX message buffers required in the system can be chosen up to a fixed maximum limit.

32.6.1.1 Normal RX Message Buffer Configuration

In CANFD module, the number of normal RX message buffers can be configured by writing to the RX Message Buffer Number Register.

The limiting values for the configuration of number of message buffers are:

- Minimum value = 0x00 (no normal RX MB)
- Maximum value = (16 × No. of CAN channels) = 16 × 2 = 32
  = 0x20 (32 flat RX MBs for 2 channels)

Do not use values outside these limits.

The AFL entries for routing the received messages to normal RX message buffers must be configured to match the requirements of the system.

The AFL entries must also be configured properly, and an AFL entry for normal RX message buffers should not exceed the number of message buffers configured in the RX Message Buffer Number Register.

Note: There is no internal check procedure provided in CANFD module against wrong configuration of the AFL.

The data field size of the RX message buffer can be configured with the CFDRMNB.RMPLS bit. The default size is 8 bytes and the maximum data payload size is 64 bytes.

When the receiving frame exceeds the data field size, then the acceptance depends on the configuration of CFDGCFG.CMPOC (message rejecting or data payload cut).

Note: RMPLS and CMPOC bit is not available in the classical CAN function, so, these feature is not valid for classical CAN.

32.6.2 FIFO Buffers

The CANFD module provides a fixed number of FIFO buffers to support storage of frames for reception, transmission and gateway functions for various CAN channels.

The number of reception-only FIFO buffers is fixed to 8. However, 3 common FIFO buffers per channel can be configured to store messages for transmission, reception, or gateway function.

These FIFO buffers can be enabled or disabled, and the following parameters can be configured to match the system requirements:

- Size
- Interrupt structure
- Message lost mechanism
- Message overwrite mechanism of the FIFO buffers
- Location of the TX FIFO or GW FIFO.

When the receiving frame exceeds the data field size, the acceptance depends on the configuration of the CFDGCFG.CMPOC bit (message rejecting or data payload cut).

32.6.2.1 FIFO Buffers Configuration

In CANFD module, the FIFO buffers can be configured to match the system requirements.

The total number of FIFO buffers = 8 RX FIFO buffers + 6 common FIFO buffers = 14 FIFO buffers for 2 channels and message overwrite mechanism.

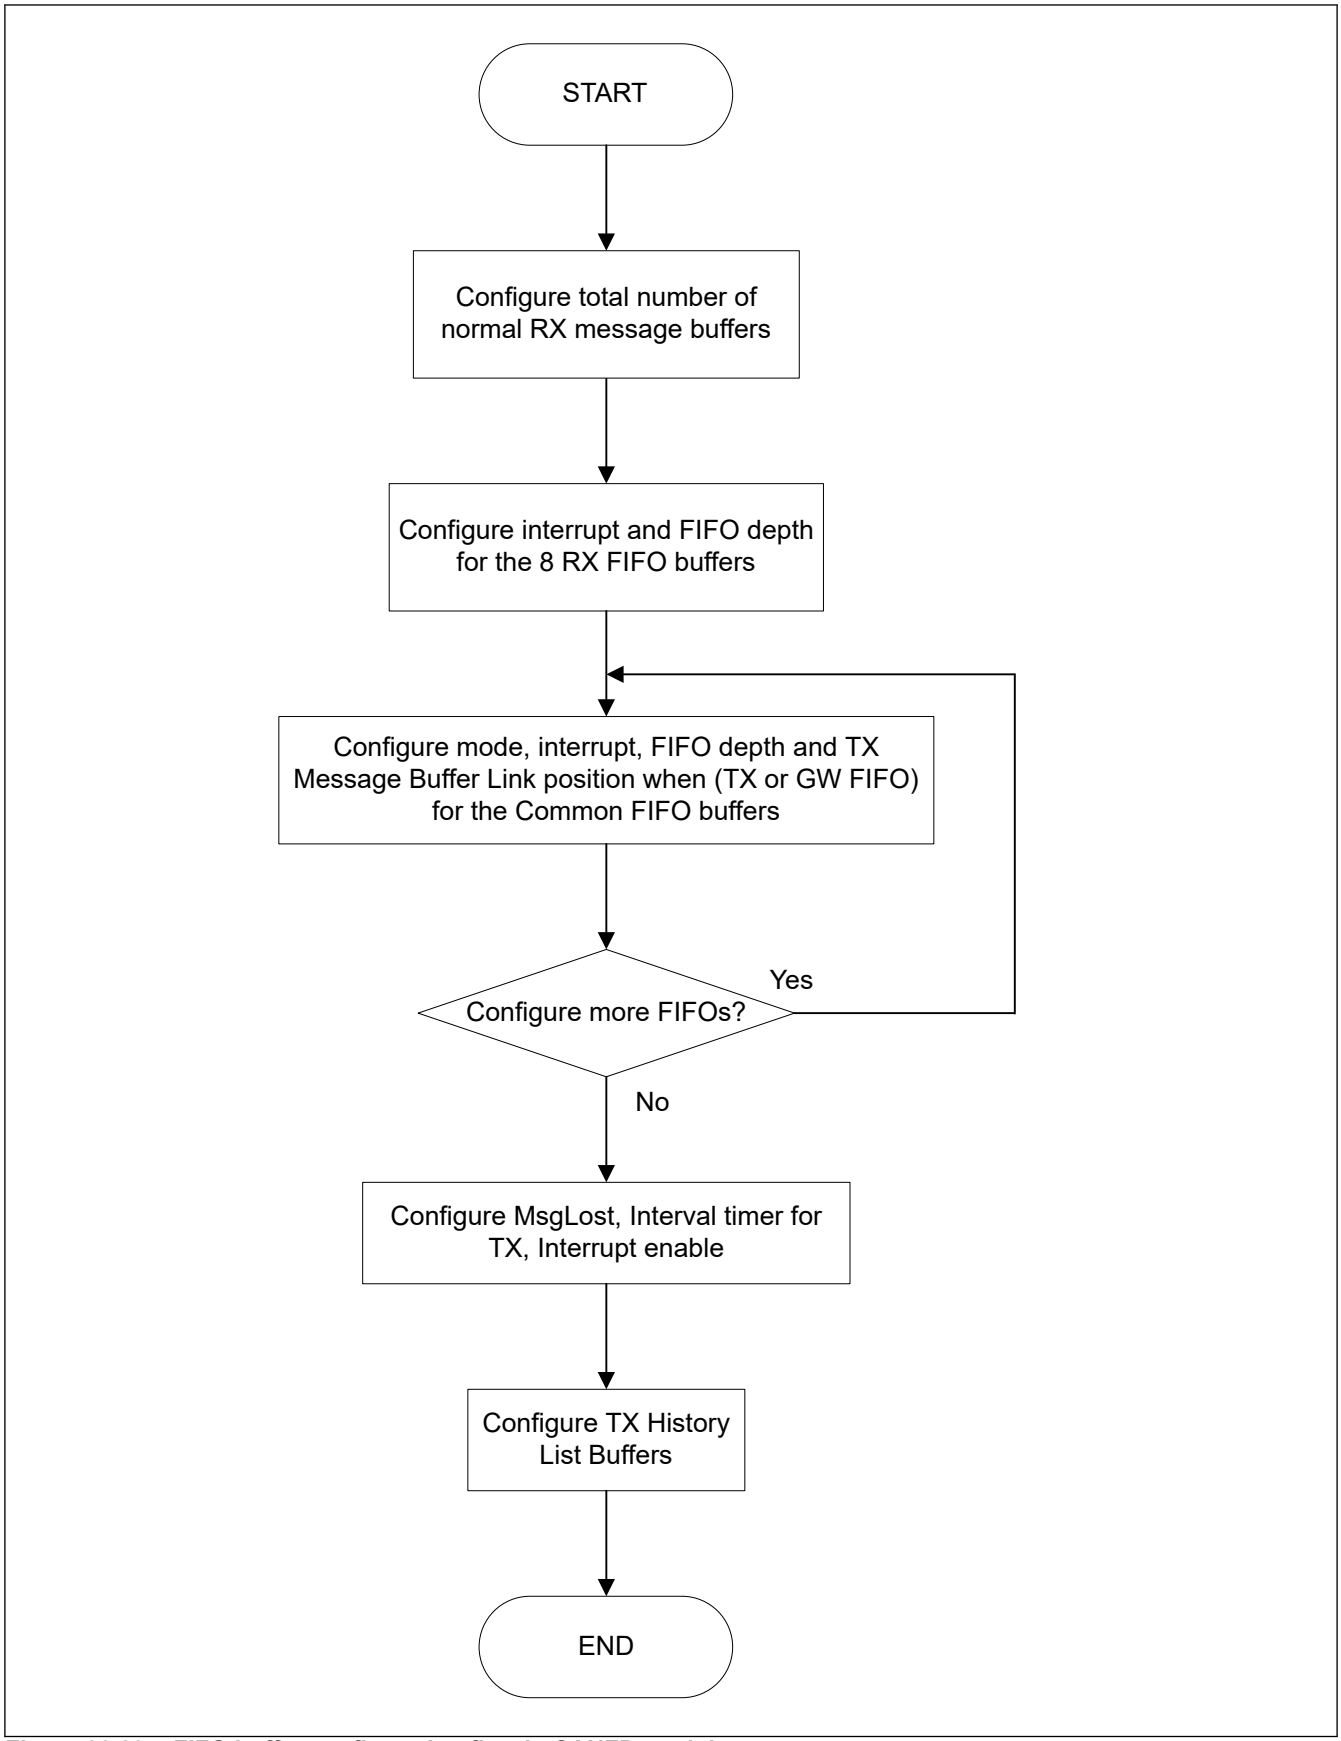

Figure 32.29 FIFO buffer configuration flow in CANFD module

As shown in Figure 32.29, the various FIFO buffers can be configured by writing to the RX FIFO Configuration/Control Registers and the Common FIFO Configuration/Control Registers.

For the 8 RX FIFO buffers, the following parameters can be configured:

- Interrupts
- FIFO depth
- FIFO payload data size.

For the common FIFO buffers, the following parameters can be configured:

- Mode
- Interrupts FIFO depth
- FIFO payload data size
- FIFO TX link position.

(1) FIFO mode configuration of Common FIFO buffers

The mode of the common FIFO buffers can be configured by writing to the CFDCFCCn.CFM[1:0] bits in the Common FIFO Configuration/Control Registers. The possible modes of configuration for Common FIFO buffers are:

- 0b RX mode (default mode after hardware reset)
- 1b TX mode
- 10b GW mode
- 11b Reserved (Do not write this value to the register bits)

Messages can only be read from the RX FIFO buffers and the Common FIFO buffers configured in RX mode. Messages are stored by the CAN module in these FIFO buffers based on the AFL entries.

Messages can be read and written into the Common FIFO buffers configured in TX mode. These messages are transmitted on the appropriate CAN channel.

Messages can only be read from the Common FIFO buffers configured in GW mode. However, the CPU read access has no impact on the read or write pointers. The pointers can only be incremented when a new message is stored in the FIFO buffer and decremented when a message is transmitted on the corresponding CAN channel by the CANFD module.

After a hardware reset, all the Common FIFO buffers are configured in RX mode by default. Only enable the FIFO buffers after configuring the Common FIFO buffers in the required modes.

In GW mode, when a transmit/receive FIFO buffer is trying to receive a new message while the transmit/receive FIFO buffer is already full of data, the oldest data of the buffer is overwritten with the message received or the message is discarded. The behavior is determined by setting the CFDCFCCEn.CFMOWM bit.

- When CFDCFCCEn.CFMOWM = 0:
  When writing of data is required due to reception of a new message while a transmit/receive FIFO buffer is full of data, the received message is discarded, and CFDCFSTSn.CFMLT bit is set to 1.

- When CFDCFCCEn.CFMOWM = 1:
  When writing of data is required due to reception of a new message while a transmit/receive FIFO buffer is full of data, the oldest data in the buffer is overwritten with the received message.
  The read pointer of the transmit/receive FIFO buffer simultaneously moves to the next oldest message.
  The CFDCFSTSn.CFMOW bit is then set to 1, which notifies that the oldest message has been overwritten with the received message.
  In addition, when a CAN bus error or arbitration-lost for the transmitting message occurs in the transmit/receive FIFO buffer full, the transmitting message is lost and retransmision for the message is not performed. The read point is then moves to the next message automatically.
  Do not write to this bit when the CFDCFCCn.CFE bit is 1.

(2) FIFO TX message buffer link configuration

When the common FIFO is configured as TX or GW FIFO, the FIFO buffer must be linked to a normal TX message buffer to participate in the transmission scan.

The link to a normal TX message buffer must be unique, for example the same TX message buffer cannot be shared between 2 or more common FIFO buffers.

Do not write data into a TX message buffer that is linked to a Common FIFO buffer. Also, the TX message buffer linked to a Common FIFO buffer should not be a part of the TX Queue.

The TX message buffer link of each Common FIFO buffer can be configured by writing to the CFDCFCCn.CFTML[4:0] bits in the Common FIFO Configuration/Control Registers. Available options for TX message buffer link configuration are:

- 0x00: TX Message Buffer 32
- 0x01: TX Message Buffer 33
- ⋮
- 0x07: TX Message Buffer 39

(3) FIFO depth configuration

The depth of each FIFO buffer can be configured by writing to the CFDRFCCn.RFDC[2:0] bits and CFDCFCCn.CFDC[2:0] bits in the RX FIFO Configuration/Control Registers and the Common FIFO Configuration/ Control Registers. The 8 available options for depth configuration are:

- 0x000: 0 Message (FIFO buffer cannot be enabled)
- 0x001: 4 Messages
- 0x010: 8 Messages
- 0x011: 16 Messages
- 0x100: 32 Messages
- 0x101: 48 Messages
- 0x110: 64 Messages
- 0x111: 128 Messages

The RAM allocation for RX message buffers along with FIFO buffers is limited to (n + 1) × 256 messages. Configuration of the RX message buffers, along with FIFO buffers, that exceeds this maximum limit should not be done.

CANFD module logic does not check the validity of the configuration.

Note: If the FIFO depth of a common FIFO is 4 messages or more (CFDCFCCn.CFDC[2:0] > 000b), then the Common FIFO TX message buffer link is valid when the FIFO is disabled or enabled.

If FIFO depth is 0 messages, then the Common FIFO TX message buffer link is not valid when the FIFO is disabled or enabled.

(4) FIFO payload size configuration

The data size of each FIFO buffer can be configured by writing to the CFDRFCCn.RFPLS[2:0] bits and CFDCFCCn.CFPLS[2:0] bits in the RX FIFO Configuration/Control Registers and the Common FIFO Configuration/ Control Registers. The eight available options for depth configuration are:

- 000b: 8 bytes
- 001b: 12 bytes
- 010b: 16 bytes
- 011b: 20 bytes
- 100b: 24 bytes
- 101b: 32 bytes
- 110b: 48 bytes
- 111b: 64 bytes

The RAM allocation for RX message buffers along with FIFO buffers is limited to (n + 1) × 256 messages with 64 data bytes. Configuration of the RX message buffers, along with FIFO buffers, that exceeds this maximum limit should not be done.

CANFD module logic does not check the validity of the configuration.

Note: This feature is not available in the classical CAN function.

(5) FIFO interrupt configuration

The Interrupt generation conditions for the FIFO buffers can be configured by writing to the CFDRFCCn.RFIM and CFDCFCCn.CFIM bit in the RX FIFO Configuration/Control Registers and the Common FIFO Configuration/Control Registers. The two available options are:

- 0:
  - RX FIFO mode: Interrupt generated when the Common FIFO counter reaches CFDRFCCn.RFIGCV/ CFDCFCCn.CFIGCV value
  - TX FIFO mode: Interrupt generated when the Common FIFO transmits the last message successfully
  - GW FIFO mode
  - Frame RX: Interrupt generated when message counter increments and reaches the interrupt threshold value
  - Frame TX: Interrupt generated when the last message is transmitted successfully from FIFO.
- 1:
  - RX FIFO mode: Interrupt generated at the end of storage of every received message
  - TX FIFO mode: Interrupt generated for every successfully transmitted message
  - GW FIFO mode
  - Frame RX: Interrupt generated when message is stored in the FIFO
  - Frame TX: Interrupt generated when message is successfully transmitted from the FIFO.

If the Interrupt Mode bit is 0 for a RX FIFO, then interrupt is generated based on the configuration of the CFDRFCCn.RFIGCV[2:0] bits.

Similarly, if the Interrupt Mode bit is 0 for a Common FIFO configured in RX mode, then interrupt is generated based on the configuration of CFDCFCCn.CFIGCV[2:0] bits.

The eight available options for configuring the FIFO counter value for generation of an interrupt are:

- 000b: Interrupt generated when FIFO is 1/8th Full
- 001b: Interrupt generated when FIFO is 1/4th Full
- 010b: Interrupt generated when FIFO is 3/8th Full
- 011b: Interrupt generated when FIFO is 1/2 Full
- 100b: Interrupt generated when FIFO is 5/8th Full
- 101b: Interrupt generated when FIFO is 3/4th Full
- 110b: Interrupt generated when FIFO is 7/8th Full
- 111b: Interrupt generated when FIFO is Full.

In this case, an interrupt is generated when the message count matches the configured value.

However, there are some limitations on the configuration of the CFDRFCCn.RFIGCV[2:0] and CFDCFCCn.CFIGCV[2:0] bits depending on the FDC[2:0] bits (FIFO Depth Configuration), see Table 32.18.

Table 32.18 FIFO interrupt generation counter and FIFO depth configuration (1 of 2)

RFDC[2:0] (CFDC[2:0])	RFIGCV[2:0] (CFIGCV[2:0])							
	111b	110b	101b	100b	011b	010b	001b	000b
000b	Don't care (FIFO cannot be enabled)							
001b	Allowed	Not allowed	Allowed	Not allowed	Allowed	Not allowed	Allowed	Not allowed
010b	Allowed							
011b	Allowed							
100b	Allowed							

Table 32.18 FIFO interrupt generation counter and FIFO depth configuration (2 of 2)

RFDC[2:0] (CFDC[2:0])	RFIGCV[2:0] (CFIGCV[2:0])							
	111b	110b	101b	100b	011b	010b	001b	000b
101b	Allowed							
110b	Allowed							
111b	Allowed							

Common FIFO buffer can set an interrupt output at the completion time of transmitting one frame, or the completion of reception. In addition, Common FIFO and RX FIFO can set an interrupt output, when stored to the setup number (CFDC/RFDC) of FIFO stages.

32.6.2.2 FIFO Buffers Control

The FIFO interrupt must be enabled by setting any one of the following bits in the RX FIFO Configuration/Control Registers:

- CFDRFCCn.RFIE
- CFDRFCCn.RFFIE.

In addition, the FIFO interrupt must be enabled by setting any one of the following bits in the Common FIFO Configuration/Control Registers:

- CFDCFCCn.CFRXIE
- CFDCFCCn.CFTXIE
- CFDCFCCEn.CFFIE
- CFDCFCCEn.CFOFRXIE
- CFDCFCCEn.CFOFTXIE.

After configuration is complete, each FIFO can be enabled by setting the CFDRFCCn.RFE and CFDCFCCn.CFE bits in the RX FIFO Configuration/Control Registers and the Common FIFO Configuration/Control Registers to allow transmission and reception of messages.

When CFDCFCCEn.CFBME = 1, it becomes FIFO buffering mode, send data is stored in the Common FIFO, and transmission is stopped. Transmission starts when CFDCFCCEn.CFBME = 0.

Do not write 1 from 0 for this bit when the CFDCFCCn.CFE bit is 1.

32.7 Interrupts and DMA

32.7.1 Interrupts

The CAN-FD module generates several interrupts. The interrupt output, which is connected to the Interrupt Controller Unit (ICU), can be controlled by the corresponding interrupt enable bit.

The status flag is set independent from this enable bit.

The channel transmission interrupt has an additional status flag register. The status bits are set when the corresponding interrupt enables are set.

The status flag register supports the identification of the interrupt source for the channel transmission, as this interrupt is driven by several trigger sources.

The interrupts in the CAN-FD module can be classified into two groups, global interrupts and channel interrupts:

- Global interrupts:
  The CAN-FD module can generate 2 global interrupts:
  - Global interrupt for successful reception into the 8 RX FIFO buffers
  - Global error interrupt.
- Channel interrupts:
  Each channel of the CAN-FD module can generate 3 channel interrupts:

1. Channel transmission
   - Transmission completion from channel
   - Transmission abort from channel
   - Transmission from TX Queue for a channel
   - Channel THL interrupt
   - Successful transmission from a Common FIFO in TX or GW mode for a channel.
2. Channel error interrupt
3. Successful reception in a Common FIFO in RX or GW mode for a channel or successful routing in a TXQ.

The interrupts are cleared when the corresponding flag bits are cleared or the Interrupt enable bits are cleared.

Table 32.19 gives an overview of interrupt sources for the different interrupt outputs. The interrupt outputs are active-high.

Table 32.19 Interrupt source overview (1 of 2)

Parameter	Interrupt	Interrupt source	Interrupt clearing
Global interrupts	Successful reception into at least one RX FIFO	Interrupt flag of corresponding RX FIFO for which interrupt is enabled	Clear the interrupt flag of corresponding RX FIFO buffer for which interrupt is enabled
	FIFO full into at least one RX FIFO	FIFO Full Interrupt flag of corresponding RX FIFO for which interrupt is enabled	Clear the FIFO Full Interrupt flags of corresponding RX FIFO buffer for which interrupt is enabled
	Global error	Interrupt source is any of the following: • DLC Error flag • Message Lost Status bit • Message Overwrite Status bit • TXQ Message Lost Status bit • TXQ Message Overwrite Status bit • TX History Entry Lost Status bit • CAN-FD Message Payload Overflow flag*1	Clear all of the following: • DLC Error flag • Message Lost flags in all of the FIFO Status Registers • Message Overwrite flags in all of the Common FIFO Status Registers • Message Lost flags in all of the TXQ Status Registers • Message Overwrite flags in all of the TXQ Status Registers • TX History List Entry Lost flag • CAN-FD Message Payload Overflow flag.*1

Table 32.19 Interrupt source overview (2 of 2)

Parameter	Interrupt	Interrupt source	Interrupt clearing
Channel transmission interrupts	Channel n successful transmission	Any channel related TX MB Successful flag when interrupt is enabled. Separate interrupts are provided for Common FIFO buffers and TX Queue. Note: These interrupts are only set for TX message buffers that do not belong to an enabled TX Queue and are not pointing to a Common FIFO.	Clear all channel related TX MB Result Status bits for which the interrupt is enabled
	Channel n abort	Any channel related TX MB Abort flag when interrupt is enabled Separate interrupts are provided for Common FIFO buffers and TX Queue Note: These interrupts are only set for TX message buffers that do not belong to an enabled TX Queue and are not pointing to a Common FIFO.	Clear all channel related TX MB Result Status bits for which the interrupt is enabled globally
	Channel n transmission from TX Queue	Related Channel TX Queue Interrupt flag	Clear related Channel TX Queue Interrupt flag
	Channel n THL Interrupt	Channel n THL Interrupt Status flag	Clear the relevant THL Interrupt Status flag
	Channel n COM FIFO TX Interrupt	Interrupt flag for Common FIFOs in TX or GW mode belonging to the related channel	Clear the interrupt flags of Common FIFOs in RX or GW mode belonging to the related channel
	Channel n COM FIFO One Frame TX Interrupt	One Frame Transmission Interrupt flag for Common FIFOs belonging to the related channel	Clear the One Frame Transmission Interrupt flags of Common FIFOs belonging to the related channel

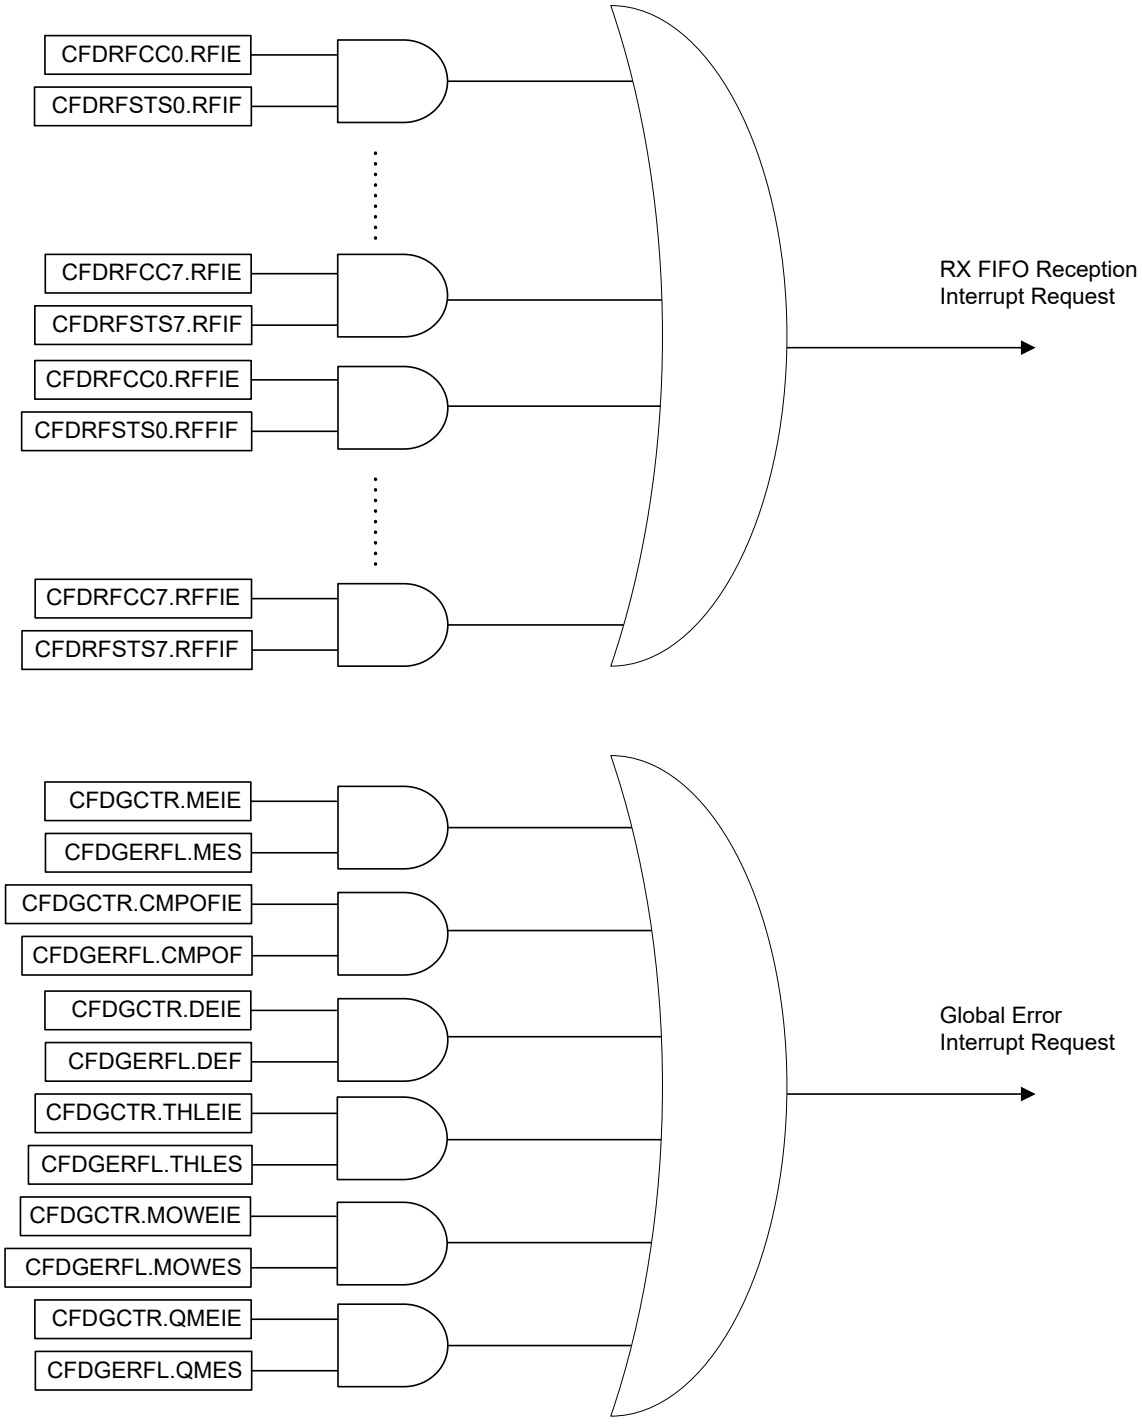
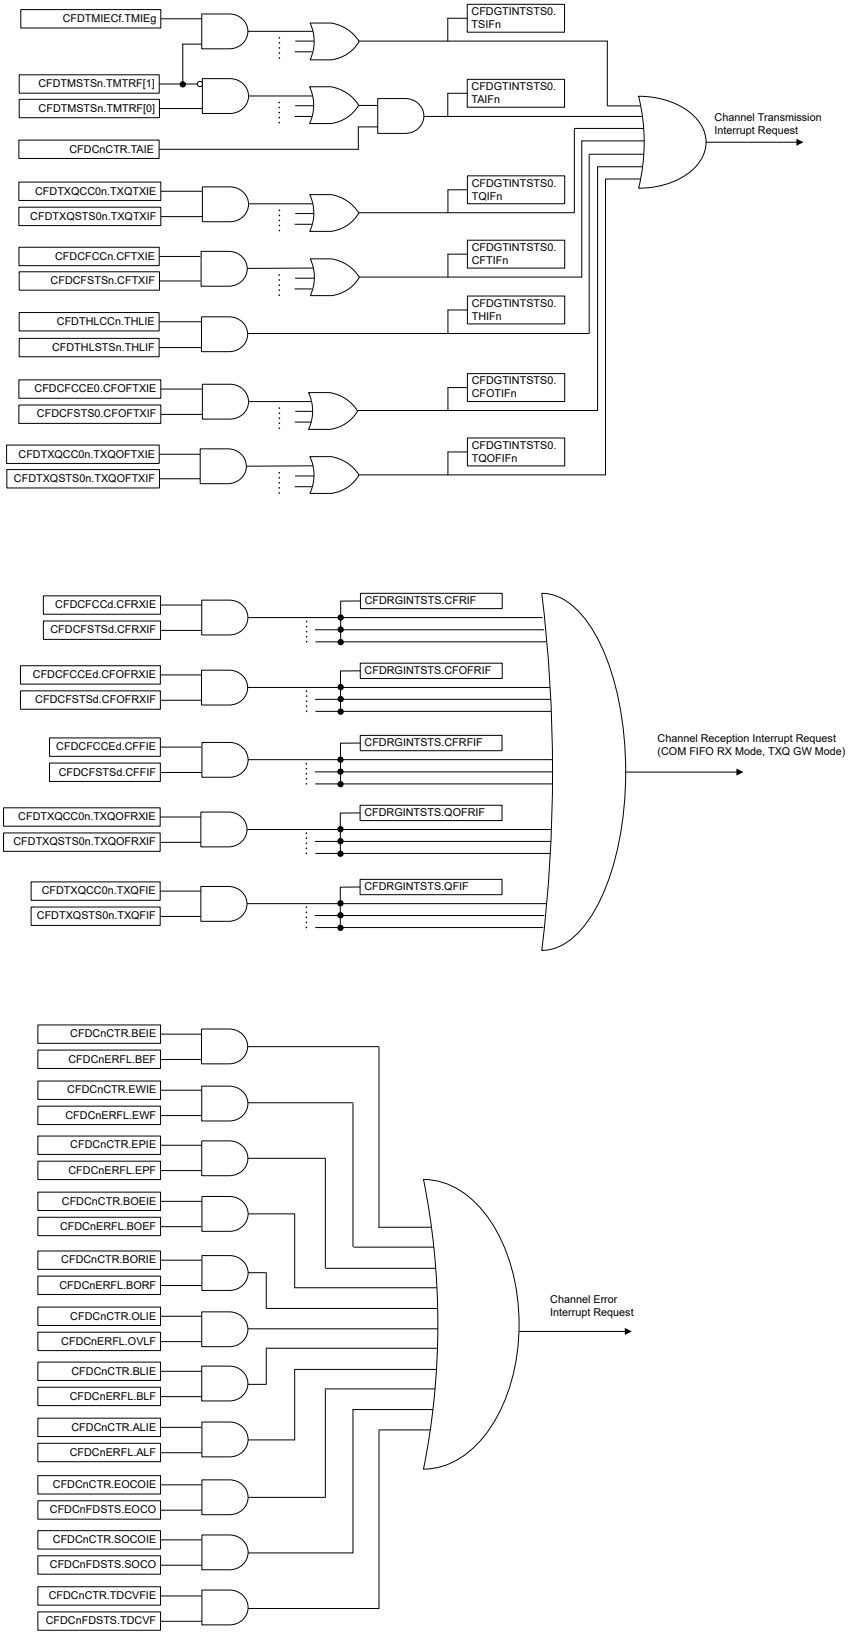
Note 1. This feature is not available in the classical CAN function.



Note: CFDGCTR.CMPOFIE and CFDGERFL.CMPOF bits are not available in the classical CAN function. For this reason, these signals and the AMD circuit to which these signals are connected are not in the classical CAN function.

Figure 32.30 Global interrupt block diagram



Note: CFDCnCTR.TDCVFIE and CFDCnFDSTS.TDCVF bits are not available in the classical CAN function. For this reason, these signals and the AMD circuit to which these signals are connected are not in the classical CAN function.

Figure 32.31 Channel interrupt block diagram

32.7.2 DMA Transfer

The CAN-FD module has message buffers that can be associated with a DMA channel:

- Reception DMA
  - 8 RX FIFO message buffers
  - 8 Common FIFO message buffers
- Transmission DMA
  - 16 TXQ message buffers (TXQ0, TXQ3)
  - 8 Common FIFO message buffers.

Figure 32.32 shows the potential DMA channels.

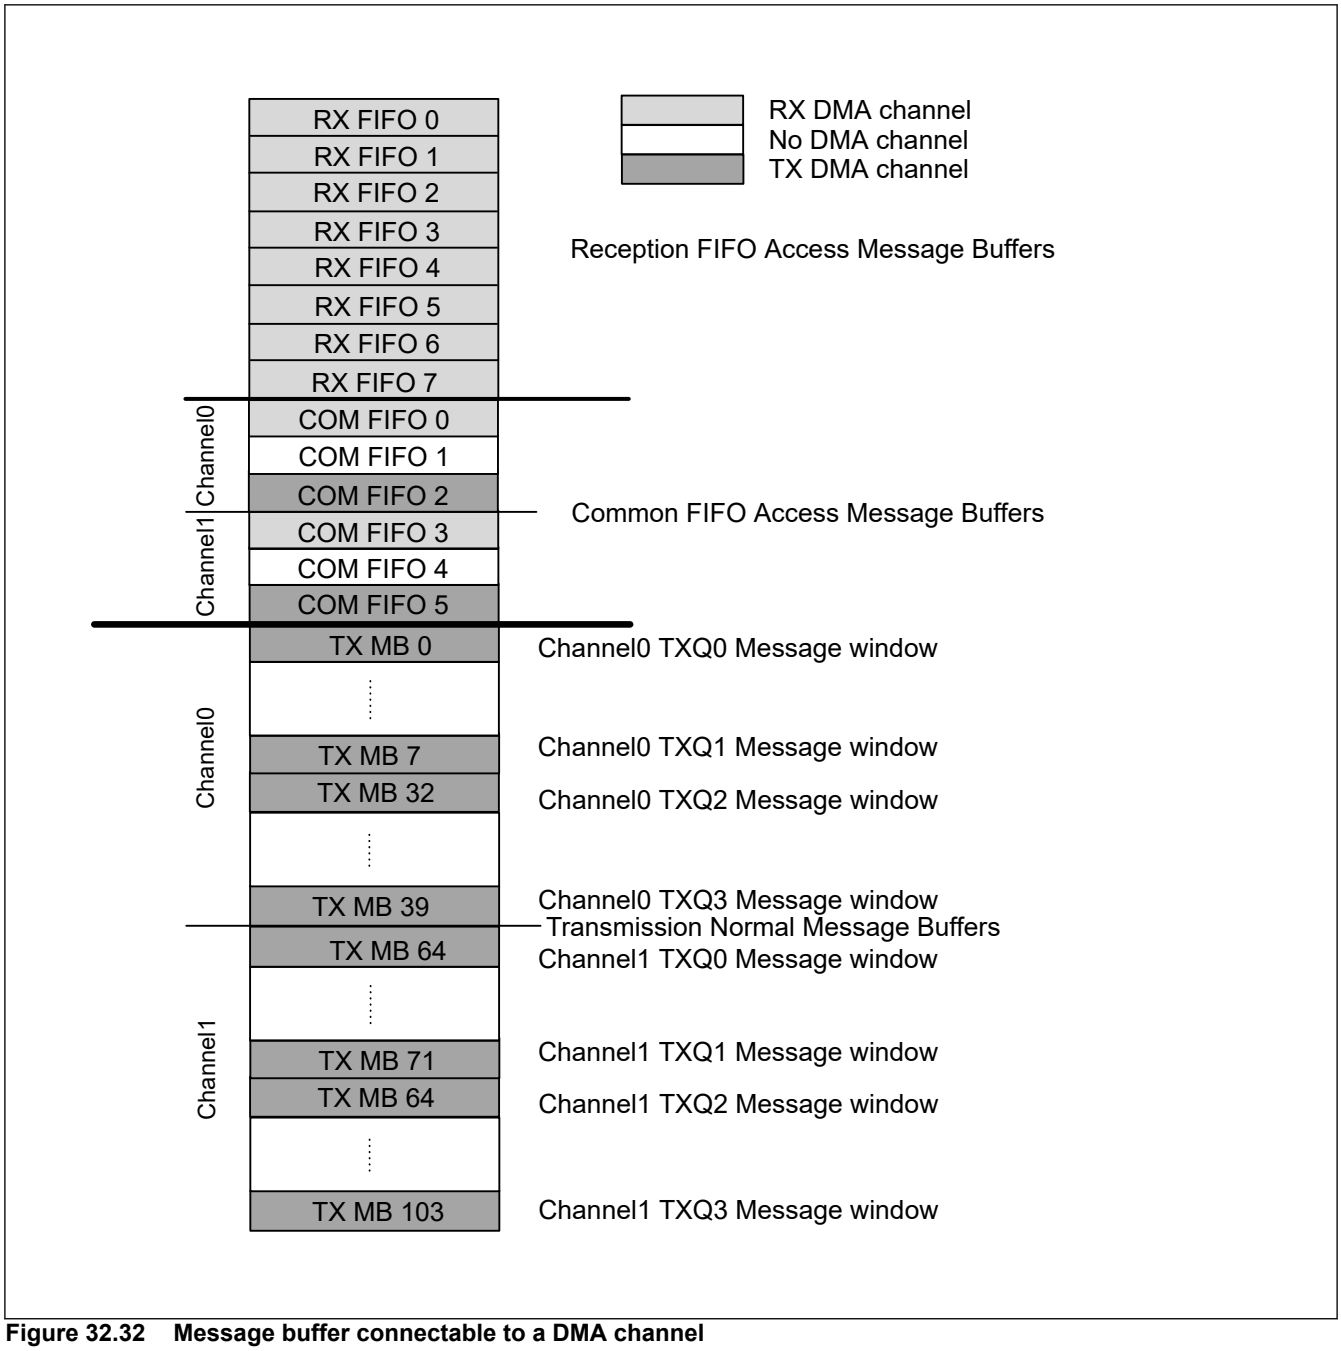


Figure 32.32 Message buffer connectable to a DMA channel

A DMA channel transfer request is generated for each FIFO entry to the DMAC when the related CFDCDTCT.RFDMAE or CFDCDTCT.CFDMAE is set to 1 and the belonging FIFO is not empty.

Reception FIFO Interrupt should be disabled for this particular FIFO (CFDRFCCn.RFIE or CFDCFCCn.CFRXIE)

Use the regular start address for the DMA access window address and add 0x8000 to the regular start address for the debugger access window. See Figure 32.33.

Table 32.20 DMA channel access window address

b = Message buffer component index	MBCP	Register	P	Regular start address n = [0, 1]
[0…7]	FRMBCPb[i]	RFIDE	x	0x6000 + b*0x0080
		RFPTRE	x	0x6004 + b*0x0080
		RFFDSTSE	x	0x6008 + b*0x0080
		RFDFpE	[0…15]	0x600C + b*0x0004 + b*0x0080
[0…2]	CFMBCPb[i]	CFIDE	x	0x6400 + b*0x0080 + n*0x180
		CFPTRE	x	0x6404 + b*0x0080 + n*0x180
		CFFDCSTSE	x	0x6408 + b*0x0080 + n*0x180
		CFDFpE	[0…15]	0x640C + b*0x0004 + b*0x0080 + n*0x180

DMA FIFO pointer decrement is done automatically by reading the last configured data payload byte (CFDRFCCn.RFPLS or CFDCFCCn.CFPLS).

Note: The DMA must read the exact length of the configured data payload size (CFDRFCCn.RFPLS or CFDCFCCn.CFPLS).

Note: This feature is not available for classical CAN function because CFDRFCCn.RFPLS and CFDCFCCn.CFPLS are not in classical CAN.

Do not write to the FIFO and TXQ control registers when DMA is enabled. The DMA enable of the particular DMA FIFO (CFDCDTCT.RFDMAE or CFDCDTCT.CFDMAE) can be set at any time. Figure 32.33 shows a configuration flow for an initial setup.

When CFDCDTTCT.TQ0DMAE or CFDCDTTCT.TQ3DMAE or CFDCDTTCT.CFDMAE is set, the messages of the corresponding TXQ or Common FIFO can be handled by a DMA controller.

The following procedure shows when the TXQ or the Common FIFO can be handled by a DMA controller.

1. CPU checks the TXQ or the Common FIFO is not full.
2. When transmit data can be used, the CPU sets this data to Common FIFO or TXQ.
   When using Common FIFO, transmit data is write in CFDCFID, CFDCFPTR, CFDCFFDCSTS and CFDTMBCPb[i] register.
   When using TXQ, transmit data is write in CFDTMID, CFDTMPTR, CFDTMFDCTR and CFDTMDFp register.
3. For Common FIFO, the common FIFO pointer is incremented automatically when DMA controller writes the last data payload byte configured by CFDCFCCn.CFPLS.
   For TXQ, if the data of 64 data payload is written, a TXQ pointer increases automatically. When payload data is less than 64 bytes, dummy data must be written in and 64 data payload size must be done.

   Note: Only 32-bit write-access can be possible on the DMA message handling.

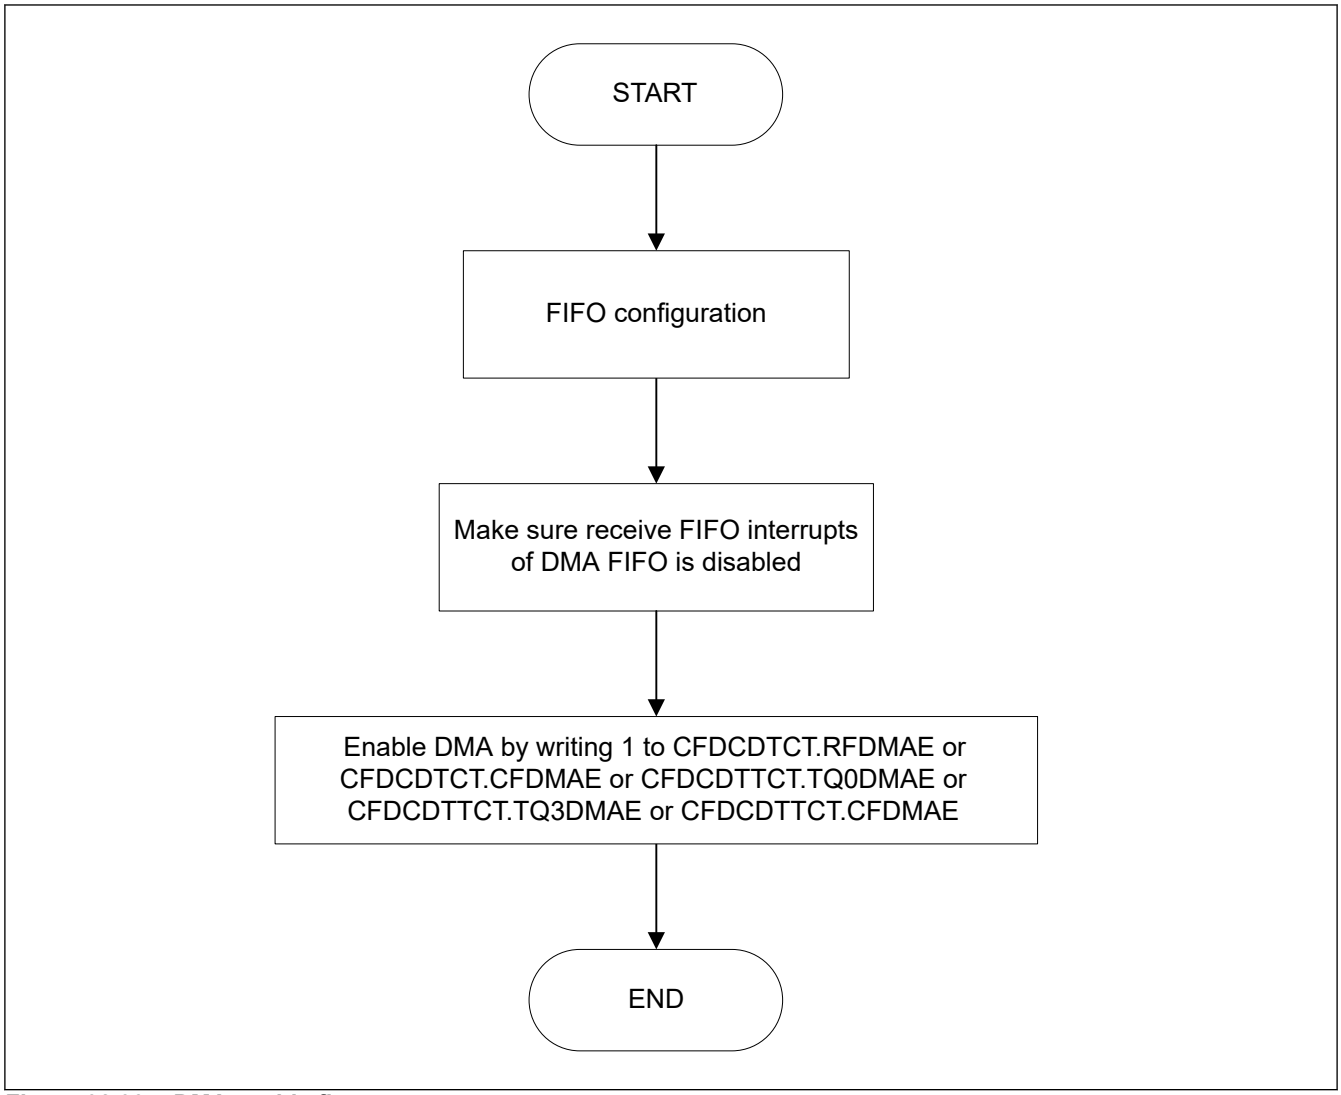

Figure 32.33 DMA enable flow

To disable a DMA transfer request, you must disable the particular DMA enable bit (CFDCDTCT.RFDMAE or CFDCDTCT.CFDMAE). If the disable is made during an ongoing transfer, then the transfer must be completed first before further action can be taken. The transfer status can be identified by the CFDCDTSTS.RFDMASTS or CFDCDTSTS.CFDMASTS bit. See Figure 32.34 for the DMA disable flow. When the DMA is disabled, consideration should be made for the remaining or new incoming messages to this particular reception FIFO.

When the FIFO is not disabled, reception to the FIFO continues.

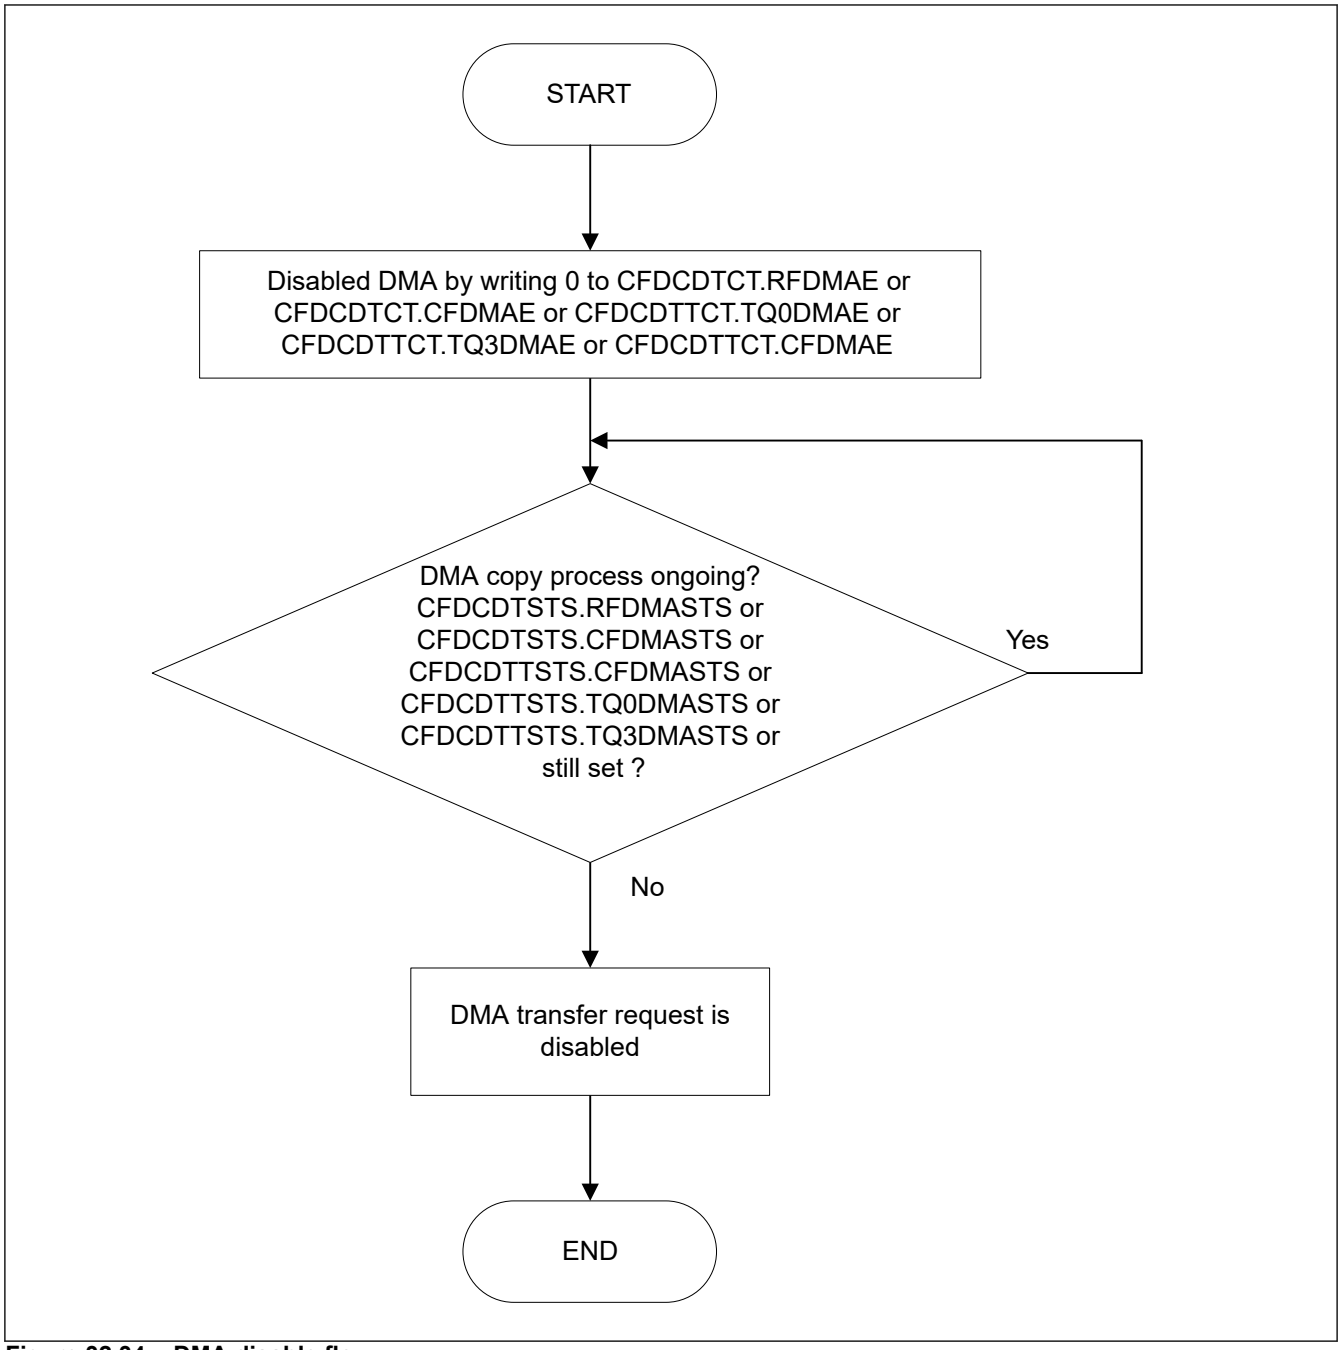

Figure 32.34 DMA disable flow

32.8 Reception and Transmission

32.8.1 Reception

In the CANFD module, CAN messages received on any of the channels are stored in RX message buffers, RX FIFO buffers, or Common FIFO buffers configured in RX mode or GW mode depending on the Acceptance Filter List entries.

- Up to 32 RX message buffers can be configured
- 8 RX FIFO buffers available
- Up to 6 Common FIFO buffers can be configured in RX mode or GW mode
- Up to 4 TX Queue can be configured in GW mode.

32.8.1.1 Message Storage in RX Message Buffers

When a message is successfully received and stored in a RX message buffer, the corresponding New Data flag is set in the RX Message Buffer New Data Register.

The CAN message can be read from the corresponding RX message buffer.

If a new message is stored into a RX message buffer before the previous message in this message buffer can be read, then the original message is overwritten. There is no mechanism for preventing a new message from overwriting the current message in the RX message buffer. If such a loss of messages is not acceptable, then RX FIFO should be used for storing related messages.

Note: Interrupts are not provided for the RX message buffers in the CANFD module and therefore, the RX Message Buffer New Data Registers should be accessed periodically to check if a new message has been stored in the RX message buffers.

Note: Unused data bytes are filled with 0x00 depending on the DLC value.

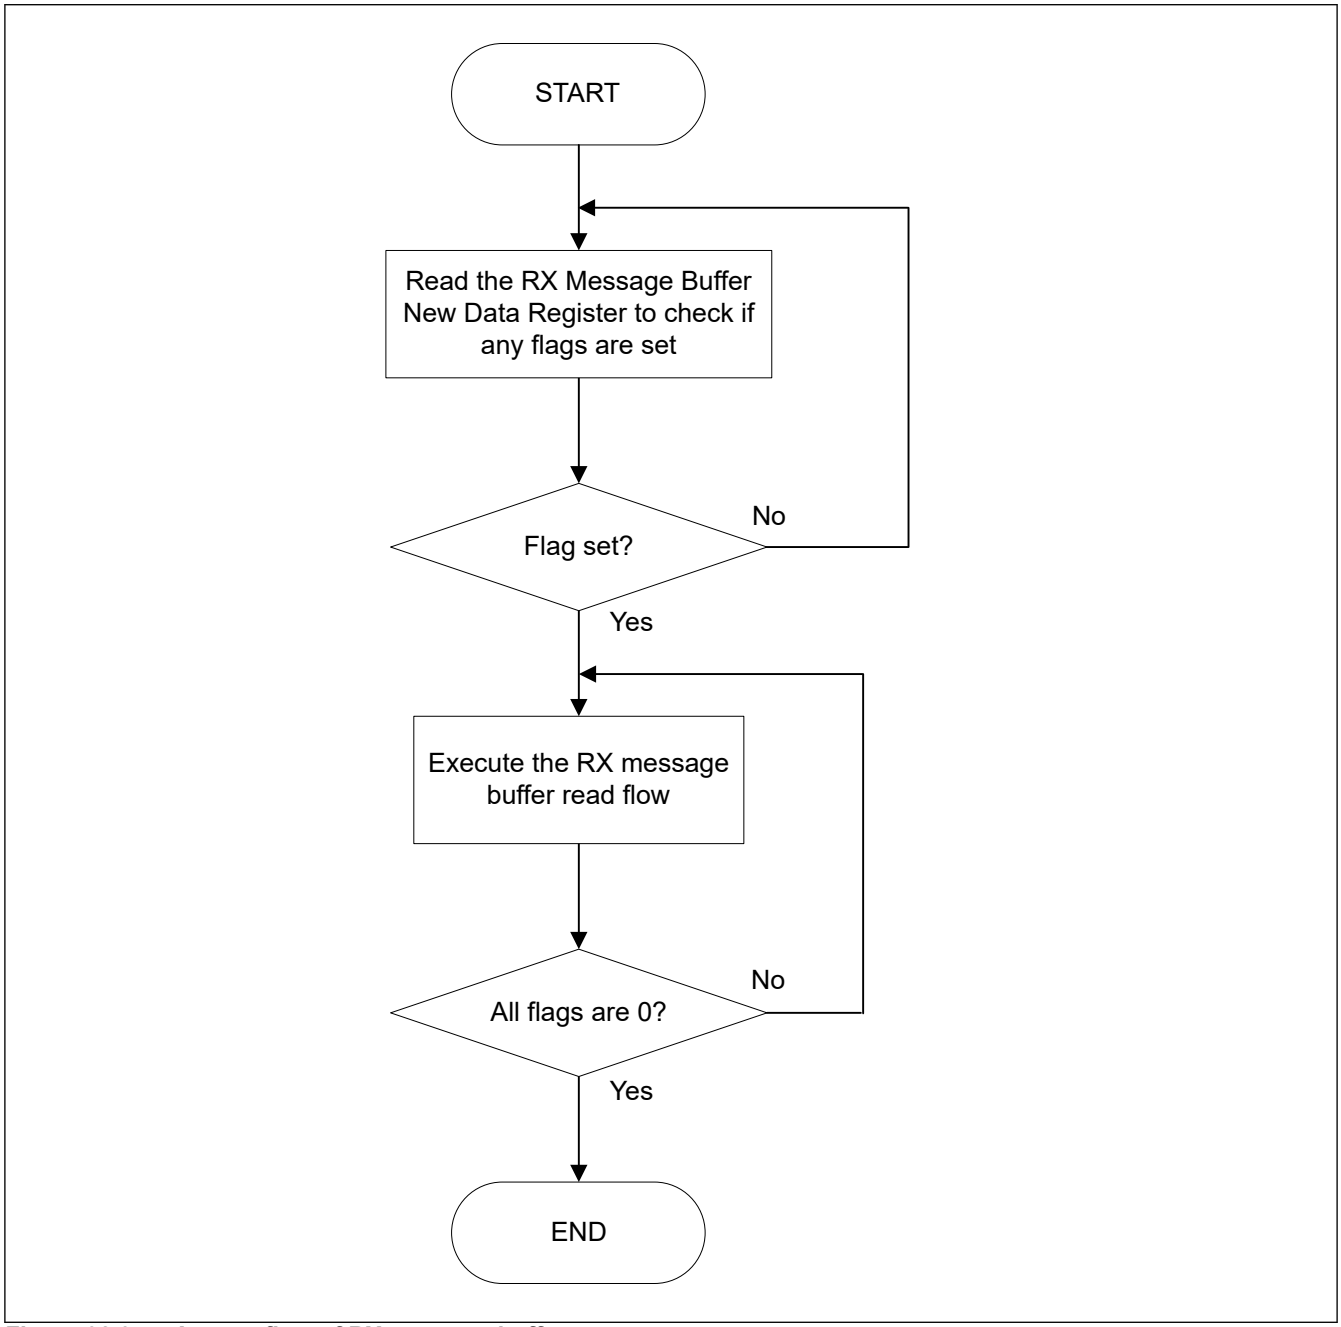

Figure 32.35 Access flow of RX message buffer

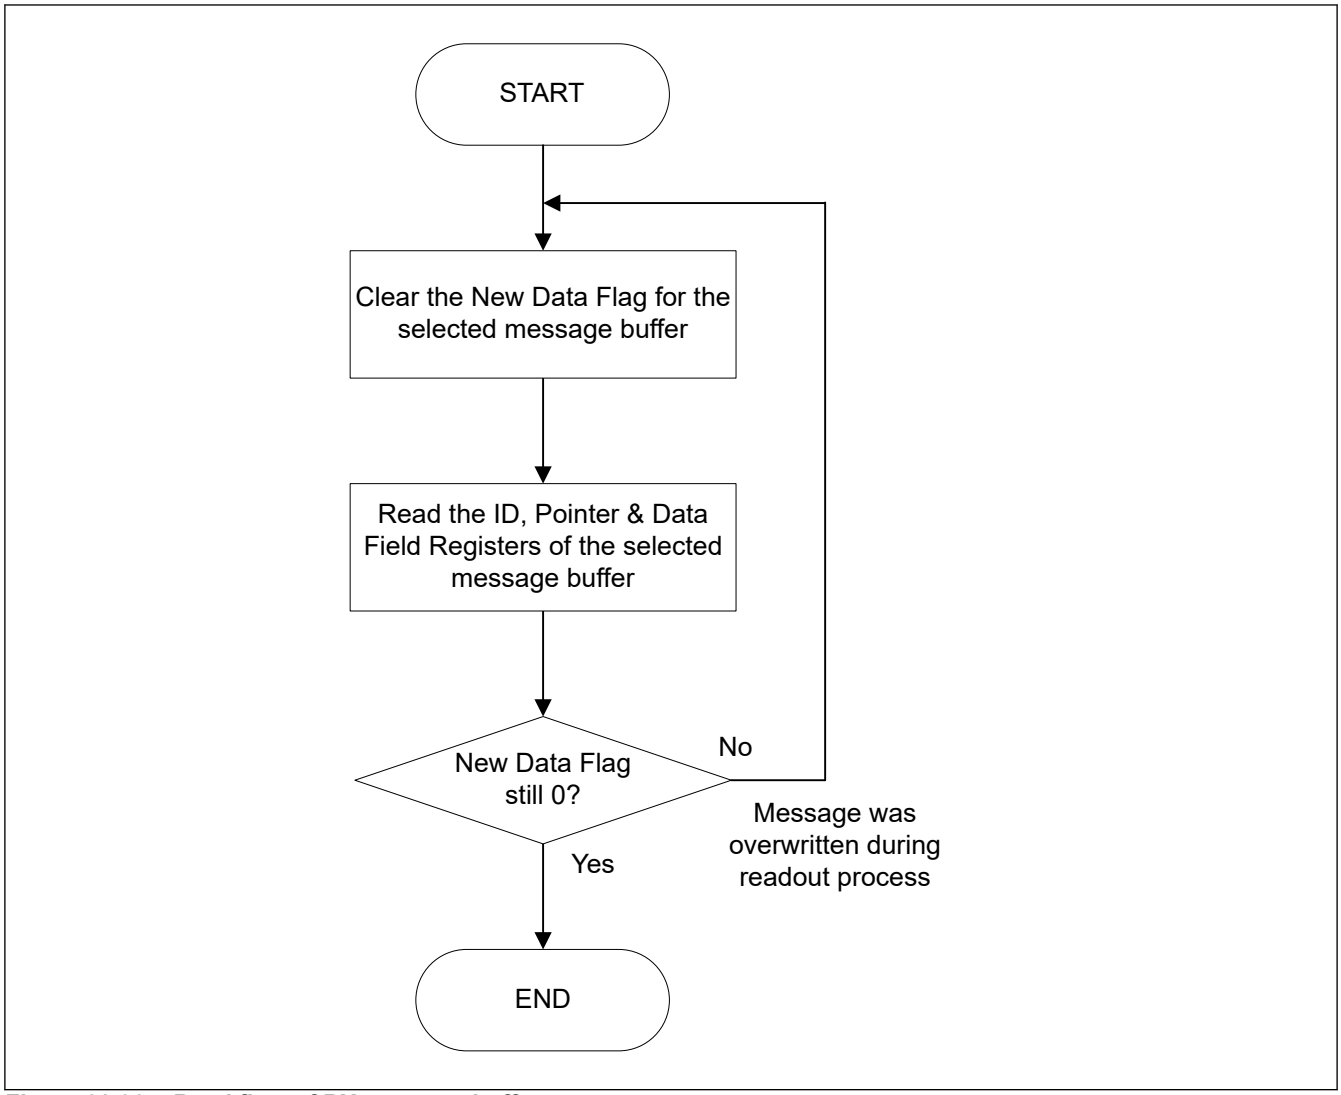

Figure 32.36 Read flow of RX message buffer

32.8.1.2 Message Storage in FIFO Buffers

The AFL entries for routing the received messages to RX FIFO buffers or Common FIFO buffers configured in RX or GW mode should be configured based on system requirements.

The CFDGAFLP1n.GAFLFDP[31:0] field in the matching AFL entry selects the FIFO buffers to which the related reception message is stored.

When the received message is stored in one or more RX FIFO buffers or Common FIFO buffers configured in RX mode or GW mode, the message counter value is incremented in the corresponding RX FIFO Status Registers or Common FIFO Status Registers.

Depending on the configuration of the FIFO buffers, an interrupt might also be generated.

The message can be read from the corresponding FIFO Access registers.

Note: Because many messages can be stored in the FIFO buffers, reading more than one message may be required to read the latest message stored in a FIFO buffer.

If the message count value matches the FIFO depth, the FIFO Full flag is set.

When the value 0xFF is written to the corresponding FIFO Pointer Control Register, the message count is decremented by 1.

Only write 0xFF to the FIFO Pointer Control register after reading the complete message from the FIFO Access registers of the corresponding FIFO.

When all the messages stored in the FIFO are read, the FIFO Empty flag is set.

If a new message is stored into the FIFO when the FIFO message count matches the FIFO depth (FIFO full condition), the FIFO Message Lost flag is set and the new message is lost (no overwrite of already stored messages takes place).

An appropriate value can be configured as warning level to generate an interrupt before the FIFO full condition occurs to avoid loss of a message due to an overrun condition.

In GW mode, when a transmit/receive FIFO buffer is receiving a new message while the transmit/receive FIFO buffer is already full of data, the oldest data of the buffer is overwritten with the message received or the message is discarded. The behavior is determined by setting CFDCFCCEn.CFMOWM bit.

- When CFDCFCCEn.CFMOWM = 0:
  When writing data is required due to reception of a new message while a transmit/receive FIFO buffer is full of data, the received message is discarded and the CFDCFSTSn.CFMLT bit is set to 1.

- When CFDCFCCEn.CFMOWM = 1:
  When writing data is required due to reception of a new message while a transmit/receive FIFO buffer is full of data, the oldest data in the buffer is overwritten with the received message.
  The read pointer of the transmit/receive FIFO buffer simultaneously moves to the next oldest message.
  The CFDCFSTSn.CFMOW bit is set to 1, which notifies that the oldest message has been overwritten with the received message.
  In addition, when a CAN bus error or arbitration-lost for the transmitting message occurs in the transmit/receive FIFO buffer full, the transmitting message is lost and retransmission for the message is not performed. The read point moves to the next message automatically.

Do not modify this bit when the CFDCFCCn.CFE bit is 1.

Common FIFO can set the interrupt when CAN frame reception is completed.

Common FIFO can set the interrupt when FIFO is in full status in RX mode or GW mode.

Note: The message lost can be set only in RX or GW mode by CAN, and the flag is not set when the CPU is overloading the FIFO buffers.

Note: When CFDGAFLP0n.GAFLSRD i (i = 0 to 2) is set and the CFDTXQCCin.TXQGWE (i = 0 to 2, n = 0 to 7) is also set, a receiving frame is stored in the target TXQ as send data by routing.

The RX FIFO buffers and the Common FIFO buffers configured in RX or GW mode can be disabled at any time by clearing the CFDRFCCn.RFE or CFDCFCCn.CFE bit in the RX FIFO Configuration/Control Registers and the Common FIFO Configuration/Control Registers.

When the CFDRFCCn.RFE or CFDCFCCn.CFE bit is cleared, the message read and write pointers of the FIFO are cleared and are no longer active. Therefore, all messages in the FIFO buffers are lost and no further messages can be stored into the FIFO.

When the RX FIFO buffers or Common FIFO buffers configured in RX mode is assigned as a DMA channel, software should not access the FIFO Access Register of this FIFO buffer or write 0xFF to the FIFO Pointer Control Register (CFDCFPCTRn.CFPC or CFDRFPCTRn.RFPC). This can lead to unintended FIFO message decrement. The DMA channel controls the FIFO decrement automatically.

Note: If the interrupt flag is set for a FIFO buffer and then the FIFO is disabled, the interrupt flag is not cleared automatically. The interrupt flag should be cleared before disabling the FIFO.

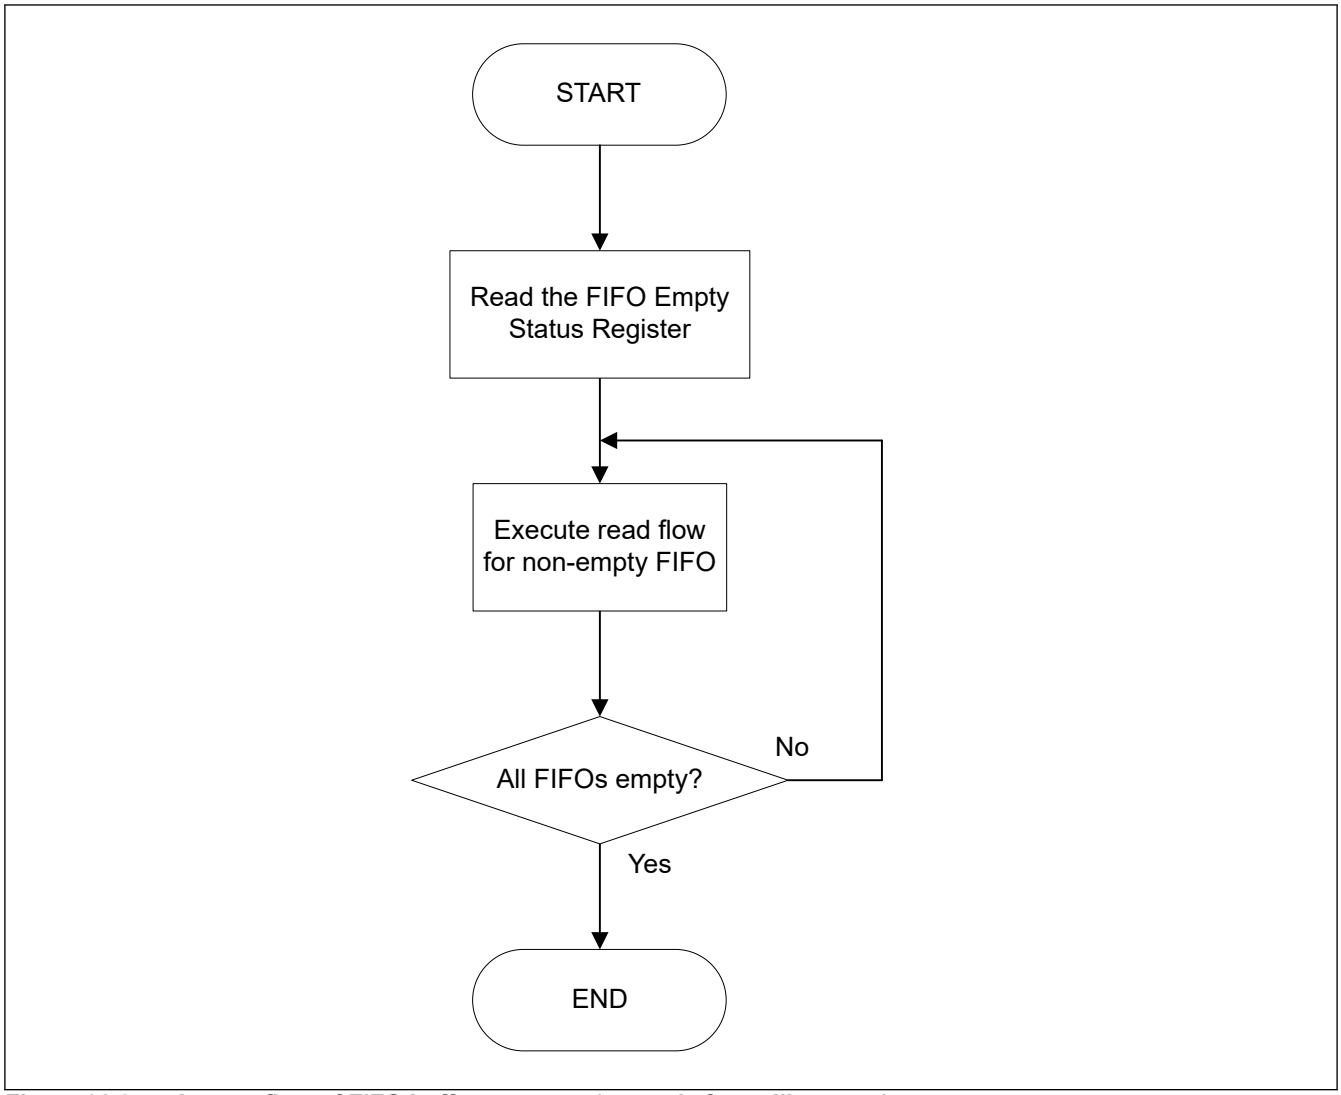

Figure 32.37 Access flow of FIFO buffer message (example for polling case)

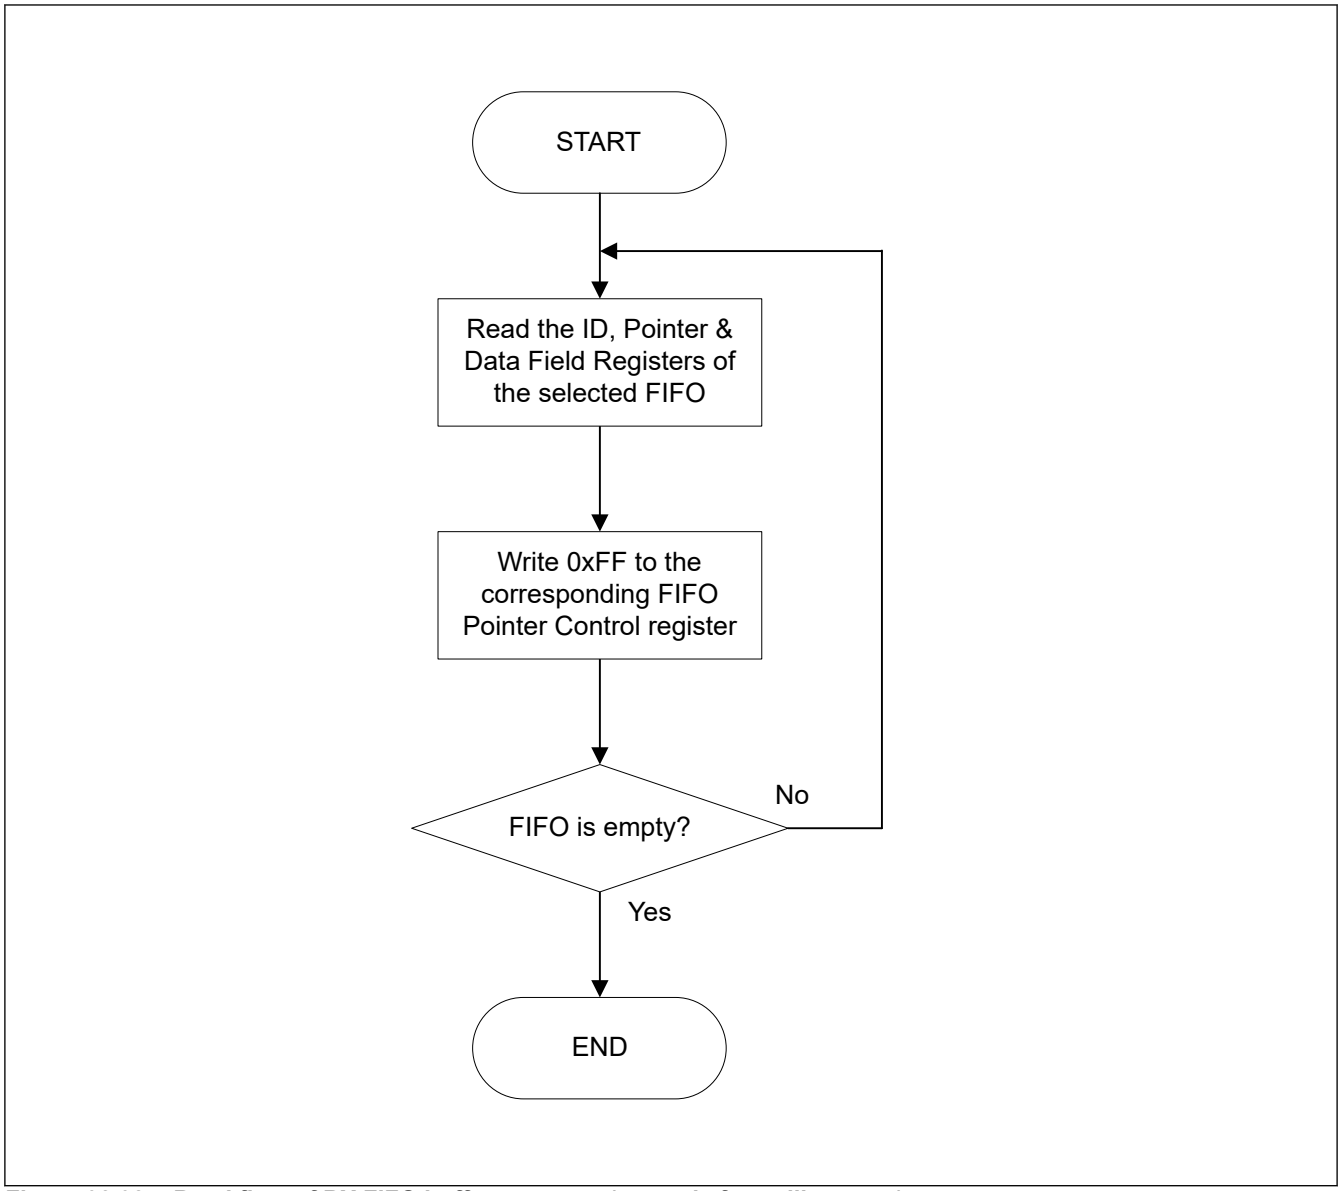

Figure 32.38 Read flow of RX FIFO buffer message (example for polling case)

Note: When the next frame is received before clearing the completion interrupt flag of reception, the completion interrupt of reception is not set again.

Even when an interruption flag is cleared after the completion processing of reception, the already received interrupt flag is not set.

It is necessary to perform the completion processing of reception even before the next completion of frame reception, and to clear an interruption flag.

When processing does not meet the condition, after checking that receiving data is empty, interrupt flag is cleared and it checks that receiving data is empty again.

32.8.1.3 Timestamp

The timestamp counter is a free-running counter that can be used to check reception time of an incoming message or transmission time of successful transmitted messages. The Timestamp counter value is captured based on the CFDGFDCFG.TSCCFG[1:0] configuration (at the sample point of start of frame, point in time when the frame is valid, or for CANFD frames also at the sample point of the RES bit). For reception, it is stored together with the message ID and data into the target RX message buffer or RX/GW FIFO.

For transmit message, the timestamp counter value is stored as part of the TX History List entry.

The counter can be clocked with the peripheral clock or with the CAN channel bit timing clock. The counter source clock can be configured with the CFDGCFG.TSSS bit of the Global Configuration Register. If this bit is 0, the peripheral clock is used. If the bit is 1, the selected CAN channel bit time clock is used.

The channel selection is performed with the CFDGCFG.TSBTCS bit of the Global Configuration Register.

Care must be taken when using selected CAN channel bit time clock as the clock source. When entering Channel Halt mode or Channel Reset node, for this channel, the timestamp counter is stopped. For other CAN channels, the timestamp counter value is not updated.

If peripheral clock is selected as the timestamp counter clock source, Channel modes do not affect the timestamp counter function.

The source clock for the timestamp counter can be divided by a factor defined by the CFDGCFG.TSP bits (timestamp prescaler) in the Global Configuration Register.

The timestamp counter can be reset to 0x0000 with the CFDGCTR.TSRST bit (timestamp reset).

32.8.2 Transmission

There are several possible transmission configurations for each channel:

- Normal transmission
- FIFO transmission
- Gateway transmission
- TX Queue transmission
  A fixed number of transmission message buffers (16 TX message buffers) are dedicated for each channel. These message buffers are only used for transmission and cannot be configured for reception.
  Additionally transmission from TX Queue or Common FIFO in TX or GW mode can be configured in the following way (see Figure 32.39):
  - TX Queue: Up to eight transmission message buffers for one channel can be grouped to form a TX Queue with a common access window.
    Upper transmission message buffers are used to form the TXQ1 or TXQ3.
    Lower transmission message buffers are used to form the TXQ0 or TXQ2.
    Transmission Control and Status registers of these transmission message buffers should not be used.
    One channel has four TX Queues.
    Each TXQ has an access window.
    - TXQ0 is transmission Message Buffer 0 of each channel.
    - TXQ1 is transmission Message Buffer 7 of each channel.
    - TXQ2 is transmission Message Buffer 32 of each channel.
    - TXQ3 is transmission Message Buffer 39 of each channel.

    When using TXQ1 and TXQ0 simultaneously, the sum of the depths of TXQ1 and TXQ0 should not exceed 8.
    When using TXQ3 and TXQ2 simultaneously, the sum of the depths of TXQ3 and TXQ2 should not exceed 8.
- Common FIFO (TX/GW mode): each Common FIFO in TX or GW mode is linked to a dedicated channel.
  Each channel has a fixed number of three Common FIFO assigned to it. Within the channel, a Common FIFO configured in TX or GW mode, can be freely linked (assigned) between 32 and 39 transmission message buffers (only one FIFO to one transmission message buffer).
  The Common FIFO buffer then replaces the transmission message buffer linked to it.
  Transmission Control and Status registers of these transmission message buffers should not be used.

See Figure 32.28 for information about Common FIFO buffer assignment to related channels.

Note: Common FIFO buffers should not be linked to TX message buffers that are already part of a TX Queue.

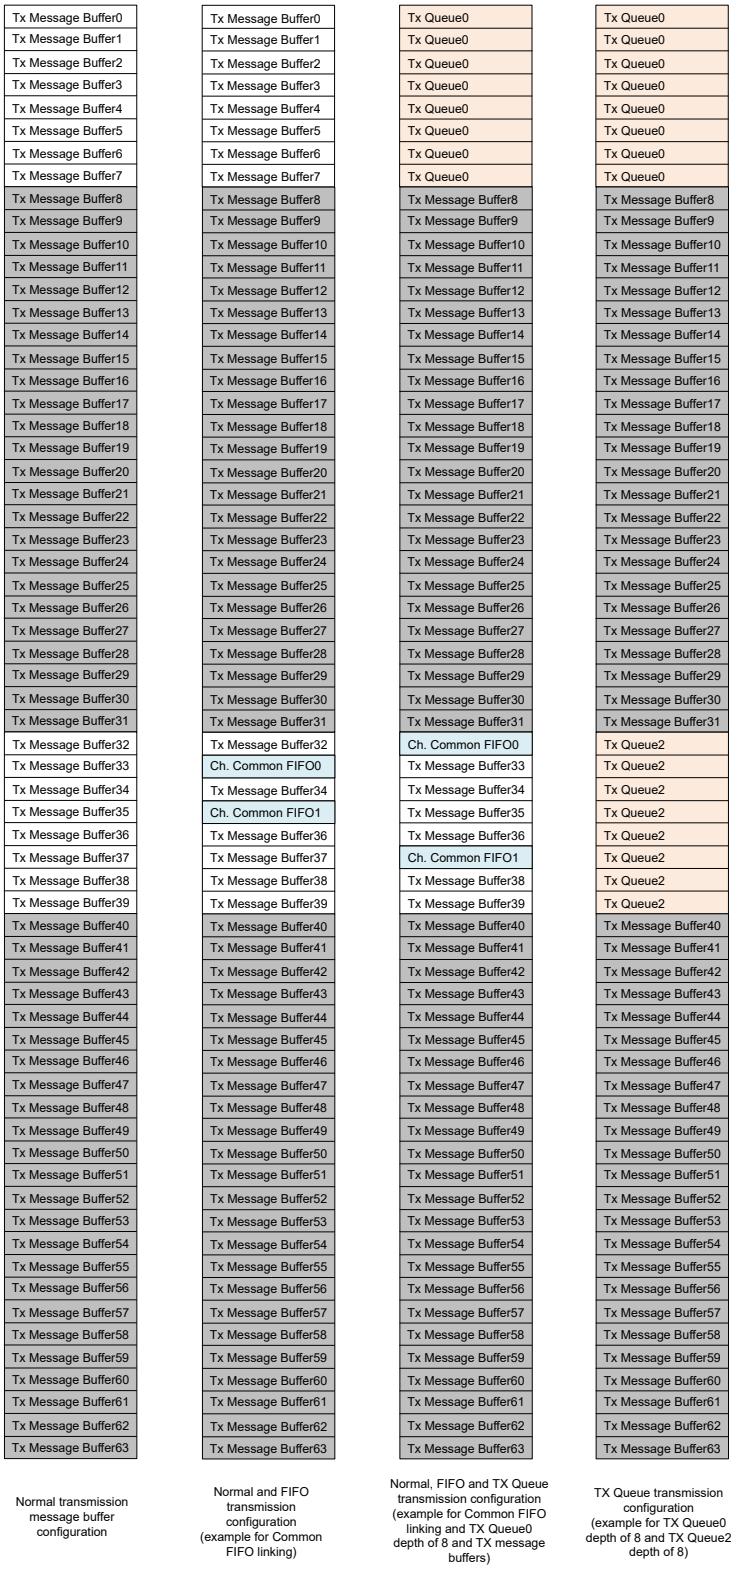

Figure 32.39 Configuration of channel transmission message buffer

32.8.2.1 Transmission Priority

If two or more transmission message buffers of a channel are configured for transmission, then the transmission priority in the CANFD module can be selected from the following two modes:

- CAN ID priority
- Message buffer number priority.

The transmission priority mode is common for all message buffers and all CAN channels. It can be configured with the CFDGCFG.TPRI bit in the Global Configuration Register.

For message buffer number priority transmission, the smallest message buffer number with transmission request has the highest priority for transmission. This also includes the TX message buffers linked to the Common FIFO buffers configured in TX mode or GW mode.

However, message buffer number priority should not be used if TX Queue is enabled.

For CAN ID priority transmission, ID priority complies with the CAN bus arbitration rule (as specified in ISO 11898-1 specification). All TX message buffers can enter the ID priority comparison for message buffers configured for transmission. This also includes the TX message buffers linked to the Common FIFO buffers configured in TX mode or GW mode and includes the TX Queue message buffers.

If the ID of two or more message buffers is the same, then the smaller message buffer number has higher priority for transmission.

Note: For Common FIFO buffers configured in TX mode or GW mode, only the message currently being pointed to by the FIFO read pointer can be included in the transmission arbitration.

If the message is being transmitted from the FIFO, then the next pending message within the same FIFO is considered in the transmission arbitration.

In contrast to this, all transmission message buffers of a TX Queue participate in internal transmission arbitration.

Figure 32.40 shows the transmission configuration flow.

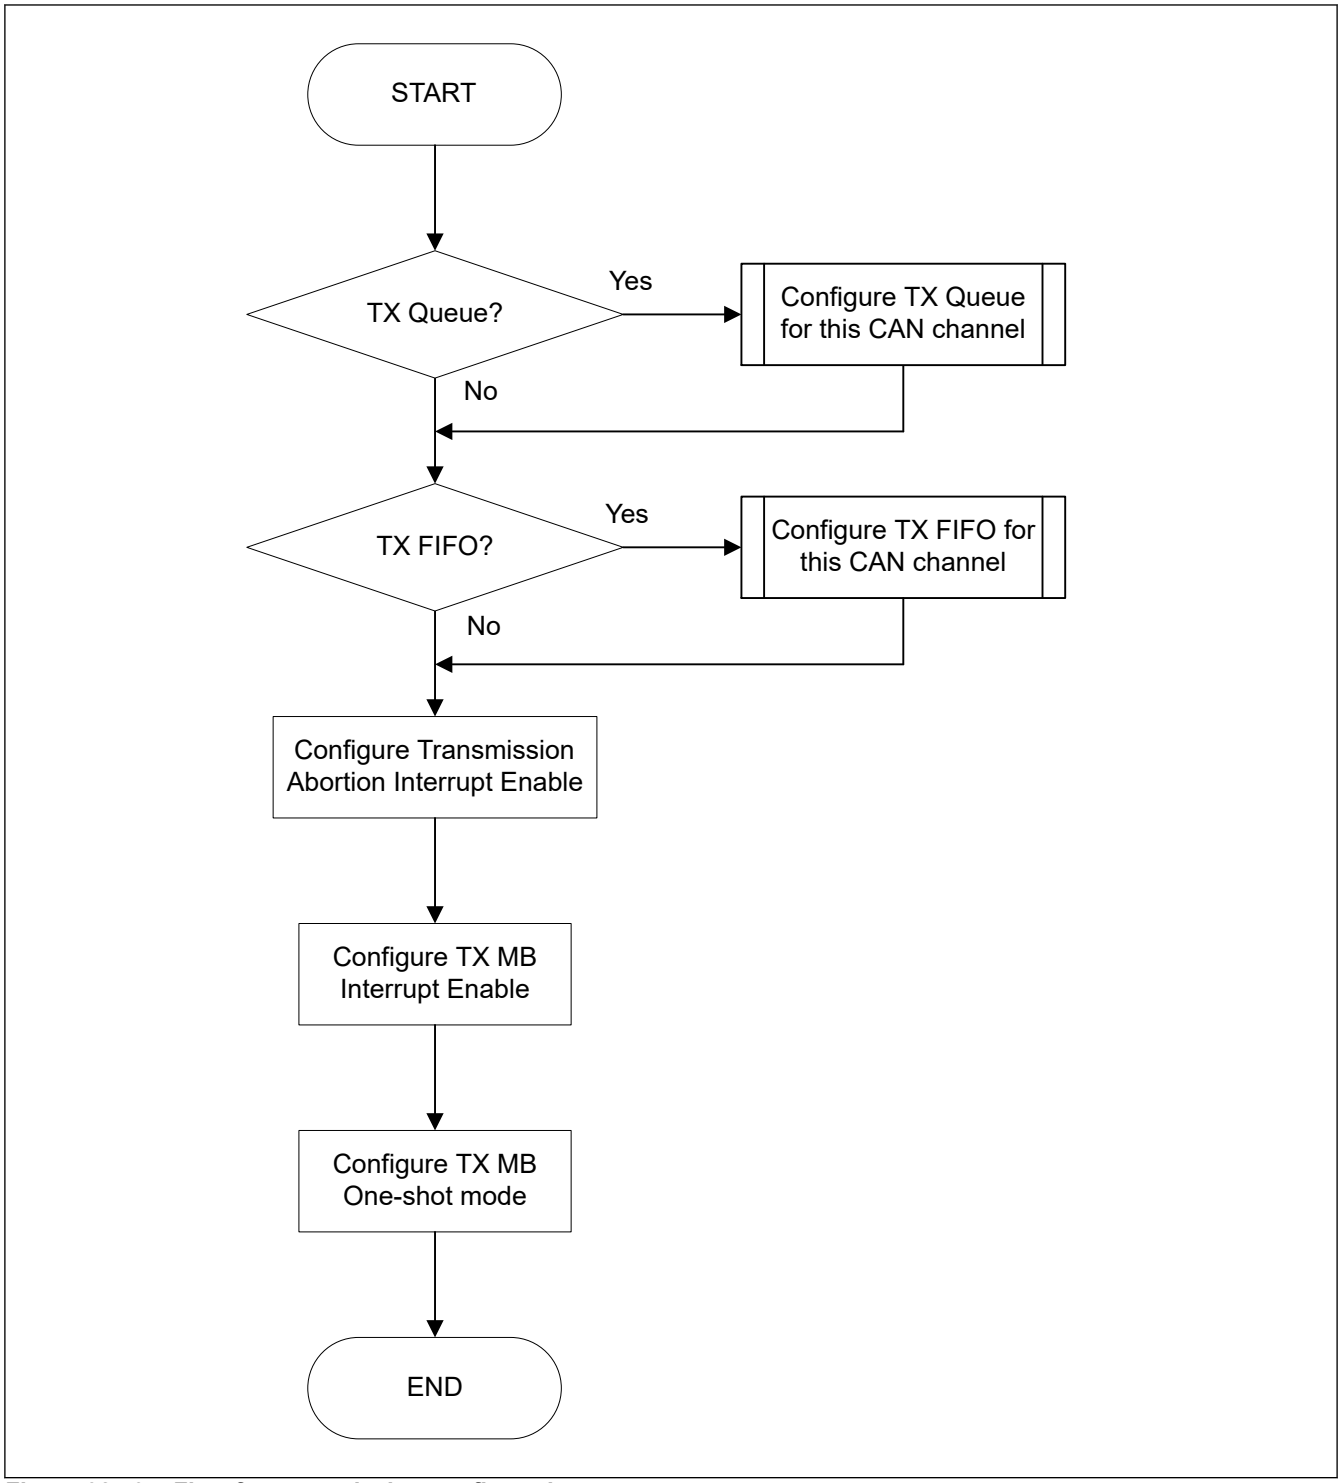

Figure 32.40 Flow for transmission configuration

32.8.2.2 Normal Transmission

Each transmission message buffer has two modes of message transmission:

1. Regular transmission mode
   If the message buffer is placed in regular transmission mode, the data frame or remote frame set in that message buffer can be transmitted.
   Completion of regular transmission can be checked through the related TX Message Buffer Transmission Result flag bits (CFDTMSTSn.TMTRF) in the TX Message Buffer Status Registers. These bits are set to 10b or 11b when the regular transmission is successful.

When arbitration is lost or an error occurs, message transmission is further attempted if no transmission abort request is set for this transmission message buffer.
New internal transmission arbitration for this channel is performed for all message buffers with transmission request.

2. One-shot transmission mode

When the CFDTMCn.TMOM bit of the TX Message Buffer Control Registers is set for a transmission message buffer, the message buffer is placed in One-shot transmission mode and attempts to transmit a message only once.

Completion of One shot transmission can be checked through the related TX Message Buffer Transmission Result Flag bits (CFDTMSTSn.TMTRF) in the TX Message Buffer Status Registers. The CFDTMSTSn.TMTRF bits are set to 10b or 11b when One-shot transmission is successful.

The CFDTMSTSn.TMTRF bits are set to 01b when arbitration is lost or an error occurs during transmission of the related message buffer.

Additional message transmission is not attempted in this case.

The regular transmission request procedure after a configuration is shown in Figure 32.41.

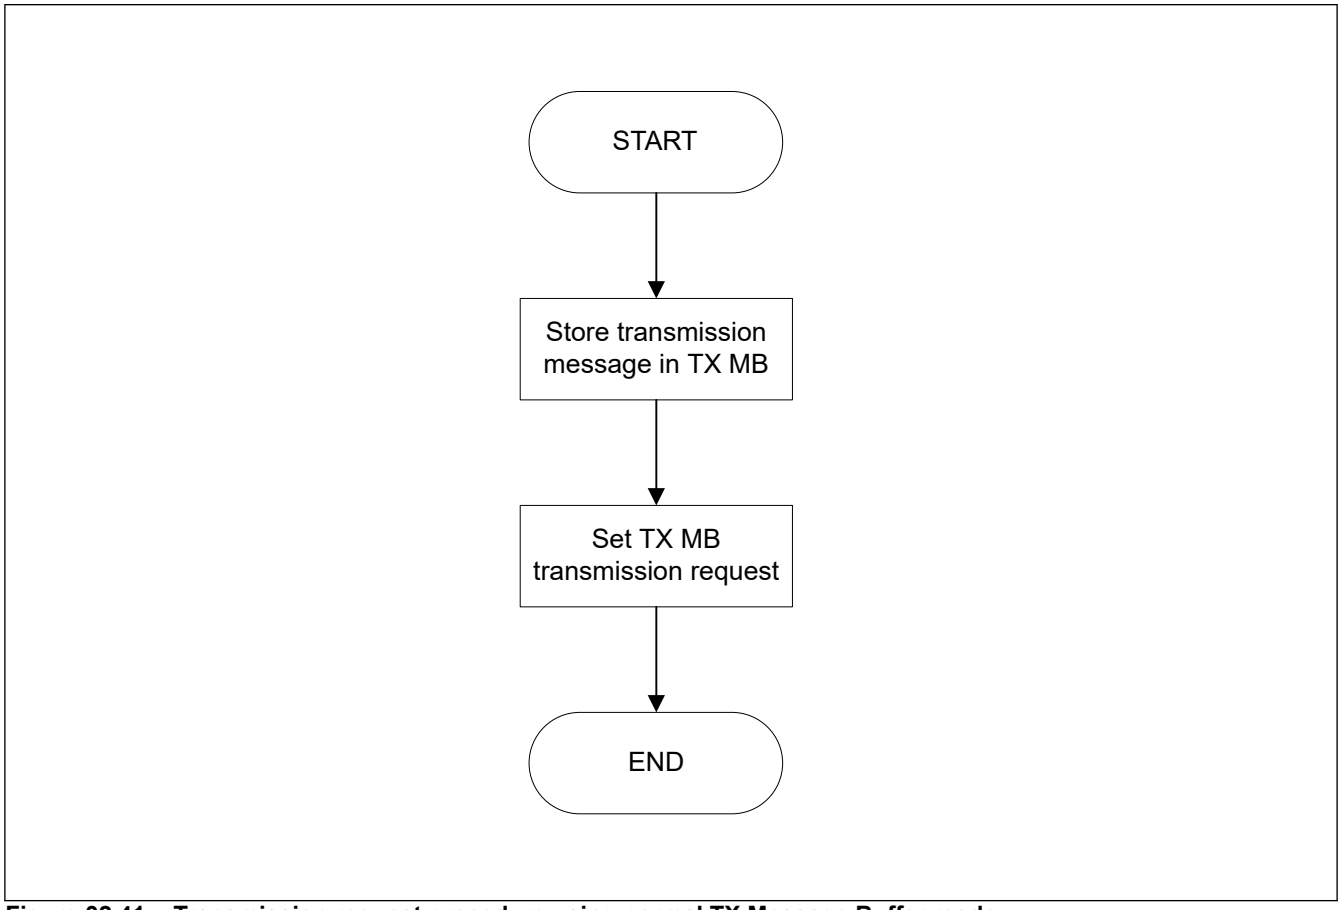

Figure 32.41 Transmission request procedure using normal TX Message Buffer mode

(1) Setting for TX Message Buffer Control Register

Table 32.21 shows configuration of a normal CAN transmission mode.

Table 32.21 Configuration of CAN transmission mode (1 of 2)

Transmission request CFDTMCn.TMTR	Transmission abort request CFDTMCn.TMTAR	One-shot enable CFDTMCn.TMOM	Communication activity
0	0	0	Message buffer disabled
0	0	1	Message buffer disabled

Table 32.21 Configuration of CAN transmission mode (2 of 2)

Transmission request CFDTMCn.TMTR	Transmission abort request CFDTMCn.TMTAR	One-shot enable CFDTMCn.TMOM	Communication activity
1	0	0	Configured as a transmission message buffer for a data frame or a remote frame
1	0	1	Configured as a one-shot transmission message buffer for a data frame or a remote frame
1	1	0	Transmission abort requested
1	1	1	One-shot transmission abort requested

The configuration bits can be configured in the TX Message Buffer Control Registers.

Figure 32.42 shows timings for successful transmission for two message buffers of one channel.

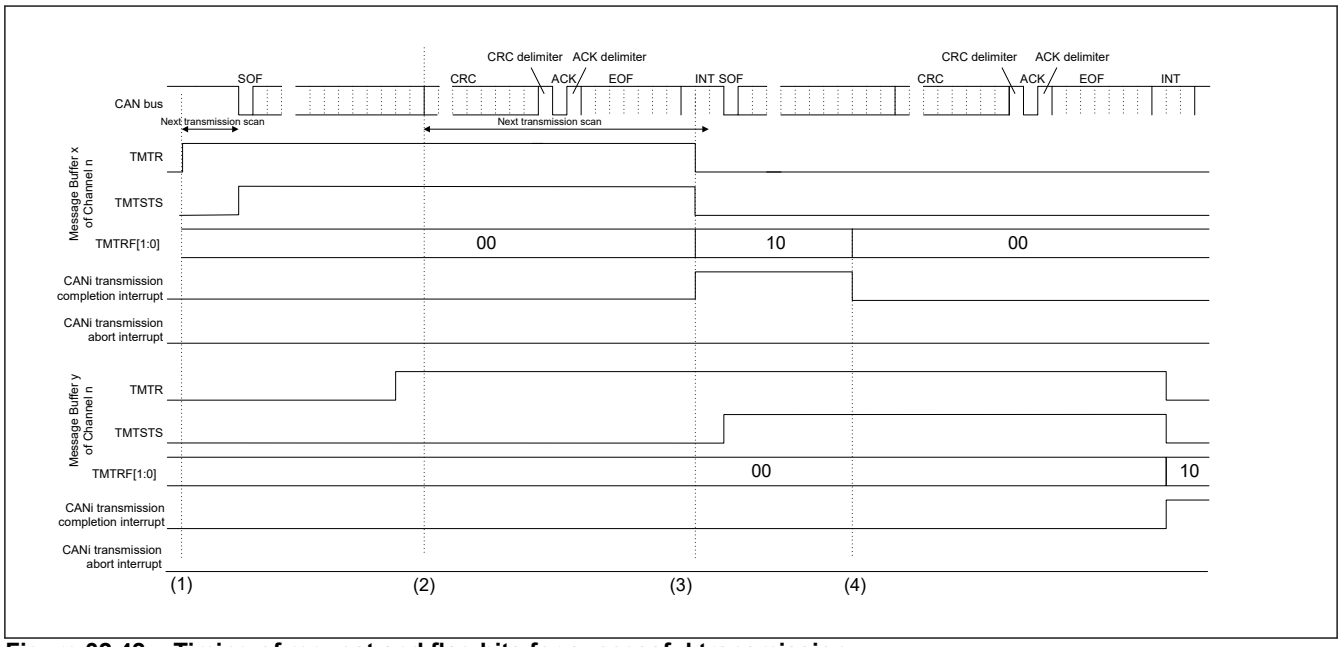

Figure 32.42 Timing of request and flag bits for successful transmission

1. If the CFDTMCn.TMTR bit in the TX Message Buffer Control Registers is set in the bus idle state, the message buffer scanning procedure determines the highest priority message buffer for transmission.
   When the transmission message buffer is determined, the CFDTMSTSn.TMTSTS bit in the related TX Message Buffer Status Registers is set (transmitting/transmitter), and CAN channel starts the transmission *1.
2. At the first bit of CRC, the transmission scanning procedure starts for the next possible transmission when pending transmission requests exist.
   The scan time can be delayed due to other transmission scan on other channels, but it finishes before intermission 3 to be able to continue transmission without any gaps.
3. If the message has been successfully transmitted, the CFDTMSTSn.TMTRF[1:0] bits in the corresponding TX Message Buffer Status Registers are set to 10b and CFDTMSTSn.TMTSTS and the CFDTMCn.TMTR bits are cleared.
   When the TMIE bit in the TX Message Buffer Interrupt Enable Configuration Registers is set (interrupt enabled), the CAN successful transmission interrupt request is generated.
   To clear the related interrupt line, clear the CFDTMSTSn.TMTRF flag bits.
4. Before starting the next transmission, clear the CFDTMSTSn.TMTRF bits. Load the next message in the transmission message buffer and set the CFDTMCn.TMTR bit again.
   CFDTMCn.TMTR bit cannot be set again before CFDTMSTSn.TMTRF[1:0] bits are cleared.

Note 1. If arbitration is lost after the CAN channel starts the transmission, the CFDTMSTSn.TMTSTS bit is cleared.

The transmission scanning procedure is performed again to search for the highest priority transmission message buffer from the beginning of the first CRC bit.

If an error occurs either during transmission or following the loss of arbitration, then during the error frame, the transmission scanning procedure is performed again to search for the highest priority transmission message buffer.

Note: The setting point of CFDTMSTSn.TMTSTS is not always fixed at the start of the SOF. It may be delayed up to the start of the standard ID due to the synchronization logic implemented for the PLL bypass.

Figure 32.43 shows timings for transmission abort for two message buffers of one channel.

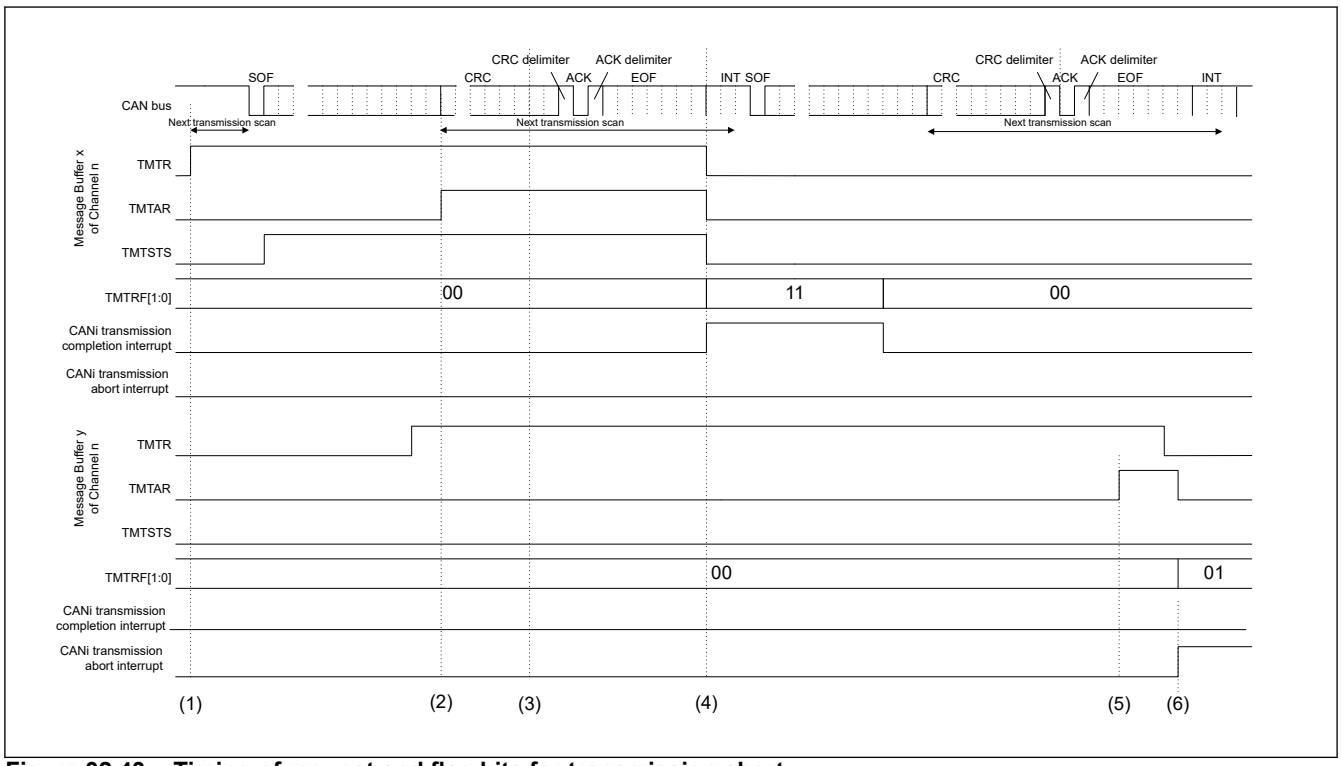

Figure 32.43 Timing of request and flag bits for transmission abort

1. If the CFDTMCn.TMTR bit in the TX Message Buffer Control Registers is set in the bus idle state, the message buffer scanning procedure determines the highest priority message buffer for transmission.
   When the transmission message buffer is determined, the CFDTMSTSn.TMTSTS bit in the TX Message Buffer Status Registers is set (transmitting/transmitter), and CAN channel starts the transmission*1.
2. If the CFDTMCn.TMTAR bit is set when the related message buffer is already selected for transmission or currently transmitting, the message is not aborted, if no error occurs or arbitration is lost.
3. At the first CRC bit, the transmission scanning procedure starts for the next transmission. In this example, timing chart message buffer y is not selected as the next transmission message buffer.
   The scan time can be delayed due to other transmission scan on other channels, but it finishes before intermission 3 to be able to continue transmission without any gaps.
4. If the message has been successfully transmitted, the CFDTMSTSn.TMTRF[1:0] bits in the corresponding TX Message Buffer Status Registers are set to 11b and the CFDTMSTSn.TMTSTS and CFDTMCn.TMTR bits are cleared.
   When the TMIE bit in the TX Message Buffer Interrupt Enable Configuration Registers is set (interrupt enabled), the CAN successful transmission interrupt request is generated.
   To clear the related interrupt line, clear the CFDTMSTSn.TMTRF[1:0] bits.
5. Another CAN node is transmitting on the CAN bus (CFDTMSTSn.TMTSTS is not set). If the CFDTMCn.TMTAR bit is set when the related channel is under transmission scan, the transmission request cannot be cleared.
6. After internal processing time, the transmission is aborted and the CFDTMSTSn.TMTRF[1:0] bits are set to 01b.
   If the message buffer is not transmitting or selected as the next transmission message buffer or under transmit scan, then the abort is immediately accepted and the corresponding CFDTMSTSn.TMTRF[1:0] bits in the TX Message Buffer Status Registers are set to 01b.
   In addition, CFDTMCn.TMTR, and CFDTMCn.TMTAR bits are cleared automatically.
   When the transmission abort interrupt enable TAIE bit of the related Channel Control Register is set then an interrupt is generated for successful transmission abort.

To clear the related interrupt line the CFDTMSTSn.TMTRF[1:0] bits have to be cleared.

Note 1. If arbitration is lost after the CAN channel starts the transmission, the CFDTMSTSn.TMTSTS bit is cleared.

The transmission scanning procedure is performed again to search for the highest priority transmission message buffer from the beginning of the first CRC bit.

If an error occurs, either during transmission, or following the loss of arbitration, then during the error frame, the transmission scanning procedure is performed again to search for the highest priority transmission message buffer.

32.8.2.3 TX FIFO or GW FIFO Transmission

Three common FIFO buffers are assigned to each Chanel. The three FIFO buffers can be linked to any normal TX message buffer position for this channel with the CFDCFCCn.CFTML bits in the Common FIFO Configuration/Control Register if configured in TX or GW mode.

When the transmission scan starts and the FIFO buffer corresponding to this TX message buffer is enabled, the relevant message in the FIFO buffer participates in the transmission scan.

Configuration of a TX message buffer linked to a FIFO buffer configured in TX or GW mode should not be done.

(1) TX FIFO Operation

CAN messages can be written into the TX FIFO by writing to the corresponding FIFO Access registers.

When the value 0xFF is written into the corresponding FIFO Pointer Control Register, the message count of the related FIFO is incremented by 1.

Only write to the FIFO Pointer Control register after writing the complete message to the corresponding FIFO Access registers. If the message count matches the FIFO depth, the FIFO Full flag is set.

The oldest message in the TX FIFO is included in the scan for transmission by the corresponding CANFD module channel logic.

When a message is successfully transmitted from the TX FIFO, the message count value is decremented by 1. When all the messages from the FIFO are transmitted, the FIFO Empty flag is set.

The interrupt generation conditions for the TX FIFO buffers can be configured by configuring the CFDCFCCn.CFIM bit in the corresponding Common FIFO Configuration/Control Registers.

If CFDCFCCn.CFIM bit is 0, then interrupt is generated when the last message is successfully transmitted from the TX FIFO buffer.

If CFDCFCCn.CFIM bit is 1, then interrupt is generated for every successfully transmitted message from the TX FIFO buffer.

The Common FIFO can set interrupt when CAN frame transmission is complete.

The Common FIFO buffer configured in TX Mode can be disabled by clearing the CFDCFCCn.CFE bit in the Common FIFO Configuration/Control Registers. If this bit is cleared to 0, the FIFO Empty flag is set as follows:

- Immediately if the message from the TX FIFO is neither scheduled for the next transmission nor in transmission
- Following the transmission completion, the detection of an error on the CAN bus, loss of arbitration or transition to Channel or Global Halt mode if the transmission from the TX FIFO is already scheduled for transmission or already in transmission.

Note: The Common FIFO buffer is considered as disabled after clearing the CFDCFCCn.CFE bit only when the Empty flag is set for the corresponding Common FIFO buffer.

Other possible messages pending from the TX FIFO are lost and their transmission must be requested again. Before CFDCFCCn.CFE is set again, ensure that CFDCFSTSn.CFEMP bit is set and that there are no pending abort from the TX FIFO.

When the CFDCFCCn.CFE bit is cleared, the message read and write pointers of the FIFO are cleared and are no longer active. Therefore, all messages in the FIFO buffers are lost and no further message can be stored into the FIFO.

The FIFO transmission request procedure after configuration is shown in Figure 32.44.

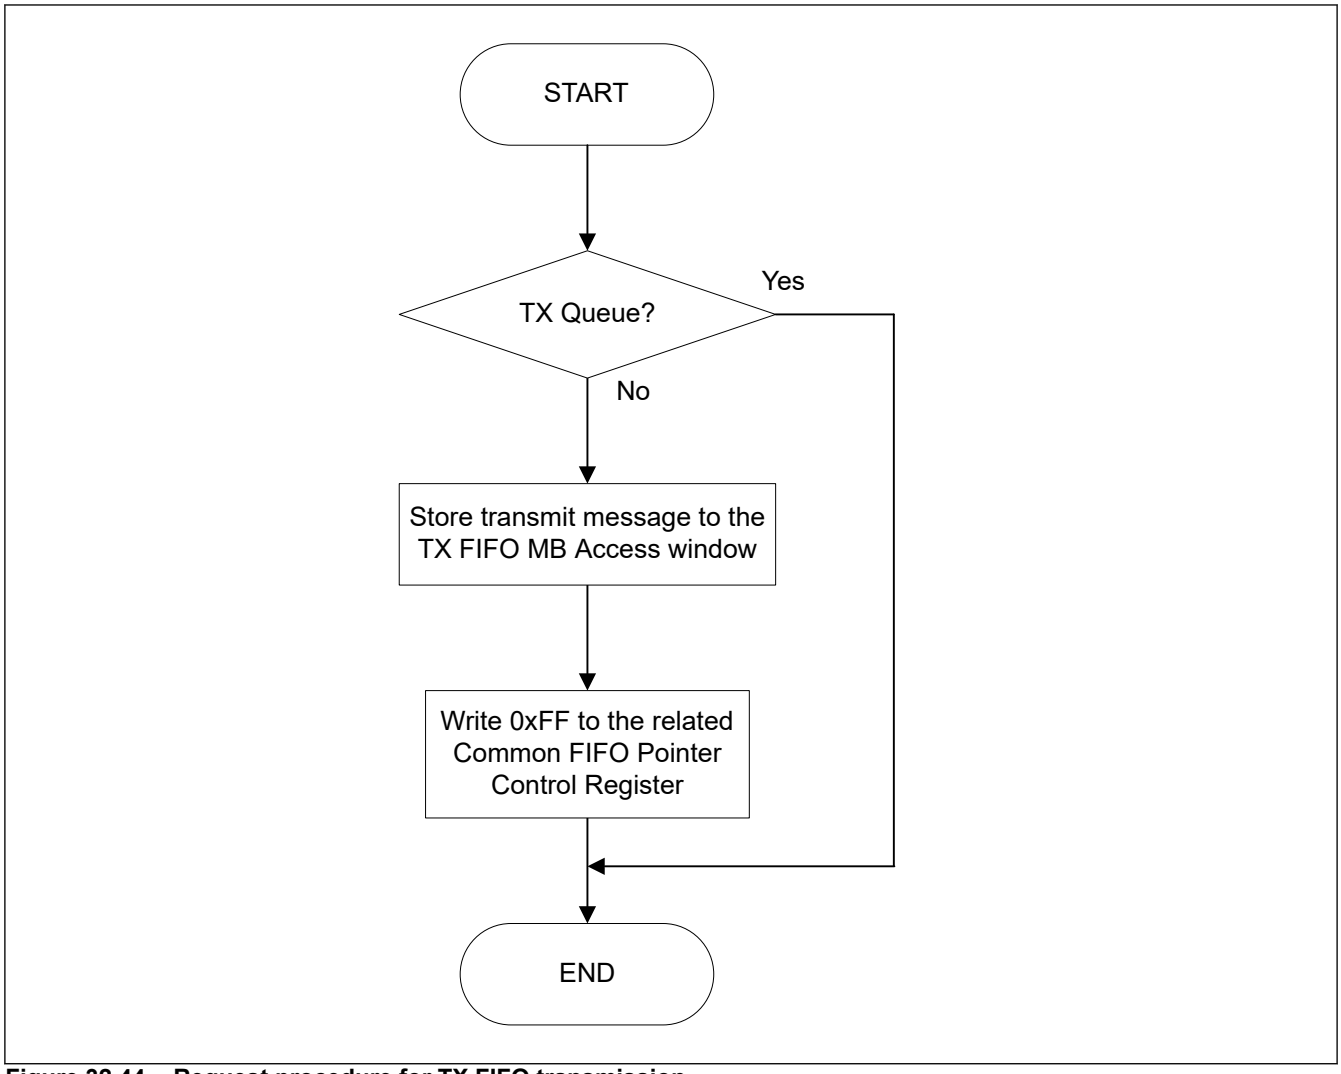

Figure 32.44 Request procedure for TX FIFO transmission

(2) GW FIFO Operation

The AFL entries for routing the received messages to GW FIFO buffers should be configured based on the system requirements. The matching AFL entry selects the GW FIFO buffer for storage of a received message on any of the CAN channels.

When a message is successfully received and stored in a GW FIFO buffer, the FIFO message count in the corresponding FIFO Status Register is incremented by 1. If the message count matches the FIFO depth, the FIFO Full flag is set.

The oldest message in the GW FIFO is included in the scan for transmission by the corresponding CANFD module channel logic.

When a message is successfully transmitted from the GW FIFO, the message count value is decremented by 1. When all messages from the GW FIFO are transmitted, the FIFO Empty flag is set.

If a new message is stored into the FIFO when the FIFO message count matches the FIFO depth (FIFO Full condition), the FIFO Message Lost flag is set and the new message is lost (no overwrite of already stored messages takes place).

In GW mode, when a transmit/receive FIFO buffer is receiving a new message while the transmit/receive FIFO buffer is already full of data, the oldest data of the buffer is overwritten with the message received or the message is discarded. The behavior is determined by setting the CFDCFCCEn.CFMOWM bit.

- When CFDCFCCEn.CFMOWM = 0:
  When writing of data is required due to reception of a new message while a transmit/receive FIFO buffer is full of data, the received message is discarded and the CFDCFSTSn.CFMLT bit is set to 1.

- When CFDCFCCEn.CFMOWM = 1:

When writing of data is required due to reception of a new message while a transmit/receive FIFO buffer is full of data, the oldest data in the buffer is overwritten with the received message.
The read pointer of the transmit/receive FIFO buffer simultaneously moves to the next oldest message. The CFDCFSTSn.CFMOW bit is then set to 1, which notifies that the oldest message has been overwritten with the received message.
In addition, when a CAN bus error or arbitration-lost for the transmitting message occurs in transmit/receive FIFO buffer full, the transmitting message is lost and retransmission of the message is not performed. The read pointer moves to the next message automatically.

The interrupt generation conditions for the GW FIFO buffers can be configured by setting the CFDCFCCn.CFIM bit in the corresponding Common FIFO Configuration/Control Registers.

If CFDCFCCn.CFIM bit is 0, the RX Interrupt flag is set when the FIFO counter increments and reaches value configured by CFDCFCCn.CFIGCV and the TX Interrupt flag is set when FIFO transmits the last message successfully.

If CFDCFCCn.CFIM bit is 1, the RX Interrupt flag is set at the end of storage of every received message and the TX Interrupt flag is set if a message is successfully transmitted from the FIFO.

The Common FIFO can set interrupt when:

- CAN frame transmitted is complete
- CAN frame reception is complete
- FIFO is in full status in RX mode or GW mode.

When CFDCFCCEn.CFBME = 1, the mode is FIFO buffering, send data is stored in Common FIFO, and transmission is stopped. Transmission is started if it is set as CFDCFCCEn.CFBME = 0.

The Common FIFO buffers configured in GW mode can be disabled by clearing the CFDCFCCn.CFE bit in the Common FIFO Configuration/Control Register. If this bit is cleared, the GW FIFO becomes empty as follows:

- Immediately if the message from the GW FIFO is neither scheduled for the next transmission nor in transmission
- Following the transmission completion, the detection of an error on the CAN bus, loss of arbitration or transition to Channel or Global Halt mode if the transmission from the GW FIFO is already scheduled for transmission or already in transmission.

Other possible messages pending from the GW FIFO are lost.

Before CFDCFCCn.CFE is set again, ensure that the CFDCFSTSn.CFEMP bit is set and that there are no pending abort from the GW FIFO.

When the CFDCFCCn.CFE bit is cleared and the CFDCFSTSn.CFEMP bit is set, the read and write pointers of the message in GW FIFO are cleared and are no longer active. Therefore, all messages in the GW FIFO buffers are lost and no further message can be stored into the GW FIFO.

In applications intended to be used as CAN-to-CAN gateways, it is recommended that if the Error State Indication (ESI) information of the routing messages is not replaced by the sending node error state indication. For this, each channel has the Control Function register CFDCnFDCFG.ESIC to replace their own ESI information by the routing ESI information.

Note: If the sending node is error-passive, the ESI bit is sent anyway as error-passive (ESI = 1).

Note: This feature is not available in classical CAN function because CFDCnFDCFG is not in classical CAN.

(3) Interval Timer for FIFO Transmission

For each Common FIFO in TX or GW mode, it is possible to specify a delay between two consecutive messages that are configured for transmission from the same FIFO buffer. This delay is called interval time. This interval time starts after the first message has been successfully transmitted from the FIFO buffer after the CFDCFCCn.CFE bit is set.

When the Common FIFO in TX or GW mode is enabled, the first message is transmitted without considering this interval time.

The interval timer stops counting when:

- FIFO is disabled by clearing the CFDCFCCn.CFE bit.
- CAN channel is in CH_RESET mode.

The interval time is specified by the CFDCFCCn.CFITT value from 0 to 255 timer units in the Common FIFO Configuration/Control Register.

The timer unit can be defined based on two different source clocks for the interval timer. To disable the interval timer for FIFO transmission, select a value of 0.

The timer source can be selected with the configuration bit CFITSS in the Common FIFO Configuration/Control Register.

If CAN channel bit time clock is configured as the clock source, and the CAN channel enters CH_HALT, CH_RESET, or CH_SLEEP mode, the interval timer is stopped for that channel.

If peripheral clock is selected as the interval timer clock source, the interval timer is stopped only when the CAN channel is in CH_RESET or CH_SLEEP mode.

The reference clock can be used to configure the interval time in fixed time units. It is based on the peripheral clock. The reference clock prescaler value CFDGCFG.ITRCP in the Global Configuration Register defines the relation between the peripheral clock frequency/period and the reference clock period.

See Table 32.22 for CFDGCFG.ITRCP configuration values to achieve different reference clock periods based on the peripheral clock frequency and period.

Table 32.22 Configuration example for the reference clock of the FIFO interval timer

Reference clock/Peripheral clock	1 µs	100 µs	500 µs
16 MHz/62.5 ns	16	1600	8000
20 MHz/50 ns	20	2000	10000
32 MHz/31.25 ns	32	3200	16000
50 MHz/20 ns	50	5000	25000

The reference clock resolution can be specified by the interval timer reference clock resolution value CFDCFCCn.CFITR in the Common FIFO Configuration/Control Register.

The interval time is based on the reference clock period multiplied by the configured value (x1 or x10). The reference clock based interval timer can be used to satisfy the requirements of the ISO 15765-2 Separation Time. The whole range for the separation time from 100 µs to 127 ms can be covered.

The specified interval time starts after successful transmission event (after EOF7 state of the CAN protocol).

When the interval time has elapsed, the next transmission request is raised by the related TX/GW FIFO. Therefore, the interval time defines the minimum time between two messages transmitted from one FIFO.

The next message is sent at earliest after this interval time. Figure 32.45 shows an example timing of the internal processing.

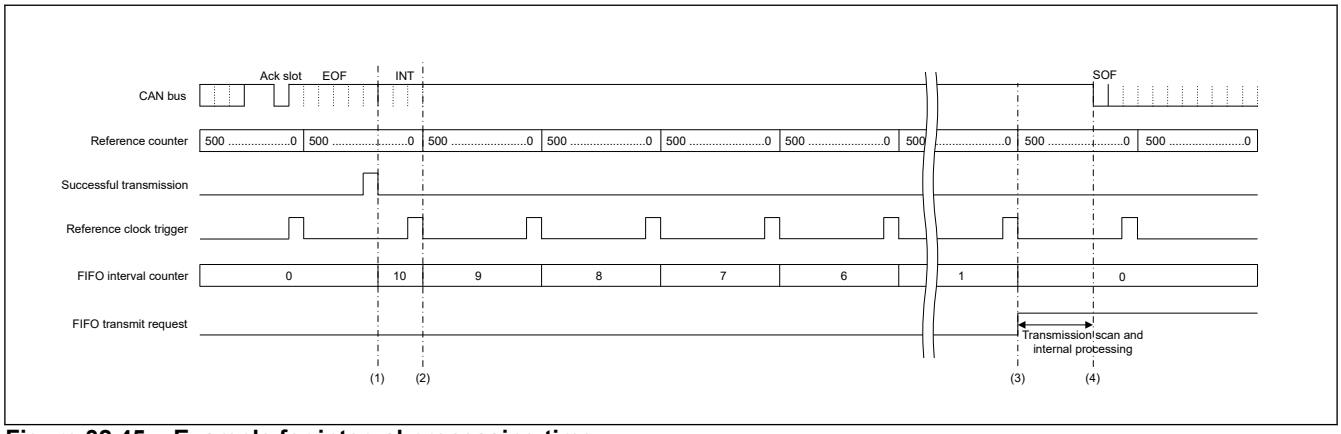

Figure 32.45 Example for interval processing time

The configuration for the timing in Figure 32.45 is as follows:

- Peripheral clock frequency = 50 MHz
- Interval timer reference clock (CFDGCFG.ITRCP) = 500 times
- Reference clock from the settings in Figure 32.45 = 10 µs

- Common FIFO interval timer source selection (CFDCFCCn.CFITSS) = 0
- Common FIFO interval timer resolution (CFDCFCCn.CFITR) = 0
- Common FIFO interval transmission time (CFDCFCCn.CFITT) = 10 times
- Theoretical message separation interval = 100 µs

1. Internal FIFO interval timer is restarted with the occurrence of successful transmission result. This restart is not synchronized to the reference clock trigger. Therefore, the first interval is counting less or equal to 1 reference clock interval.
2. With the next reference clock trigger the FIFO interval timer is decremented.
3. When the FIFO interval timer reached the value 0, the FIFO transmit request is set.
4. When the FIFO is selected for transmission, the transmission starts. Due to internal processing, this usually takes less than 3 CAN bit time, between the internal FIFO transmit request set in step 3. and the actual transmission.

In the worst case when multiple events such as a reception scan, an internal message routing, a transmit scan on all channels occur, it can take up to 1152 peripheral clock cycles.

As shown in Figure 32.45, it is not guaranteed that the minimum interval is always equal to the configured value. If a minimum time must never be breached, configure CFDCFCCn.CFITT to the required minimum value plus 1.

If additional TX message buffers or TX/GW FIFO are configured for transmission of the same channel, the real delay between two messages transmitted from a TX FIFO can be much longer than specified by the interval time. This is due to higher priority message transmission from these TX message buffers or TX/GW FIFO.

Figure 32.46 shows a block diagram of the FIFO interval time generation circuit.

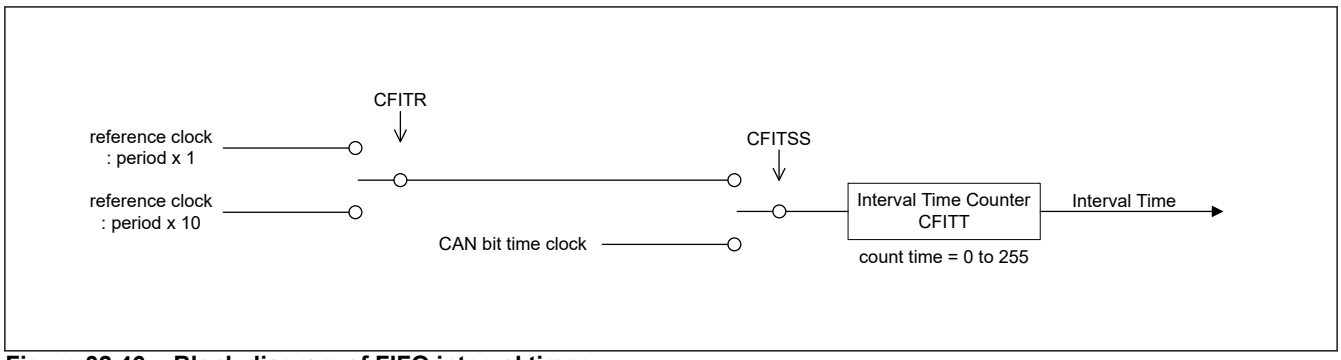

Figure 32.46 Block diagram of FIFO interval timer

32.8.2.4 TX Queue

Each enabled TX Queue for a specific channel consists of three to 16 TX message buffers, which are accessed through one access window. One channel has four TX Queues:

- The first TX Queue can be configured with a depth of three up to eight buffers and uses TX Message Buffer No. 0 as access window (referred to as TXQ0)
- The second TX Queue can be configured with a depth of three up to eight buffers and uses TX Message Buffer No. 7 as access window (referred to as TXQ1)
- The third TX Queue can be configured with a depth of three up to eight buffers and uses TX Message Buffer No. 32 as access window (referred to as TXQ2)
- The fourth TX Queue can be configured with a depth of three up to eight buffers and uses TX Message Buffer No. 39 as access window (referred to as TXQ3).

All the TXQ0, TXQ1, TXQ2 and TXQ3 messages enter the priority comparison for transmission, which should be only ID Priority (CFDGCFG.TPRI = 0).

The registers for TXQ0 are:

- CFDTXQCC0[n]
- CFDTXQSTS0[n]

- CFDTXQPCTR0[n].

The registers for TXQ1 are:

- CFDTXQCC1[n]
- CFDTXQSTS1[n]
- CFDTXQPCTR1[n].

The registers for TXQ2 are:

- CFDTXQCC2 [n]
- CFDTXQSTS2[n]
- CFDTXQPCTR2[n].

The registers for TXQ3 are:

- CFDTXQCC3[n]
- CFDTXQSTS3[n]
- CFDTXQPCTR3[n].

See related access registers TX Message Buffer ID Registers (TMID[m]), TX Message Buffer Pointer Registers (TMPTR[m]), TX Message Buffer Data Field 0 Registers, and TX Message Buffer Data Field 1 Registers (TMDF[0:1][m]) when access window TXQ0, TXQ1, TXQ2, or TXQ3 is used.

The depth of each TXQ0 buffer can be configured by writing to the CFDTXQCC0n.TXQDC[12:8] bits of the TX Queue Configuration/Control Register. TXQ0 can be set from TXMB0 to TXMB7 as a queue buffer at the maximum.

The 15 available options for the depth configuration of TXQ0 buffer are:

- 0x00: TX Queue disabled
- 0x01: Reserved
- 0x02: 3 messages
- ⋮
- 0x0D: 14 messages
- 0x0E: 15 messages
- 0x0F: 16 messages

The depth of each TXQ1 buffer can be configured by writing to the CFDTXQCC1n.TXQDC[12:8] bits of the TX Queue Configuration/Control Register. TXQ1 can be set from TXMB7 to TXMB0 as a queue buffer at the maximum.

The 15 available options for the depth configuration of TXQ1 buffer are:

- 0x00: TX Queue disabled
- 0x01: Reserved
- 0x02: 3 messages
- ⋮
- 0x0D: 14 messages
- 0x0E: 15 messages
- 0x0F: 16 messages

The depth of each TXQ2 buffer can be configured by writing to the CFDTXQCC2n.TXQDC[12:8] bits of the TX Queue Configuration/Control Register. TXQ2 can be set from TXMB32 to TXMB39 as a queue buffer at the maximum.

The 15 available options for the depth configuration of TXQ2 buffer are:

- 0x00: TX Queue disabled
- 0x01: Reserved

- 0x02: 3 messages
- ⋮
- 0x0D: 14 messages
- 0x0E: 15 messages
- 0x0F: 16 messages

The depth of each TXQ3 buffer can be configured by writing to the CFDTXQCC3n.TXQDC[12:8] bits of the TX Queue Configuration/Control Register. TXQ3 can be set from TXMB39 to TXMB32 as a queue buffer at the maximum.

The 15 available options for the depth configuration of TXQ3 buffer are:

- 00000b: TX Queue disabled
- 00001b: Reserved
- 00010b: 3 messages
- ⋮
- 0x0D: 14 messages
- 0x0E: 15 messages
- 0x0F: 16 messages

When using TXQ1 and TXQ0 simultaneously, the depth of TXQ is 8 or less in total.

When using TXQ3 and TXQ2 simultaneously, the depth of TXQ is 8 or less in total.

Do not access all the TX message buffers forming the TX Queue directly (except TX Message Buffer No. 39, TX Message Buffer No. 32, TX Message Buffer No. 7 and TX Message Buffer No. 0, which act as TX Queue access window).

When CFDGAFLP0n.GAFLSRD i (i = 0 to 2) is set and the CFDTXQCCin.TXQGWE (i = 0 to 2, n = 0 to 7) is also set, a receiving frame is stored in the target TXQ as send data by routing.

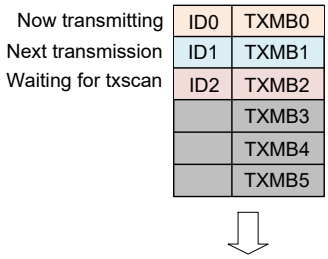
When CFDTXQCCn.TXQOWE bit is 1, the TX Queue is in TX Queue Overwrite mode. If the message of the same ID is stored in TX Queue when a frame is received and it is stored in TX Queue, an old message is overwritten by a new message. Therefore, an old message is not transmitted. When the old message of the same ID is transmitting and a CAN bus error and an arbitration-lost occur, the message of old ID is not resent.

When using the function in GW mode and TX Queue Overwrite mode, the depth of TXQ (CFDTXQCC0n.TXQDC) should be configured to a value that is the various number of ID used in the TX Queue plus 3. If it accesses by routing in GW mode when a TXQ buffer is full, CFDTXQSTS.TXQMLT is set and send data is thrown away. The function is valid for the standard ID frame and is invalid for the extended ID frame.

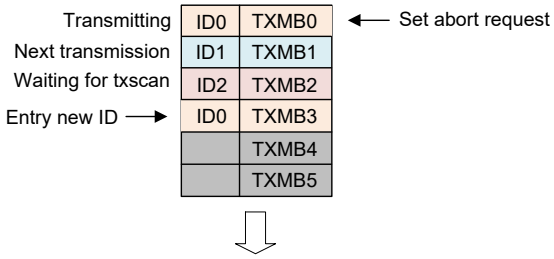
Operation of the TXQ same ID over-writing function in GW mode is shown in the following figure.

TXQ0 depth = 6 buffers, ID is 3, TXQ0 GW mode

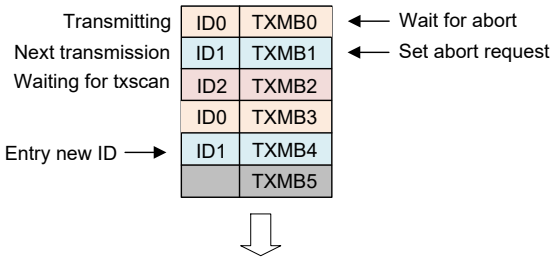
1. Three frames are stored.



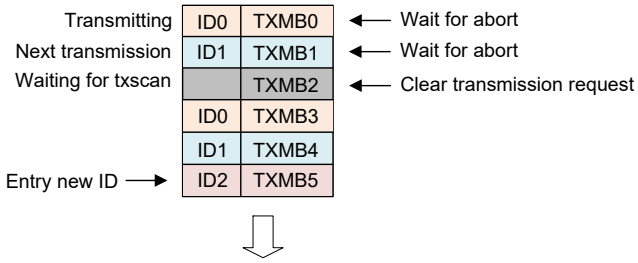
2. ID0 is stored in TXMB3 and abort is set as TXMB0.



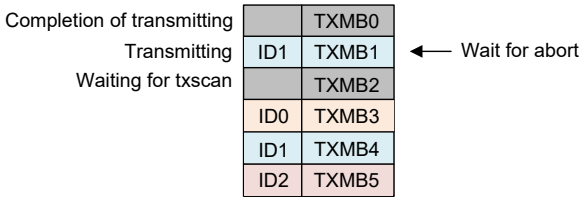
3. ID1 is stored in TXMB4 and abort is set as TXMB1.



4. ID2 is stored in TXMB5 and the transmit request of TXMB2 is cleared.



5. Transmission of TXMB0 is complete and transmission of ID1 of TXMB1 is started.



When a system writes in TXQ, it writes in send data, after checking the state of TXQ.

Do not access or configure the related TX Message Buffer Control Registers.

The messages stored to the TX Queue access window are internally stored to a free buffer of the TX Queue.

When the buffer is full, no further access should be done to the queue, until it is no longer full. If access is a software write when the buffer of TXQ is full, send data is overwritten.

The TX Queue can be disabled by clearing the TXQE bit in the TX Queue Configuration/Control Register. If this bit is cleared, the TX Queue Empty flag is set as follows:

- Immediately if the message from the TX Queue is neither scheduled for the next transmission nor in transmission
- Following the transmission completion, the detection of an error on the CAN bus, loss of arbitration or transition to Channel or Global Halt mode if the transmission from the TX Queue is already scheduled for transmission or already in transmission.

Note: The TX Queue is disabled only when the Empty flag is set after clearing the TXQE bit for the corresponding TX Queue.

Other possible messages pending from the TX Queue are lost and their transmission must be requested again.

Before TXQE is set again, ensure that the CFDTXQSTSn.TXQEMP bit is set and that there is no pending abort from the TX Queue.

When the TXQE bit is cleared, all messages in the TX Queue buffers are lost and no further message should be stored in the TX Queue.

When a message has been stored to the TX Queue, write 0xFF in the TX Queue Pointer Control Register. This sets the transmit request automatically and changes the internal message buffer pointer to the next free message buffer location of the TX Queue.

Note: If two messages with the same ID are stored in the TX Queue, the order of transmission of these messages can be different from the order in which they were stored in the TX Queue.

To avoid this condition, it is important to confirm that the previous message with the same ID was successfully transmitted before a new message with the same ID is stored in the TX Queue.

If TX Queue Overwrite mode is used, the frame of the same ID is rewritten on a new frame.

For the TX Queue, a dedicated interrupt can be enabled by setting the TXQIE bit of the TX Queue Configuration/Control Register.

The interrupt mode can be configured with the CFDTXQCCn.TXQIM bit of the same register either to generate an interrupt for every transmitted message or for the last transmitted message.

The TX Queue transmission request procedure after configuration is shown in Figure 32.48.

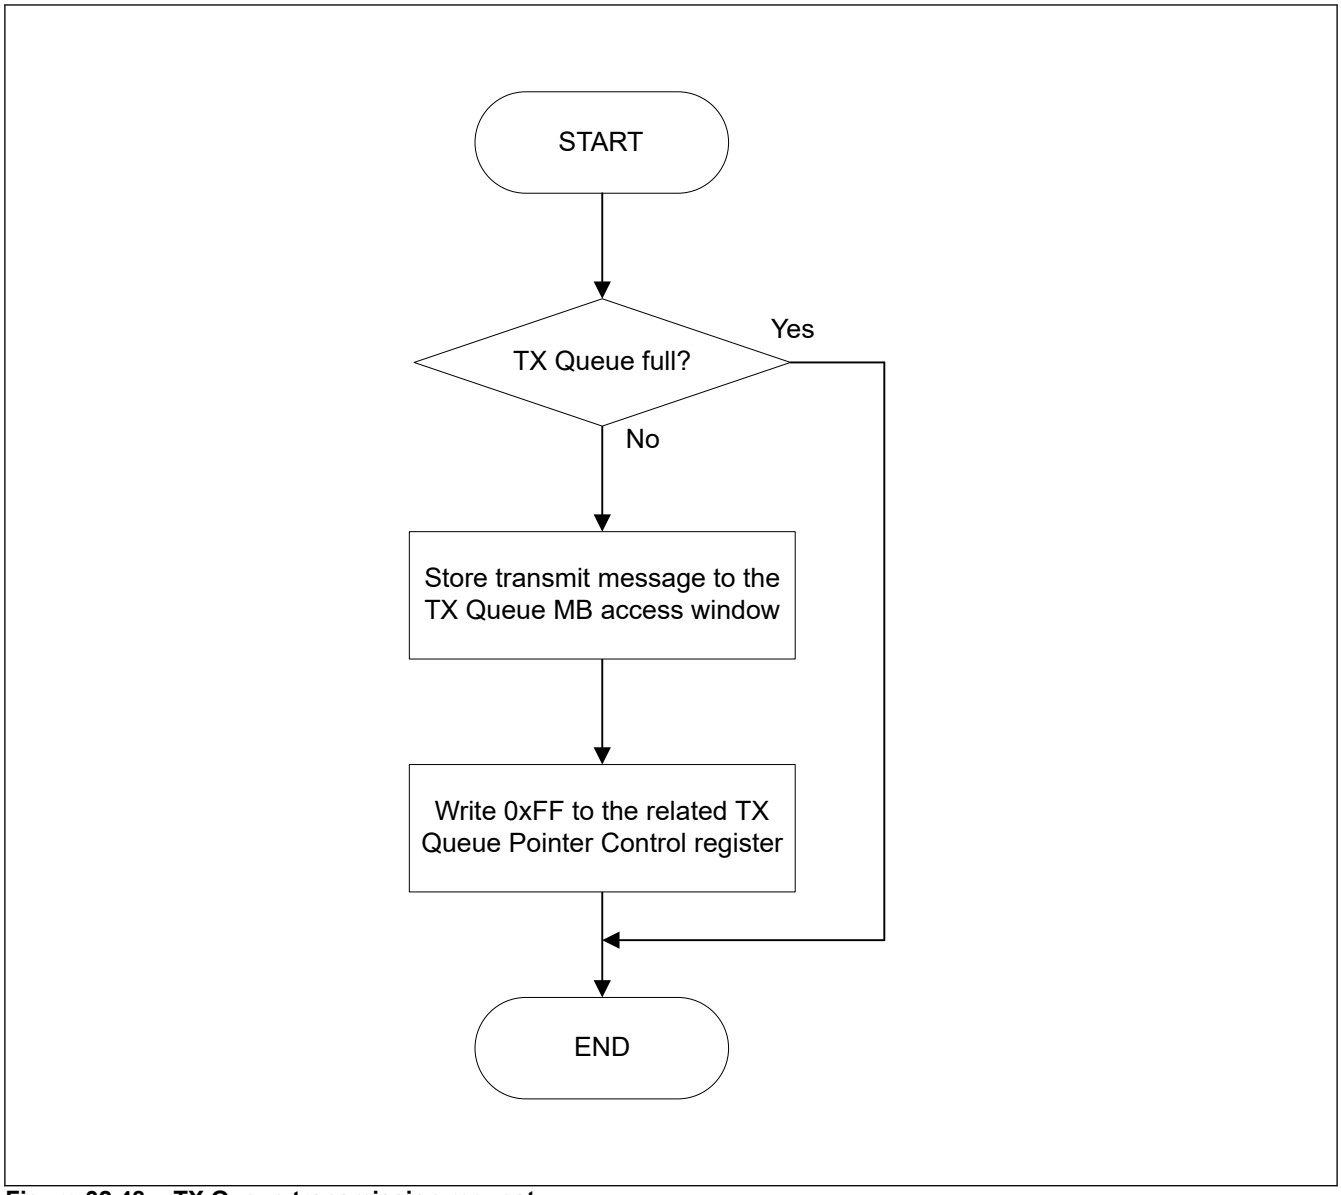


Figure 32.48 TX Queue transmission request

TXQ name	Access window	Range width	Direction	Hardware routing access point	CPU access point	DMA access point	Note
TXQ0	TXMB0	0, 3-16	TXMB0 → TXMB7	Yes	Yes	Yes	When using both TXQ0 and TXQ1, the total number of stages is 8 or less
TXQ1	TXMB7	0, 3-16	TXMB7 → TXMB0	Yes	No	No	
TXQ2	TXMB32	0, 3-16	TXMB32 → TXMB39	Yes	No	No	When using both TXQ2 and TXQ3, the total number of stages is 8 or less
TXQ3	TXMB39	0, 3-16	TXMB39 → TXMB32	No	Yes	Yes	

TXQ0 can use hardware routing access, CPU access, and DMA access. However, these access methods should not be used simultaneously. Only choose one access method.

32.8.2.5 TX History List

The TX History List function records the information of the successfully transmitted message in the TX History List Buffers for each CAN channel. Two TX History List buffers are provided for each CAN channel and each THL buffer can store up to 16 TX History List entries for a CAN channel.

The CFDTHLCCn.THLDTE bit of the TX History List Configuration/Control Register can be used to configure if only message information from TX FIFO or TX Queue is stored, or if all transmit message information from TX Queue, TX FIFO, or normal TX message buffers is stored in the TX History List for a CAN channel.

When a CFDTHLCCn.THLDGE bit is set, the information on all the frames transmitted in Gateway mode is stored in TX History List. Each transmit message can be individually configured for acceptance to the TX History List with the CFDCFID.THLEN bit in the Message Buffer Pointer Register.

The message information is stored to the TX History List Buffer of a CAN channel after the message is successfully transmitted on that CAN channel.

Storing to the list is not synchronized with the status of CFDTMSTSn.TMTRF[1:0] bits in the TX Message Buffer Status Register.

Due to internal processing, the storage to the list can happen with a delay after the successful transmission indication.

Storing the TX History List data can be recognized by the condition that the THLIF is set to 1 when the THLIE bit is configured to 1 or when the TX History List counter CFDTHLSTSn.THLMC[5:0] is increased.

The delay time is dependent on the number of channels due to internal processing.

- Maximum delay time from setting the CFDTMSTSn.TMTRF to store the TX History List data is 224 peripheral bus clock cycles.

The History list records the following information of a transmitted message:

- Buffer type:
  - 001: TX Message Buffer
  - 010: TX FIFO
  - 100: TX Queue
- Buffer number:
  TX message buffer, TX Queue message buffer or TX message buffer link for the Common FIFO buffer from which transmission occurred. The number depends on the buffer type. See Table 32.23.
- Transmission ID:
  Transmission pointer stored in the transmission message
- Transmit timestamp:
  Message timestamp captured at capture point as configured by CFDGFDCFG.TSCCFG.
- Transmission information label:
  Transmission information label stored in the transmission message.
- Transmit gateway buffer indication:
  When data is transmitted from gateway, CFDTHLACC0n.TGW bit is set to 1.

Table 32.23 TX History List Buffer number entry

BT[2:0] Buffer Type		
001b	**101b**	**100b**
TX Message Buffer	**TX FIFO**	**TX Queue**
TXMB0	Number shown corresponds to the common FIFO. TX Message Buffer Link CFTML of the related Common FIFO configuration	Number shown corresponds to the message buffer belonging to the TX Queue for which the frame was transmitted
TXMB1		
TXMB2		
TXMB3		
TXMB4		
TXMB5		
TXMB6		
TXMB7		
TXMB32		
TXMB33		
TXMB34		
TXMB35		
TXMB36		
TXMB37		
TXMB38		
TXMB39		

The Transmission ID entry is used to identify which message of a TX FIFO or TX Queue has been successfully transmitted because the TX FIFO or TX Queue number alone is not sufficient.

Therefore, a unique number can be attached to each transmission message stored in a TX FIFO or TX Queue. This unique identification number should be written to the CFDCFFDCSTSn.CFPTR[15:0] part of the Common FIFO Access Pointer Register for a TX FIFO or to the CFDTMFDCTRn.TMPTR[15:0] part of the TX Message Buffer Pointer Register of the TX Queue access window message buffer.

When the message is successfully transmitted, this identification number is stored together with the other message related information to the TX History List and can be read using the Transmission ID (TID) of the TX History List Access Register.

Also, for normal TX message buffers, the CFDTMFDCTRn.TMPTR[15:0] part of the TX Message Buffer Pointer Register is stored in the Transmission History List and the information label is the same.

Figure 32.48 shows a transmission preparation flow when TX History List is used.

Read access to the TX History List Access Register is done for every single entry.

After reading one entry, 0xFF must be written to the corresponding TX History List Pointer Control Register to be able to access the next entry until TX History List is empty.

Figure 32.49 shows an example flow for processing the TX History List information.

The TX History Lists have dedicated interrupts, which can be configured with the CFDTHLCCn.THLIM bit of the corresponding TX History List Configuration/Control Registers and enabled with the CFDTHLCCn.THLIE bit of the same registers, either to generate an interrupt when the History List reached a filling level of 75% or for every new TX History List entry.

An entry lost indication is flagged by the CFDTHLSTSn.THLELT bit in the TX History List Status Register. The status of this bit is also shown by the THLES bit in the Global Error Flag Register.

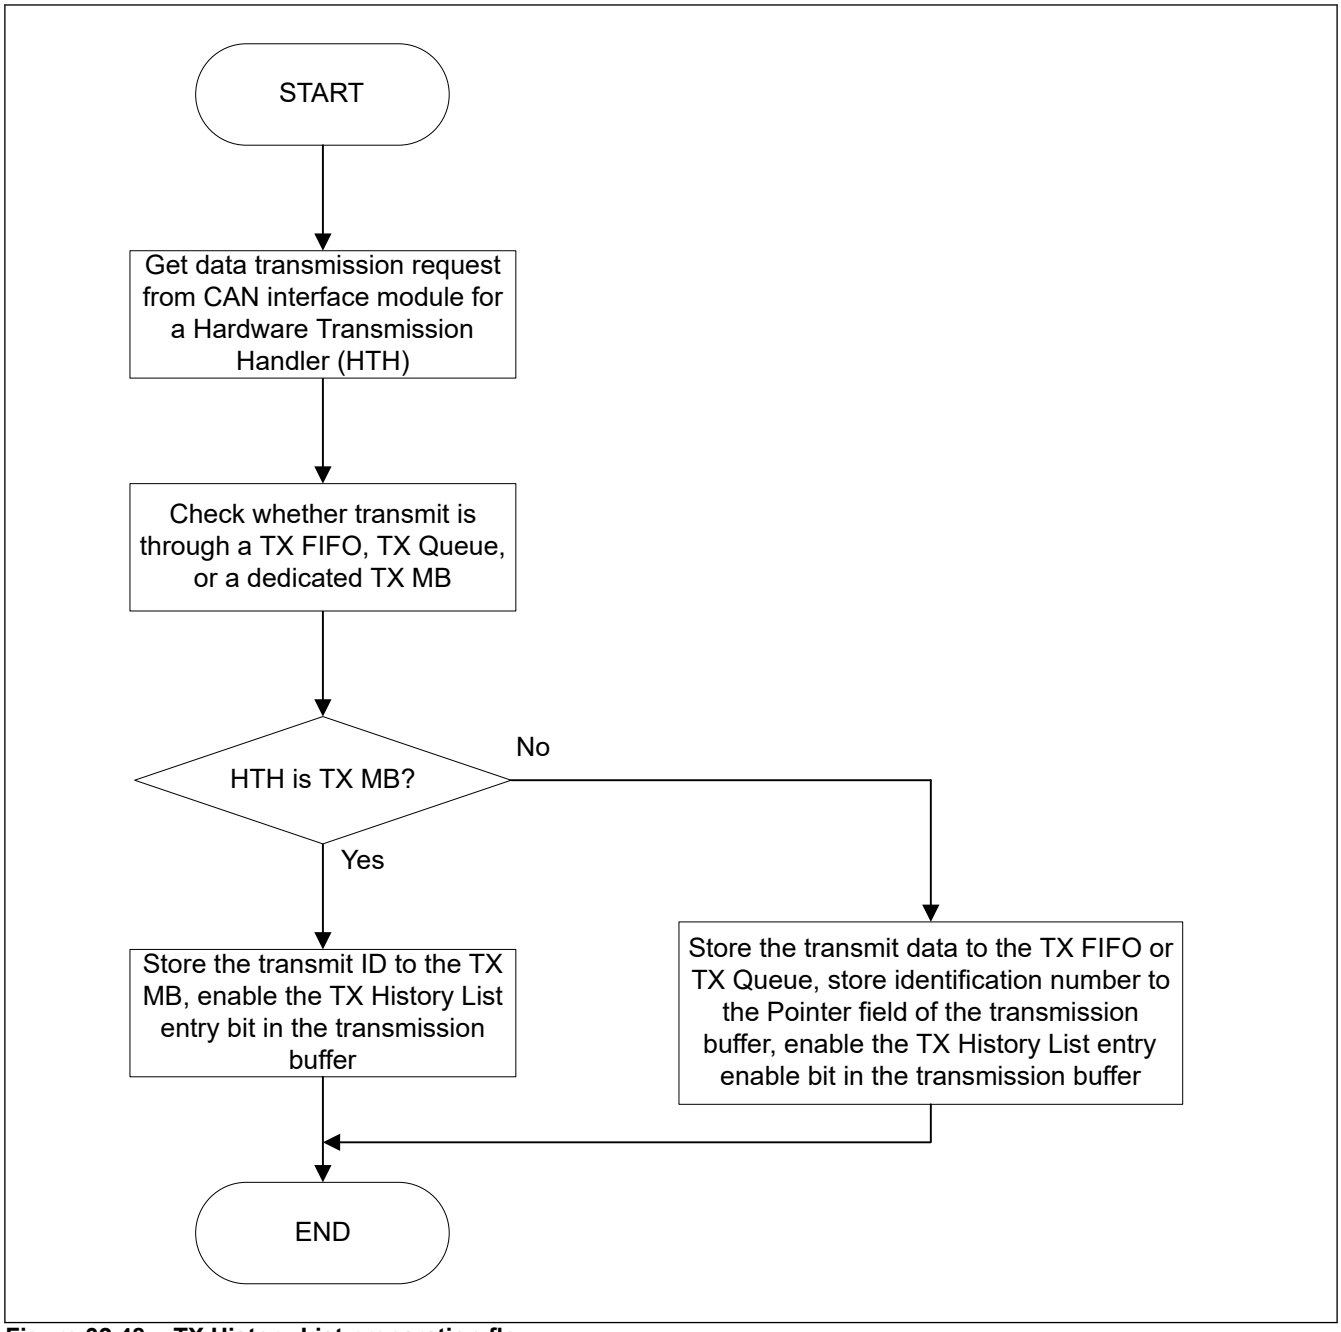

Figure 32.48 TX History List preparation flow

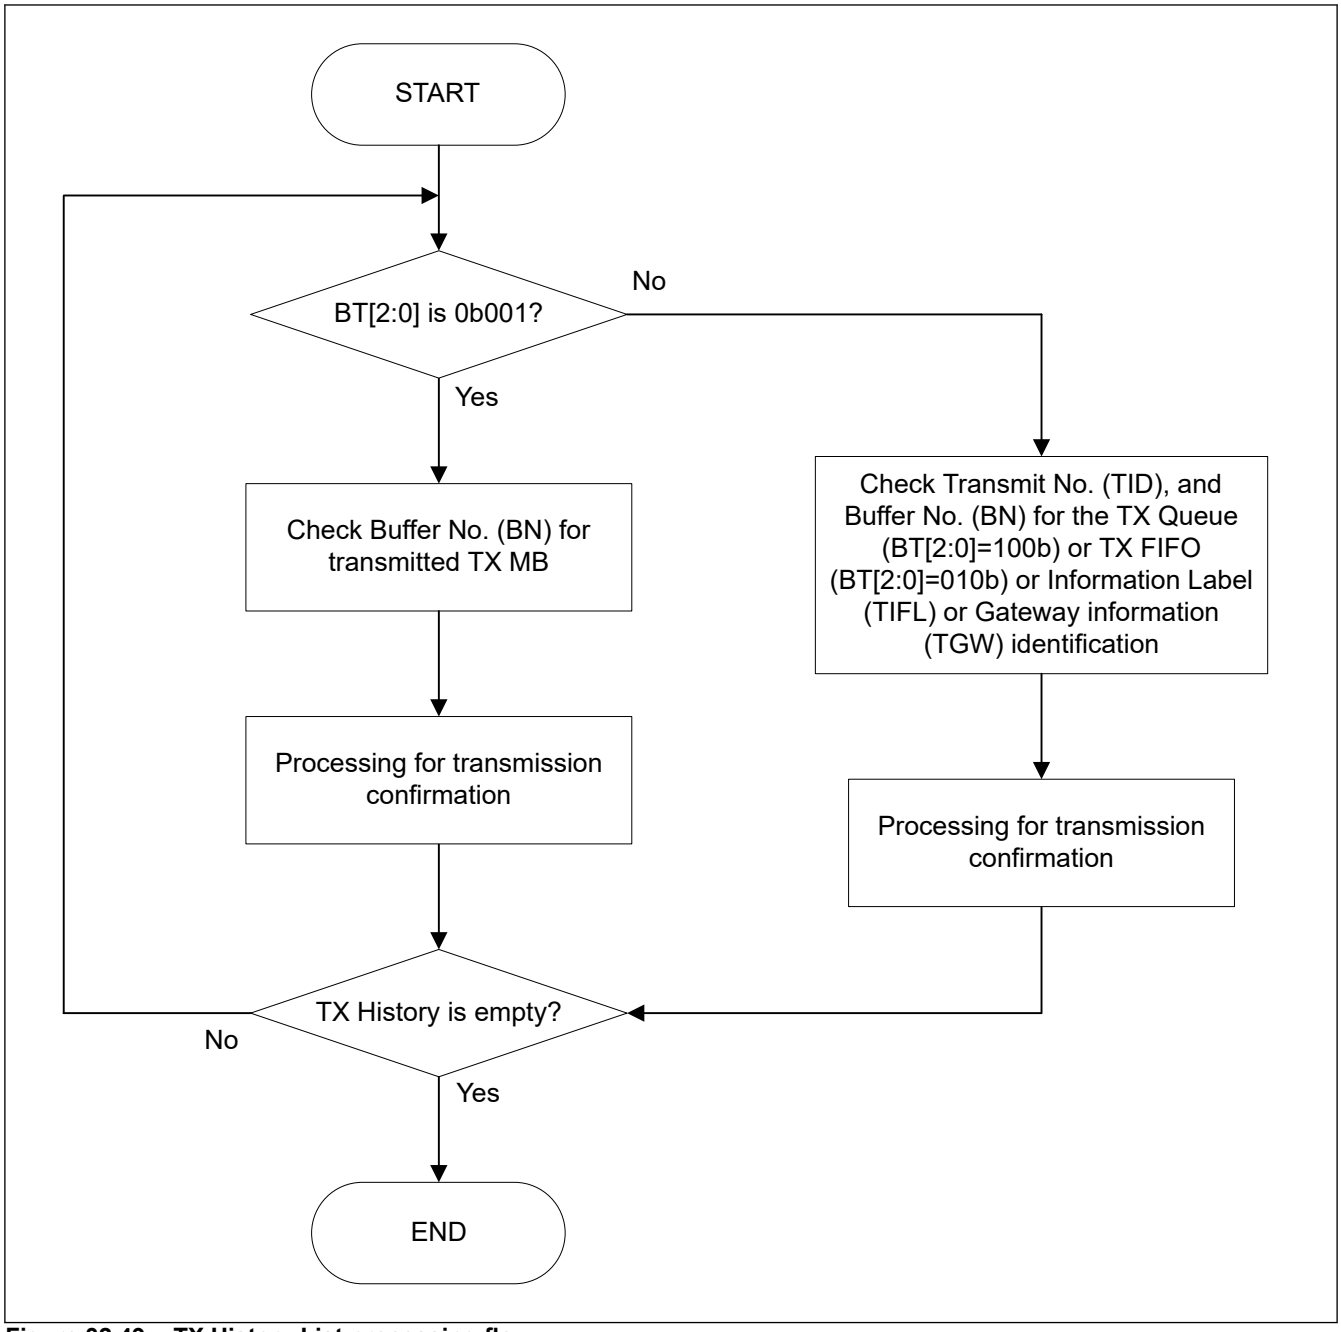

Figure 32.49 TX History List processing flow

32.8.2.6 TX Data Padding

This chapter is not valid for classical CAN.

If the data length code (DLC) of the transmitting message has a higher number of data bytes than the buffer size, the data bytes beyond the restricted range are replaced by bytes with the value of 0xCC.

This can happen for Common FIFOs configured as (TX or GW mode) when the transmit message DLC is higher than the CFDCFCCn.CFPLS.

This can also happen in FD only mode, if a Classical frame is configured with a DLC bigger than 8.

32.9 Test Mode

The CANFD module can be configured into test modes to allow testing of certain features. These features are provided only for special purposes and care must be taken when configuring the CANFD module in test modes.

Note: All test modes are mutually exclusive unless it is explicitly stated that some functions can be enabled across other test modes.

Do not enable any combination of the various test modes specified in this section.

The test modes can be broadly split into 2 groups:

- Channel specific test modes
- Global test modes.

32.9.1 Channel Specific Test Modes

Each CAN channel can be configured into the following test modes:

- Basic test mode
- Listen-only mode
- Self-test mode 0 (External loop back mode)
- Self-test mode 1 (Internal loop back mode)
- Restricted operation mode.

32.9.1.1 Basic Test Mode

The basic test mode should be used when there is requirement for a particular test setting to be enabled other than when in Listen-only and Self-test modes.

32.9.1.2 Listen-only Mode

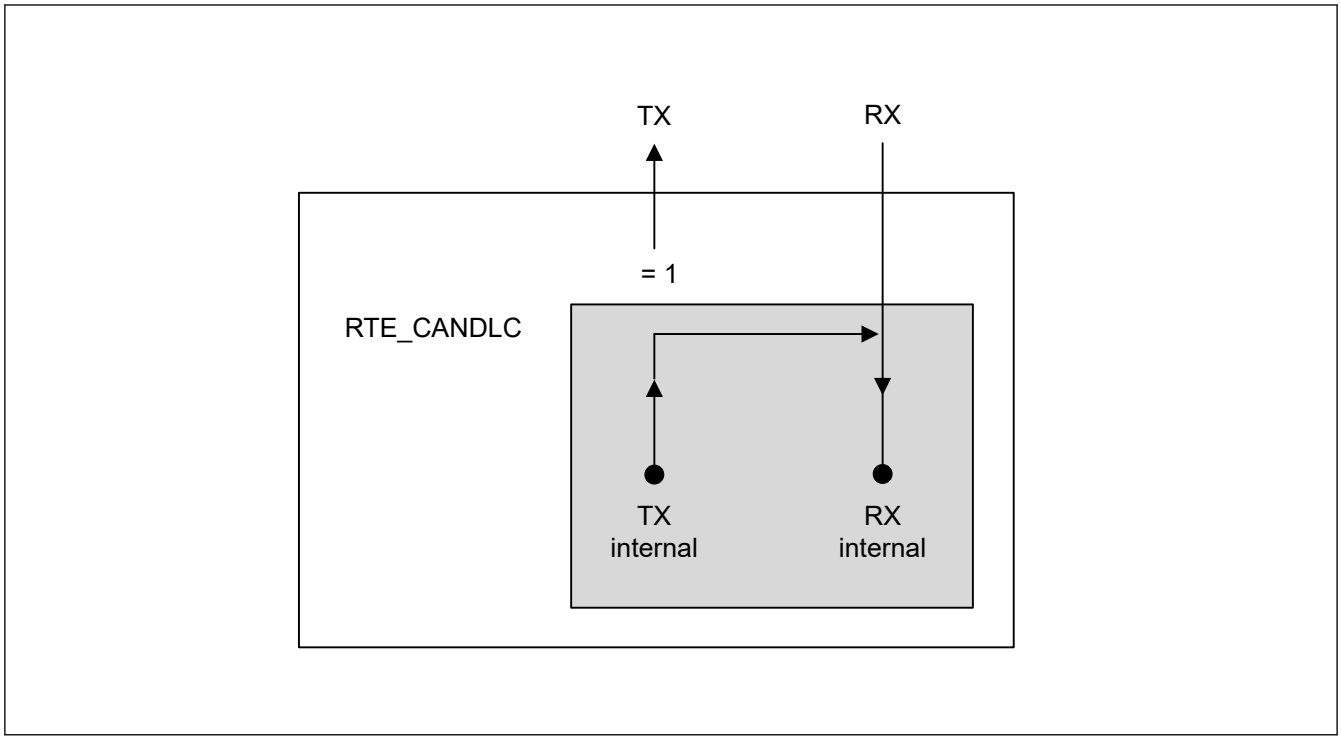
The ISO 11898-1 recommends an optional bus-monitoring mode. In this mode, the CAN channel is able to receive valid data frames and valid remote frames. However, it sends only recessive bits on the CAN bus and is not allowed to transmit.

If the CAN engine is required to send a dominant bit (ACK bit, overload flag, active error flag), the bit is routed internally so that the CAN engine monitors this as dominant. The external TX pin remains in recessive state.

This mode can be used for baud rate detection. In this mode, an error interrupt is generated if a bus error occurs and the interrupt is enabled.

In this mode, it is not permitted to request transmission from any normal TX message buffer or TX/GW FIFO of this channel.

Note: If a message is stored in GW FIFO or routing TXQ, ensure that the transmitting channel is not in Listen-only mode so that transmission is not requested for this channel from the GW FIFO or routing TXQ.

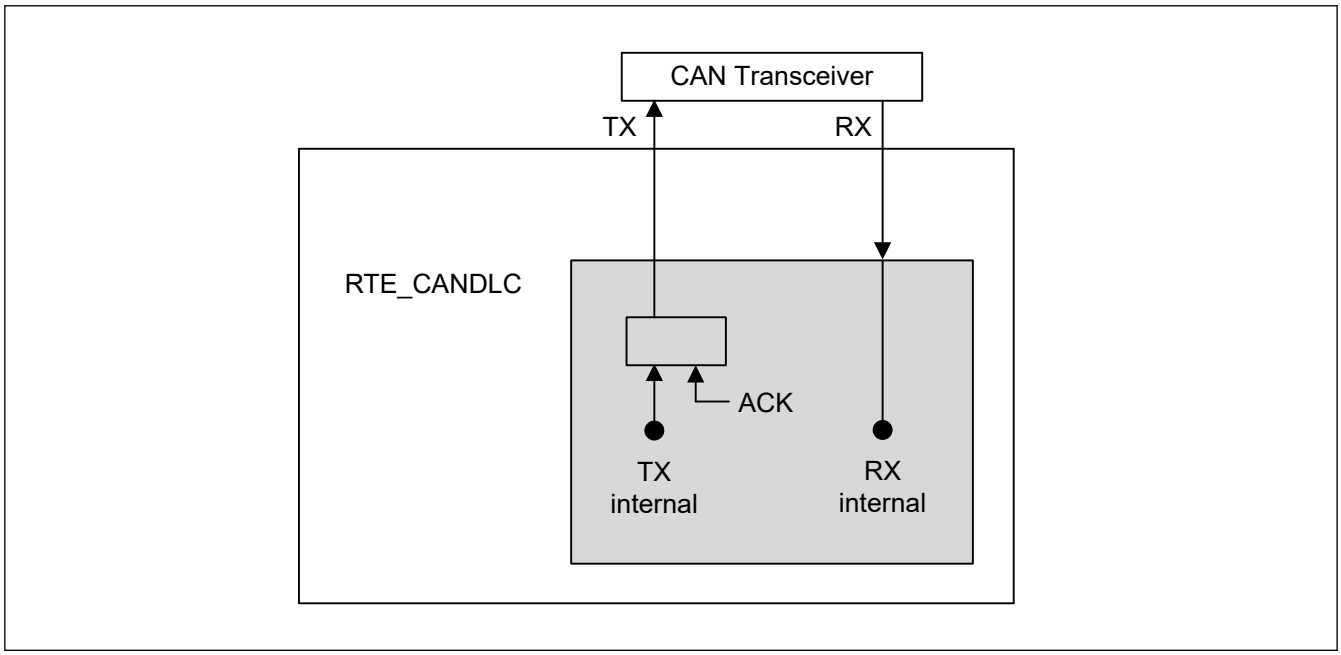


32.9.1.3 Self-test Mode 0 (External loopback mode)

In Self-test mode 0, the CAN engine treats its own transmitted messages as received messages through the CAN transceiver and stores them into its receive message buffers.

To be independent from external stimulation, the engine generates its own Acknowledge bit.

This test can be used for CAN transceiver tests and the RX/TX pins should be connected to the transceiver.



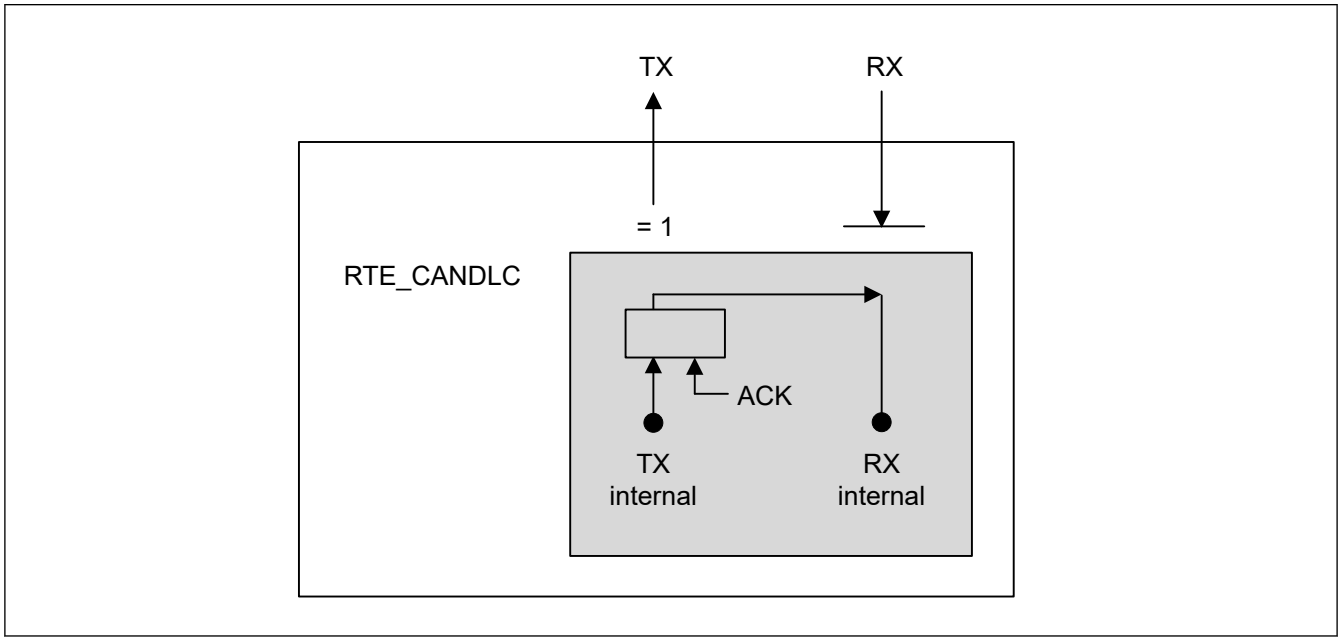
32.9.1.4 Self-test Mode 1 (Internal loopback mode)

In Self-test mode 1, the CAN engine treats its own transmitted messages as received messages and stores them into the receive buffer. This mode is provided for self-test functions. To be independent from external stimulation, the CAN engine

generates its own Acknowledge bit. In this mode the CAN engine performs an internal feedback from TX internal to RX internal. The actual value of the external RX input is disregarded by the CAN engine.

The external TX pin outputs only recessive bits. The RX/TX pins do not need to be connected to the CAN bus or any external device.

Note: The channel pins are also disconnected from the internal CAN bus communication line.



32.9.1.5 Restricted Operation Mode

This chapter is not valid for classical CAN.

In Restricted operation mode, the CAN node is able to receive valid data and remote frames generating the Acknowledge bit.

Active error or overload frames cannot be transmitted, instead it waits for the occurrence of bus idle condition to resynchronize itself to the CAN communication after an error or overload condition occurs.

Additionally, the Receive and Transmit Error Counter (REC and TEC) are frozen independently from the occurrence of errors. The mode is specified in ISO 11898-1 and the setting of transmit request is permitted.

32.9.2 Global Test Modes

The CANFD module can be configured into the following test modes:

- RAM test mode
- Internal CAN bus communication mode
- CRC error test

The test modes in the following table are protected by a special software procedure to enable the mode. This software procedure enables write access to the test mode by a specific unlock key as shown in the table.

Test mode	Unlock key 1	Unlock key 2
RAM test mode	0x7575	0x8A8A

If the software sequence of the two consecutive unlock key write accesses (half-word or word access) is interrupted by any other write access to the register or if incorrect data is written to the Global Unlock Key Register, the corresponding test mode cannot be set and the sequence must be restarted.

After the two unlock key write accesses, the next write access should be to set the corresponding test mode enable bit. If this is not followed, the unlock mechanism reset and the test mode enable bit cannot be set and the unlock sequence must be restarted.

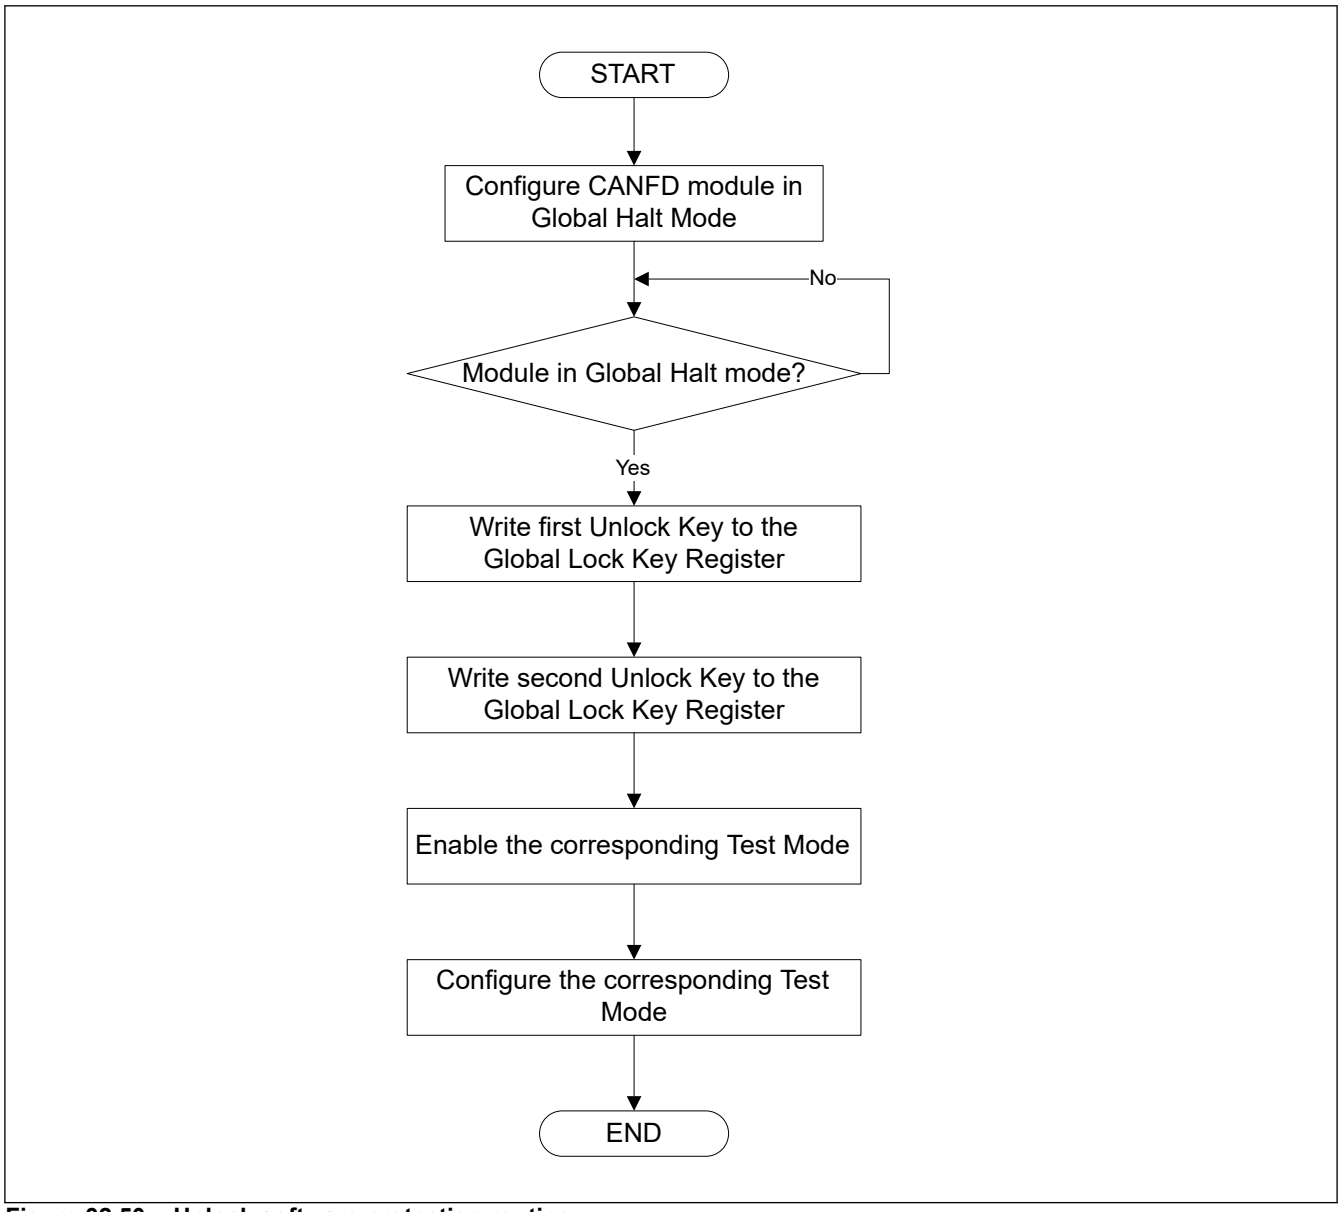


Figure 32.50 Unlock software protection routine

32.9.2.1 RAM Test Mode

The CANFD module can be configured in RAM test mode by setting the CFDGTSTCTR.RTME bit in the Global Test Control Register when the corresponding lock key is previously written. This is a special test mode, in which, the complete RAM area can be accessed.

Note: The actual RAM size is bigger than the RAM area initialized after a hardware reset. Therefore, ECC error flag (of the ECC macro) may be set if CPU reads data from this uninitialized RAM area while CANFD module is in RAM test mode.

In this mode, the RAM area is split into number of pages (pn) of 256 bytes, each which can be accessed with the CFDRPGACCn register.

The page should be selected for read/write access by writing to the CFDGTSTCFG.RTMPS[9:0] bits in the Global Test Control Register. Data can then be read from or written in to the RAM Test Page Access Registers.

Figure 32.51 shows the structure of the pages in the RAM when performing a RAM test mode.

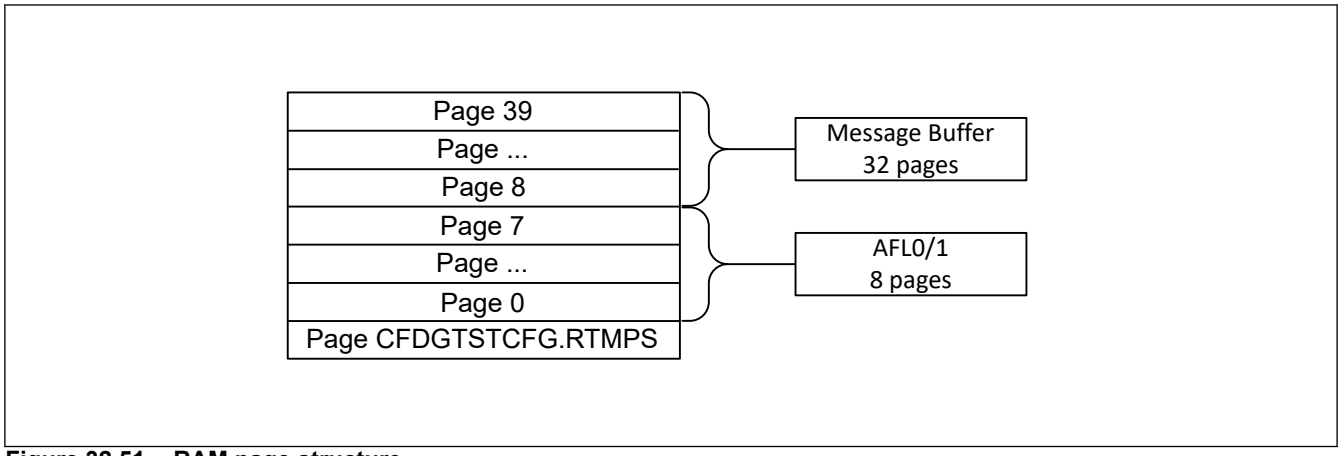

Figure 32.51 RAM page structure

The total available RAM size for a 2-CAN channel version is 2048 bytes for the AFL RAM and 8192 bytes for the Message Buffer RAM.

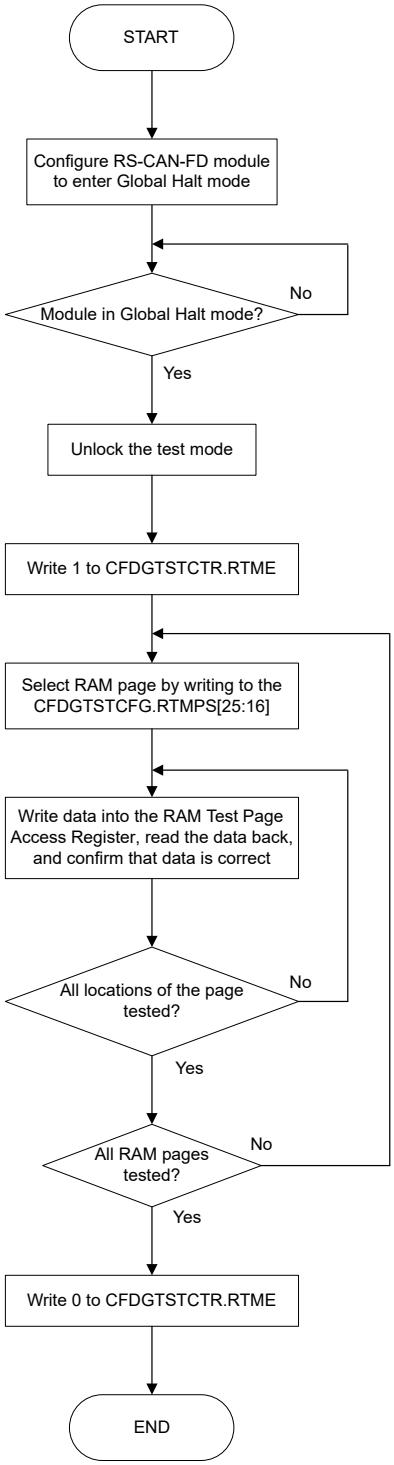
AFL RAM0/1 can treat RAM test mode as one RAM.

The pn and CFDGTSTCFG.RTMPS[9:0] values for the AFL and MB RAMs are calculated in the following way:

pn = ceil (total RAM size in bytes / number of bytes per page)

- AFL RAM:
  pn = ceil (2048 / 256) = 8 pages
  CFDGTSTCFG.RTMPS[9:0] = 0 to 7 (0x00F) inclusive
- MB RAM:
  pn = ceil (8192 / 256) = 32 pages
  CFDGTSTCFG.RTMPS[9:0] = 8 to 39 (0x27) inclusive

Figure 32.52 shows the software flow for RAM test mode.



Note 1. Change into the following status before changing to RAMTEST.
- Cancel of a request for transmission.
- Disable of all the FIFO and TXQ.
- Clear of the receiving flag for a receiving buffer.

Figure 32.52 Software flow for RAM test mode

To exit this test mode, the CFDGTSTCTR.RTME bit must be cleared. The CFDGTSTCTR.RTME bit is cleared by writing 0 to it.

The CFDGTSTCTR.RTME bit is cleared automatically when the CANFD module enters Global Reset mode from the test mode.

32.9.2.2 Internal CAN Bus Communication Test Mode

The CANFD module can be configured in internal CAN bus communication test mode by setting the CFDGTSTCTR.ICBCTME bit in the Global Test Control Register. This is a special test mode, in which the CAN channels can be connected together internally to generate a CAN cluster within the CANFD module.

Only use the following sequence to enter internal CAN bus communication test mode:

1. Configure all channels in Halt mode and check that all channels have entered Halt mode (Global Halt mode).
2. Write data into the Global Test Configuration Register to select the channels participating in the internal CAN bus communication test.
3. Set the CFDGTSTCTR.ICBCTME bit of the Global Test Control Register.
4. Check that CFDGTSTCTR.ICBCTME bit is set in the Global Test Control Register.

In this mode, the TXD outputs of the channels participating (configured) in internal CAN bus communication mode are connected together using AND gate. The output of the AND gate is connected to the RXD inputs of all participating channels to create a CAN cluster within the CANFD module. The channels are isolated from the external CAN bus while the CANFD module is in this test mode.

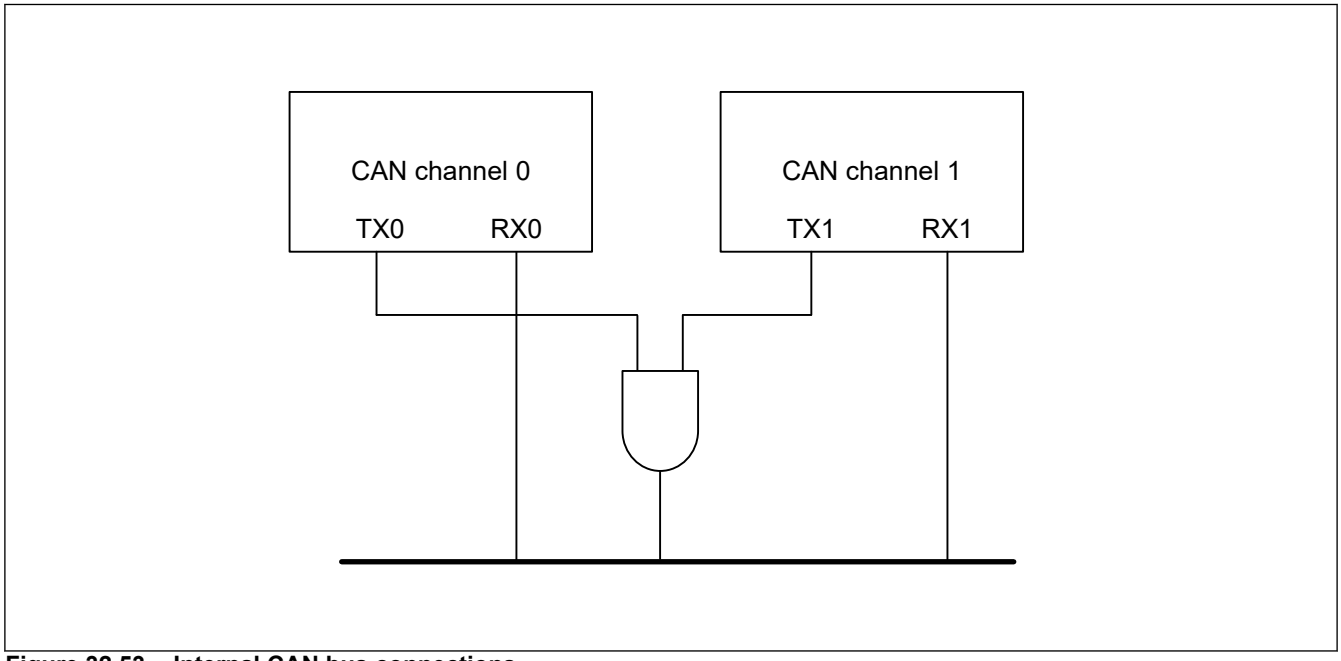


Figure 32.53 Internal CAN bus connections

The AFL, Flat RX message buffers, FIFO buffers, Flat TX message buffers and various registers can now be configured as normal to start communication between channels.

The channels not participating in internal CAN bus should only be configured in Halt mode.

(1) CRC Error Test

After the CANFD module has been configured in internal CAN bus communication test mode, use the following sequence to perform CRC Error testing. In this sequence, channel x is the reference transmitter CANFD module and channel y is the receiver CANFD module where (x,y = [0…n] and $x \neq y$):

1. Configure channel x node to transmit 1 reference message.
2. Set the CFDCyCTR.CRCT bit to 1 to invert the first bit of the incoming bit stream from channel x.
3. Set the CFDTMCx.TMTR.
4. Read either the CFDCyERFL.CRCREG or the CFDCyCRC.CRCREG (depending on the received frame type: Classical or FD). The value should be different from the received CRC value of the reference message from channel x.

5. Check that CFDCyERFL.CERR is 1

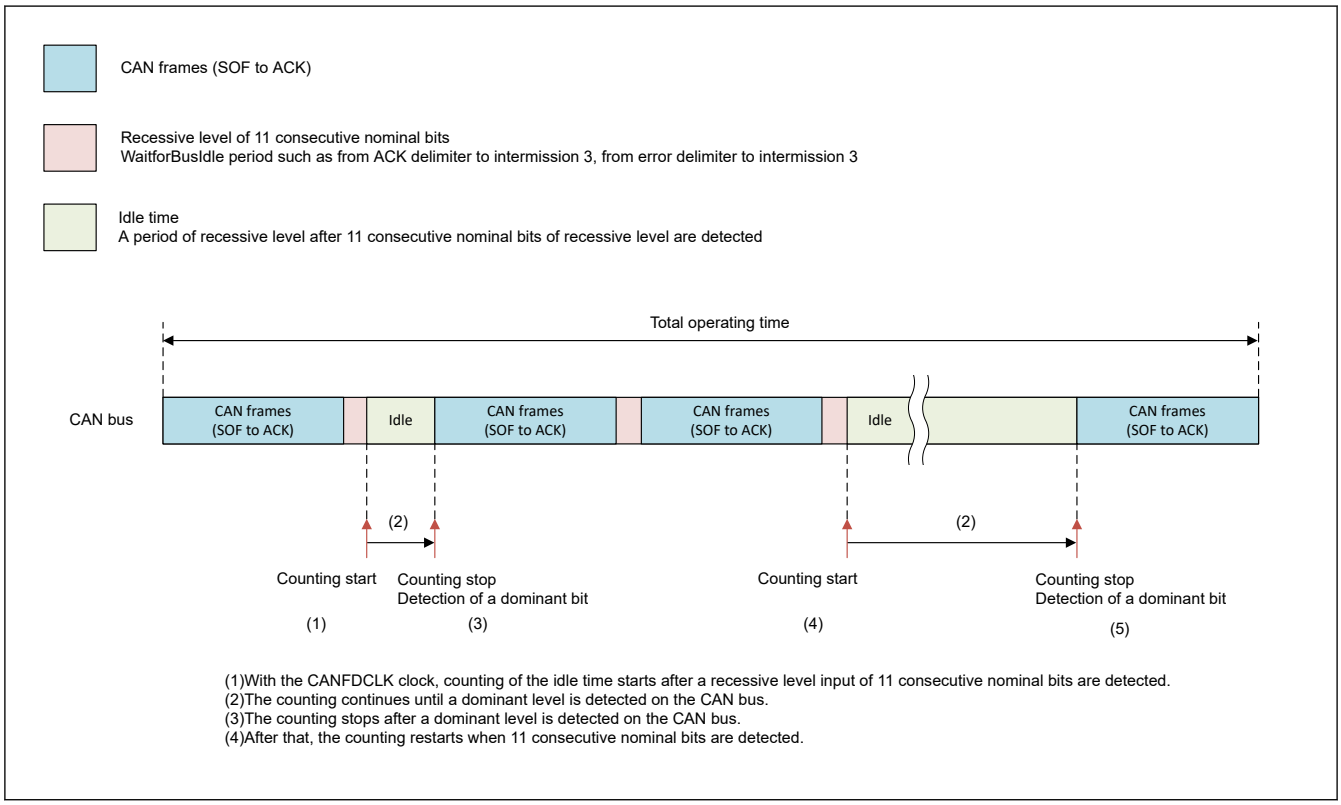
The CRC generator logic is shared between RX and TX so there is no need to create a separate TX CRC error test.

32.10 Bus Traffic Measurement

The idle time of the CAN bus can be measured using the CANFDCLK or CANMCLK. Bus traffic can be calculated based on the measurement results.

32.10.1 How to Count the CAN Bus Idle Time

The following figure shows the concept for measuring idle time of the CAN bus.



32.10.2 Operations and Measurement Procedure

The following procedure shows the steps for measuring idle time of the CAN bus.

1. The channel to be measured exters operation mode.
2. Write 1 to CFDCnBLCT.BLCE bit to set the measuring counter to operating mode.
3. Write 1 to CFDCnBLCT.BLCLD bit to clear the counter register.
4. Detect a recessive level input of 11 consecutive nominal bits.
5. Start counting the bus idle time.
6. Detect a dominant level.
7. The counting stops.
8. Detect a recessive level input of 11 consecutive nominal bits.
9. The counting starts.
10. Write 1 to CFDCnBLCT.BLCLD bit to clear the counter register and simultaneously load the counter value to CFDCnBLSTS.
11. Read the value of CFDCnBLSTS.

To stop the measurement counter, write 0 to CFDCnBLCT.BLCE bit.

To initialize the counter, write 1 to CFDCnBLCT.BLCLD bit.

This measurement is enabled when the channel to be measured is in operation mode.

When the relevant channels are in reset mode, the counter does not operate.

Also, accurate measurements are not available in test mode.

Write 1 to CFDCnBLCT.BLCLD bit to clear the counter register and simultaneously load the value of the counter to CFDCnBLSTS.

The lower three bits of CFDCnBLSTS are fixed to 0.

Based on the values of the counter, software can calculate the CAN bus traffic according to the following formulas.

$$\frac{(\text{total operating time} - \text{total idle time})}{\text{Total operating time}} = \frac{\text{bus operating time}}{\text{total operating time}} = \text{Bus usage ratio}$$

- Total idle time: a value read from CFDCnBLSTS × a clock cycle of CANFDCLK
- Total operating time: a setting interval of CFDCnBLCT.BLCLD bit

Example: Below is a calculation example under the following conditions.

- Conditions: nominal bit rate = 1 Mbps
- CANFDCLK clock = 40 MHz (= 25 ns)
- A setting interval of CFDCnBLCT.BLCLD bit = cycle of 1 ms
- A read value of CFDCnBLSTS register = 0x4E20

$$\frac{(\text{total operating time} - \text{total idle time})}{\text{Total operating time}} = \frac{(1000000\text{ns} - 20000 * 25\text{ns})}{1000000\text{ns}} = 50\,\%$$

32.11 Usage Notes

32.11.1 Settings for the Module-Stop State

The MSTPCRC can enable or disable CANFD operation. The CANFD module is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

33. CANFD ECC (CNECC)

33.1 Overview

AFLRAM0, AFLRAM1 and MBRAM have ECC function of 2-bit ECC error detection and 1-bit ECC error detection and correction*1. The ECC module adds 7 bits ECC data to 32 bits RAM data.

Note 1. The ECC module cannot detect 3 or more bits error. In this case, the ECC module detects 1-bit or 2-bit error, does not detect errors, or corrects the erroneous bit to erroneous data by setting. When all RAM data are fixed to 0 or 1, it is detected as 2-bit ECC error.

33.2 Register Descriptions

33.2.1 EC710CTL : ECC Control Register

Base address: ECCAFLn = 0x4012_F000 + 0x0100 × n (n = 0, 1)
ECCMB = 0x4012_F200

Offset address: 0x00

3	EC1EDIC	ECC 1-bit Error Detection Interrupt Control 0: Disable 1-bit error detection interrupt request 1: Enable 1-bit error detection interrupt request	R/W
4	EC2EDIC	ECC 2-bit Error Detection Interrupt Control 0: Disable 2-bit error detection interrupt request 1: Enable 2-bit error detection interrupt request	R/W
5	EC1ECP	ECC 1-bit Error Correction Permission 0: At 1-bit error detection, the error correction is executed 1: At 1-bit error detection, the error correction is not executed	R/W
6	ECERVF	ECC Error Judgment Enable Flag 0: Error judgment disable 1: Error judgment enable	R/W
8:7	—	These bits are read as 0. The write value should be 0.	R/W
9	ECER1C	Accumulating ECC Error Detection and Correction Flag Clear 0: No effect 1: Clear accumulating ECC error detection and correction flag	R/W

Bit	Symbol	Function	R/W
10	ECER2C	2-bit ECC Error Detection Flag Clear 0: No effect 1: Clear 2-bit ECC error detection flag	R/W
11	ECOVFF	ECC Overflow Detection Flag 0: No effect 1: ECC overflow detection flag	R
13:12	—	These bits are read as 0. The write value should be 0.	R/W
15:14	EMCA[1:0]	Access Control to ECC Mode Select bit These bits enable or disable write access to ECERVF bit.	R/W
16	ECSEDF0	ECC Single bit Error Address Detection Flag 0: There is no bit error in EC710EAD0 after reset or clearing ECER1F bit 1: Address captured in EC710EAD0 shows that 1-bit error occurred and captured	R
17	ECDEDF0	ECC Dual Bit Error Address Detection Flag 0: There is no bit error in EC710EAD0 after reset or clearing ECER2F bit 1: Address captured in EC710EAD0 shows that 2-bit error occurred and captured	R
31:18	—	These bits are read as 0. The write value should be 0.	R/W

ECEMF bit (ECC Error Message Flag)

The ECEMF bit shows that there is error in present read data bus. This bit is updated by every RAM output data.

When RAM output data is undefined and the ECERVF bit is set to 1, the value of this bit is undefined.

[Setting condition]

There is bit error in present RAM output data under the condition that error judgement is enabled.

[Clearing condition]

- Under the condition that there is no 1-bit error in input data to decode circuit
- When ECC error judgement is disabled (ECERVF = 0).

ECER1F bit (ECC Error Detection and Correction Flag)

The ECER1F bit shows that the bit errors are detected in the one part of RAM read data [38:0] at RAM read access when the error judgment is enabled.

When the 1-bit error interrupt output is enabled, error interrupt is generated by setting this flag.

This bit is read-only, so writing 1 or 0 has no effect.

At clearing, write 1 to the ECER1C bit.

When 1-bit error is detected again under the condition that this bit is set, the interrupt is not generated.

[Setting condition]

When the error judgment is enabled and there is 1-bit error to RAM output data (when not setting ECER1C = 1).

[Clearing condition]

- Writing ECER1C = 1
- When ECC error judgement is disabled (ECERVF = 0).

ECER2F bit (2-bit ECC Error Detection Flag)

The ECER2F bit shows that the bit errors are detected in the two parts of RAM read data [38:0] at RAM read access when the error judgment is enabled.

When the 2-bit error interrupt output is enabled, error interrupt is generated by setting this flag.

This bit is read-only, so writing 1 or 0 has no effect.

At clearing, write 1 to the ECER2C bit.

When 2-bit error is detected again under the condition that this bit is set, the interrupt is not generated.

[Setting condition]

When the error judgment is enabled and there is 2-bit error to RAM output data (when not setting ECER2C = 1).

[Clearing condition]

- Writing ECER2C = 1
- When ECC error judgement is disabled (ECERVF = 0).

EC1EDIC bit (ECC 1-bit Error Detection Interrupt Control)

The EC1EDIC controls the interrupt output at detecting 1-bit error. By setting 1 to this bit, the 1-bit error interrupt is outputted when 1-bit error detected.

EC2EDIC bit (ECC 2-bit Error Detection Interrupt Control)

The EC2EDIC controls the interrupt output at detecting 2-bit error. By setting 1 to this bit, the 2-bit error interrupt is outputted when 2-bit error detected.

EC1ECP bit (ECC 1-bit Error Correction Permission)

The EC1ECP sets enable or disable to correct the 1-bit error when ECC error detection and correction is valid. By setting 1 to this bit, the non-corrected data is outputted if 1-bit error is detected.

ECERVF bit (ECC Error Judgment Enable Flag)

Setting the ECERVF bit to 1 enables the judgment of error. The correction of output data and the interrupt output depend on setting of the EC1ECP bit, EC2EDIC bit, and EC1EDIC bit.

The write access to this bit is valid when the write value of the EMCA[1:0] is 01b. So only the 16 bits or 32 bits operation command is valid in the case of the write access to this bit.

ECER1C bit (Accumulating ECC Error Detection and Correction Flag Clear)

The ECER1C bit clears the status flag of the ECER1F bit.

The read value is always 0. By writing 0, the internal condition is not changed. When the competition between writing 1 to this bit and setting the ECER1F bit, the former has priority.

The ECER1F bit is cleared by writing 1 to this bit while the ECER1F bit is set. Additionally, the Overflow Detection flag (ECOVFF), ECC Dual Bit Error flag (ECDEDF0) and ECC Single Bit Error flag (ECSEDF0) are also cleared.

ECER2C bit (2-bit ECC Error Detection Flag Clear)

The ECER2C bit clears the status flag of the ECER2F bit.

The read value is always 0. By writing 0, the internal condition is not changed. When the competition between writing 1 to this bit and setting the ECER2F bit, the former has priority.

The ECER2F bit is cleared by writing 1 to this bit while the ECER2F bit is set. Additionally, the Overflow Detection flag (ECOVFF), ECC Dual Bit Error flag (ECDEDF0), and ECC Single Bit Error flag (ECSEDF0) are also cleared.

ECOVFF bit (ECC Overflow Detection Flag)

The ECOVFF bit is set and the overflow interruption is outputted by detecting the new error address under the condition that error address is already captured in the EC710EAD0 register. The overflow interrupt is outputted again when this bit is set and new error is detected.

This bit is read-only, so writing 1 or 0 has no effect.

To clear this bit, write 1 to the ECER2C bit and the ECER1C bit.

[Setting condition]

When new error address is captured under the condition that error address is already captured in the EC710EAD0 register (when not setting ECER2C = 1 or ECER1C = 1).

[Clearing condition]

- Writing ECER2C = 1 or ECER1C = 1
- When ECC error judgement is disabled (ECERVF = 0).

EMCA[1:0] bit (Access Control to ECC Mode Select bit)

The EMCA[1:0] bits are the write trigger reserved bits to the ECERVF bit. The read value is always 0. When the value of these bits is 01b, it is possible to have write access to the ECERVF bit. If these bits are not 01b, write access to the ECERVF bit is ignored and the value is not written.

ECSEDF0 bit (ECC Single bit Error Address Detection Flag)

The ECSEDF0 bit shows that the error is captured in the error address register when error detection is valid. This bit is set by 1-bit error detection.

When 1-bit error is detected after the 2-bit error address is already captured in the EC710EAD0 register, this bit is not updated but the EC710EAD0 register is updated.

This bit is read-only, so writing 1 or 0 has no effect. To clear these bits, write 1 to the ECER1C bit.

[Setting condition]

When there is 1-bit error to RAM output data and error address is captured in EC710EAD0 under the condition that the error judgment is permitted (when not setting ECER1C = 1).

[Clearing condition]

- Writing ECER1C = 1
- When ECC error judgement is disabled (ECERVF = 0).

ECDEDF0 bit (ECC Dual Bit Error Address Detection Flag)

The ECDEDF0 bit shows that the error is captured in the error address register when error detection is valid. This bit is set by 2-bit error detection.

When 2-bit error is detected after the 1-bit error address is already captured in the EC710EAD0 register, this bit is not updated and the EC710EAD0 register is updated.

This bit is read-only, so writing 1 or 0 has no effect. To clear these bits, write 1 to the ECER2C bit.

[Setting condition]

When there is 2-bit error to RAM output data and error address is captured in EC710EAD0 under the condition that the error judgment is permitted (when not setting ECER2C = 1).

[Clearing condition]

- Writing ECER2C = 1
- When ECC error judgement is disabled (ECERVF = 0).

33.2.2 EC710TMC : ECC Test Mode Control Register

Base address: ECCAFLn = 0x4012_F000 + 0x0100 × n (n = 0, 1)
ECCMB = 0x4012_F200

Offset address: 0x04

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ETMA[1:0]		—	—	—	—	—	—	ECTMCE	—	—	—	—	—	ECDCS	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	—	This bit is read as 0. The write value should be 0.	R/W
1	ECDCS	ECC Decode Input Select 0: Input lower 32 bits of RAM output data to data area of decode circuit 1: Input ECEDB31-0 in EC710TED register to data area of decode circuit	R/W
6:2	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
7	ECTMCE	ECC Test Mode Control Enable 0: The access to test mode register and bit is disabled 1: The access to test mode register and bit is enabled	R/W
13:8	—	These bits are read as 0. The write value should be 0.	R/W
15:14	ETMA[1:0]	ECC Test Mode Bit Access Control These bits enable or disable write access to ECTMCE bit.	R/W

ECDCS bit (ECC Decode Input Select)

The ECDCS bit selects either the lower 32 bits data value from RAM or value from the internal test register (EDEDB[31:0] in EC710TED) as input signal to decoder.

The write access to this bit is valid under the condition of ECTMCE = 1 (it is possible to set them at the same time.)

This bit is cleared by setting ECTMCE = 0.

ECTMCE bit (ECC Test Mode Control Enable)

The ECTMCE bit selects the access enable or disable to test register and test control bit.

The write access to this bit is valid under the condition that the value of the ETMA[1:0] bits is 10b.

ETMA[1:0] bits (ECC Test Mode Bit Access Control)

The ETMA[1:0] bits are the write trigger reserved bits to the ECTMCE bit. The read value is always 0. When the value of these bits is 10b, it is possible to have write access to the ECTMCE bit. If these bits are not 10b, the write access to the ECTMCE bit is ignored and the value is not written.

33.2.3 EC710TED : ECC Test Substitute Data Register

Base address: ECCAFLn = 0x4012_F000 + 0x0100 × n (n = 0, 1)
ECCMB = 0x4012_F200

Offset address: 0x0C

Bit position:	31																												0
Bit field:	ECEDB[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	ECEDB[31:0]	ECC Test Substitute Data Substitute data in ECC test mode.	R/W

This register is for the 32 bits data for ECC decode. It is possible to read and write using 32 bits operation command when ECTMCE = 1. When ECTMCE = 0, all bits are always 0.

ECEDB[31:0] bits (ECC Test Substitute Data)

When ECDCS in EC710TMC register is 1, the value of this register is bits [31:0] of the input data to the decode circuit.

33.2.4 EC710EAD0 : ECC Error Address Register

Base address: ECCAFLn = 0x4012_F000 + 0x0100 × n (n = 0, 1)
ECCMB = 0x4012_F200

Offset address: 0x10

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	ECEAD[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
10:0	ECEAD[10:0]	ECC Error Address	R
31:11	—	These bits are read as 0. The write value should be 0.	R

This is a read-only register to hold the ECC error address.

ECEAD[10:0] bits (ECC Error Address)

When ECC error is detected for permitting ECC error judgment, RAM address is captured by the detected signal as a trigger and is hold as the error occurring address. The error address is not captured when the error occurred again to the one held by the same factor.

If 2-bit error occurred under the condition that 1-bit error address is already captured, the 2-bit error address is over-written and the ECDEDF0 bit is set to 1.

If 1-bit error occurred under the condition that 2-bit error address is already captured, the 1-bit error address is not overwritten and the ECSEDF0 bit is not set to 1.

33.3 Operation

33.3.1 ECC Function Setting

Figure 33.1 shows a procedure for ECC function setting.

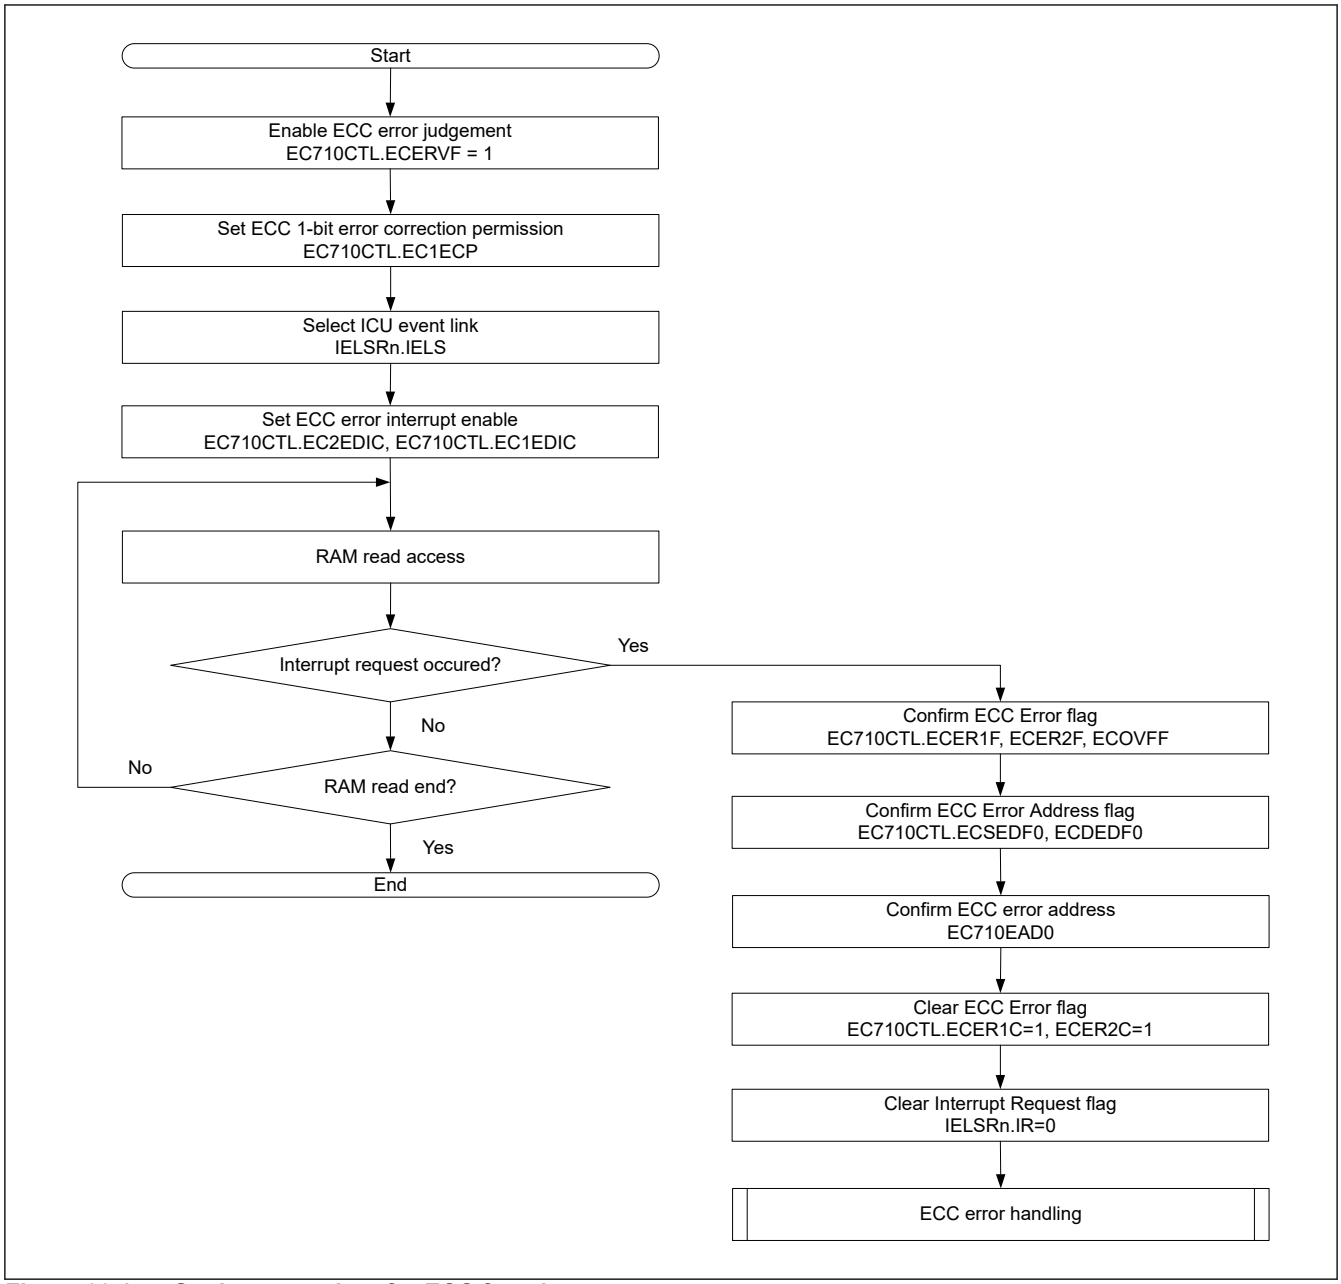

Figure 33.1 Setting procedure for ECC function

33.3.2 ECC Decoder Testing

ECC interrupts can be intentionally generated by ECC test mode. Figure 33.2 shows a procedure for ECC decoder testing.

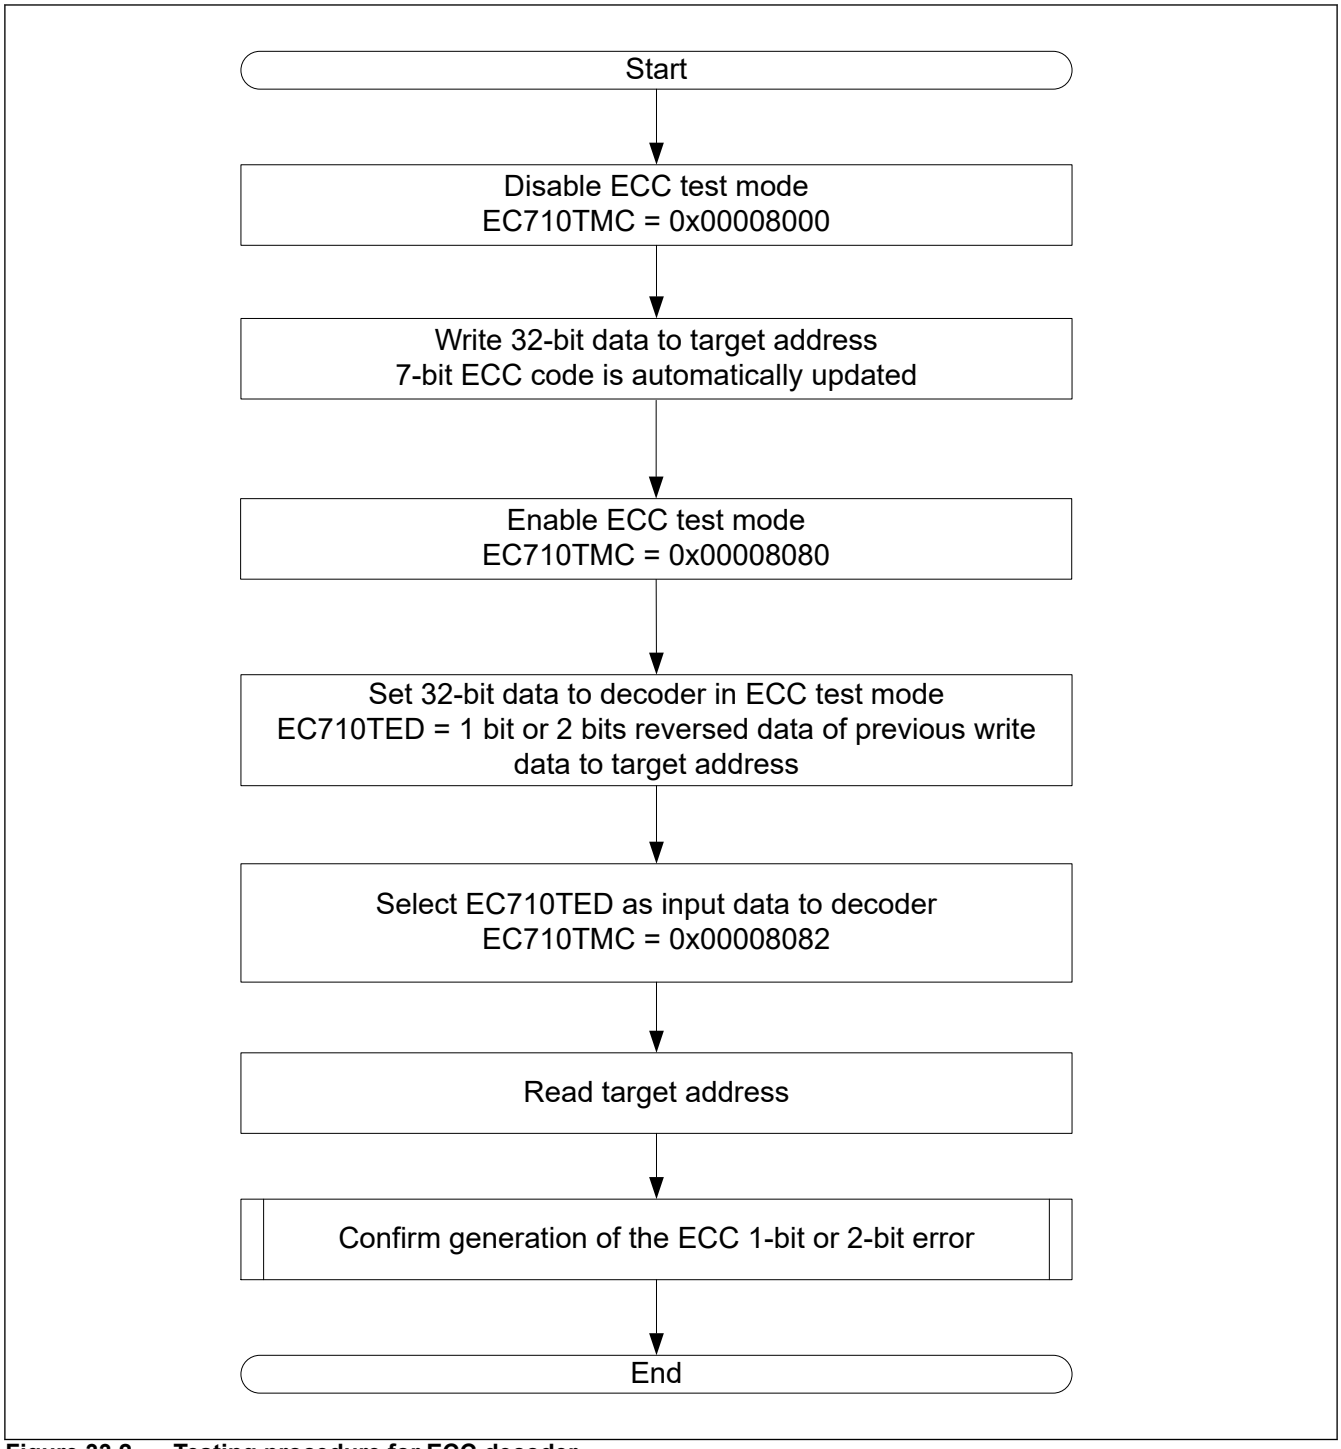

Figure 33.2 Testing procedure for ECC decoder

33.4 Interrupts

The ECC module issues three interrupt requests:

- CAN_AFLRAM0_ERI
- CAN_AFLRAM1_ERI
- CAN_MRAM_ERI.

Interrupt sources of each interrupt request include:

- 1-bit ECC error
- 2-bit ECC error

- ECC error overflow.

34. Serial Peripheral Interface (SPI)

34.1 Overview

The Serial Peripheral Interface (SPI) has 2 channels. The SPI provides high-speed full-duplex synchronous serial communications with multiple processors and peripheral devices. Table 34.1 lists the SPI specifications, Figure 34.1 shows a block diagram, and Table 34.2 lists the I/O pins.

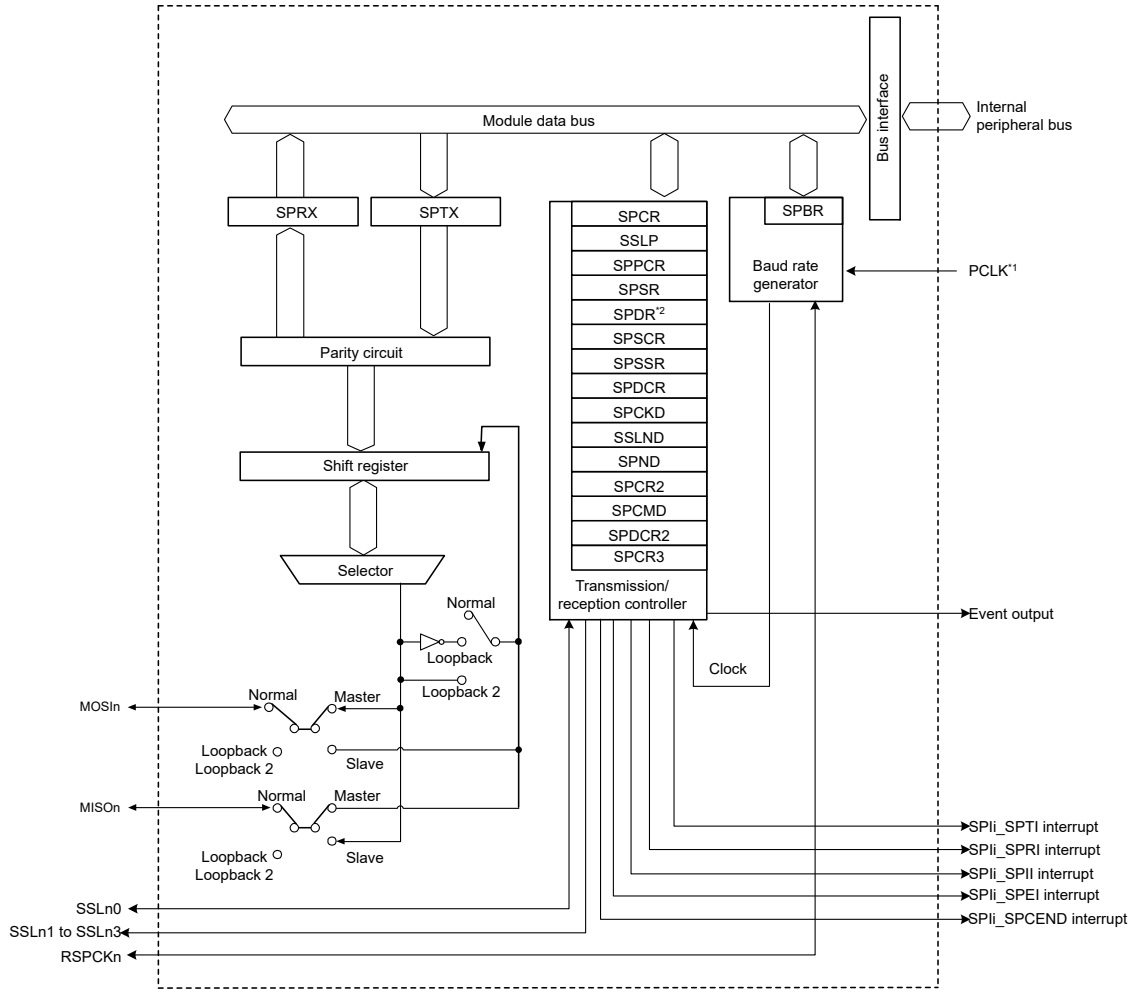
Table 34.1 SPI specifications (1 of 2)

Parameter	Specifications
Number of channels	Two channels
SPI transfer functions	• Use of MOSI (master out/slave in), MISO (master in/slave out), SSL (slave select), and RSPCK (SPI clock) signals allows serial communications through SPI operation (4-wire method) or clock synchronous operation (3-wire method) • Transmit-only operation available • Receive-only operation is available (Slave mode only) • Communication mode selectable to full-duplex or transmit-only • RSPCK polarity switching • RSPCK phase switching
Data format	• MSB-first or LSB-first selectable • Transfer bit length selectable to 8, 9, 10, 11, 12, 13, 14, 15, 16, 20, 24, or 32 bits • 128-bit transmit and receive buffers • Up to four frames transferable in one round of transmission or reception (each frame consisting of up to 32 bits) • Byte swap operating function • Transmit/receive data can be inverted.
Bit rate	• In master mode, the on-chip baud rate generator generates RSPCK by frequency-dividing PCLKA (the division ratio ranges from divided by 2 to divided by 4096) • In slave mode, the minimum PCLKA clock divided by 4 can be input as RSPCK (PCLKA divided by 4 is the maximum RSPCK frequency) Width at high level: 2 PCLKA cycles; width at low level: 2 PCLKA cycles
Buffer configuration	• Double buffer configuration for the transmit and receive buffers • 128 bits for the transmit and receive buffers
Error detection	• Mode fault error detection • Underrun error detection • Overrun error detection*1 • Parity error detection
SSL control function	• Four SSL pins (SSLni: SSLn0 to SSLn3) (n = A, B) for each channel • In single-master mode, SSLn0 to SSLn3 pins are output • In multi-master mode, SSLn0 pin for input, and SSLn1 to SSLn3 pins either for output or unused • In slave mode, SSLn0 pin for input and SSLn1 to SSLn3 pins unused • Controllable delay from SSL output assertion to RSPCK operation (RSPCK delay) Range: 1 to 8 RSPCK cycles (set in RSPCK-cycle units) • Controllable delay from RSPCK stop to SSL output negation (SSL negation delay) Range: 1 to 8 RSPCK cycles (set in RSPCK-cycle units) • Controllable wait for next-access SSL output assertion (next-access delay) Range: 1 to 8 RSPCK cycles (set in RSPCK-cycle units) • Function for changing SSL polarity • Delay between frames in burst transfer is settable
Control in master transfer	• Transfers of up to eight commands each can be executed sequentially in looped execution • For each command, the following can be set: SSL signal value, bit rate, RSPCK polarity and phase, transfer data length, MSB- or LSB-first, burst, RSPCK delay, SSL negation delay, and next-access delay • Transfers can be initiated by writing to the transmit buffer • MOSI signal value specifiable in SSL negation • RSPCK auto-stop function
Interrupt sources	Interrupt sources: • Receive buffer full interrupt • Transmit buffer empty interrupt • SPI error interrupt (mode fault error, overrun error, parity error) • SPI idle interrupt (SPI idle) • Transmission-complete interrupt

Table 34.1 SPI specifications (2 of 2)

Parameter	Specifications
Event link function	The following events can be output to the Event Link Controller (ELC): ● Receive buffer full signal ● Transmit buffer empty signal ● Mode fault, underrun, overrun, or parity error signal ● SPI idle signal ● Communication end signal
Other functions	● Switching between CMOS output and open-drain output ● SPI initialization function ● Loopback mode
Module-stop function	Module-stop state can be set to reduce power consumption.
TrustZone Filter	Security attribution can be set

Note 1. In master reception and when the RSPCK auto-stop function is enabled, an overrun error does not occur because the transfer clock is stopped on overrun error detection.



Note 1. PCLK = PCLKA
Note 2. SPDR = SPDR/SPDR_HA/SPDR_BY
Note 3. m = 0 to 7

Figure 34.1 SPI block diagram

The SPI automatically switches the I/O direction of the SSLn0 pin. SSLn0 is set as an output when the SPI is a single master, and as an input when the SPI is a multi-master or a slave. The RSPCKn, MOSIn, and MISOn pins are automatically set as inputs or outputs based on the master or slave setting and the level input on the SSLn0 pin. For details, see section 34.3.2. Controlling the SPI Pins.

Table 34.2 SPI I/O pins

Channel	Pin name	I/O	Description
SPI0	RSPCKA	I/O	Clock input/output pin
	SSLA0	I/O	Slave selection input/output
	SSLA1 to SSLA3	Output	Slave selection output
	MOSIA	I/O	Master transmit data input/output
	MISOA	I/O	Slave transmit data input/output
SPI1	RSPCKB	I/O	Clock input/output pin
	MOSIB	I/O	Master transmit data input/output
	MISOB	I/O	Slave transmit data input/output
	SSLB0	I/O	Slave selection input/output
	SSLB1 to SSLB3	Output	Slave selection output

Note: Pin names are indicated as “...A” or “...An” for SPI0, and “...B” or “...Bn” for SPI1 (n = 0, 1, 2, or 3).

34.2 Register Descriptions

34.2.1 SPCR : SPI Control Register

Base address: SPIn = 0x4011_A000 + 0x0100 × n (n = 0, 1)

Offset address: 0x00

Bit position:	7	6	5	4	3	2	1	0
Bit field:	SPRIE	SPE	SPTIE	SPEIE	MSTR	MODFEN	TXMD	SPMS
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SPMS	SPI Mode Select 0: Select SPI operation (4-wire method) 1: Select clock synchronous operation (3-wire method)	R/W
1	TXMD	Communications Operating Mode Select 0: Select full-duplex synchronous serial communications 1: Select serial communications with transmit-only	R/W
2	MODFEN	Mode Fault Error Detection Enable 0: Disable detection of mode fault errors 1: Enable detection of mode fault errors	R/W
3	MSTR	SPI Master/Slave Mode Select 0: Select slave mode 1: Select master mode	R/W
4	SPEIE	SPI Error Interrupt Enable 0: Disable SPI error interrupt requests 1: Enable SPI error interrupt requests	R/W
5	SPTIE	Transmit Buffer Empty Interrupt Enable 0: Disable transmit buffer empty interrupt requests 1: Enable transmit buffer empty interrupt requests	R/W
6	SPE	SPI Function Enable 0: Disable SPI function 1: Enable SPI function	R/W

Bit	Symbol	Function	R/W
7	SPRIE	SPI Receive Buffer Full Interrupt Enable 0: Disable SPI receive buffer full interrupt requests 1: Enable SPI receive buffer full interrupt requests	R/W

SPMS bit (SPI Mode Select)

The SPMS bit selects SPI operation (4-wire method) or clock synchronous operation (3-wire method).

The SSLn0 to SSLn3 pins are not used in clock synchronous operation. The RSPCKn, MOSIn, and MISOn pins handle communications. For clock synchronous operation in master mode (MSTR = 1), the SPCMDm.CPHA bit can be set to either 0 or 1. For clock synchronous operation in slave mode (MSTR = 0), always set the CPHA bit to 1. Do not perform operations if the CPHA bit is set to 0 for clock synchronous operation in slave mode (MSTR = 0).

TXMD bit (Communications Operating Mode Select)

The TXMD bit selects full-duplex synchronous serial communications or transmit-only operations. When this bit is set to 1, the SPI only performs transmit operations and not receive operations (see section 34.3.6. Data Transfer Modes), and receive buffer full interrupt requests cannot be used.

TXMD setting is invalid in receive only slave mode.

MODFEN bit (Mode Fault Error Detection Enable)

The MODFEN bit enables or disables the detection of mode fault errors (see section 34.3.9. Error Detection). In addition, the SPI determines the I/O direction of the SSLni pins based on combination of the MODFEN and MSTR bits (see section 34.3.2. Controlling the SPI Pins).

MSTR bit (SPI Master/Slave Mode Select)

The MSTR bit selects master or slave mode for the SPI. Based on the MSTR bit settings, the SPI determines the direction of the RSPCKn, MOSIn, MISOn, and SSLni pins.

SPEIE bit (SPI Error Interrupt Enable)

The SPEIE bit enables or disables the generation of SPI error interrupt requests when one of the following occurs:

- The SPI detects a mode fault error or underrun error and sets the SPSR.MODF flag to 1
- The SPI detects an overrun error and sets the SPSR.OVRF flag to 1
- The SPI detects a parity error and sets the SPSR.PERF flag to 1

For details, see section 34.3.9. Error Detection.

SPTIE bit (Transmit Buffer Empty Interrupt Enable)

The SPTIE bit enables or disables the generation of transmit buffer empty interrupt requests when the SPI detects that the transmit buffer is empty. To generate a transmit buffer empty interrupt request when transmission starts, set the SPE and SPTIE bits to 1 at the same time or set the SPE bit to 1 after setting the SPTIE bit to 1.

When the SPTIE bit is 1, transmit buffer interrupts are generated even when the SPI function is disabled (when the SPE bit is changed to 0).

SPE bit (SPI Function Enable)

The SPE bit enables or disables the SPI function. The SPE bit cannot be set to 1 when the SPSR.MODF flag is 1. For details, see section 34.3.9. Error Detection.

Setting the SPE bit to 0 disables the SPI function and initializes a part of the module function. For details, see section 34.3.10. Initializing the SPI. In addition, a transmit buffer empty interrupt request is generated when the SPE bit is changed from 0 to 1 or from 1 to 0.

SPRIE bit (SPI Receive Buffer Full Interrupt Enable)

The SPRIE bit enables or disables the generation of an SPI receive buffer full interrupt request when the SPI detects a receive buffer full write after completion of a serial transfer.

34.2.2 SSLP : SPI Slave Select Polarity Register

Base address: SPIn = 0x4011_A000 + 0x0100 × n (n = 0, 1)

Offset address: 0x01

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	SSL3P	SSL2P	SSL1P	SSL0P
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SSL0P	SSLn0 Signal Polarity Setting 0: Set SSLn0 signal to active-low 1: Set SSLn0 signal to active-high	R/W
1	SSL1P	SSLn1 Signal Polarity Setting 0: Set SSLn1 signal to active-low 1: Set SSLn1 signal to active-high	R/W
2	SSL2P	SSLn2 Signal Polarity Setting 0: Set SSLn2 signal to active-low 1: Set SSLn2 signal to active-high	R/W
3	SSL3P	SSLn3 Signal Polarity Setting 0: Set SSLn3 signal to active-low 1: Set SSLn3 signal to active-high	R/W
7:4	—	These bits are read as 0. The write value should be 0.	R/W

34.2.3 SPPCR : SPI Pin Control Register

Base address: SPIn = 0x4011_A000 + 0x0100 × n (n = 0, 1)

Offset address: 0x02

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	MOIFE	MOIFV	—	—	SPLP2	SPLP
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SPLP	SPI Loopback 0: Normal mode 1: Loopback mode (receive data = inverted transmit data)	R/W
1	SPLP2	SPI Loopback 2 0: Normal mode 1: Loopback mode (receive data = transmit data)	R/W
3:2	—	These bits are read as 0. The write value should be 0.	R/W
4	MOIFV	MOSI Idle Fixed Value 0: Set level output on MOSIn pin during MOSI idling to low 1: Set level output on MOSIn pin during MOSI idling to high	R/W
5	MOIFE	MOSI Idle Value Fixing Enable 0: Set MOSI output value to equal final data from previous transfer 1: Set MOSI output value to equal value set in the MOIFV bit	R/W
7:6	—	These bits are read as 0. The write value should be 0.	R/W

SPLP bit (SPI Loopback)

The SPLP bit selects the mode of the SPI pins. When this bit is set to 1, the SPI shuts off the path between the MISOn pin and the shift register if the SPCR.MSTR bit is 1, and between the MOSIn pin and the shift register if the SPCR.MSTR bit is 0. The SPI then inverts the value of the input path for the shift register and connects it to the output path (loopback mode). For more information, see section 34.3.13. Loopback Mode.

SPLP2 bit (SPI Loopback 2)

The SPLP2 bit selects the mode of the SPI pins. When this bit is set to 1, the SPI shuts off the path between the MISOn pin and the shift register if the SPCR.MSTR bit is 1, and between the MOSIn pin and the shift register if the SPCR.MSTR bit is 0. The SPI then connects the value of the input path for the shift register to the output path (loopback mode) without inverting the value. For more information, see section 34.3.13. Loopback Mode.

MOIFV bit (MOSI Idle Fixed Value)

The MOIFV bit determines the MOSIn pin output value during the SSL negation period (including the SSL retention period during a burst transfer) when the MOIFE bit is 1 in master mode.

MOIFE bit (MOSI Idle Value Fixing Enable)

The MOIFE bit fixes the MOSIn output value when the SPI is in master mode and in an SSL negation period (including the SSL retention period during a burst transfer).When the MOIFE bit is 0, the SPI outputs the last data from the previous serial transfer during the SSL negation period to the MOSIn pin. When the MOIFE bit is 1, the SPI outputs the fixed value set in the MOIFV bit to the MOSIn pin.

34.2.4 SPSR : SPI Status Register

Base address: SPIn = 0x4011_A000 + 0x0100 × n (n = 0, 1)

Offset address: 0x03

Bit position:	7	6	5	4	3	2	1	0
Bit field:	SPRF	CENDF	SPTEF	UDRF	PERF	MODF	IDLNF	OVRF
Value after reset:	0	0	1	0	0	0	0	0

Bit	Symbol	Function	R/W
0	OVRF	Overrun Error Flag 0: No overrun error occurred 1: Overrun error occurred	R/W*1
1	IDLNF	SPI Idle Flag 0: SPI is in the idle state 1: SPI is in the transfer state	R
2	MODF	Mode Fault Error Flag 0: No mode fault or underrun error occurred 1: Mode fault error or underrun error occurred	R/W*1
3	PERF	Parity Error Flag 0: No parity error occurred 1: Parity error occurred	R/W*1
4	UDRF	Underrun Error Flag The UDRF bit is valid when MODF flag is 1. 0: Mode fault error occurred (MODF = 1) 1: Underrun error occurred (MODF = 1)	R/W*1 *2
5	SPTEF	SPI Transmit Buffer Empty Flag 0: Data is in the transmit buffer 1: No data is in the transmit buffer	R/W*3
6	CENDF	Communication End Flag 0: Not communicating or communicating 1: Communication completed	R/W*1
7	SPRF	SPI Receive Buffer Full Flag 0: No valid data is in SPDR/SPDR_HA 1: Valid data is in SPDR/SPDR_HA	R/W*3

Note 1. Only 0 can be written to clear the flag after reading 1.
Note 2. Clear the UDRF flag at the same time as the MODF flag.
Note 3. The write value should be 1.

OVRF flag (Overrun Error Flag)

The OVRF flag indicates the occurrence of an overrun error. In master mode (SPCR.MSTR bit = 1) and when the RSPCK clock auto-stop function is enabled (SPCR1.SCKASE bit = 1), overrun errors do not occur. This flag does not set to 1. For details, see section 34.3.9.1. Overrun errors.

[Setting condition]

When the next serial transfer ends and the receive buffer is full, and satisfy one of following.

- The SPCR.TXMD bit = 0. (transmit-receive master mode or transmit-receive slave mode or receive only slave mode)
- The SPCR.MSTR bit = 0, and the SPCR3.ETXMD bit = 1. (receive only slave mode)

[Clearing condition]

- When 0 is written to the OVRF flag after the OVRF flag is confirmed to be 1 by a read of SPSR.

IDLNF flag (SPI Idle Flag)

The IDLNF flag indicates the transfer status of the SPI.

[Setting conditions]

Master mode

- When none of the conditions in the master mode [Clearing condition] is met.

Slave mode

- When the SPE bit in SPCR is 1, enabling the SPI function.

[Clearing conditions]

Master mode

When condition 1 or all other conditions are satisfied.

Condition 1: The SPE bit in SPCR is 0, indicating that the SPI is initialized.

Condition 2: The transmit buffer (SPTX) is empty, indicating that data for the next transfer is not set.

Condition 3: The SPI internal sequencer is in the idle state, indicating that operation up to next-access delay is complete.

Condition 4: The SPCP[2:0] bits in SPSSR are 000 (at the beginning of sequence control)

Slave mode

- When condition 1 is satisfied.

MODF flag (Mode Fault Error Flag)

The MODF flag indicates the occurrence of a mode fault error or an underrun error. The UDRF flag indicates which error occurred.

[Setting conditions]

Multi-master mode

- When the input level of the SSLni pin changes to the active level while the SPCR.MSTR bit is 1 (master mode) and the SPCR.MODFEN bit is 1 (mode fault error detection is enabled), triggering a mode fault error.

Slave mode

- When condition 1 or 2 is satisfied.

Condition 1: The SSLni pin is negated before the RSPCK cycle required for data transfer ends while the SPCR.MSTR bit is 0 (slave mode) and the SPCR.MODFEN bit is 1 (mode fault error detection is enabled), triggering a mode fault error.

Condition 2: The serial transfer begins with the SPCR.MSTR bit is set to 0 (slave mode), the SPCR.SPE bit is set to 1, and the transmission data not prepared, triggering an underrun error.

The active level of the SSLni signal is determined by the SSLP.SSLiP bit (SSLi signal polarity setting).

[Clearing condition]

- When SPSR is read while this flag is 1, and then 0 is written to this flag.

PERF flag (Parity Error Flag)

The PERF flag indicates the occurrence of a parity error.

[Setting condition]

When a serial transfer ends while the SPCR2.SPPE bit is 1, triggering a parity error, and satisfy one of following.

- The SPCR.TXMD bit = 0. (transmit-receive master mode or transmit-receive slave mode or receive only slave mode)
- The SPCR.MSTR bit = 0, and the SPCR3.ETXMD bit = 1. (receive only slave mode)

[Clearing condition]

- When SPSR is read while this flag is 1, and then 0 is written to this flag.

UDRF flag (Underrun Error Flag)

The UDRF flag indicates the occurrence of an underrun error.

[Setting condition]

- When the serial transfer begins with the SPCR.MSTR bit is set to 0 (slave mode), the SPCR3.ETXMD bit =0 (transmit-receive slave mode or transmit slave mode) the SPCR.SPE bit is set to 1, and the transmission data not prepared, triggering an underrun error.

[Clearing condition]

- When SPSR is read while this flag is 1, and then 0 is written to this flag.

SPTEF flag (SPI Transmit Buffer Empty Flag)

The SPTEF flag indicates the status of the transmit buffer for the SPI Data Register (SPDR/SPDR_HA).

[Setting conditions]

- When condition 1. or 2. is satisfied.
  1. The SPCR.SPE bit is 0, indicating that the SPI is initialized.
  2. Transmit data (the frame size specified by the SPDCR.SPFC[1:0]) is transferred from the transmit buffer to the shift register.

[Clearing condition]

- When data is written to SPDR/SPDR_HA/SPDR_BY equals the number of frames set in the SPFC[1:0] bits in the SPI Data Control Register (SPDCR).

Data can only be written to SPDR/SPDR_HA/SPDR_BY when the SPTEF flag is 1. If data is written to the transmit buffer of SPDR/SPDR_HA when the SPTEF flag is 0, data in the transmit buffer is not updated.

CENDF flag (Communication End Flag)

This flag indicates communication end status of SPI. It turns 1 at communication end, and turns 0 at starting next communication.

[Setting condition]

Mastar mode

The following 3 conditions are met.

- The transmit buffer(SPTX) is empty. (There is no next transmission data.)
- The SPSSR.SPCP[2:0] are 000b. (It means the head of the sequential control.)
- The state of SPI internal sequencer transferred to the idle state. (It means the next access delay has been completed.)

Transmit-receive / transmit only slave mode in SPI serial communication (4-wire: the SPCR.SPMS bit is 0)

The following 3 conditions are met.

- The transmit buffer(SPTX) is empty. (There is no next transmission data.)

- The transmission shift register is empty. (It means SPI does not do serial transfer.)
- SSL0 was negated.

Transmit-receive / transmit only slave mode in clock synchronous (3-wire: the SPCR.SPMS bit is 1)

The following 3 conditions are met.

- The transmit buffer(SPTX) is empty. (There is no next transmission data.)
- The transmission shift register is empty. (It means SPI does not do serial transfer.)
- The last even edge of RSPCK of the last data was detected. (When the SPCMD.CPHA bit is “1”.)

Receive only slave mode in SPI serial communication (4-wire: the SPCR.SPMS bit is 0)

The following condition is met.

- SSL0 was negated after the last data was written in the received buffer.

Receive only slave mode in clock synchronous (3-wire: the SPCR.SPMS bit is 1)

The following condition is met.

- The last even edge of RSPCK of the last data was detected. (When the SPCMD.CPHA bit is 1.)

[Clearing condition]

Master mode

Satisfy one of following.

- The next transmit data was written to the transmit buffer (SPTX).
- The CENDF flag was written 0 after reading the SPSR when the CENDF flag was 1

Transmit-receive / transmit only slave mode

Satisfy one of following.

- The next transmit data was written to the transmit buffer(SPTX).
- The CENDF flag was written 0 after reading the SPSR when the CENDF flag was 1.

Receive only slave mode in SPI serial communication (4-wire: the SPCR.SPMS bit is 0)

Satisfy one of following.

- SSL0 assertion of next data was detected.
- The CENDF flag was written 0 after reading the SPSR when the CENDF flag was 1.

Receive only slave mode in clock synchronous (3-wire: the SPCR.SPMS bit is 1)

Satisfy one of following.

- The first edge of RSPCK of the next data was detected.
- The CENDF flag was written 0 after reading the SPSR when the CENDF flag was 1.

SPRF flag (SPI Receive Buffer Full Flag)

The SPRF flag indicates the status of the receive buffer for the SPI Data Register (SPDR/SPDR_HA).

[Setting condition]

- Received data with the frame size specified by the SPDCR.SPFC[1:0] bits have been transferred to the SPDR from the shift register while the SPRF flag is 0. And satisfy one of following. However, the SPRF flag does not change from 0 to 1 while the OVRF flag = 1.
  - The SPCR.TXMD bit is 0 (transmit-receive master mode, transmit-receive slave mode, or receive only slave mode)
  - The SPCR.MSTR bit is 0 and the SPCR3.ETXMD bit is 1 (receive only slave mode)

[Clearing condition]

- When received data is read from the SPDR/SPDR_HA.

34.2.5 SPDR/SPDR_HA/SPDR_BY : SPI Data Register

Base address: SPIn = 0x4011_A000 + 0x0100 × n (n = 0, 1)

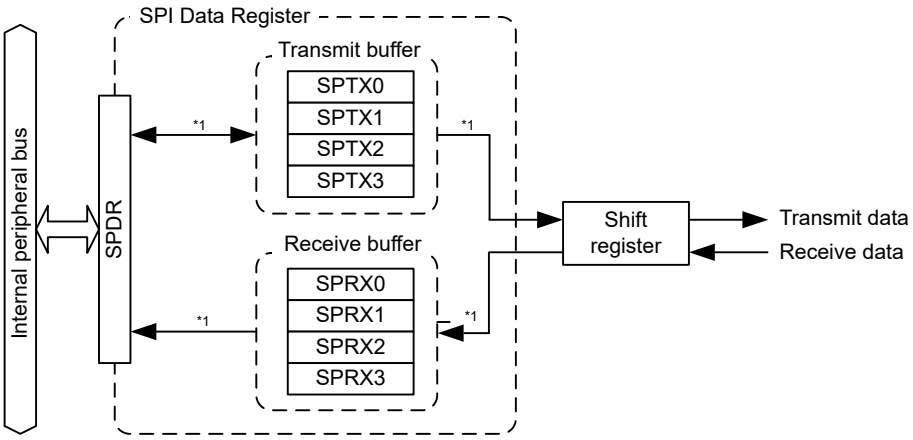
Offset address: 0x04

Bit position:	31																												0
Bit field:																													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	n/a	SPI Data	R/W

SPDR/SPDR_HA/SPDR_BY is the interface with the buffers that hold data for transmission and reception by the SPI. When accessing this register in words (the SPDCR.SPLW bit is 1), access SPDR. When accessing it in halfwords (the SPLW bit is 0), access SPDR_HA. When accessing it in byte (the SPDCR.SPBYT bit is 1), access SPDR_BY.

The transmit buffer (SPTX) and receive buffer (SPRX) are independent but are both mapped to SPDR/SPDR_HA. Figure 34.2 shows the configuration of the SPDR/SPDR_HA register.



Note: SPDR = SPDR/SPDR_HA/SPDR_BY
Note 1. The destination buffer and stage for access is automatically switched by the hardware.

Figure 34.2 Configuration of SPDR/SPDR_HA/SPDR_BY

The transmit and receive buffers each have one stages. The four stages of the buffer are all mapped to the single address of SPDR/SPDR_HA/SPDR_BY.

Data written to SPDR/SPDR_HA/SPDR_BY is written to a transmit-buffer stage (SPTXn) (n = 0 to 3), and then transmitted from the buffer. The receive buffer holds received data on completion of reception. The receive buffer is not updated if an overrun is generated.

Additionally, if the data length is not 32 bits, bits not referred to in SPTXn (n = 0 to 3) are stored in the associated bits in SPRXn (n = 0 to 3). For example, if the data length is 9 bits, the received data is stored in the SPRXn[8:0] bits, and the SPTXn[31:9] bits are stored in the SPRXn[31:9] bits.

(1) Bus interface

SPDR/SPDR_HA/SPDR_BY is an interface with 32-bit wide transmit and receive buffers, each of which has one stages, for a total of 32 bytes. The 32 bytes are mapped to the 4-byte address space for SPDR/SPDR_HA/SPDR_BY. Additionally, the unit of access for SPDR/SPDR_HA/SPDR_BY is selected by the SPI Word Access/Halfword Access Specification bit in the

SPI Data Control Register (SPDCR.SPLW). SPDR can also be accessed with the access size specified by the SPI Byte Access bit in the SPI Data Control Register (SPDCR.SPBYT).

Flush the transmission data at the LSB end of the register, and store the received data at the LSB end.

The following sections describe the operations involved in writing to and reading from SPDR/SPDR_HA/SPDR_BY.

Writing

Data written to SPDR/SPDR_HA/SPDR_BY is written to a transmit buffer (SPTXn). This is not affected by the value of the SPDCR.SPRDTD bit, unlike when reading from SPDR/SPDR_HA/SPDR_BY. The transmit buffer includes a transmit buffer write pointer that is automatically updated to reference the next stage each time data is written to SPDR/SPDR_HA/SPDR_BY.

Figure 34.3 shows the configuration of the bus interface with the transmit buffer when writing to SPDR/SPDR_HA/SPDR_BY.

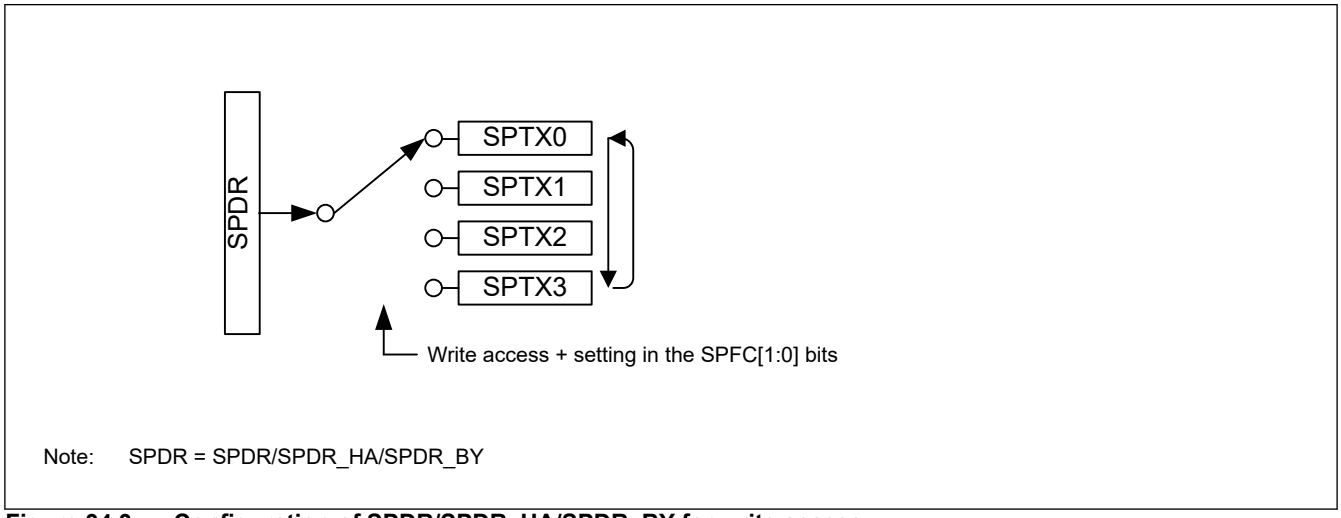


Figure 34.3 Configuration of SPDR/SPDR_HA/SPDR_BY for write access

The sequence for switching the transmit buffer write pointer differs with the setting of the number of frames specification bits in the SPI Data Control Register (SPDCR.SPFC[1:0]). The relationship of the SPFC[1:0] setting and the sequence of pointer switching from SPTX0 to SPTX3 is as follows:

- When SPFC[1:0] = 00b: SPTX0 → SPTX0 → SPTX0 → …
- When SPFC[1:0] = 01b: SPTX0 → SPTX1 → SPTX0 → SPTX1 → …
- When SPFC[1:0] = 10b: SPTX0 → SPTX1 → SPTX2 → SPTX0 → SPTX1 → …
- When SPFC[1:0] = 11b: SPTX0 → SPTX1 → SPTX2 → SPTX3 → SPTX0 → SPTX1 → …

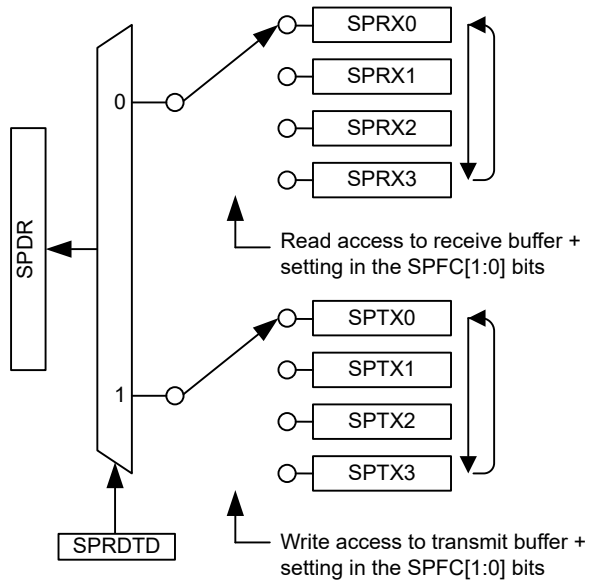
When 1 is written to the SPI Function Enable bit in the SPI Control Register (SPCR.SPE) while the bit is 0, SPTX0 is the destination for the next write.

When writing to the transmit buffer (SPTXn) after generating the transmit buffer empty interrupt (when SPSR.SPTEF is 1), write the number of frames set in SPFC[1:0] in the SPI Data Control Register (SPDCR). Even when the specified number of frames is written to the transmit buffer (SPTXn), the value of the buffer is not updated after completion of the writing and before generation of the next transmit buffer empty interrupt (when SPTEF is 0).

Reading

SPDR/SPDR_HA/SPDR_BY can be accessed to read the value of a receive buffer (SPRXn) or a transmit buffer (SPTXn). The setting in the SPI Receive/Transmit Data Select bit in the SPI Data Control Register (SPDCR.SPRDTD) selects whether reading is of the receive or transmit buffer. The sequence of reading the SPDR/SPDR_HA/SPDR_BY register is controlled by the independent receive buffer and transmit buffer read pointers.

Figure 34.4 shows the configuration of the bus interface with the receive and transmit buffers for reading from SPDR/SPDR_HA/SPDR_BY.



Note: SPDR = SPDR/SPDR_HA/SPDR_BY

Figure 34.4 Configuration of SPDR/SPDR_HA/SPDR_BY for read access

Reading the receive buffer switches the receive buffer read pointer to the next buffer automatically. The switching sequence for the receive buffer read pointer is the same as that for the transmit buffer write pointer. However, when 1 is written to the SPI Function Enable bit in the SPI Control Register (SPCR.SPE) while the value of the bit is 1, SPRX0 is referenced by the buffer read pointer for the next read.

The transmit buffer read pointer is updated when writing to SPDR/SPDR_HA/SPDR_BY, but not updated when reading from the transmit buffer. When reading from the transmit buffer, the value most recently written to SPDR/SPDR_HA/SPDR_BY is read.

After a transmit buffer empty interrupt is generated, reading from the transmit buffer returns all 0s after the completion of writing the number of frames of data specified in the SPDCR.SPFC[1:0] bits, until the next buffer empty interrupt is generated (when SPTEF is 0).

34.2.6 SPSCR : SPI Sequence Control Register

Base address: SPIn = 0x4011_A000 + 0x0100 × n (n = 0, 1)

Offset address: 0x08

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	SPSLN[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	SPSLN[2:0]	SPI Sequence Length Specification The sequence length that is set in these bits determines the order in which the SPCMD0 to SPCMD07 registers are referenced. The setting defines the relationship between the sequence length and the SPCMD0 to SPCMD7 registers referenced by the SPI. In slave mode, the SPI references SPCMD0. 0 0 0: Sequence Length is 1 (Referenced SPCMDn, n = 0→0→…) 0 0 1: Sequence Length is 2 (Referenced SPCMDn, n = 0→1→0→…) 0 1 0: Sequence Length is 3 (Referenced SPCMDn, n = 0→1→2→0→…) 0 1 1: Sequence Length is 4 (Referenced SPCMDn, n = 0→1→2→3→0→…) 1 0 0: Sequence Length is 5 (Referenced SPCMDn, n = 0→1→2→3→4→0→…) 1 0 1: Sequence Length is 6 (Referenced SPCMDn, n = 0→1→2→3→4→5→0→…) 1 1 0: Sequence Length is 7 (Referenced SPCMDn, n = 0→1→2→3→4→5→6→0→…) 1 1 1: Sequence Length is 8 (Referenced SPCMDn, n = 0→1→2→3→4→5→6→7→0→…)	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W

SPSCR specifies the sequence length when the SPI operates in master mode. Before changing the SPSLN[2:0] bits while both the SPCR.MSTR and SPCR.SPE bits are 1, check that the SPSR.IDLNF flag is 0.

SPSLN[2:0] bits (SPI Sequence Length Specification)

The SPSLN[2:0] bits specify the sequence length when the SPI in master mode performs sequential operations. The SPI in master mode changes the SPCMD0 to SPCMD7 registers to be referenced, and the order in which they are referenced is based on this sequence length setting. In slave mode, SPCMD0 is referenced.

34.2.7 SPSSR : SPI Sequence Status Register

Base address: SPIn = 0x4011_A000 + 0x0100 × n (n = 0, 1)

Offset address: 0x09

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	SPECM[2:0]			—	SPCP[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	SPCP[2:0]	SPI Command Pointer 0 0 0: SPCMD0 0 0 1: SPCMD1 0 1 0: SPCMD2 0 1 1: SPCMD3 1 0 0: SPCMD4 1 0 1: SPCMD5 1 1 0: SPCMD6 1 1 1: SPCMD7	R
3	—	This bit is read as 0.	R
6:4	SPECM[2:0]	SPI Error Command 0 0 0: SPCMD0 0 0 1: SPCMD1 0 1 0: SPCMD2 0 1 1: SPCMD3 1 0 0: SPCMD4 1 0 1: SPCMD5 1 1 0: SPCMD6 1 1 1: SPCMD7	R
7	—	This bit is read as 0.	R

SPSSR indicates the sequence control status when the SPI operates in master mode. Any writes to SPSSR are ignored.

SPCP[2:0] bits (SPI Command Pointer)

The SPCP[2:0] bits indicate the SPCMDm register that is referenced to by the pointer during sequence control by the SPI. For the SPI sequence control, see section 34.3.11.1. Master mode operation.

SPECM[2:0] bits (SPI Error Command)

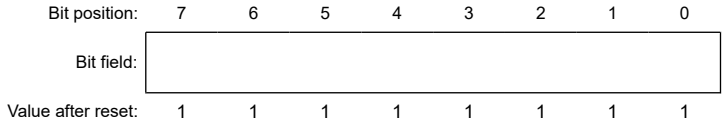
The SPECM[2:0] bits indicate the SPCMDm register that is specified in the SPCP[2:0] bits when an error is detected during sequence control by the SPI. The SPI updates the SPECM[2:0] bits only when an error is detected. If both the SPSR.OVRF and SPSR.MODF flags are 0 and there is no error, the values of the SPECM[2:0] bits have no meaning.

For the SPI error detection function, see section 34.3.9. Error Detection. For the SPI sequence control, see section 34.3.11.1. Master mode operation.

34.2.8 SPBR : SPI Bit Rate Register

Base address: SPIn = 0x4011_A000 + 0x0100 × n (n = 0, 1)

Offset address: 0x0A



Bit	Symbol	Function	R/W
7:0	n/a	Bit rate	R/W

SPBR sets the bit rate in master mode.

When the SPI is in slave mode, the bit rate depends on the bit rate of the input clock, regardless of the settings in SPBR and the SPCMDm.BRDV[1:0] bits (bit rate division setting). Use bit rates that satisfy the electrical characteristics of the device.

The bit rate is determined by combinations of the SPBR and SPCMDm.BRDV[1:0] settings in the SPI Command Register. The equation for calculating the bit rate is given as follows:

$$\text{Bit rate} = \frac{f(\text{PCLK})}{2 \times (n+1) \times 2^{N}}$$

(PCLK = PCLKA)

In the equation, n denotes an SPBR setting (0, 1, 2, …, 255), and N denotes a BRDV[1:0] setting (0, 1, 2, 3).

Table 34.3 lists examples of the relationship between the SPBR settings, the BRDV[1:0] settings, and bit rates.

Table 34.3 Relationship between SPBR settings, BRDV[1:0] settings, and bit rates

SPBR(n)	BRDV[1:0] bits (N)	Division ratio	Bit rate
			PCLKA = 32 MHz
0	0	2	16.0 Mbps
1	0	4	8.00 Mbps
2	0	6	5.33 Mbps
3	0	8	4.00 Mbps
4	0	10	3.20 Mbps
5	0	12	2.67 Mbps
5	1	24	1.33 Mbps
5	2	48	667 kbps
5	3	96	333 kbps
255	3	4096	7.81 kbps

34.2.9 SPDCR : SPI Data Control Register

Base address: SPIn = 0x4011_A000 + 0x0100 × n (n = 0, 1)

Offset address: 0x0B

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	SPBYT	SPLW	SPRDTD	—	—	SPFC[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	SPFC[1:0]	Number of Frames Specification 0 0: 1 frame 0 1: 2 frames 1 0: 3 frames 1 1: 4 frames	R/W
3:2	—	These bits are read as 0. The write value should be 0.	R/W
4	SPRDTD	SPI Receive/Transmit Data Select 0: Read SPDR/SPDR_HA values from receive buffer 1: Read SPDR/SPDR_HA values from transmit buffer, but only if the transmit buffer is empty	R/W
5	SPLW	SPI Word Access/Halfword Access Specification 0: Set SPDR_HA to valid for halfword access 1: Set SPDR to valid for word access	R/W
6	SPBYT	SPI Byte Access Specification 0: SPDR/SPDR_HA is accessed in halfword or word (SPLW is valid) 1: SPDR_BY is accessed in byte (SPLW is invalid)	R/W
7	—	This bit is read as 0. The write value should be 0.	R/W

The SPI Data Control Register (SPDCR) is used to read the number of frames that can be stored in the SPDR register,read the SPDR register, and to set the access width for the SPDR register to word access, halfword access, or byte access. Up to four frames can be transmitted or received in one round of transmission or reception. The amount of data in each transfer is controlled by the combination of the SPCMDm.SPB[3:0] bits, the SPSCR.SPSLN[2:0] bits, and the SPFC[1:0] bits.

When changing the SPFC[1:0] bits while the SPCR.SPE bit is 1, check that the SPSR.IDLNF flag is 0.

SPFC[1:0] bits (Number of Frames Specification)

The SPFC[1:0] bits specify the number of frames that can be stored in SPDR/SPDR_HA per transfer activation. Up to four frames can be transmitted or received in one round of transmission or reception.

When the number of transmission data frames specified in the SPFC[1:0] bits is written to the SPDR/SPDR_HA register, SPI clears the SPSR.SPTEF flag to 0 and begins transmitting. After that, when the number of transmission data frames specified in the SPFC[1:0] bits is transmitted to the shift register, the SPI generates the transmit buffer empty interrupt (SPSR.SPTEF sets to 1).

When the number of data frames specified in the SPFC[1:0] bits is received, the SPI generates the receive buffer full interrupt (SPSR.SPRF sets to 1).

Table 34.4 Settable combinations of the SPSLN[2:0] and SPFC[1:0] bits (1 of 2)

Setting	SPSLN[2:0]	SPFC[1:0]	Number of frames in a single sequence	Number of frames at which transmission or receive buffer is filled
1-1	000b	00b	1	1
1-2	000b	01b	2	2
1-3	000b	10b	3	3
1-4	000b	11b	4	4
2-1	001b	01b	2	2

Table 34.4 Settable combinations of the SPSLN[2:0] and SPFC[1:0] bits (2 of 2)

Setting	SPSLN[2:0]	SPFC[1:0]	Number of frames in a single sequence	Number of frames at which transmission or receive buffer is filled
2-2	001b	11b	4	4
3	010b	10b	3	3
4	011b	11b	4	4
5	100b	00b	5	1
6	101b	00b	6	1
7	110b	00b	7	1
8	111b	00b	8	1

SPRDTD bit (SPI Receive/Transmit Data Select)

The SPRDTD bit selects whether the SPDR/SPDR_HA reads values from the receive buffer or from the transmit buffer. If reading is from the transmit buffer, the last value written to SPDR/SPDR_HA register is read. Read the transmit buffer after an SPI transmit buffer empty interrupt is generated until data of frames specified by SPFC[1:0] has been written (while the SPSR.SPTEF flag is 1).

For details, see section 34.2.5. SPDR/SPDR_HA/SPDR_BY : SPI Data Register.

SPLW bit (SPI Word Access/Halfword Access Specification)

The SPLW bit specifies the access width for SPDR. Access to SPDR_HA in halfwords is valid when the SPLW bit is 0 and access to SPDR in words is valid when the SPLW bit is 1. Also, when this bit is 0, set the SPI data length setting bits, SPCMDm.SPB[3:0], from 8 to 16 bits. Do not perform any operations when a data length of 20, 24, or 32 bits is specified.

SPBYT bit (SPI Byte Access Specification)

The SPBYT bit is used to set the data width of access to the SPI Data Register (SPDR). When SPBYT = 0, use word or half word access to SPDR/SPDR_HA. When SPBYT = 1 (in that case, SPLW is invalid), use byte access to SPDR_BY.

When SPBYT = 1, set the SPI data length bits (SPB[3:0]) in the SPI Command Register m (SPCMDm) to 8 bits. If SPB[3:0] are set to 9 to 16, 20, 24, or 32 bit, subsequent operation is not guaranteed.

34.2.10 SPCKD : SPI Clock Delay Register

Base address: SPIn = 0x4011_A000 + 0x0100 × n (n = 0, 1)

Offset address: 0x0C

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	SCKDL[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	SCKDL[2:0]	RSPCK Delay Setting 0 0 0: 1 RSPCK 0 0 1: 2 RSPCK 0 1 0: 3 RSPCK 0 1 1: 4 RSPCK 1 0 0: 5 RSPCK 1 0 1: 6 RSPCK 1 1 0: 7 RSPCK 1 1 1: 8 RSPCK	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W

SPCKD specifies the RSPCK delay, the period from the beginning of SSLni signal assertion to RSPCK oscillation, when the SPCMDm.SCKDEN bit is 1.

SCKDL[2:0] bits (RSPCK Delay Setting)

The SCKDL[2:0] bits specify an RSPCK delay value when the SPCMDm.SCKDEN bit is 1. When using the SPI in slave mode, set the SCKDL[2:0] bits to 000b.

34.2.11 SSLND : SPI Slave Select Negation Delay Register

Base address: SPIn = 0x4011_A000 + 0x0100 × n (n = 0, 1)

Offset address: 0x0D

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	SLNDL[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	SLNDL[2:0]	SSL Negation Delay Setting 0 0 0: 1 RSPCK 0 0 1: 2 RSPCK 0 1 0: 3 RSPCK 0 1 1: 4 RSPCK 1 0 0: 5 RSPCK 1 0 1: 6 RSPCK 1 1 0: 7 RSPCK 1 1 1: 8 RSPCK	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W

SSLND specifies the SSL negation delay, the period from the transmission of a final RSPCK edge to the negation of the SSLni signal during a serial transfer by the SPI in master mode. If the contents of SSLND are changed while both the SPCR.MSTR and SPCR.SPE bits are 1, do not perform subsequent operations.

SLNDL[2:0] bits (SSL Negation Delay Setting)

The SLNDL[2:0] bits specify an SSL negation delay value when the SLNDEN bit in SPCMDn is 1 and the SPI is in master mode. When using the SPI in slave mode, set the SLNDL[2:0] bits to 000b.

34.2.12 SPND : SPI Next-Access Delay Register

Base address: SPIn = 0x4011_A000 + 0x0100 × n (n = 0, 1)

Offset address: 0x0E

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	SPNDL[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	SPNDL[2:0]	SPI Next-Access Delay Setting 0 0 0: 1 RSPCK + 2 PCLKA 0 0 1: 2 RSPCK + 2 PCLKA 0 1 0: 3 RSPCK + 2 PCLKA 0 1 1: 4 RSPCK + 2 PCLKA 1 0 0: 5 RSPCK + 2 PCLKA 1 0 1: 6 RSPCK + 2 PCLKA 1 1 0: 7 RSPCK + 2 PCLKA 1 1 1: 8 RSPCK + 2 PCLKA	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W

SPND specifies the next-access delay, the non-active period of the SSLni signal after termination of a serial transfer, when the SPCMDm.SPNDEN bit is 1.

SPNDL[2:0] bits (SPI Next-Access Delay Setting)

The SPNDL[2:0] bits specify a next-access delay when the SPCMDm.SPNDEN bit is 1. When using the SPI in slave mode, set the SPNDL[2:0] bits to 000b.

34.2.13 SPCR2 : SPI Control Register 2

Base address: SPIn = 0x4011_A000 + 0x0100 × n (n = 0, 1)

Offset address: 0x0F

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	SCKASE	PTE	SPIIE	SPOE	SPPE
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SPPE	Parity Enable 0: Do not add parity bit to transmit data and do not check parity bit of receive data 1: When SPCR.TXMD = 0: Add parity bit to transmit data and check parity bit of receive data When SPCR.TXMD = 1: Add parity bit to transmit data but do not check parity bit of receive data	R/W
1	SPOE	Parity Mode 0: Select even parity for transmission and reception 1: Select odd parity for transmission and reception	R/W
2	SPIIE	SPI Idle Interrupt Enable 0: Disable idle interrupt requests 1: Enable idle interrupt requests	R/W
3	PTE	Parity Self-Testing 0: Disable self-diagnosis function of the parity circuit 1: Enable self-diagnosis function of the parity circuit	R/W
4	SCKASE	RSPCK Auto-Stop Function Enable 0: Disable RSPCK auto-stop function 1: Enable RSPCK auto-stop function	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W

SPPE bit (Parity Enable)

The SPPE bit enables or disables the parity function.

When the SPCR.TXMD bit is 0 and this bit is 1, the parity bit is added to transmit data and parity checking is performed for receive data.

When the SPCR.TXMD bit is 1 and this bit is 1, the parity bit is added to transmit data but parity checking is not performed for receive data.

SPOE bit (Parity Mode)

The SPOE bit specifies odd or even parity.

When even parity is set, parity bit addition is performed so that the total number of bits whose value is 1 in the transmit or receive character plus the parity bit is even. Similarly, when odd parity is set, parity bit addition is performed so that the total number of bits whose value is 1 in the transmit or receive character plus the parity bit is odd.

The SPOE bit is only valid when the SPPE bit is 1.

SPIIE bit (SPI Idle Interrupt Enable)

The SPIIE bit enables or disables the generation of SPI idle interrupt requests when an idle state is detected in the SPI and the SPSR.IDLNF flag clears is set to 0.

PTE bit (Parity Self-Testing)

The PTE bit enables self-diagnosis of the parity circuit to check whether the parity function is operating correctly.

SCKASE bit (RSPCK Auto-Stop Function Enable)

The SCKASE bit enables or disables the RSPCK auto-stop function. When this function is enabled, the RSPCK clock is stopped before an overrun error occurs, when data is received in master mode. For details, see section 34.3.9.1. Overrun errors.

34.2.14 SPCMDm : SPI Command Register m (m = 0 to 7)

Base address: SPIn = 0x4011_A000 + 0x0100 × n (n = 0, 1)

Offset address: 0x10 + 0x02 × m

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	SCKDEN	SLNDEN	SPNDEN	LSBF	SPB[3:0]				SSLKP	SSLA[2:0]			BRDV[1:0]		CPOL	CPHA
Value after reset:	0	0	0	0	0	1	1	1	0	0	0	0	1	1	0	1

Bit	Symbol	Function	R/W
0	CPHA	RSPCK Phase Setting 0: Select data sampling on leading edge, data change on trailing edge 1: Select data change on leading edge, data sampling on trailing edge	R/W
1	CPOL	RSPCK Polarity Setting 0: Set RSPCK low during idle 1: Set RSPCK high during idle	R/W
3:2	BRDV[1:0]	Bit Rate Division Setting 0 0: Base bit rate 0 1: Base bit rate divided by 2 1 0: Base bit rate divided by 4 1 1: Base bit rate divided by 8	R/W
6:4	SSLA[2:0]	SSL Signal Assertion Setting 0 0 0: SSL0 0 0 1: SSL1 0 1 0: SSL2 0 1 1: SSL3 Others: Setting prohibited	R/W
7	SSLKP	SSL Signal Level Keeping 0: Negate all SSL signals on completion of transfer 1: Keep SSL signal level from the end of transfer until the beginning of the next access	R/W
11:8	SPB[3:0]	SPI Data Length Setting 0x0: 20 bits 0x1: 24 bits 0x2: 32 bits 0x3: 32 bits 0x8: 9 bits 0x9: 10 bits 0xA: 11 bits 0xB: 12 bits 0xC: 13 bits 0xD: 14 bits 0xE: 15 bits 0xF: 16 bits Others: 8 bits	R/W
12	LSBF	SPI LSB First 0: MSB-first 1: LSB-first	R/W
13	SPNDEN	SPI Next-Access Delay Enable 0: Select next-access delay of 1 RSPCK + 2 PCLKA 1: Select next-access delay equal to the setting in the SPI Next-Access Delay Register (SPND)	R/W

Bit	Symbol	Function	R/W
14	SLNDEN	SSL Negation Delay Setting Enable 0: Select SSL negation delay of 1 RSPCK 1: Select SSL negation delay equal to the setting in the SPI Slave Select Negation Delay Register (SSLND)	R/W
15	SCKDEN	RSPCK Delay Setting Enable 0: Select RSPCK delay of 1 RSPCK 1: Select RSPCK delay equal to the setting in the SPI Clock Delay Register (SPCKD)	R/W

The SPCMDm registers specify the transfer format for the SPI in master mode. Each channel has eight SPCMDm (m = 0 to 7). Some of the bits in the SPCMD0 registers are used to set the transfer mode for the SPI in slave mode. The SPI in master mode sequentially references the SPCMDm registers based on the settings in the SPSCR.SPSLN[2:0] bits and executes the serial transfer that is set in the referenced SPCMDm registers.

Set the SPCMDm registers while the transmit buffer is empty (SPSR.SPTEF is 1 and data for the next transfer is not set) and before the setting of the data to be transmitted when that SPCMDm registers is referenced.

The SPCMDm registers referenced by the SPI in master mode can be checked by means of the SPSSR.SPCP[2:0] bits.

CPHA bit (RSPCK Phase Setting)

The CPHA bit selects the RSPCK phase of the SPI in master or slave mode. Data communications between SPI modules require the same RSPCK phase setting between the modules.

CPOL bit (RSPCK Polarity Setting)

The CPOL bit selects the RSPCK polarity of the SPI in master or slave mode. Data communications between SPI modules require the same RSPCK polarity setting between the modules.

BRDV[1:0] bits (Bit Rate Division Setting)

The BRDV[1:0] bits determine the bit rate in combination with the settings in the SPBR register. (see section 34.2.8. SPBR : SPI Bit Rate Register). The SPBR settings determine the base bit rate. The BRDV[1:0] setting selects the bit rate obtained by dividing the base bit rate by 1, 2, 4, or 8. Different BRDV[1:0] bit settings can be specified in the SPCMD0 register. This enables execution of serial transfers at different bit rates for each command.

SSLA[2:0] bits (SSL Signal Assertion Setting)

The SSLA[2:0] bits control the SSLni signal assertion when the SPI performs serial transfers in master mode. When an SSLni signal is asserted, its polarity is determined by the value set in the associated SSLP. When the SSLA[2:0] bits are set to 000b in multi-master mode, serial transfers are performed with all the SSL signals in the negated state (as the SSLn0 pin acts as input).

When using the SPI in slave mode, set the SSLA[2:0] bits to 000b.

SSLKP bit (SSL Signal Level Keeping)

When the SPI in master mode performs a serial transfer, the SSLKP bit specifies whether the SSLni signal level for the current command is to be kept or negated between the SSL negation associated with the current command and the SSL assertion associated with the next command. Setting the SSLKP bit to 1 enables a burst transfer. For details, see section 34.3.11.1. Master mode operation. When using the SPI in slave mode, set the SSLKP bit to 0.

SPB[3:0] bits (SPI Data Length Setting)

The SPB[3:0] bits specify the transfer data length for the SPI in master or slave mode.

LSBF bit (SPI LSB First)

The LSBF bit specifies the data format of the SPI in master or slave mode to MSB-first or LSB-first.

SPNDEN bit (SPI Next-Access Delay Enable)

The SPNDEN bit specifies the next-access delay, the period from the time the SPI in master mode terminates a serial transfer and sets the SSLni signal inactive until the SPI enables the SSLni signal assertion for the next access. If the SPNDEN bit is 0, the SPI sets the next-access delay to 1 RSPCK + 2 PCLKA. If the SPNDEN bit is 1, the SPI inserts a next-access delay according to the SPND setting.

When using the SPI in slave mode, set the SPNDEN bit to 0.

SLNDEN bit (SSL Negation Delay Setting Enable)

The SLNDEN bit specifies the SSL negation delay, the period from the time the SPI in master mode stops RSPCK oscillation until the SPI sets the SSLni signal to inactive. If the SLNDEN bit is 0, the SPI sets the SSL negation delay to 1 RSPCK. If the SLNDEN bit is 1, the SPI negates the SSL signal at the SSL negation delay according to the SSLND setting.

When using the SPI in slave mode, set the SLNDEN bit to 0.

SCKDEN bit (RSPCK Delay Setting Enable)

The SCKDEN bit specifies the SPI clock delay, the period from the point when the SPI in master mode asserts the SSLni signal until the RSPCK starts oscillation. If the SCKDEN bit is 0, the SPI sets the RSPCK delay to 1 RSPCK. If the SCKDEN bit is 1, the SPI starts the oscillation of RSPCK at an RSPCK delay according to the SPCKD setting.

When using the SPI in slave mode, set the SCKDEN bit to 0.

34.2.15 SPDCR2 : SPI Data Control Register 2

Base address: SPIn = 0x4011_A000 + 0x0100 × n (n = 0, 1)

Offset address: 0x20

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	SINV	BYSW
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	BYSW	Byte Swap Operating Mode Select 0: Byte Swap OFF 1: Byte Swap ON	R/W
1	SINV	Serial Data Invert Bit 0: Not invert serial data 1: Invert serial data	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W

SPI Data Control Register 2 (SPDCR2) is the setting register, that is to swap a transmit/receive data in byte units and to invert serial data. If these bits are modified while the SPI in slave mode is enabled (SPCR.SPE = 1), subsequent operation is not guaranteed.

BYSW bit (Byte Swap Operating Mode Select)

It is a setting bit, that is to swap a transmit/receive data in byte units. When byte access is valid (SPDCR.SPBYT = 1), byte swap is invalid. When byte swap is valid, parity function must be invalid (SPCR2.SPPE bit = 0). Setting change of BYSW bit must be SPCR.SPE bit = 0.

A data after byte swap is different by a data length (setting of SPCMD.SPB[3:0]).

When byte swap, A data length (setting of SPB[3:0]) must be set to 32 bit or 16bit. Other case of data length (that is 8 to 15, 20, 24 bit length), byte swap is not guaranteed. Before swap and after swap are shown below (length data (32 bit/16 bit)).

- Length data 32 bits (SPB[3:0] = 0010b or 0011b)

  Before swap: [31:24] [23:16] [15:8] [7:0]

  After swap: [7:0] [15:8] [23:16] [31:24]
- Length data 16 bit (SPB[3:0] = 1111b)

  Before swap: [31:24] [23:16]

  After swap: [23:16] [31:24]

When byte access mode (SPDCR.SPBT = 1), byte swap setting is invalid.

When byte swap is valid, set parity function to invalid (SPCR2.SPPE = 0). When the parity function set to valid, the behavior is not guaranteed.

SINV bit (Serial Data Invert Bit)

This bit is used to invert transmit data and receive data.

When the SINV bit is set to 1, transmit buffer (SPTX) data is inverted to invert transmit data and receive data, and then the inverted data is stored in the receive buffer (SPRX). The parity bit is the value corresponding to the inverted transmission/ reception data.

34.2.16 SPCR3 : SPI Control Register 3

Base address: SPIn = 0x4011_A000 + 0x0100 × n (n = 0, 1)

Offset address: 0x21

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	CENDIE	—	—	BFDS	ETXMD
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	ETXMD	Extended Communication Mode Select 0: Full-duplex synchronous or transmit-only serial communications. [the SPCR.TXMD bit is enabled] 1: Receive-only serial communications in slave mode (SPCR.MSTR bit = 0). [the SPCR.TXMD bit is disabled] Setting is prohibited in master mode (SPCR.MSTR bit = 1).	R/W
1	BFDS	Between Burst Transfer Frames Delay Select 0: Delay (RSPCK delay, SSL negation delay and next-access delay) between frames is inserted in burst transfer. 1: Delay between frames is not inserted in burst transfer.	R/W
3:2	—	These bits are read as 0. The write value should be 0.	R/W
4	CENDIE	SPI Communication End Interrupt Enable 0: Communication end interrupt request is disabled. 1: Communication end interrupt request is enabled.	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W

SPI control register 3 (SPCR3) is control register for operation mode. If you change the value of ETXMD and BFDS when the SPCR.SPE bit is 1, the SPI operation does not guarantee.

ETXMD bit (Extended Communication Mode Select)

This bit is valid on slave mode only (the SPCR.MSTR bit is 0). This bit select receive only operation. When the ETXMD bit is 1 on slave mode, the communication is only received not transmit (see section 34.3.6. Data Transfer Modes). When the ETXMD is 1, transmit data empty interrupt can not be used.

The communication state by each mode (master mode, slave mode) is shown as below. It is controlled by the ETXMD bit, the SPCR.MSTR bit and the TXMD bit.

Table 34.5 SPI communication state (master/slave mode)

SPCR.MSTR bit	SPCR3.ETXMD bit	SPCR.TXMD bit	Communication state
1	0	0	Transmit-receive master mode
1	0	1	Transmit master mode
0	0	0	Transmit-receive slave mode (default)
0	0	1	Transmit slave mode
0	1	—	Receive slave mode

BFDS bit (Between Burst Transfer Frames Delay Select)

This bit controls whether insert the delay time between the burst transfer frames.

This bit is valid when the SPCMD.SSLKP bit is 1 in master mode (the SPCR.MSTR bit is 1).

This bit should be set to 0 in slave mode. The usage of SSL delay control between transfer frames is shown as below. For details, see (4)Burst transfers.

Table 34.6 Usage of SSL delay control between transfer frames (Master mode)

Transmit		SPCMD.SSLKP bit	SPCR3.BFDS bit	SSL delay control register*1 (RSPCK clock delay, SSL negation delay, next access delay)
Non-burst transmit		0	0	Any given value. You can control each delay value according to setting for RSPCK clock delay, SSL negation delay and next access delay.
Burst transmit with delay between frames	From the 1st frame to the last previous frame	1	0	
	The last frame	0	0	
Burst transmit with no delay between frames	From the 1st frame to the last previous frame	1	1	Any given value. But delay is inserted only below. • RSPCK clock delay of the 1st frame • SSL negation delay and next access delay of the last frame
	The last frame	0	1	

Note 1. Whether the setting value of following bits are valid or not depends on the setting value of the SPCMD.SPNDEN bit (see section 34.2.14. SPCMDm : SPI Command Register m (m = 0 to 7)).
The SPCKD.SCKDL[2:0] bits: RSPCK delay
The SSLND.SLNDL[2:0] bits: SSL negate delay
The SPND.SPNDL[2:0] bits: Next access delay

CENDIE bit (SPI Communication End Interrupt Enable)

This bit controls generation of a communication end interrupt request.

34.3 Operation

In this section, the serial transfer period refers to the period from the beginning of driving valid data to the fetching of the final valid data.

34.3.1 Overview of SPI Operation

The SPI is capable of synchronous serial transfers in the following modes:

- Slave mode (SPI operation)
- Single master mode (SPI operation)
- Multi-master mode (SPI operation)
- Slave mode (clock synchronous operation)
- Master mode (clock synchronous operation)

The SPI mode can be selected by using the MSTR, MODFEN, and SPMS bits in SPCR. Table 34.7 lists the relationship between SPI modes and SPCR settings, and a description of each mode.

Table 34.7 Relationship between SPCR settings and SPI modes (1 of 2)

Mode	Slave (SPI operation)	Single-master (SPI operation)	Multi-master (SPI operation)	Slave (clock synchronous operation)	Master (clock synchronous operation)
MSTR bit setting	0	1	1	0	1
MODFEN bit setting	0 or 1	0	1	0	0
SPMS bit setting	0	0	0	1	1
RSPCKn pins	Input	Output	Output/Hi-Z	Input	Output
MOSIn pin	Input	Output	Output/Hi-Z	Input	Output
MISOn pin	Output/Hi-Z	Input	Input	Output	Input

Table 34.7 Relationship between SPCR settings and SPI modes (2 of 2)

Mode	Slave (SPI operation)	Single-master (SPI operation)	Multi-master (SPI operation)	Slave (clock synchronous operation)	Master (clock synchronous operation)
SSLn0 pins	Input	Output	Input	Hi-Z*1	Hi-Z*1
SSLn1 to SSLn3 pins	Hi-Z*1	Output	Output/Hi-Z	Hi-Z*1	Hi-Z*1
SSL polarity change function	Supported	Supported	Supported	—	—
Max transfer rate	PCLKA/4	PCLKA/2	PCLKA/2	PCLKA/4	PCLKA/2
Clock source	RSPCK input	On-chip baud rate generator	On-chip baud rate generator	RSPCK input	On-chip baud rate generator
Clock polarity	Two				
Clock phase	Two	Two	Two	One (CPHA = 1)	Two
First transfer bit	MSB/LSB				
Transfer data length	8 to 16, 20, 24, 32 bits				
Burst transfer	Possible (CPHA = 1)	Possible (CPHA = 0, 1)	Possible (CPHA = 0, 1)	—	—
RSPCK delay control	Not supported	Supported	Supported	Not supported	Supported

Parity error detection	Supported*3*2				
Mode fault error detection	Supported (MODFEN = 1)	Not supported	Supported	Not supported	Not supported
Underrun error detection	Supported*5	Not supported	Not supported	Supported*5	Not supported

Note 1. This function is not supported in this mode.
Note 2. When the SPCR.TXMD bit is 1, detection of receiver buffer full, overrun error, and parity error are not performed.
Note 3. When the SPCR2.SPPE bit is 0, parity error detection is not performed.
Note 4. When the SPCR2.SCKASE bit is 1, overrun error detection does not proceed.
Note 5. When SPI is receive only slave mode, none of transmit buffer empty and underrun error is detected.

34.3.2 Controlling the SPI Pins

Based on the settings of the MSTR, MODFEN, and SPMS bits in SPCR and the PmnPFS.NCODR bit for I/O Ports, the SPI can switch pin states. Table 34.8 lists the relationship between pin states and bit settings. Setting the PmnPFS.NCODR bit for an I/O port to 0 selects the CMOS output. Setting it to 1 selects the open-drain output. The I/O port settings must follow this relationship.

Table 34.8 Relationship between pin states and bit settings

Mode	Pin	Pin state*2	
		PmnPFS.NCODR bit for I/O ports = 0	PmnPFS.NCODR bit for I/O ports = 1
Single-master mode (SPI operation) (MSTR = 1, MODFEN = 0, SPMS = 0)	RSPCKn	CMOS output	Open-drain output
	SSLn0 to SSLn3	CMOS output	Open-drain output
	MOSIn	CMOS output	Open-drain output
	MISOn	Input	Input
Multi-master mode (SPI operation) (MSTR = 1, MODFEN = 1, SPMS = 0)	RSPCKn*3	CMOS output/Hi-Z	Open-drain output/Hi-Z
	SSLn0	Input	Input
	SSLn1 to SSLn3*3	CMOS output/Hi-Z	Open-drain output/Hi-Z
	MOSIn*3	CMOS output/Hi-Z	Open-drain output/Hi-Z
	MISOn	Input	Input
Slave mode (SPI operation) (MSTR = 0, SPMS = 0)	RSPCKn	Input	Input
	SSLn0	Input	Input
	SSLn1 to SSLn3*5	Hi-Z*1	Hi-Z*1
	MOSIn	Input	Input
	MISOn*4	CMOS output/Hi-Z	Open-drain output/Hi-Z
Master mode (clock synchronous operation) (MSTR = 1, MODFEN = 0, SPMS = 1)	RSPCKn	CMOS output	Open-drain output
	SSLn0 to SSLn3*5	Hi-Z*1	Hi-Z*1
	MOSIn	CMOS output	Open-drain output
	MISOn	Input	Input
Slave mode (clock synchronous operation) (MSTR = 0, SPMS = 1)	RSPCKn	Input	Input
	SSLn0 to SSLn3*5	Hi-Z*1	Hi-Z*1
	MOSIn	Input	Input
	MISOn	CMOS output	Open-drain output

Note 1. This function is not supported in this mode.
Note 2. SPI settings are not reflected in multiplexed pins for which the SPI function is not selected.
Note 3. When SSLn0 is at the active level, the pin state is Hi-Z. Whether or not the input signal is at the active level determines the setting of the SSLP.SSL0P bit.
Note 4. When SSLn0 is at the non-active level or the SPCR.SPE bit is 0, the pin state is Hi-Z. Whether or not the input signal is at the active level determines the setting of the SSLP.SSL0P bit.
Note 5. These pins are available for use as I/O port pins.

The SPI in single-master mode (SPI operation) or multi-master mode (SPI operation) determines the MOSI signal values during the SSL negation period (including the SSL retention period during a burst transfer) based on the MOIFE and MOIFV bit settings in SPPCR, as listed in Table 34.9.

Table 34.9 MOSI signal value determination during SSL negation

MOIFE bit	MOIFV bit	MOSIn signal value during SSL negation
0	0, 1	Final data from previous transfer
1	0	Low
1	1	High

34.3.3 SPI System Configuration Examples

34.3.3.1 Single-master/single-slave with the MCU as a master

Figure 34.5 shows a single-master/single-slave SPI system configuration example where the MCU is used as a master. In the single-master/single-slave configuration, the SSLni outputs of the MCU (master) are not used. The SSL input of the SPI slave is fixed to the low level, and the SPI slave is maintained in the selected state.*1

Note 1. In the transfer format configured when the SPCMDm.CPHA bit is 0, the SSL signal for some slave devices cannot be fixed to an active level. In this case, always connect the SSLni output of the MCU to the SSL input of the slave device.

The MCU (master) drives the RSPCKn and MOSIn signals. The SPI slave drives the MISO signal.

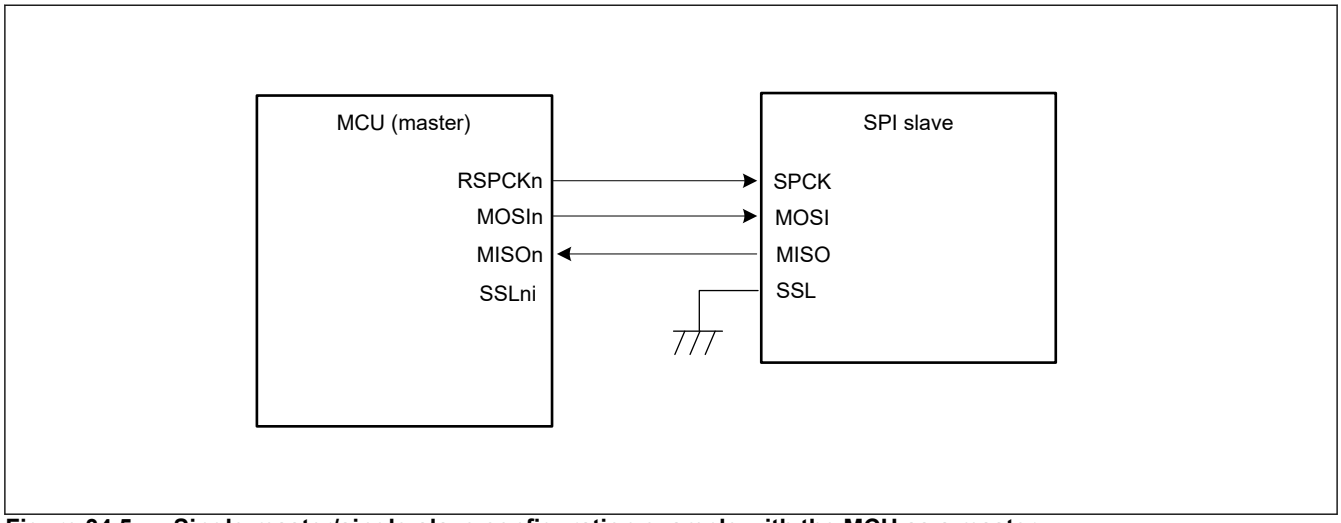

Figure 34.5 Single-master/single-slave configuration example with the MCU as a master

34.3.3.2 Single-master/single-slave with the MCU as a slave

Figure 34.6 shows a single-master/single-slave SPI system configuration example where the MCU is used as a slave. When the MCU operates as a slave, the SSLn0 pin is used as SSL input. The SPI master drives the RSPCK and MOSI signals. The MCU (slave) drives the MISOn signal.*1

Note 1. When SSLn0 is at a non-active level, the pin state is Hi-Z.

In the single-slave configuration when the SPCMDm.CPHA bit is set to 1, the SSLn0 input of the MCU (slave) is fixed to the low level and the MCU (slave) is maintained in the selected state. This enables serial transfer execution (Figure 34.7). However, the communication end interrupt does not output when SSL0 input is fixed as Figure 34.7.

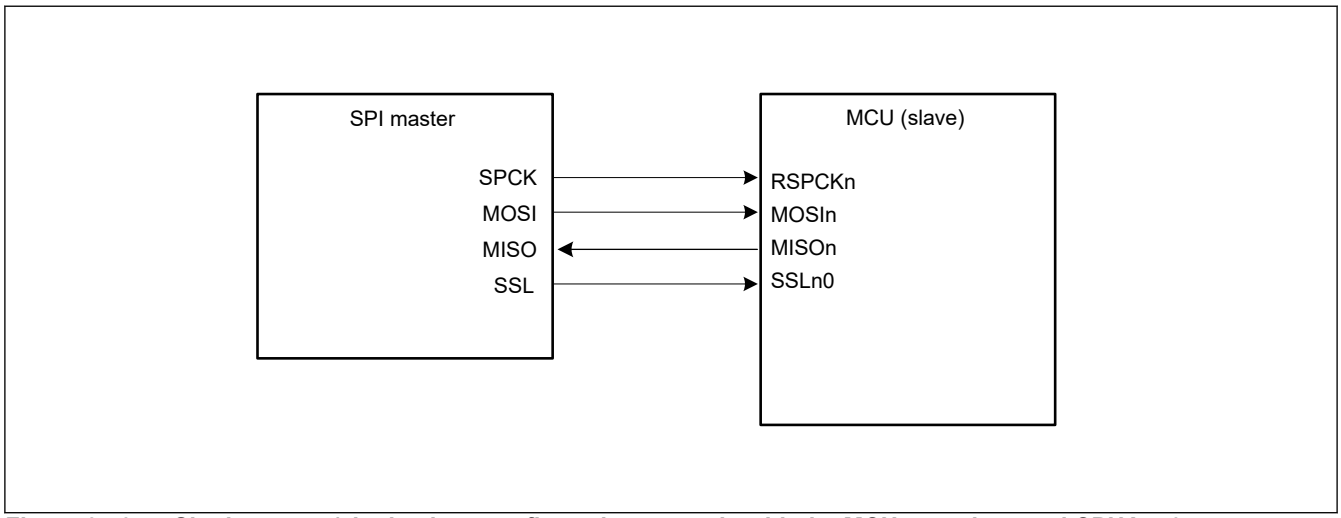

Figure 34.6 Single-master/single-slave configuration example with the MCU as a slave and CPHA = 0

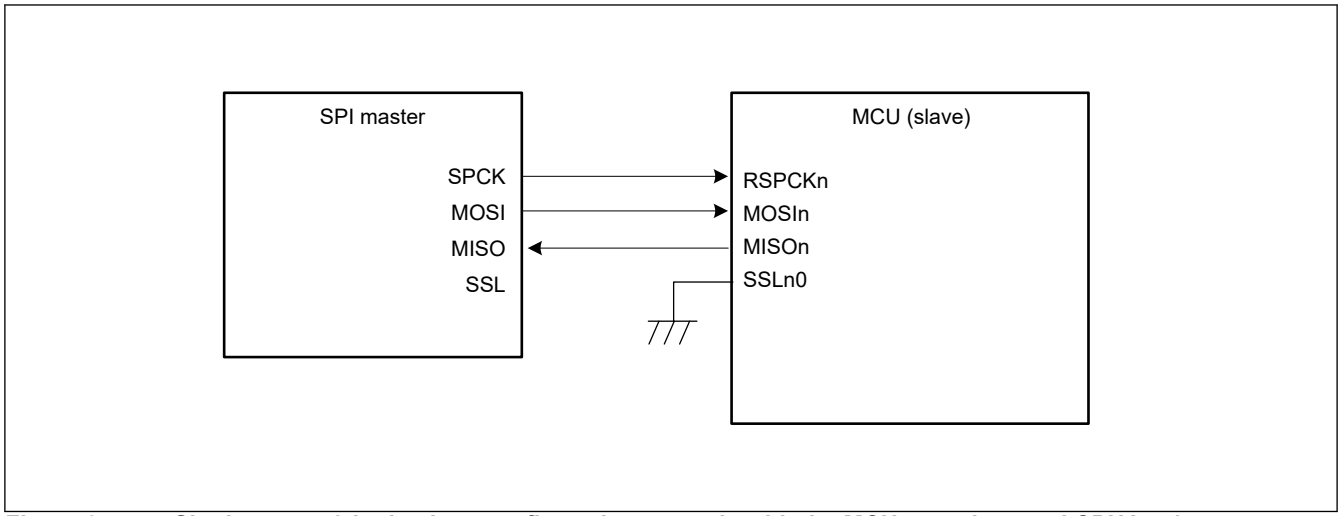

Figure 34.7 Single-master/single-slave configuration example with the MCU as a slave and CPHA = 1

34.3.3.3 Single-master/multi-slave with the MCU as a master

Figure 34.8 shows a single-master/multi-slave SPI system configuration example where the MCU is used as a master. In this example, the SPI system includes the MCU (master) and four slaves (SPI slave 0 to SPI slave 3).

The RSPCKn and MOSIn outputs of the MCU (master) are connected to the RSPCK and MOSI inputs of SPI slaves 0 to 3. The MISO outputs of SPI slaves 0 to 3 are all connected to the MISOn input of the MCU (master). The SSLn0 to SSLn3 outputs of the MCU (master) are connected to the SSL inputs of SPI slaves 0 to 3, respectively.

The MCU (master) drives the RSPCKn, MOSIn, and SSLn0 to SSLn3 signals. Out of the SPI slaves 0 to 3, the slave that receives low-level input into the SSL input drives the MISO signal.

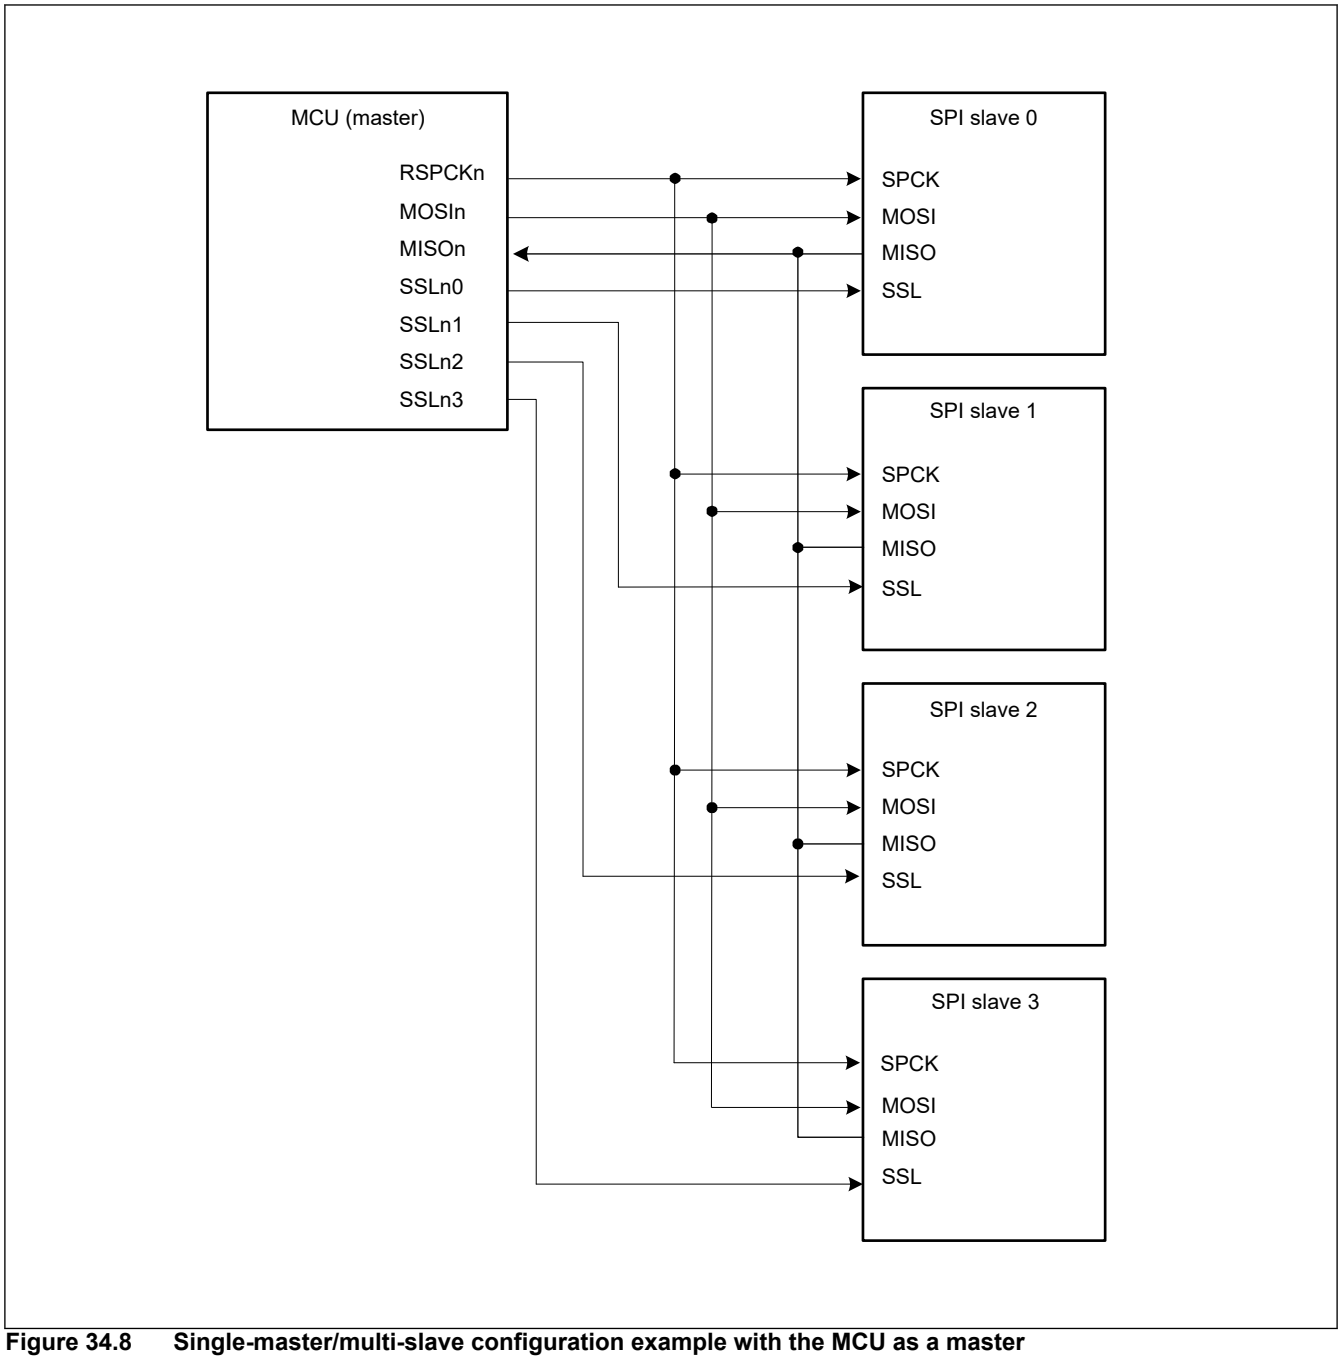

Figure 34.8 Single-master/multi-slave configuration example with the MCU as a master

34.3.3.4 Single-master/multi-slave with the MCU as a slave

Figure 34.9 shows a single-master/multi-slave SPI system configuration example where the MCU is used as a slave. In this example, the SPI system includes an SPI master and two MCUs (slaves X and Y).

The SPCK and MOSI outputs of the SPI master are connected to the RSPCKn and MOSIn inputs of the MCUs (slaves X and Y). The MISOn outputs of the MCUs (slaves X and Y) are all connected to the MISO input of the SPI master. The SSLX and SSLY outputs of the SPI master are connected to the SSLn0 inputs of the MCUs (slaves X and Y, respectively).

The SPI master drives the SPCK, MOSI, SSLX, and SSLY signals. Of the MCUs (slaves X and Y), the slave that receives low-level input into the SSLn0 input drives the MISOn signal.

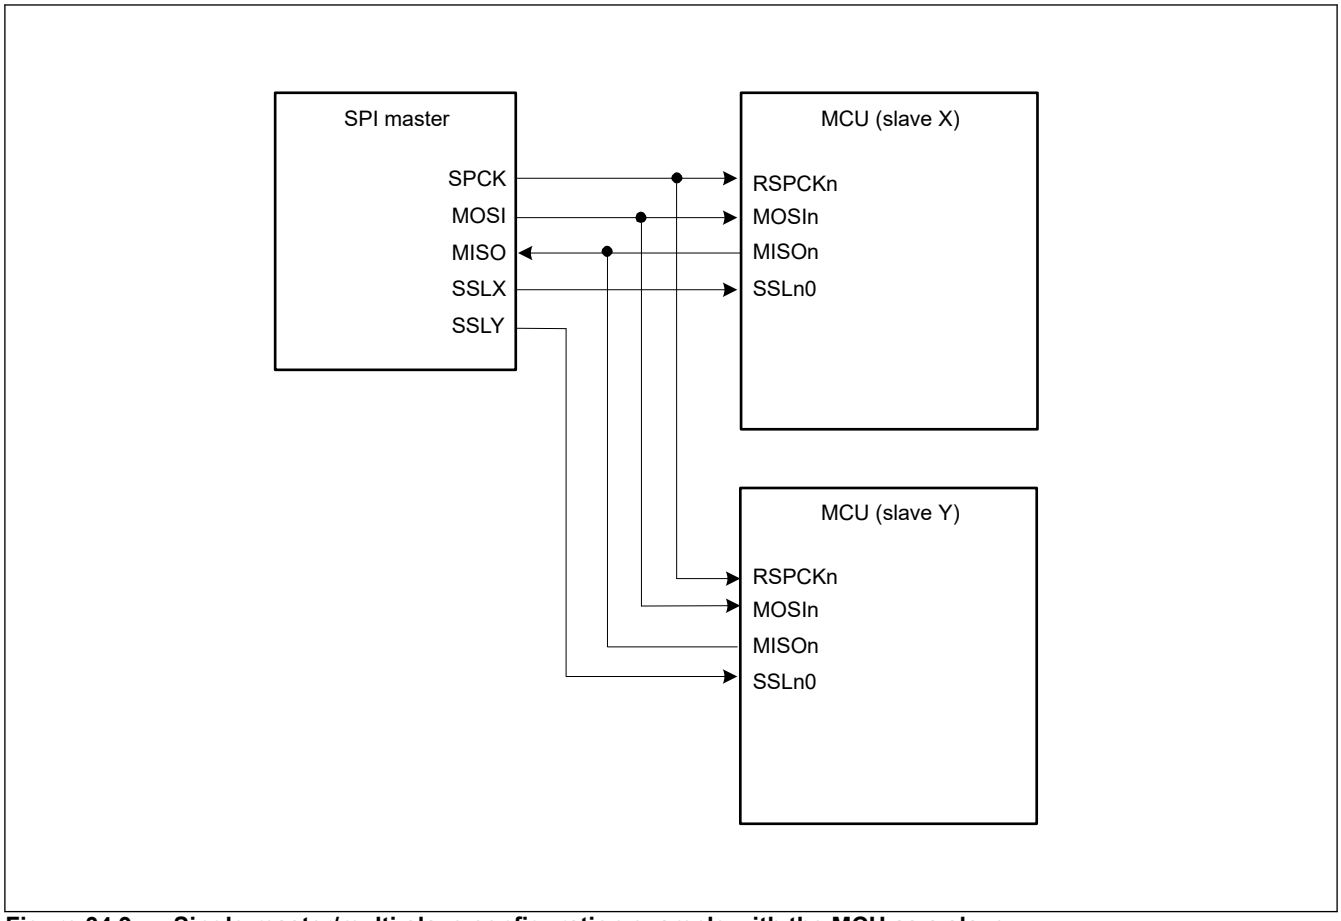

Figure 34.9 Single-master/multi-slave configuration example with the MCU as a slave

34.3.3.5 Multi-master/multi-slave with the MCU as a master

Figure 34.10 shows a multi-master/multi-slave SPI system configuration example where the MCU is used as a master. In this example, the SPI system includes two MCUs (masters X and Y) and two SPI slaves (SPI slaves 1 and 2).

The RSPCKn and MOSIn outputs of the MCUs (masters X and Y) are connected to the RSPCK and MOSI inputs of SPI slaves 1 and 2. The MISO outputs of SPI slaves 1 and 2 are connected to the MISOn inputs of the MCUs (masters X and Y). Any generic port Y output from the MCU (master X) is connected to the SSLn0 input of the MCU (master Y). Any generic port X output of the MCU (master Y) is connected to the SSLn0 input of the MCU (master X). The SSLn1 and SSLn2 outputs of the MCUs (masters X and Y) are connected to the SSL inputs of the SPI slaves 1 and 2. In this configuration example, because the system can be comprised solely of SSLn0 input, and SSLn1 and SSLn2 outputs for slave connections, the SSLn3 output of the MCU is not required.

The MCU drives the RSPCKn, MOSIn, SSLn1, and SSLn2 signals when the SSLn0 input level is high. When the SSLn0 input level is low, the MCU detects a mode fault error, sets RSPCKn, MOSIn, SSLn1, and SSLn2 to Hi-Z, and releases the SPI bus directly to the other master. Of the SPI slaves 1 and 2, the slave that receives low-level input into the SSL input drives the MISO signal.

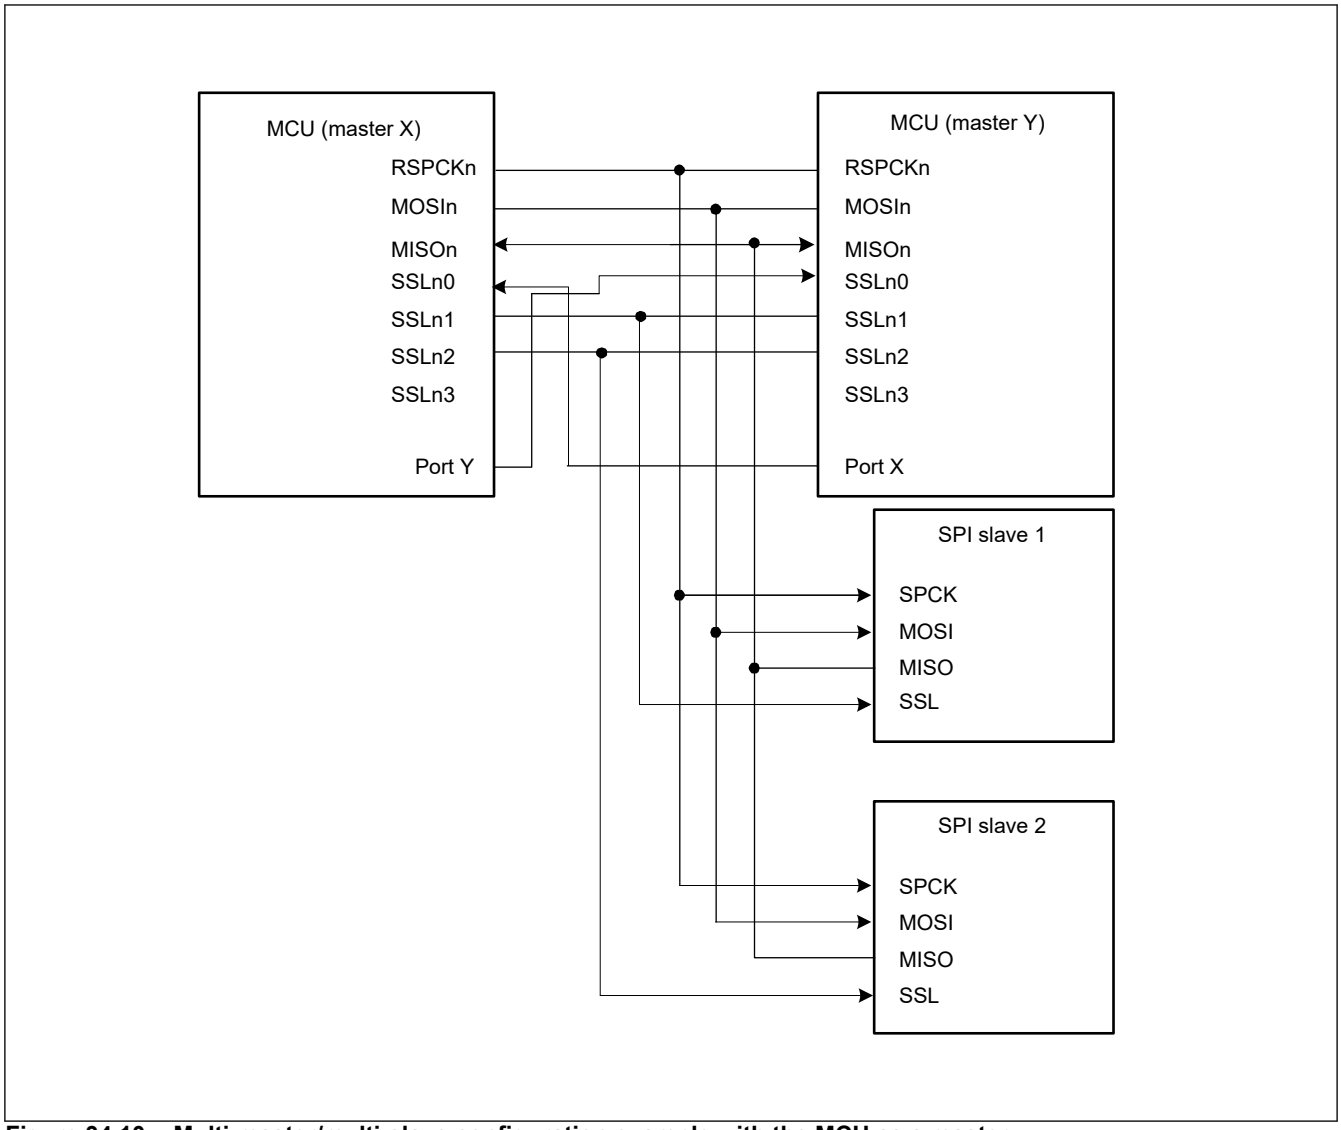

Figure 34.10 Multi-master/multi-slave configuration example with the MCU as a master

34.3.3.6 Master and slave in clock synchronous mode with the MCU configured as a master

Figure 34.11 shows a master and slave in clock synchronous mode configuration example where the MCU is used as a master. In this configuration, SSLni of the MCU (master) are not used.

The MCU (master) drives the RSPCKn and MOSIn signals. The SPI slave drives the MISO signal.

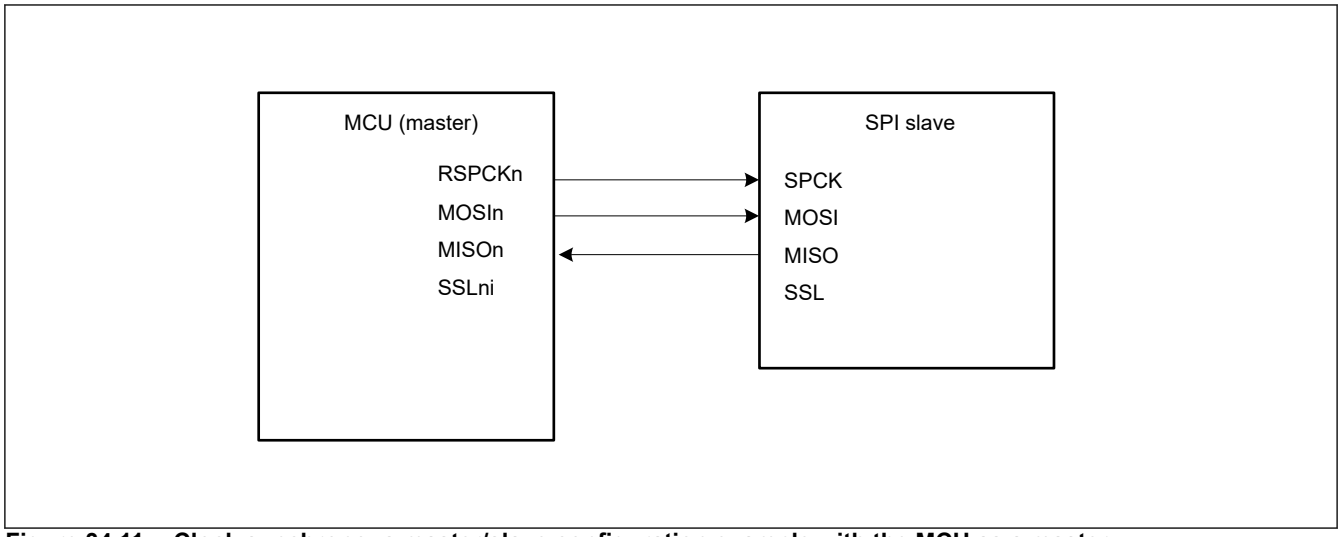

Figure 34.11 Clock synchronous master/slave configuration example with the MCU as a master

34.3.3.7 Master and slave in clock synchronous mode with the MCU as a slave

Figure 34.12 shows a master and slave in clock synchronous mode configuration example where the MCU is used as a slave. When the MCU operates as a slave (clock synchronous operation), the MCU (slave) drives the MISOn signal and the SPI master drives the SPCK and MOSI signals. In addition, SSLn0 to SSLn3 of the MCU (slave) are not used.

The MCU (slave) can only execute serial transfers in the single-slave configuration when the SPCMDm.CPHA bit is set to 1.

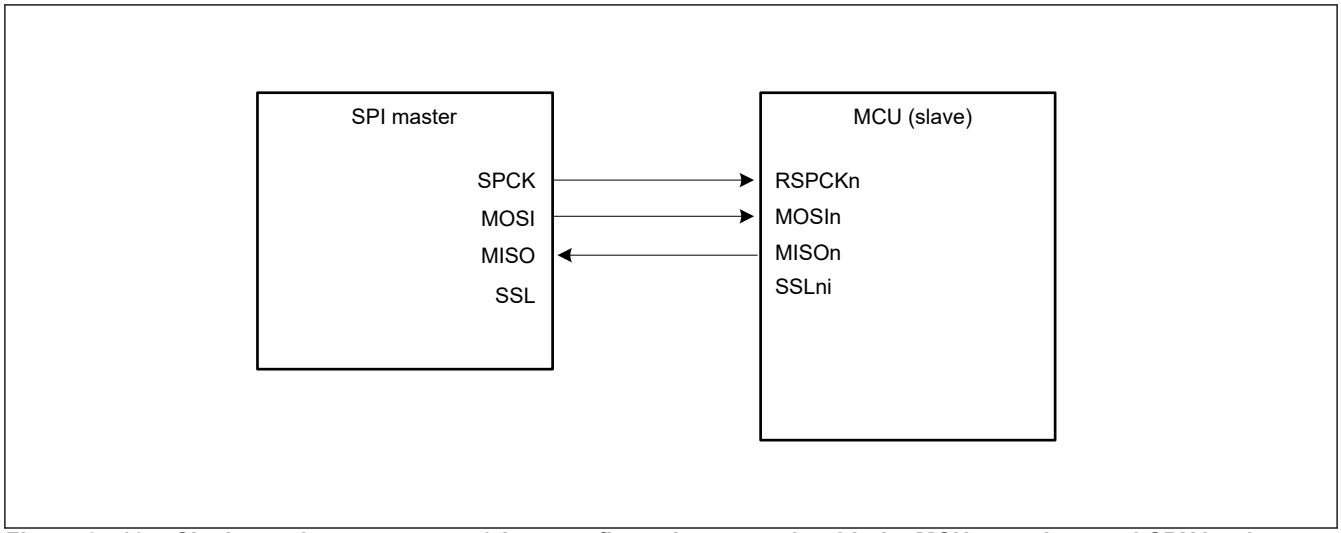

Figure 34.12 Clock synchronous master/slave configuration example with the MCU as a slave and CPHA = 1

34.3.4 Data Formats

The data format of the SPI depends on the settings in SPI Command Register m (SPCMDm) and the parity enable bit in SPI Control Register 2 (SPCR2.SPPE). Regardless of whether the MSB or LSB is first, the SPI treats the range from the LSB bit in the SPI Data Register (SPDR/SPDR_HA) to the bit associated with the selected data length, as transfer data.

This section shows the format of one frame of data before or after transfer.

Data format with parity disabled

When parity is disabled, transmission or reception of data proceeds with the length in bits selected in the SPI data length setting in SPI Command Register m (SPCMDm.SPB[3:0]).

Data format with parity enabled

When parity is enabled, transmission or reception of data proceeds with the length in bits selected in the SPI data length setting in SPI Command Register m (SPCMDm.SPB[3:0]). In this case, however, the last bit is a parity bit.

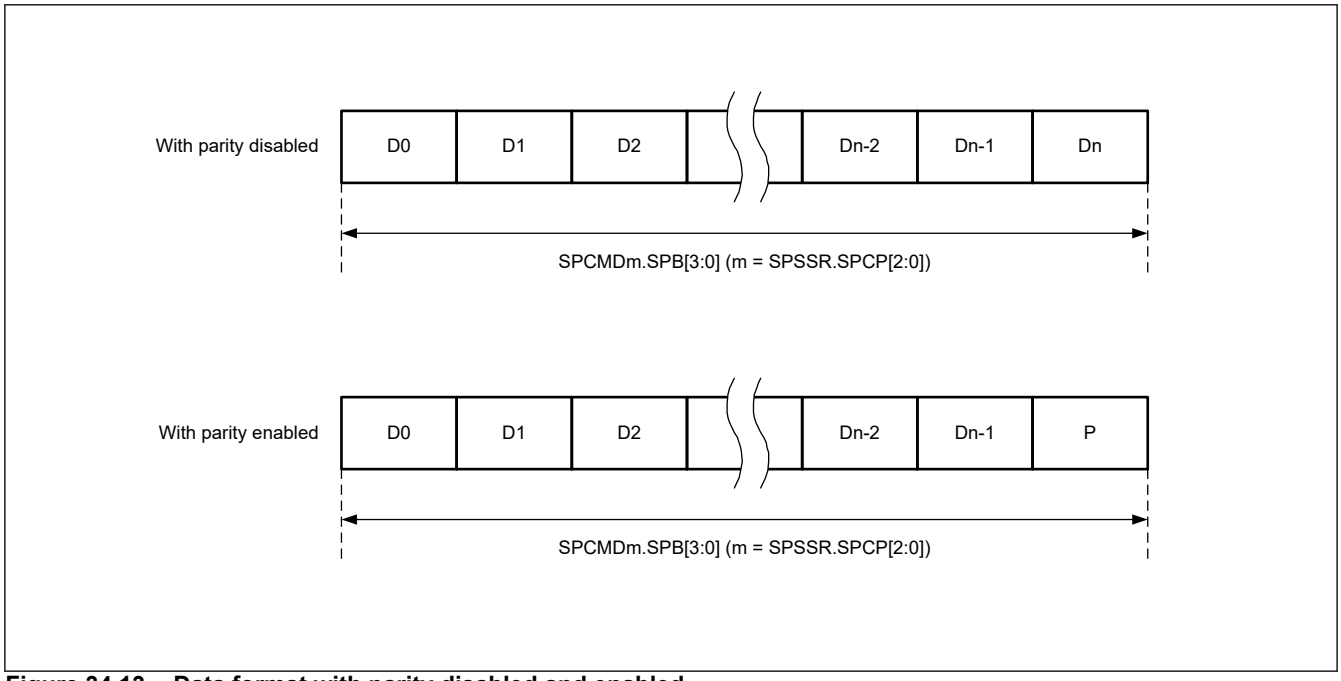

Figure 34.13 Data format with parity disabled and enabled

34.3.4.1 Operation when parity is disabled (SPCR2.SPPE = 0)

When parity is disabled, data for transmission is copied to the shift register with no pre-processing. This section describes the connection between the SPI Data Register (SPDR/SPDR_HA) and the shift register in terms of the combination of MSB- or LSB-first order and data length.

(1) MSB-first transfer with 32-bit data

Figure 34.14 shows the operation of the SPI Data Register (SPDR) and the shift register in a transfer with parity disabled, a SPI data length of 32 bits, and MSB-first selected.

In transmission, bits T31 to T00 from the current stage of the transmit buffer are copied to the shift register. Data for transmission is shifted out from the shift register from T31 to T30, and continuing to T00.

In reception, received data is shifted in bit-by-bit through bit[0] of the shift register. When the R31 to R00 bits are collected after input of the required number of RSPCK cycles, the value in the shift register is copied to the receive buffer.

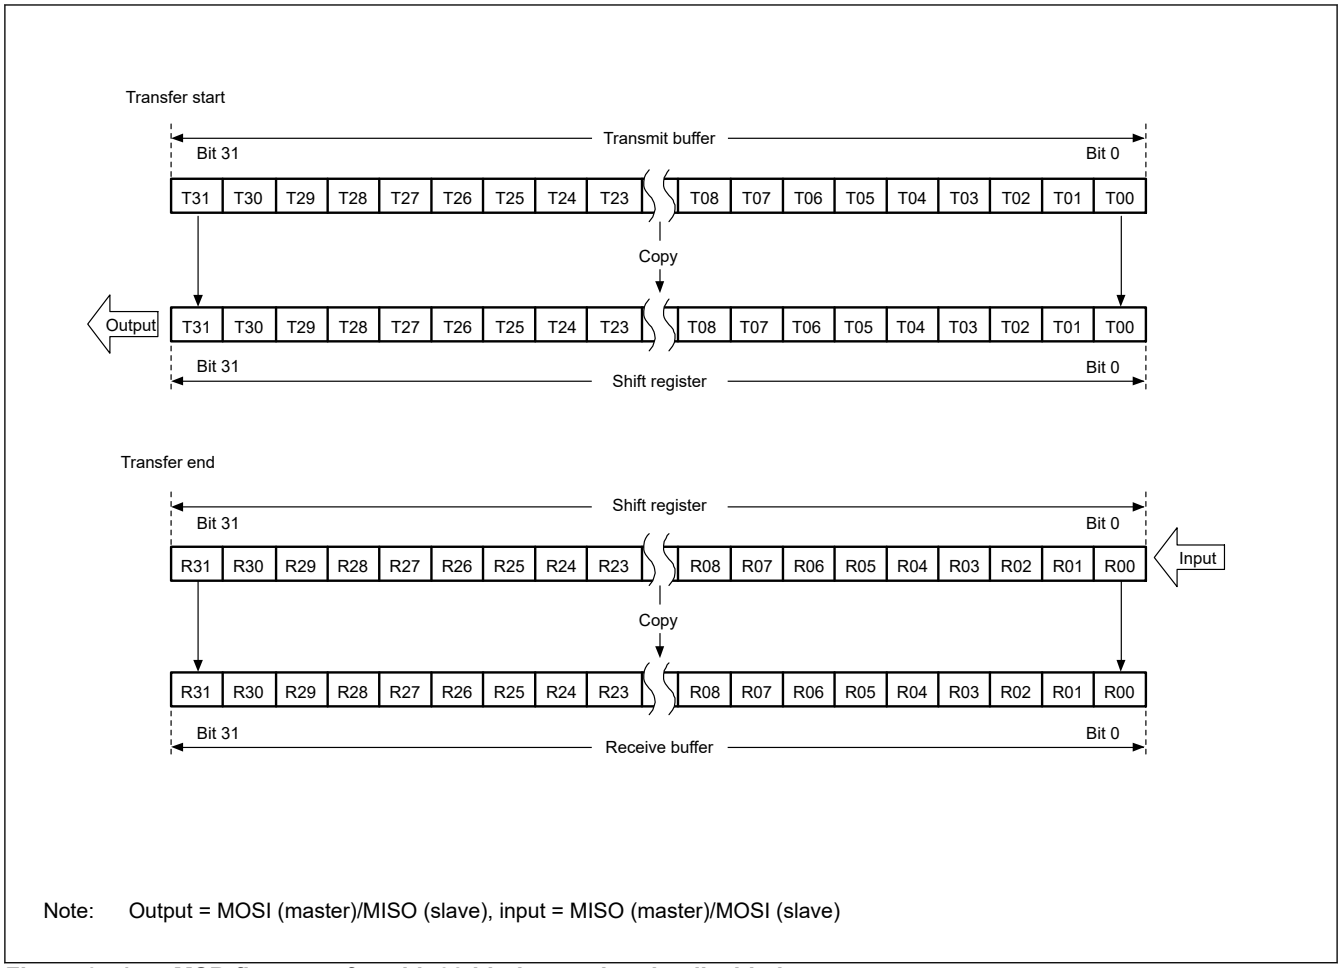

Figure 34.14 MSB-first transfer with 32-bit data and parity disabled

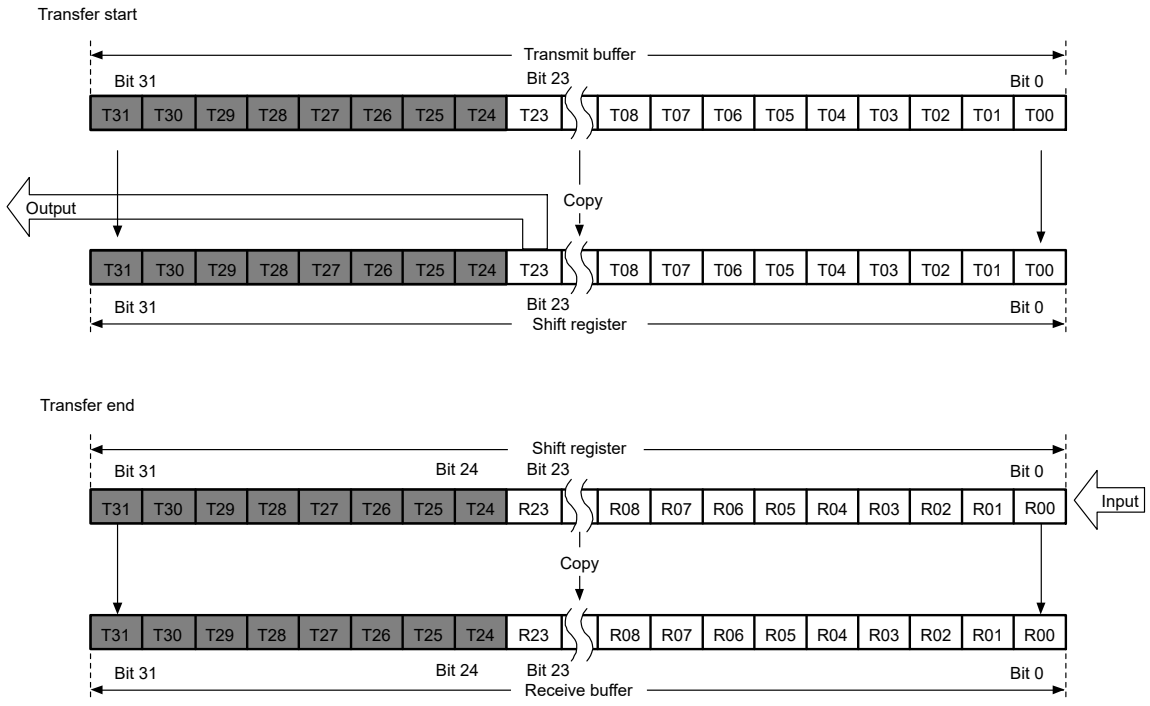
(2) MSB-first transfer with 24-bit data

Figure 34.15 shows the operation of the SPI Data Register (SPDR) and the shift register in a transfer with parity disabled, an SPI data length of 24 bits for an example that is not 32 bits, and MSB-first selected.

In transmission, the lower 24 bits (T23 to T00) from the current stage of the transmit buffer are copied to the shift register. Data for transmission is shifted out from the shift register from T23 to T22, and continuing to T00.

In reception, received data is shifted in bit-by-bit through bit[0] of the shift register. When the R23 to R00 bits are collected after input of the required number of RSPCK cycles, the value in the shift register is copied to the receive buffer. The upper 8 bits of the transmit buffer are stored in the upper 8 bits of the receive buffer in case of transmit-receive operation. Writing 0 to bits T31 to T24 during transmission leads to 0 being inserted in the upper 8 bits of the receive buffer. On the other hand, the upper 8-bits of the receive buffer is written 0 in case of receive only operation.



Note: Output = MOSI (master)/MISO (slave), input = MISO (master)/MOSI (slave)

Figure 34.15 MSB-first transfer with 24-bit data and parity disabled

(3) LSB-first transfer with 32-bit data

Figure 34.16 shows the operation of the SPI Data Register (SPDR) and the shift register in a transfer with parity disabled, an SPI data length of 32 bits, and LSB-first selected.

In transmission, bits T31 to T00 from the current stage of the transmit buffer are reordered bit-by-bit to obtain the order T00 to T31 for copying to the shift register. Data for transmission is shifted out from the shift register in order from T00 to T01, and continuing to T31.

In reception, received data is shifted in bit-by-bit through bit[0] of the shift register. When the R00 to R31 bits are collected after input of the required number of RSPCK cycles, the value in the shift register is copied to the receive buffer.

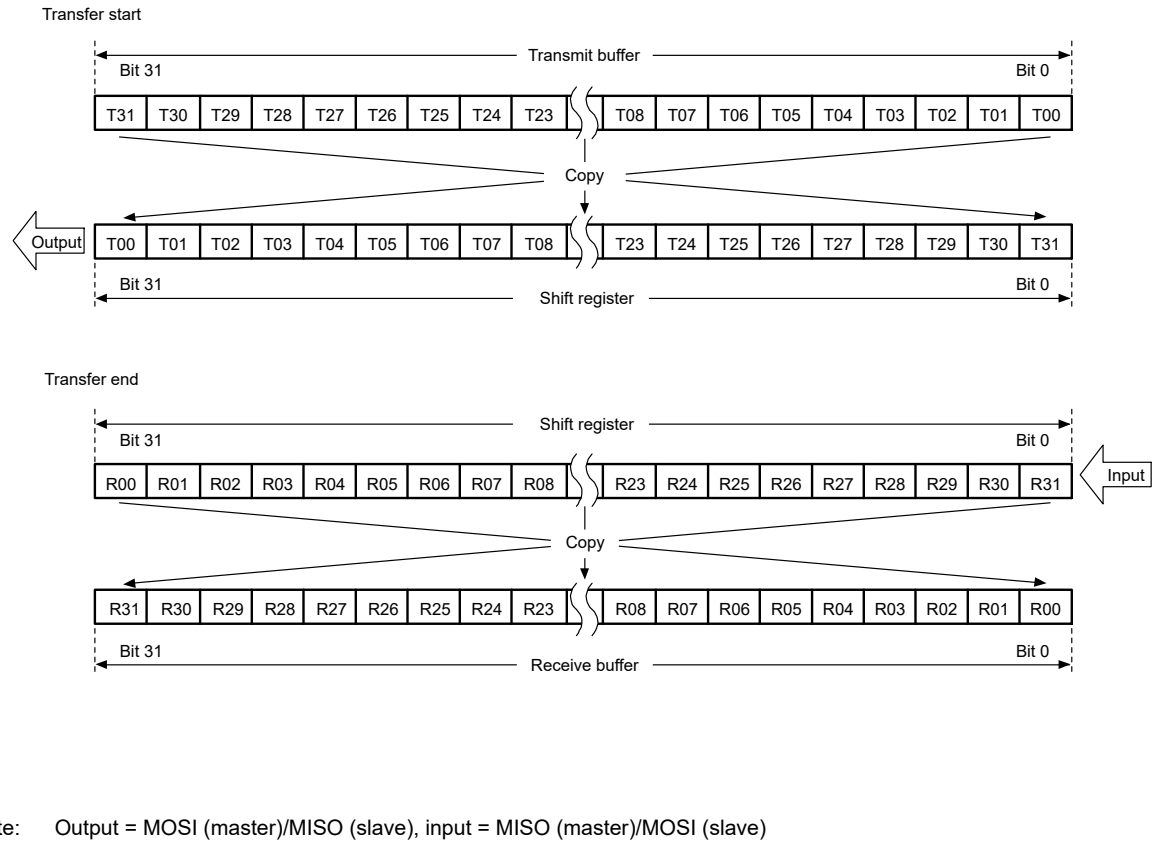


Figure 34.16 LSB-first transfer with 32-bit data and parity disabled

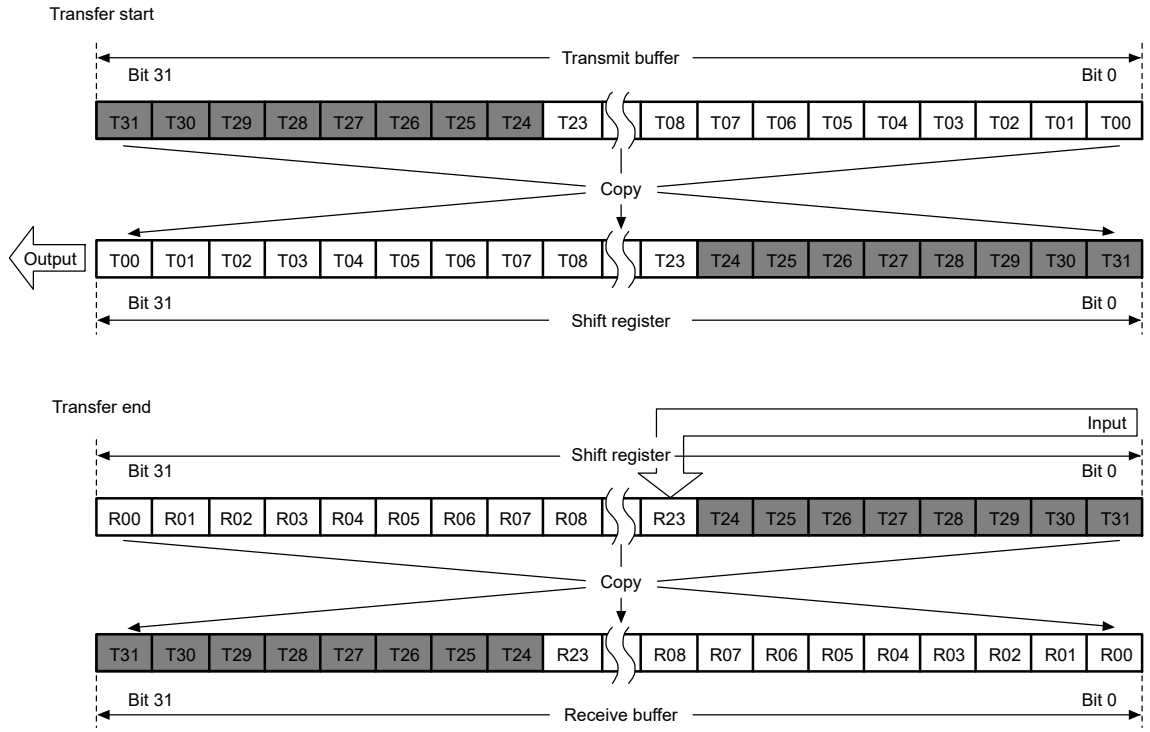
(4) LSB-first transfer with 24-bit data

Figure 34.17 shows the operation of the SPI Data Register (SPDR) and the shift register in transfers with parity disabled, an SPI data length of 24 bits for an example that is not 32, and LSB-first selected.

In transmission, the lower 24 bits (T23 to T00) from the current stage of the transmit buffer are reordered bit-by-bit to obtain the order T00 to T23 for copying to the shift register. Data for transmission is shifted out from the shift register from T00 to T01, and continuing to T23.

In reception, received data is shifted in bit-by-bit through bit[8] of the shift register. When the R00 to R23 bits are collected after input of the required number of RSPCK cycles, the value in the shift register is copied to the receive buffer.

The upper 8 bits of the transmit buffer are stored in the upper 8 bits of the receive buffer in case of transmit-receive operation. Writing 0 to T31 to T24 during transmission leads to 0 being inserted in the upper 8 bits of the receive buffer. On the other hand, the upper 8-bits of the receive buffer is written 0 in case of receive only operation.



Note: Output = MOSI (master)/MISO (slave), input = MISO (master)/MOSI (slave)

Figure 34.17 LSB-first transfer with 24-bit data and parity disabled

34.3.4.2 Operation when parity is enabled (SPCR2.SPPE = 1)

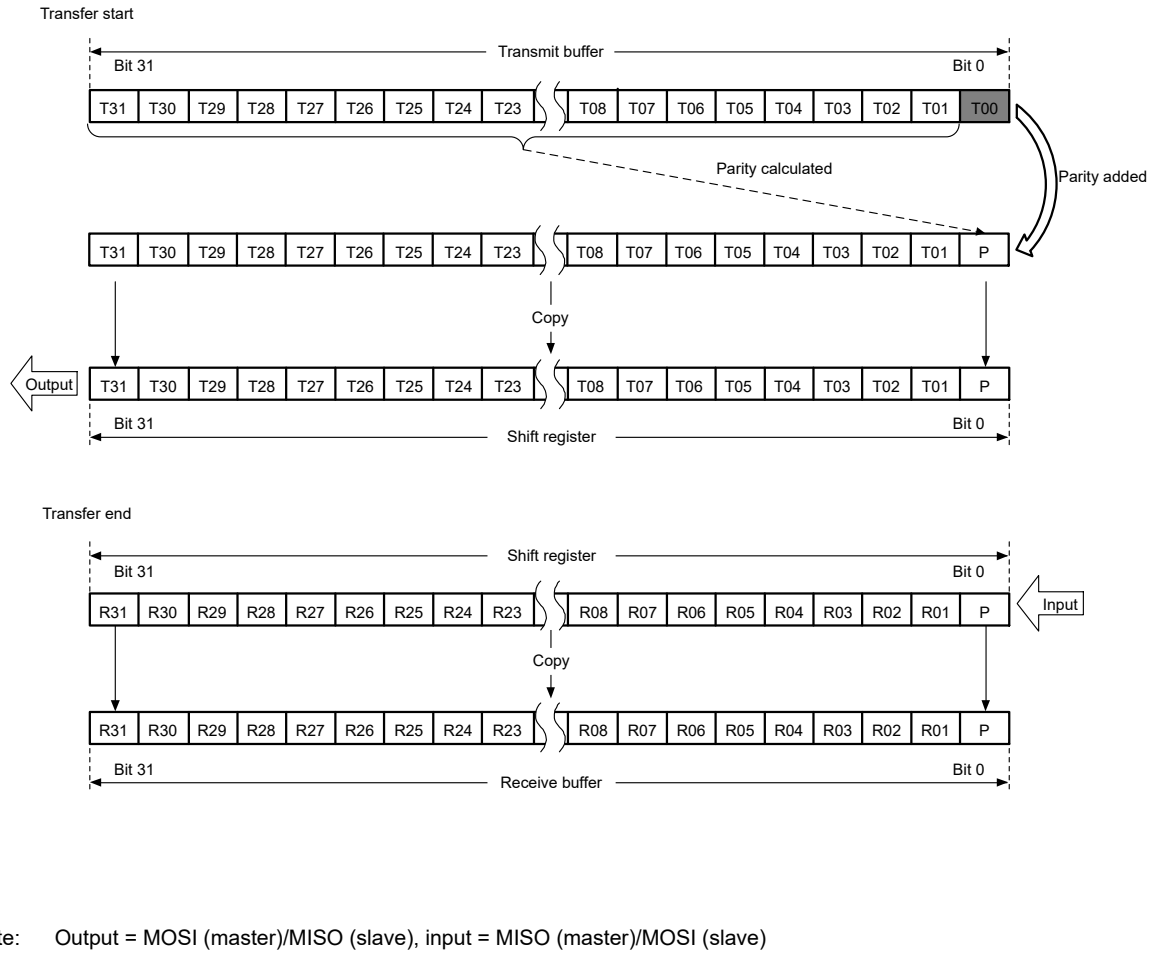
When parity is enabled, the lowest-order bit of the data for transmission becomes a parity bit. Hardware calculates the value of the parity bit.

(1) MSB-first transfer with 32-bit data

Figure 34.18 shows the operation of the SPI Data Register (SPDR) and the shift register in a transfer with parity enabled, an SPI data length of 32 bits, and MSB-first selected.

In transmission, the value of the parity bit (P) is calculated from bits T31 to T01. This replaces the final bit, T00, and the whole value is copied to the shift register. Data is transmitted in the order T31, T30, …, T01, and P.

In reception, received data is shifted in bit-by-bit through bit[0] of the shift register. When the R31 to P bits are collected after input of the required number of RSPCK cycles, the value in the shift register is copied to the receive buffer. On copying of data to the shift register, the data from R31 to P is checked for parity.



Note: Output = MOSI (master)/MISO (slave), input = MISO (master)/MOSI (slave)

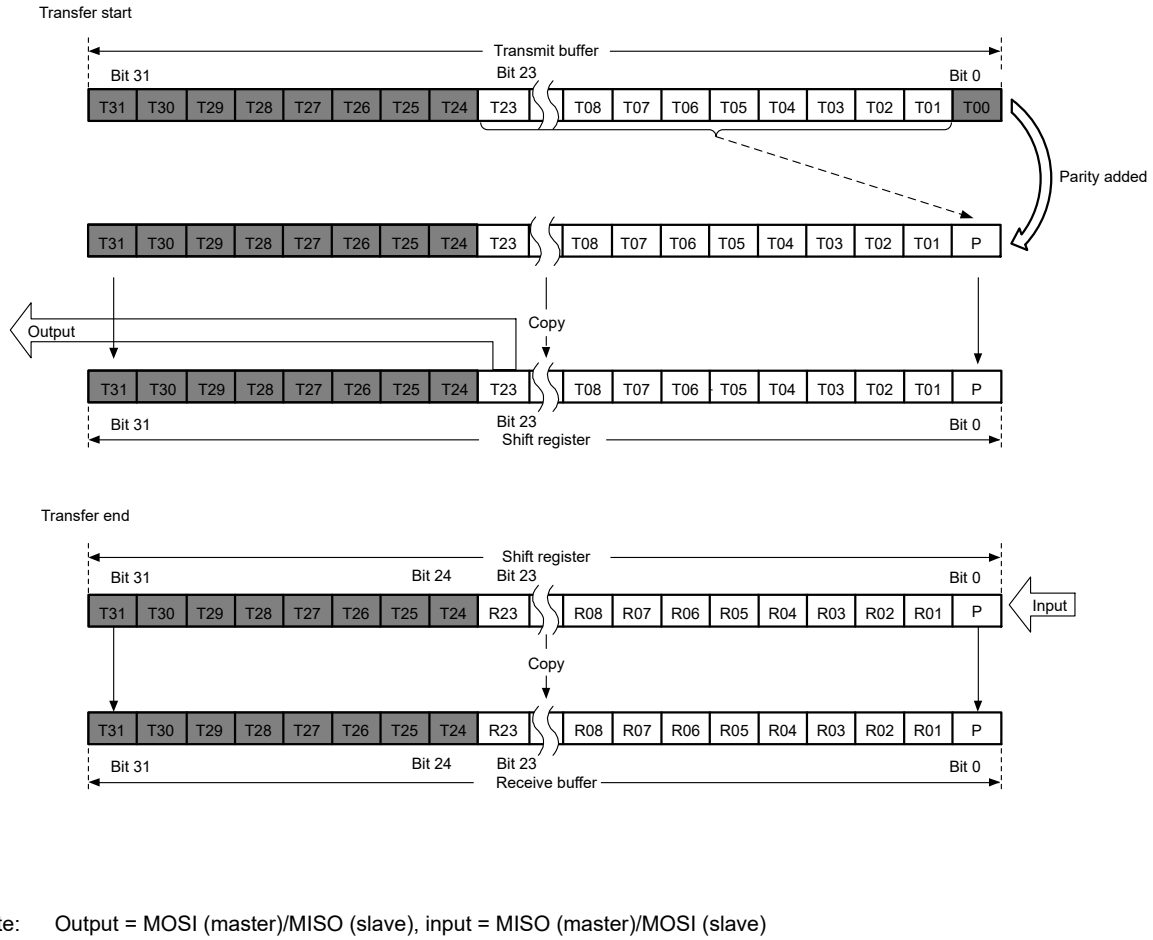
Figure 34.18 MSB-first transfer with 32-bit data and parity enabled

(2) MSB-first transfer with 24-bit data

Figure 34.19 shows the operation of the SPI Data Register (SPDR) and the shift register in a transfer with parity enabled, a SPI data length of 24 bits, and MSB-first selected.

In transmission, the value of the parity bit (P) is calculated from bits T23 to T01. This replaces the final bit, T00, and the whole value is copied to the shift register. Data is transmitted in the order T23, T22, …, T01, and P.

In reception, received data is shifted in bit-by-bit through bit[0] of the shift register. When the R23 to P bits are collected after input of the required number of RSPCK cycles, the value in the shift register is copied to the receive buffer. On copying of data to the shift register, the data from R23 to P is checked for parity. The upper 8 bits of the transmit buffer is stored in the upper 8 bits of the receive buffer in case of transmit-receive operation. Writing 0 to T31 to T24 during transmission leads to 0 being inserted in the upper 8 bits of the receive buffer. On the other hand, the upper 8-bits of the receive buffer is written 0 in case of receive only operation.



Note: Output = MOSI (master)/MISO (slave), input = MISO (master)/MOSI (slave)

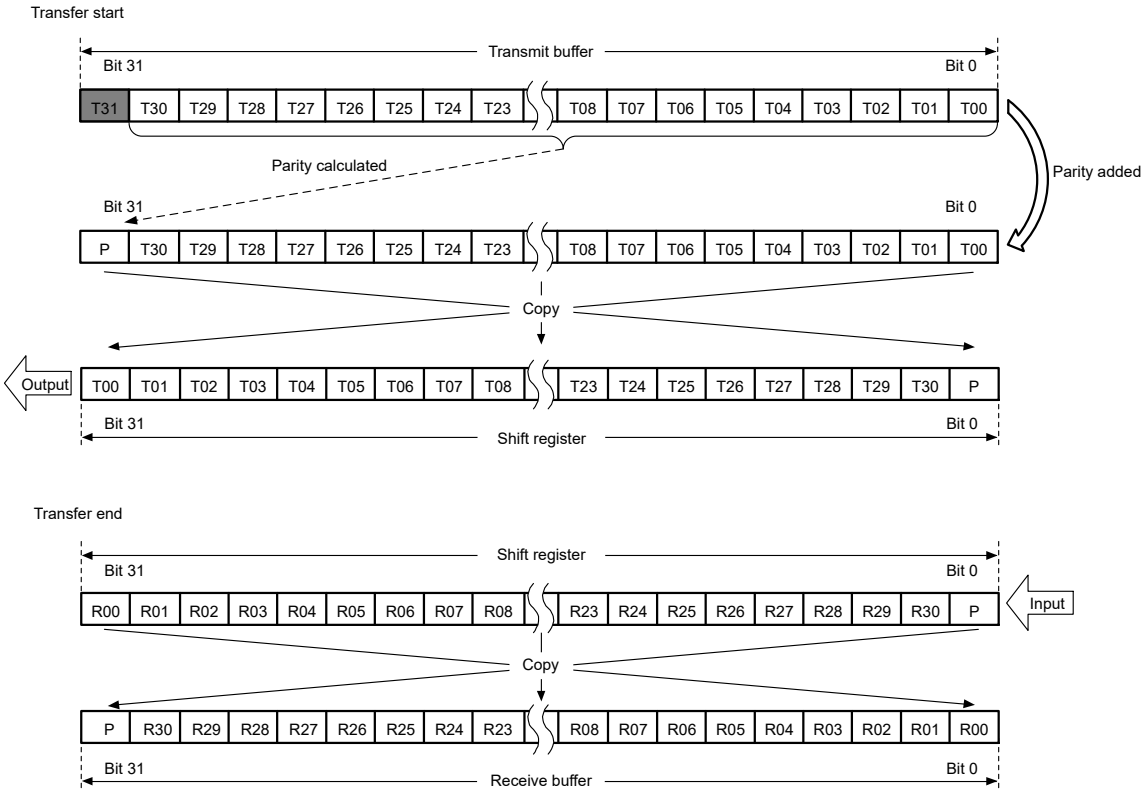
Figure 34.19 MSB-first transfer with 24-bit data and parity enabled

(3) LSB-first transfer with 32-bit data

Figure 34.20 shows the operation of the SPI Data Register (SPDR) and the shift register in a transfer with parity enabled, an SPI data length of 32 bits, and LSB-first selected.

In transmission, the value of the parity bit (P) is calculated from bits T30 to T00. This replaces the final bit, T31, and the whole value is copied to the shift register. Data is transmitted in the order T00, T01, …, T30, and P.

In reception, received data is shifted in bit-by-bit through bit[0] of the shift register. When the R00 to P bits are collected after input of the required number of RSPCK cycles, the value in the shift register is copied to the receive buffer. On copying of data to the shift register, the data from R00 to P is checked for parity.



Note: Output = MOSI (master)/MISO (slave), input = MISO (master)/MOSI (slave)

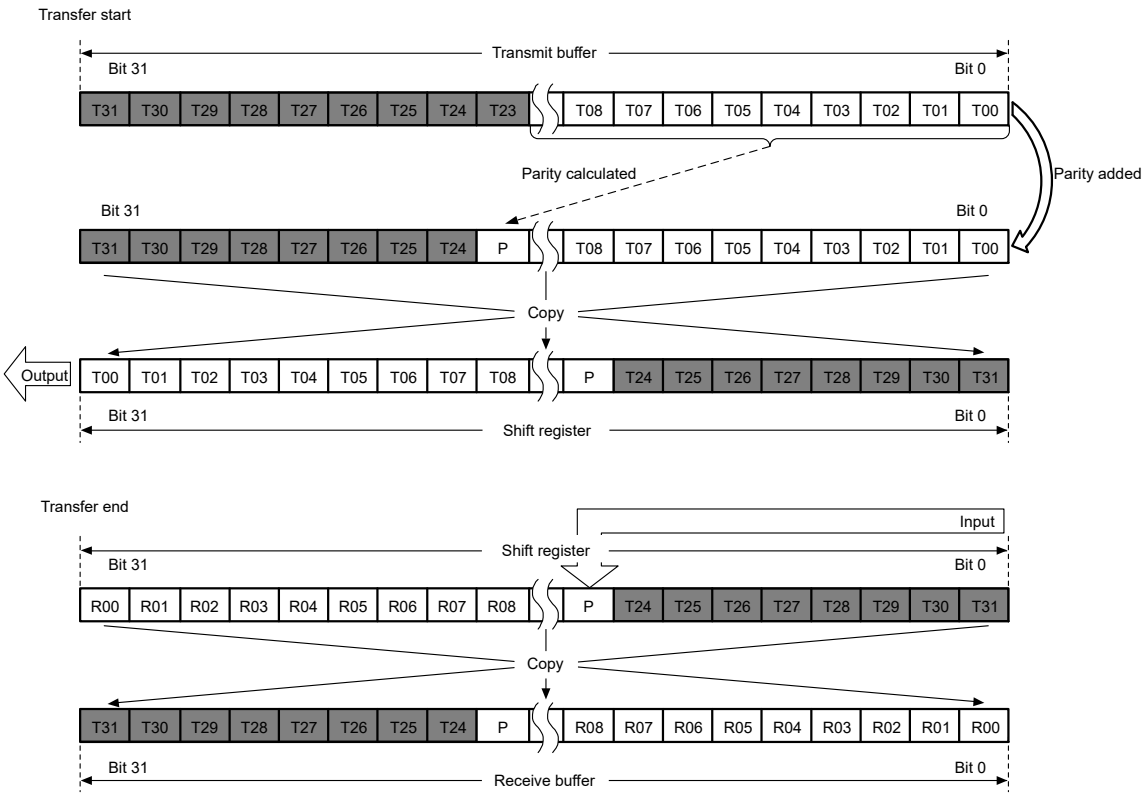
Figure 34.20 LSB-first transfer with 32-bit data and parity enabled

(4) LSB-first transfer with 24-bit data

Figure 34.21 shows the operation of the SPI Data Register (SPDR) and the shift register in a transfer with parity enabled, a SPI data length of 24 bits, and LSB-first selected.

In transmission, the value of the parity bit (P) is calculated from bits T22 to T00. This replaces the final bit, T23, and the whole value is copied to the shift register. Data is transmitted in the order T00, T01, …, T22, and P.

In reception, received data is shifted in bit-by-bit through bit[8] of the shift register. When the R00 to P bits are collected after input of the required number of RSPCK cycles, the value in the shift register is copied to the receive buffer. On copying of data to the shift register, the data from R00 to P is checked for parity. The upper 8 bits of the transmit buffer is stored in the upper 8 bits of the receive buffer in case of transmit-receive operation. Writing 0 to T31 to T24 during transmission leads to 0 being inserted in the upper 8 bits of the receive buffer. On the other hand, the upper 8-bits of the receive buffer is written 0 in case of receive only operation.



Note: Output = MOSI (master)/MISO (slave), input = MISO (master)/MOSI (slave)

Figure 34.21 LSB-first transfer with 24-bit data and parity enabled

34.3.4.3 Byte Swap Transmission

(1) MSB-first transfer. (When the byte swap is disabled.)

Data (Byte0 [T31 to T24] to Byte3 [T07 to T00]) in the transmit buffer are copied to the shift register.

Bit values in the shift register are shifted and transmitted in the order of T31 → T30 → … → T00 as transmit data.

(2) MSB-first transfer. (When the byte swap is enabled.)

Byte values of the transmit buffer (Byte0 [T31 to T24] to Byte3 [T07 to T00]) are reversed in byte units and are copied to the shift register in the order of Byte3 [T07 to T00] to Byte0 [T31 to T24].

Bit values in the shift register are shifted and transmitted in the order of T07 → T06 → … → T00 → T15 → T14 → … → T08 → T23 → T22 → … → T16 → T31 → T30 → … → T24 as transmit data.

(3) LSB-first transfer. (When the byte swap is disabled.)

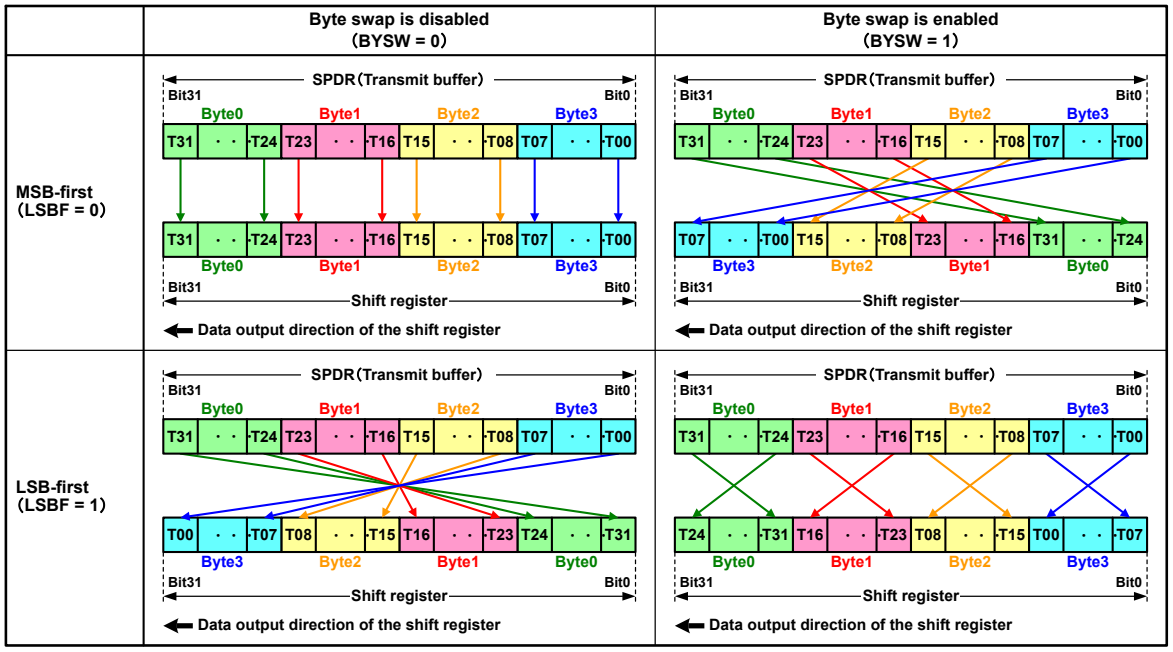
Bit values of the transmit buffer (Byte0 [T31 to T24] to Byte3 [T07 to T00]) are reversed in bit units and are copied to the shift register in the order of Byte3 [T00 to T07] to Byte0 [T24 to T31].

Bit values in the shift register are shifted and transmitted in the order of T00 → T01 → … → T31 as transmit data.

(4) LSB-first transfer. (When the byte swap is enabled.)

Bit values of each byte of the transmit buffer (Byte0 [T31 to T24] to Byte3 [T07 to T00]) are reversed in bit units and are copied to the shift register in the order of Byte0 [T24 to T31] to Byte3 [T00 to T07].

Bit values in the shift register are shifted and transmitted in the order of T24 → T25 → … → T31 → T16 → T17 → … → T23 → T08 → T09 → … → T15 → T00 → T01 → … → T07 as transmit data.



Note: 1. When using the byte swap, set 16 bits or 32 bits to the data length (SPCMD.SPB[3:0] setting). If setting the other length (8 to 15, 20, 24 bits), the behavior is not guaranteed.
2. When the byte swap is valid, set the parity function as invalid (SPCR2.SPPE bit = 0). If setting the parity function as valid (SPPE bit = 1), the behavior is not guaranteed.
3. Set SPDCR2.BYSW bit, when SPCR.SPE bit is 0. If rewriting BYSW bit, when SPE bit is 1, the behavior after it is not guaranteed.

Figure 34.22 Byte swap with MSB/LSB transfer

34.3.4.4 Byte Swap Reception

(1) MSB-first transfer. (When the byte swap is disabled.)

The first received data (R31) is stored in bit 0 of the shift register, and received data is shifted in the order of R31 → R30 → … → R00.

When necessary RSPCK cycles are input and data is stored from Byte0 [R31 to R24] to Byte3 [R07 to R00], the shift register value is copied to the receive buffer.

(2) MSB-first transfer. (When the byte swap is enabled.)

The first received data (R07) is stored in bit 0 of the shift register, and received data is shifted in the order of R07 → R06 → … → R00 → R15 → R14 → … → R08 → R23 → R22 → … → R16 → R31 → R30 → … → R24.

When necessary RSPCK cycles are input and data is stored from Byte3 [R07 to R00] to Byte0 [R31 to R24], byte values in the shift register are reversed in byte units and are copied to the receive buffer in the order of Byte0 [R31 to R24] to Byte3 [R07 to R00].

(3) LSB-first transfer. (When the byte swap is disabled.)

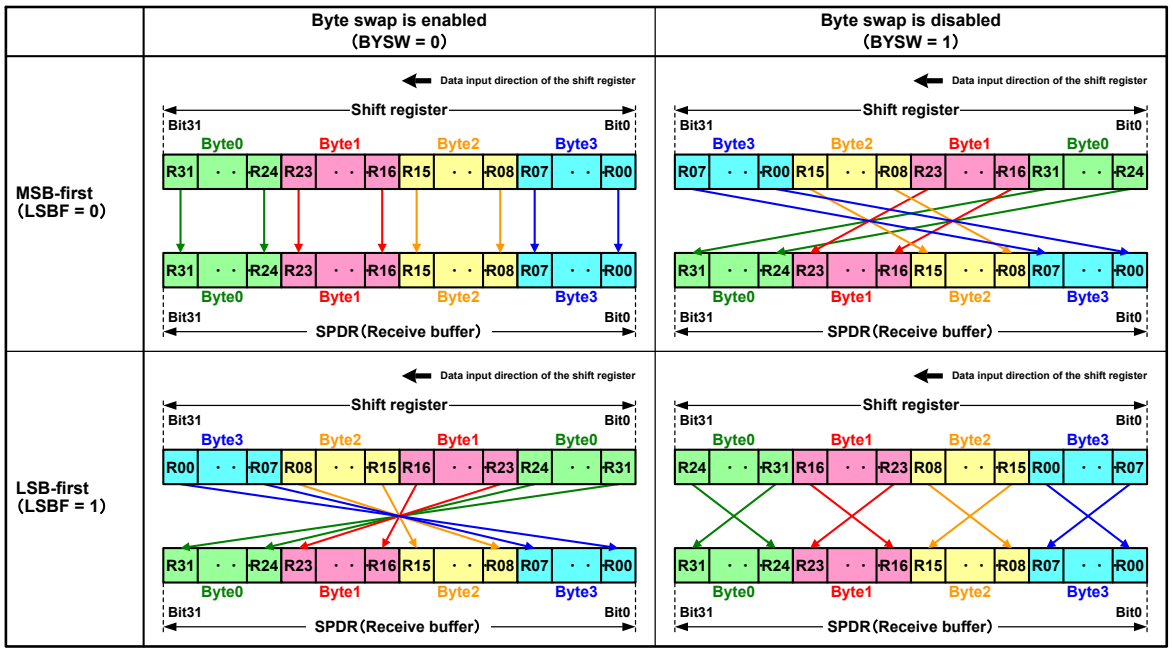
The first received data (R00) is stored in bit 0 of the shift register, and received data is shifted in the order of R00 → R01 → … → R31.

When necessary RSPCK cycles are input and data is stored from Byte3 [R00 to R07] to Byte0 [R24 to R31], bit values in the shift register are reversed in bit units and are copied to the receive buffer in the order of Byte0 [R31 to R24] to Byte3 [R07 to R00].

(4) LSB-first transfer. (When the byte swap is enabled.)

The first received data (R24) is stored in bit 0 of the shift register, and received data is shifted in the order of R24 → R25 → … → R31 → R16 → R17 → … → R23 → R08 → R09 → … → R15 → R00 → R01 → … → R07.

When necessary RSPCK cycles are input and data is stored from Byte0 [R24 to R31] to Byte3 [R00 to R07], bit values of each byte in the shift register are reversed in bit units and are copied to the receive buffer in the order of Byte0 [R31 to R24] to Byte3 [R07 to R00].



Note: 1. When using the byte swap, set 16 bits or 32 bits to the data length (SPCMD.SPB[3:0] setting). If setting the other length (8 to 15, 20, 24 bits), the behavior is not guaranteed.
2. When the byte swap is valid, set the parity function as invalid (SPCR2.SPPE bit = 0). If setting the parity function as valid (SPPE bit = 1), the behavior is not guaranteed.
3. Set SPDCR2.BYSW bit, when SPCR.SPE bit is 0. If rewriting BYSW bit, when SPE bit is 1, the behavior after it is not guaranteed.

Figure 34.23 Byte swap with MSB/LSB transfer

34.3.5 Transfer Formats

34.3.5.1 When CPHA = 0

Figure 34.24 shows an example transfer format for the serial transfer of 8-bit data when the SPCMDm.CPHA bit is 0. Do not perform clock synchronous operation (SPCR.SPMS = 1) when the SPI operates in slave mode (SPCR.MSTR = 0) and the CPHA bit is 0. In Figure 34.24, RSPCKn (CPOL = 0) indicates the RSPCKn signal waveform when the SPCMDm.CPOL bit is 0, and RSPCKn (CPOL = 1) indicates the RSPCKn signal waveform when the CPOL bit is 1. The sampling timing represents the timing at which the SPI fetches serial transfer data into the shift register. The I/O directions of the signals depend on the SPI settings. For details, see section 34.3.2. Controlling the SPI Pins.

When the SPCMDm.CPHA bit is 0, the driving of valid data to the MOSIn and MISOn signals begins at an SSLni signal assertion. The first RSPCKn signal change that occurs after the SSLni signal assertion becomes the first transfer data fetch. After this, data is sampled every 1 RSPCKn cycle. The change timing for MOSIn and MISOn signals is 1/2 RSPCK cycles after the transfer data fetch timing. The CPOL bit setting does not affect the RSPCK signal operation timing as it only affects the signal polarity.

t1 denotes the RSPCK delay, the period from an SSLni signal assertion to RSPCKn oscillation. t2 denotes the SSL negation delay, the period from the termination of RSPCKn oscillation to an SSLni signal negation. t3 denotes the next-access delay,

the period in which SSLni signal assertion is suppressed for the next transfer after the end of serial transfer. t1, t2, and t3 are controlled by a master device running on the SPI system. For a description of t1, t2, and t3 when the SPI is in master mode, see section 34.3.11.1. Master mode operation.

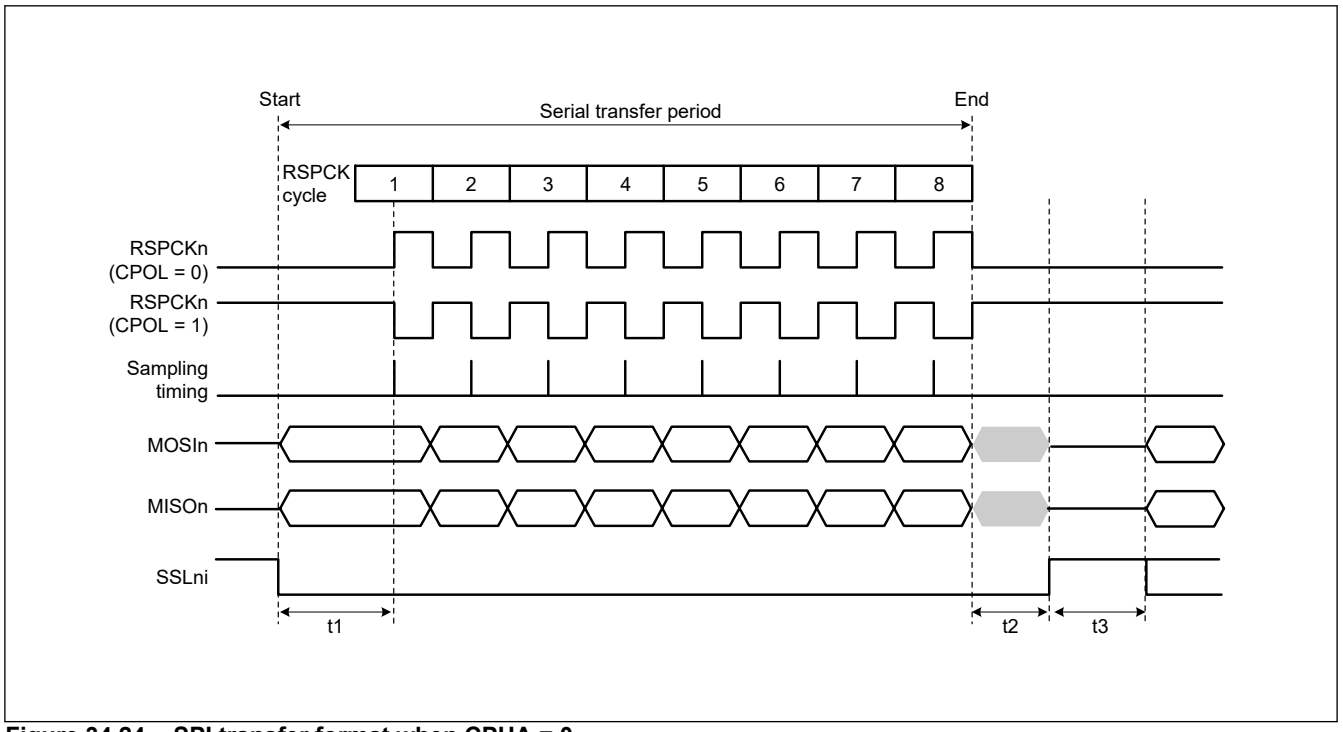


Figure 34.24 SPI transfer format when CPHA = 0

34.3.5.2 When CPHA = 1

Figure 34.25 shows an example transfer format for the serial transfer of 8-bit data when the SPCMDm.CPHA bit is 1. However, when the SPCR.SPMS bit is 1, the SSLni signals are not used, and only the three signals RSPCKn, MOSIn, and MISOn handle communications. In Figure 34.25, RSPCK (CPOL = 0) indicates the RSPCKn signal waveform when the SPCMDm.CPOL bit is 0 and RSPCK (CPOL = 1) indicates the RSPCKn signal waveform when the CPOL bit is 1. The sampling timing represents the timing at which the SPI fetches serial transfer data into the shift register. The I/O directions of the signals depend on the SPI mode (master or slave mode). For details, see section 34.3.2. Controlling the SPI Pins.

When the SPCMDm.CPHA bit is 1, the driving of invalid data to the MISOn signal begins at an SSLni signal assertion. The output of valid data to the MOSIn and MISOn signals begins at the first RSPCKn signal change that occurs after the SSLni signal assertion. After this, data is updated every 1 RSPCK cycle. The transfer data fetch timing is 1/2 RSPCK cycles after the data update timing. The SPCMDm.CPOL bit setting does not affect the RSPCKn signal operation timing. It only affects the signal polarity.

t1, t2, and t3 are the same as those when CPHA = 0. For a description of t1, t2, and t3 when the SPI of the MCU is in master mode, see section 34.3.11.1. Master mode operation.

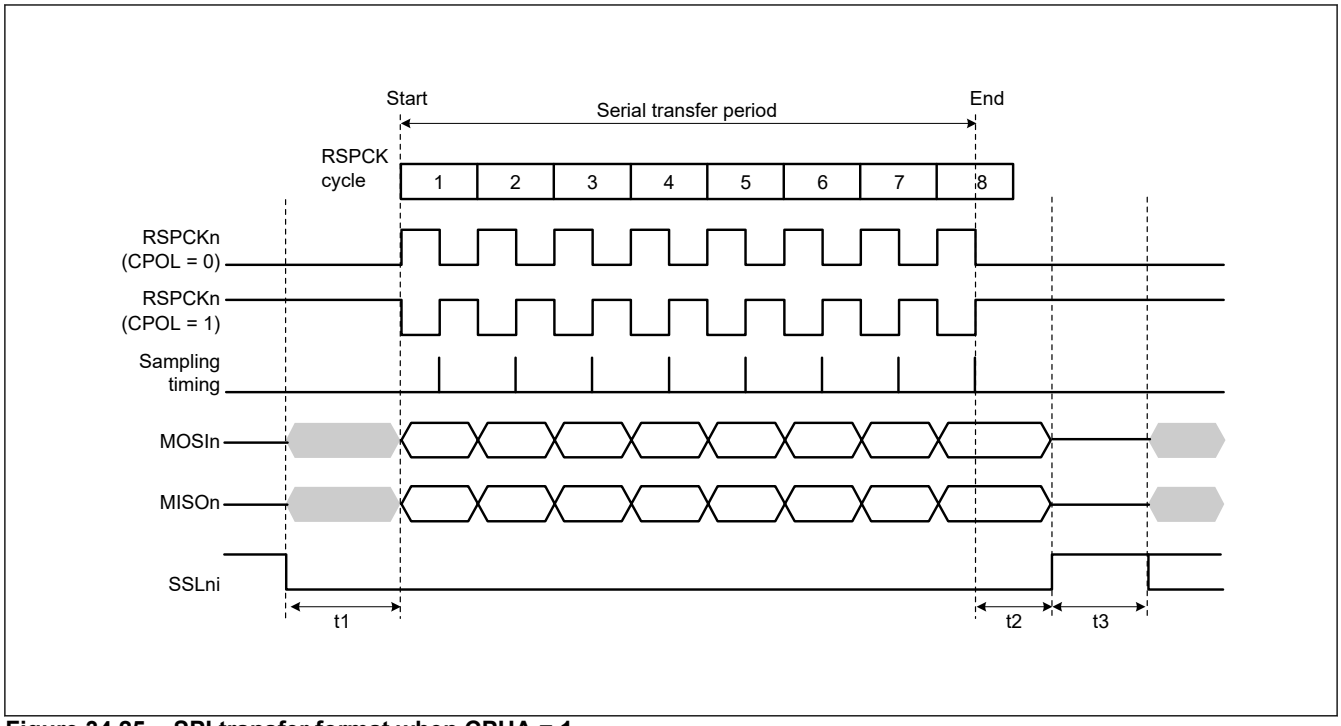

Figure 34.25 SPI transfer format when CPHA = 1

34.3.6 Data Transfer Modes

Full-duplex synchronous serial communications or transmit operations can only be selected in the Communications Operating Mode Select bit (SPCR.TXMD) when the extended communication mode select bit (ETXMD) in the SPI control register 3 (SPCR3) is 0. The SPI operation is receive only in slave mode (SPCR.MSTR = 0) when the SPCR3.ETXMD bit is 1, because SPCR.TXMD bit does not affect the SPI operation. The register accesses shown in Figure 34.26, Figure 34.27, and Figure 34.28 indicate the condition of access to the SPDR/SPDR_HA register, where W denotes a write cycle.

34.3.6.1 Full-duplex synchronous serial communications (SPCR3.ETXMD = 0, SPCR.TXMD = 0)

Figure 34.26 shows an example of operation when the extended communication mode select bit (ETXMD) in the SPI control register 3 (SPCR3) is set to 0 and the Communications Operating Mode Select bit (SPCR.TXMD) is set to 0. In this example, the SPI performs an 8-bit serial transfer when SPDCR.SPFC[1:0] bits are 00b, the SPCMDm.CPHA bit is 1, and the SPCMDm.CPOL bit is 0. The numbers given for RSPCKn in the waveform represent the number of RSPCK cycles, such as the number of transferred bits.

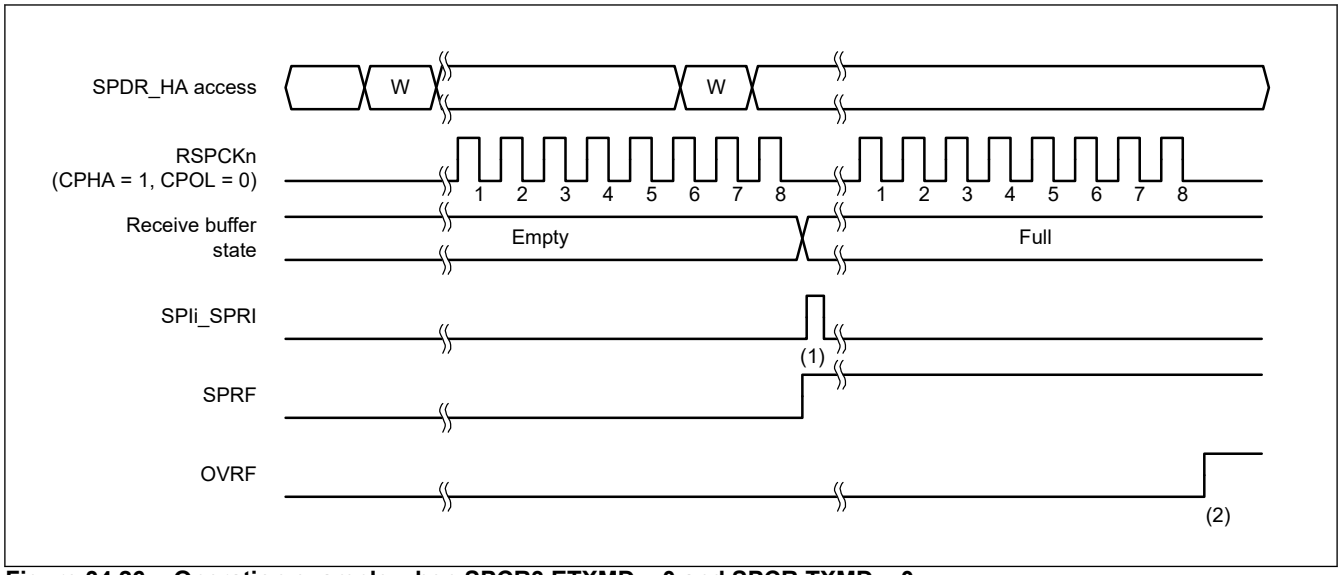

Figure 34.26 Operation example when SPCR3.ETXMD = 0 and SPCR.TXMD = 0

The operation of the flags at timings (1) and (2) in Figure 34.26 is as follows:

1. When a serial transfer ends with the receive buffer of SPDR_HA empty, the SPI generates a receive buffer full interrupt request (SPIi_SPRI), the SPI sets the SPSR.SPRF flag to 1, and copies the received data in the shift register to the receive buffer.
2. When a serial transfer ends with the receive buffer of SPDR_HA holding data that was received in the previous serial transfer, the SPI sets the SPSR.OVRF flag to 1, and discards the received data in the shift register. For details about the operation of the SPSR.OVRF flag, see section 34.3.9.1. Overrun errors.

34.3.6.2 Transmit-Only Serial Communications (SPCR3.ETXMD = 0, SPCR.TXMD = 1)

Figure 34.27 shows an example of operation when the extended communication mode select bit (ETXMD) in the SPI control register 3 (SPCR3) is set to 0 and the Communications Operating Mode Select bit (SPCR.TXMD) is set to 1. In this example, the SPI performs an 8-bit serial transfer when SPDCR.SPFC[1:0] bits are 00b, the SPCMDm.CPHA bit is 1, and the SPCMDm.CPOL bit is 0. The numbers given for RSPCKn in the waveform represent the number of RSPCK cycles, such as the number of transferred bits.

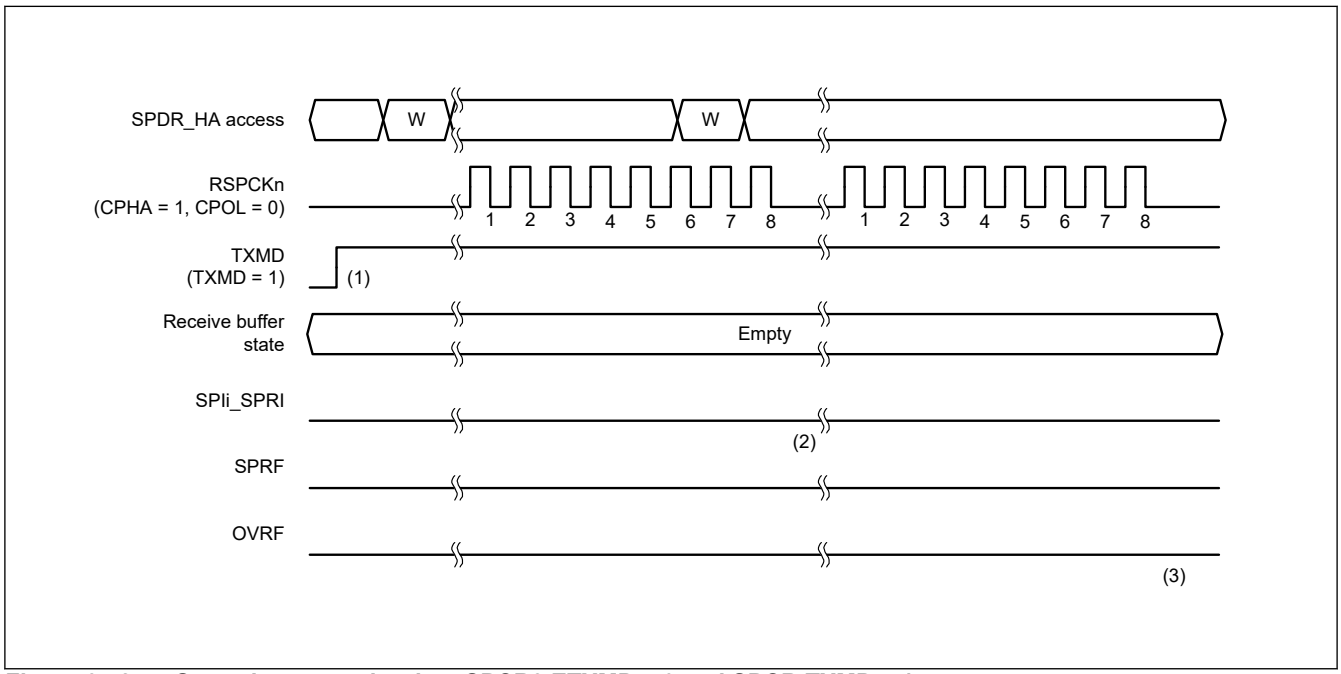

Figure 34.27 Operation example when SPCR3.ETXMD = 0 and SPCR.TXMD = 1

The operation of the flags at timings (1) to (3) in Figure 34.27 is as follows:

1. Make sure there is no data left in the receive buffer (the SPSR.SPRF flag is 0) and the SPSR.OVRF flag is 0 before entering transmit-only mode (SPCR3.ETXMD = 0, SPCR.TXMD = 1).
2. When a serial transfer ends with the receive buffer of SPDR_HA empty, if the transmit-only mode is selected (SPCR3.ETXMD = 0, SPCR.TXMD = 1), the SPSR.SPRF flag retains the value of 0, and the SPI does not copy the data in the shift register to the receive buffer.
3. Because the receive buffer of SPDR_HA does not hold data that was received in the previous serial transfer, even when a serial transfer ends, the SPSR.OVRF flag retains the value of 0, and the data in the shift register is not copied to the receive buffer.

In transmit-only mode (SPCR3.ETXMD = 0, SPCR.TXMD = 1), the SPI transmits data but does not receive data. Therefore, the SPSR.SPRF and SPSR.OVRF flags remain 0 at timings (1) to (3).

34.3.6.3 Receive-Only Serial Communication (MSTR = 0, ETXMD = 1)

Figure 34.28 shows an example of operation when the SPI master/slave mode select bit (MSTR) in the SPI control register (SPCR) is set to 0 and the extended communication mode select bit (ETXMD) in the SPI control register 3 (SPCR3) is set to 1. In the example in Figure 34.28, the SPI performs 8-bit data serial transfer with the settings of SPFC[1:0] in the SPI data control register (SPDCR) = 00b, CPHA in the SPI command register (SPCMD) = 1, and CPOL in SPCMD = 0. Numbers under the RSPCK waveform show the number of RSPCK cycles (number of transfer bits).

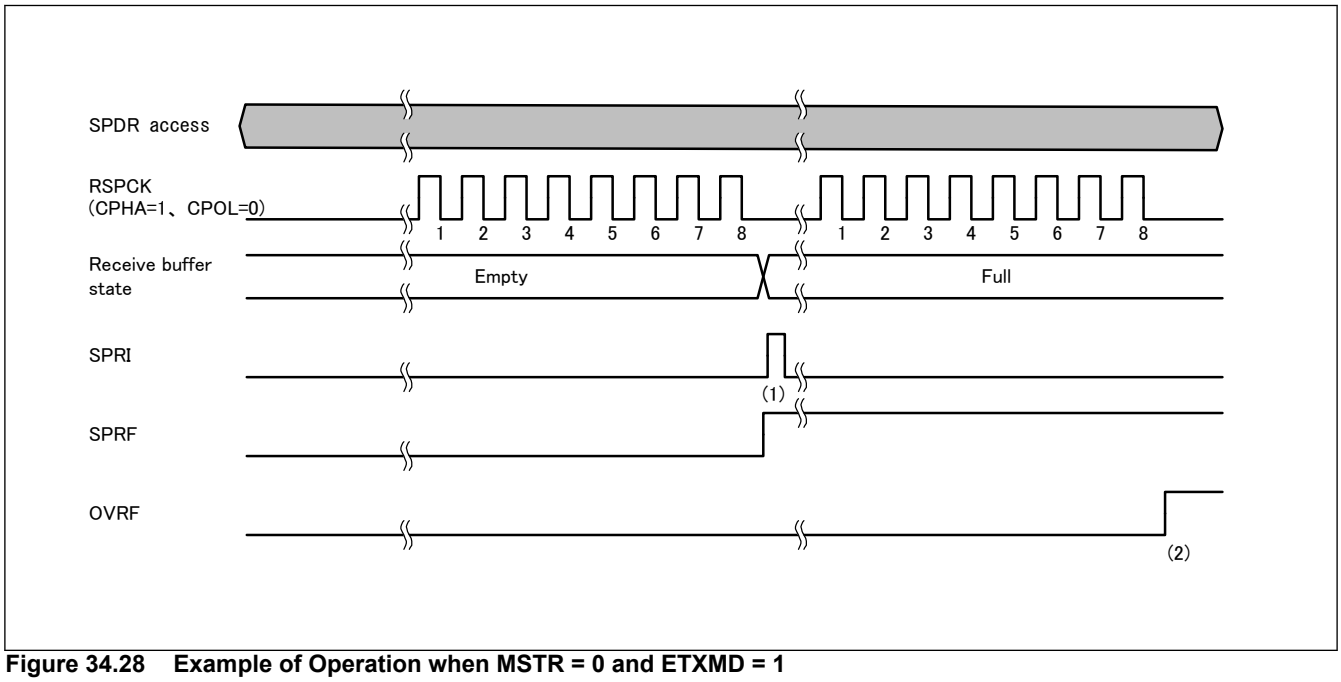

Figure 34.28 Example of Operation when MSTR = 0 and ETXMD = 1

The following describes operation of flags at timings (1) and (2) in the figure above.

(1) When serial transfer ends while the SPDR's receive buffer is empty, the SPI generates a receive buffer full interrupt request SPRI (setting the SPSR.SPRF flag to 1) and copies the received data in the shift register to the receive buffer

(2) When serial transfer ends while previously received data is remaining in the SPDR's receive buffer, the SPI sets the OVRF flag in the SPI status register (SPSR) to 1 and discards the received data in the shift register.

34.3.7 Transmit Buffer Empty and Receive Buffer Full Interrupts

Figure 34.29 and Figure 34.30 show examples of operation of the transmit buffer empty interrupt (SPIi_SPTI) and the receive buffer full interrupt (SPIi_SPRI). The SPDR_HA register accesses shown in these figures indicate the conditions of access to the register, where W denotes a write cycle and R a read cycle. In Figure 34.29, the SPI performs an 8-bit serial transfer when SPCR.TXMD bit is 0, the SPDCR.SPFC[1:0] bits are 00b, the SPCMDm.CPHA bit is 0, and the SPCMDm.CPOL bit is 0. In Figure 34.30, the SPI performs an 8-bit serial transfer when SPCR.TXMD bit is 0, the

SPDCR.SPFC[1:0] bits are 00b, the SPCMDm.CPHA bit is 1, and the SPCMDm.CPOL bit is 0. The numbers given for RSPCKn in the waveform represent the number of RSPCK cycles, such as the number of transferred bits.

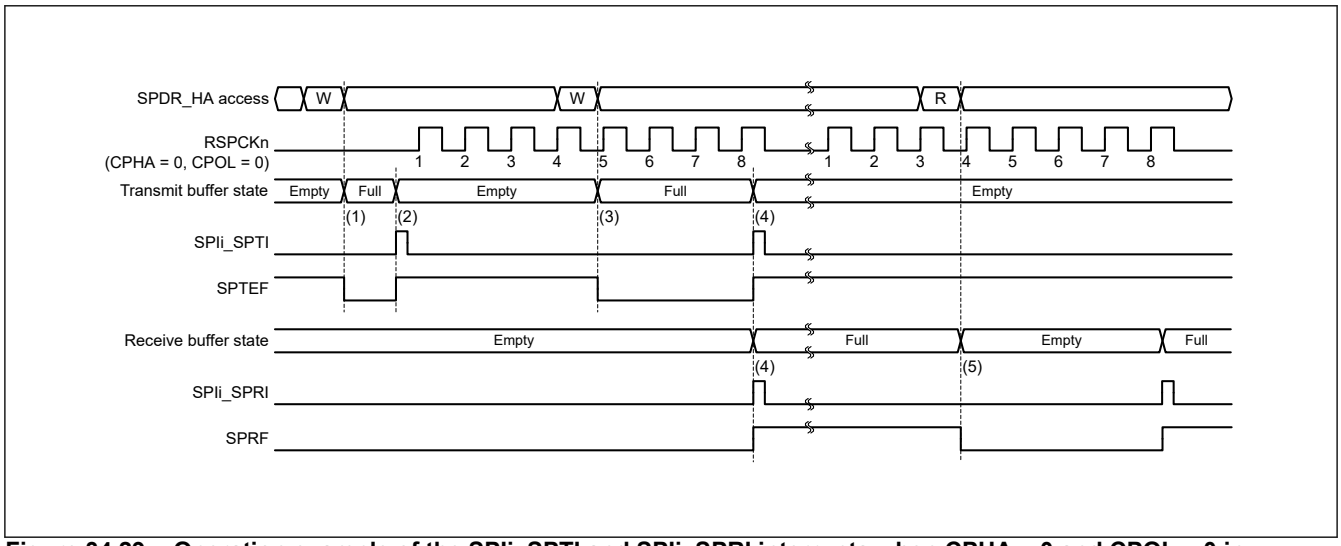

Figure 34.29 Operation example of the SPIi_SPTI and SPIi_SPRI interrupts when CPHA = 0 and CPOL = 0 in master mode

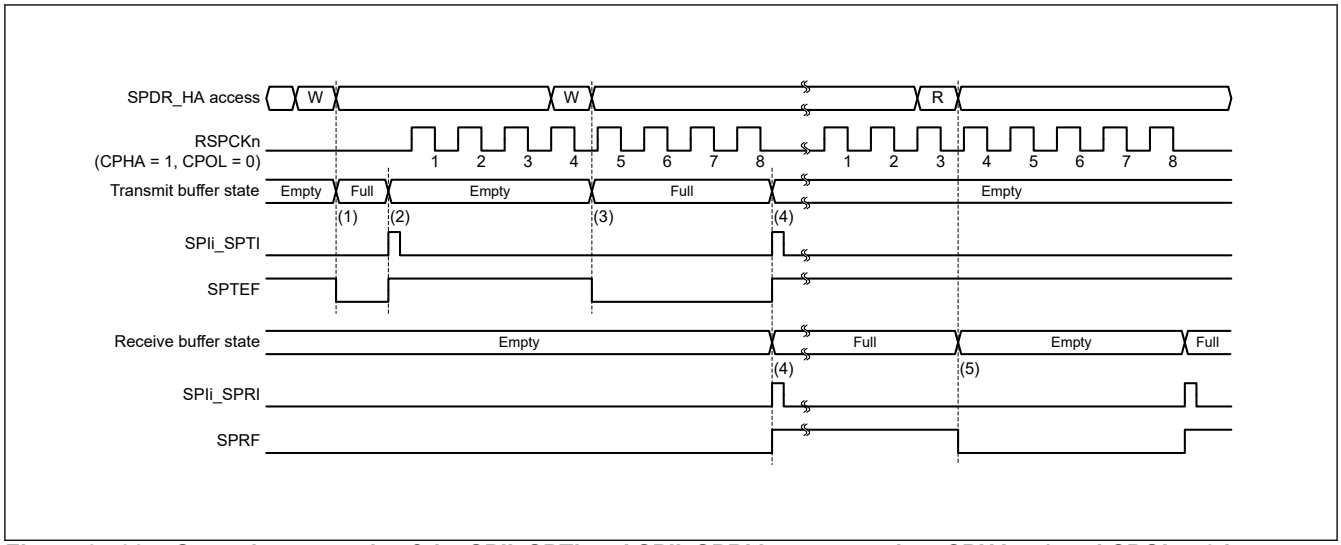

Figure 34.30 Operation example of the SPIi_SPTI and SPIi_SPRI interrupts when CPHA = 1 and CPOL = 0 in master mode

The operation of the SPI at timings (1) to (5) in Figure 34.29 and Figure 34.30 is as follows:

1. When transmit data is written to SPDR_HA with the transmit buffer of SPDR_HA is empty and data for the next transfer is not set, the SPI writes data to the transmit buffer and clears the SPSR.SPTEF flag to 0.
2. If the shift register is empty, the SPI copies the data in the transmit buffer to the shift register, generates a transmit buffer empty interrupt request (SPIi_SPTI), and sets the SPSR.SPTEF flag to 1. How a serial transfer is started depends on the SPI mode. For details, see section 34.3. Operation, and section 34.3.12. Clock Synchronous Operation.
3. When transmit data is written to SPDR_HA either by the transmit buffer empty interrupt routine, or by the processing of the transmit buffer empty using the SPTEF flag, the SPI writes data to the transmit buffer and clears the SPTEF flag to 0. Because the data being transferred serially is stored in the shift register, the SPI does not copy the data in the transmit buffer to the shift register.
4. When the serial transfer ends with the receive buffer of SPDR_HA empty, the SPI copies the receive data in the shift register to the receive buffer, generates a receive buffer full interrupt request (SPIi_SPRI), and sets the SPRF flag to 1. Because the shift register becomes empty on completion of the serial transfer, if the transmit buffer is full before the serial transfer ended, the SPI sets the SPTEF flag to 1 and copies data in the transmit buffer to the shift register. Even

when received data is not copied from the shift register to the receive buffer in an overrun error status, on completion of the serial transfer, the SPI determines that the shift register is empty, so data transfer from the transmit buffer to the shift register is enabled.

5. When SPDR_HA is read either by the receive buffer full interrupt routine or processing of the receive buffer full interrupt using the SPRF flag, the receive data can be read.

If SPDR_HA is written to when the transmit buffer holds data that is not yet transmitted (the SPTEF flag is 0), the SPI does not update data in the transmit buffer. When writing to SPDR_HA, always use either a transmit buffer empty interrupt request or processing of the transmit buffer empty interrupt using the SPTEF flag. To use a transmit buffer empty interrupt, set the SPTIE bit in SPCR to 1. If the SPI function is disabled (the SPCR.SPE bit is 0), set the SPTIE bit to 0.

When serial transfer ends and the receive buffer is full (the SPRF flag is 1), the SPI does not copy data from the shift register to the receive buffer, and it detects an overrun error (see section 34.3.9. Error Detection). To prevent a receive data overrun error, read the received data using a receive buffer full interrupt request before the next serial transfer ends. To use an SPI receive buffer full interrupt, set the SPCR.SPRIE bit to 1.

Transmission and reception interrupts or the associated IELSRn.IR flags (where n is the interrupt vector number) in the ICU can be used to confirm the states of the transmit and receive buffers.

Similarly, the SPTEF and SPRF flags can be used to confirm the states of the transmit and receive buffers. See section 13, Interrupt Controller Unit (ICU) for the interrupt vector numbers.

34.3.8 Communication End Interrupt

34.3.8.1 Transmit-Receive/Transmit in Master Mode

The communication end interrupt (SPCI) is made and the CENDF flag is set to 1, when following conditions are satisfied in transmit-receive master mode and transmit master mode. The set timing of the CENDF flag is same as IDLNF flag. The communication end interrupt (SPCI) is one PCLKA width and low active.

- When the value of the SPSSR.SPCP[2:0] bits are same as the SPSCR.SPSLN[2:0] bits.
- When there is no next transmission data.

The CENDF flag will not be cleared even if the SPCR.SPE bit is cleared after CENDF = 1. The CENDF flag will be cleared in one of following tow conditions.

- When the next transmission data is written to the transmit buffer (SPTX).
- The CENDF flag was written 0 after reading the SPSR when the CENDF flag was 1.

Figure 34.31 shows an example of communication end interrupt operation during transmit-receive/transmit master mode.

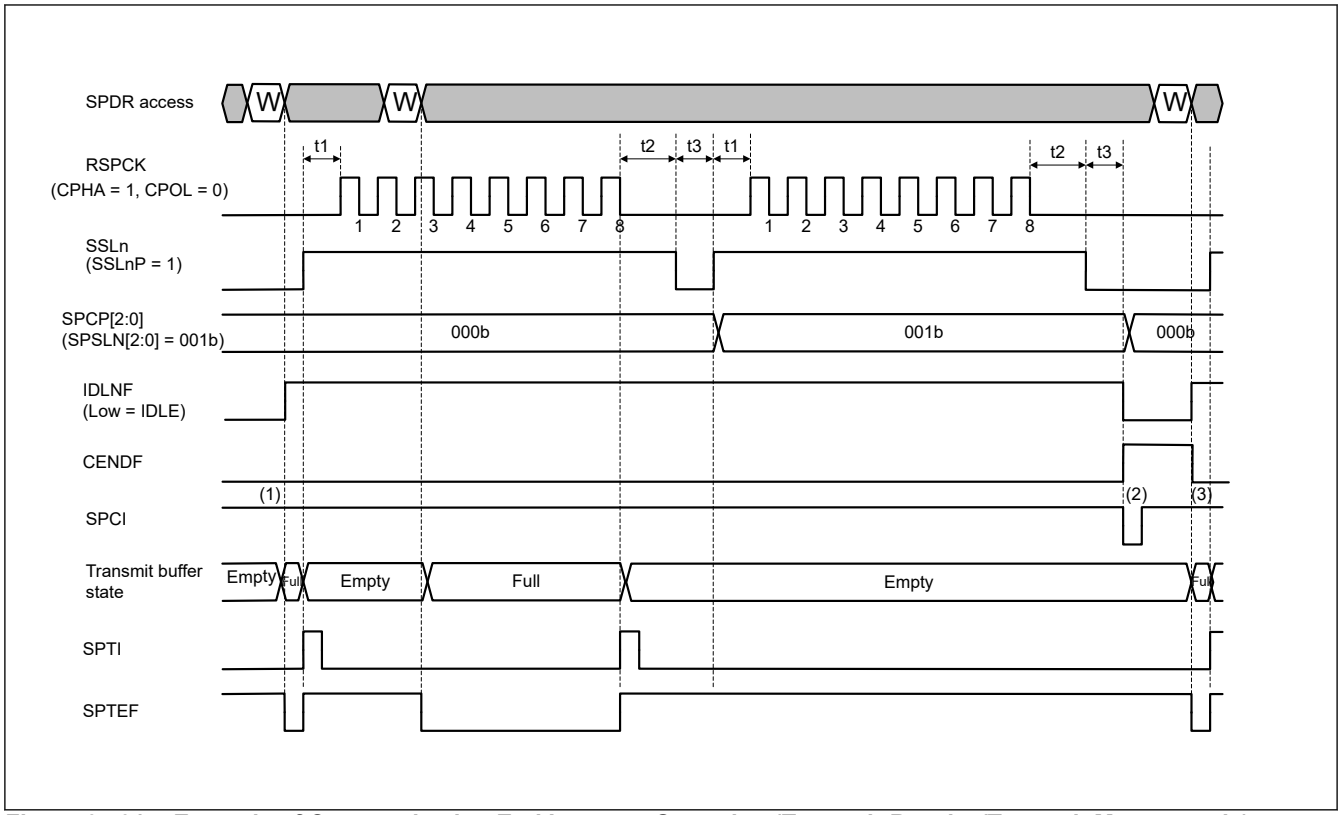

Figure 34.31 Example of Communication End Interrupt Operation (Transmit-Receive/Transmit Master mode)

1. The CNEDF flag is 0 and the level of SPCI is 1 before communication start, and these have kept during communication.
2. The CENDF flag will be 1 (Communication End) at the end of t3 cycle, because the next command is 000b and there is no next transmit data, and then the SPCI interrupt output when the CENDIE bit is 1.
3. The CENDF flag is cleared when the next transmission data is written to the transmit buffer (SPTX). Or the CENDF flag is cleared if the CENDF flag was written 0 after reading the SPCR when the CENDF flag was 1.

In slave mode operation, the output timing of the communication end interrupt is deferent due to the value of the SPCR.SPMS bit (SPI mode select bit), and the clear timing of the communication end interrupt is deferent due to the communication mode (transmit-receive or transmit-only or receive-only).

34.3.8.2 Transmit-Receive/Transmit in Slave Mode on SPI Operation (4-wire)

The communication end interrupt (SPCI) is made and the CENDF flag is set to 1, when both SPTX buffer and transmit shift buffer are empty in transmit-receive/transmit slave mode on SPI Operation (4-wire). The set timing of the CENDF flag is same as SSL0 negate timing. The communication end interrupt (SPCI) is one PCLKA width and low active.

The CENDF flag will not be cleared even if the SPCR.SPE bit is cleared after CENDF = 1. The CENDF flag will be cleared in one of following tow conditions.

- When the next transmission data is written to the transmit buffer (SPTX).
- The CENDF flag was written 0 after reading the SPSR when the CENDF flag was 1.

Figure 34.32 shows an example of communication end interrupt operation during transmit-receive/transmit slave mode on SPI operation.

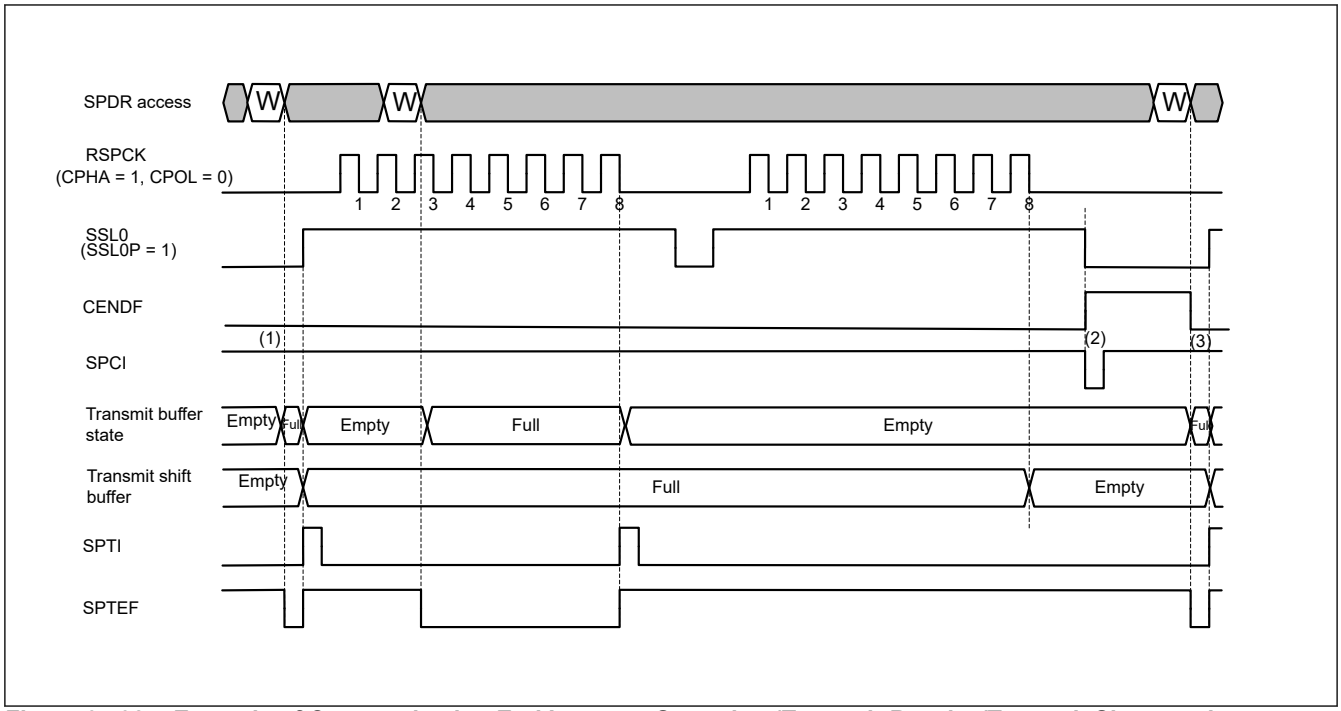

Figure 34.32 Example of Communication End Interrupt Operation (Transmit-Receive/Transmit Slave mode on SPI Operation)

1. The CNEDF flag is 0 and the level of SPCI is 1 before communication start, and these have kept during communication.
2. The CENDF flag will be 1 (Communication End) at the timing of SSL0 negate, when both SPTX buffer and transmit shift buffer are empty, and then the SPCI interrupt output when the CENDIE bit is 1.
3. The CENDF flag is cleared when the next transmission data is written to the transmit buffer (SPTX). Or the CENDF flag is cleared if the CENDF flag was written 0 after reading the SPCR when the CENDF flag was 1.

34.3.8.3 Receive Only in Slave Mode on SPI Operation (4-wire)

The communication end interrupt (SPCI) is made and the CENDF flag is set to 1 at the SSL0 negate timing in receive only slave mode on SPI operation (4-wire). The number of transmission frame is set by the SPDCR.SPFC[1:0]. Then the SSL0 is negated at the last frame transmission end. The communication end interrupt (SPCI) is one PCLKA width and low active.

The CENDF flag will not be cleared even if the SPCR.SPE bit is cleared after CENDF = 1. The CENDF flag will be cleared in one of following tow conditions.

- The SSL0 assert timing of next transmission.
- The CENDF flag was written 0 after reading the SPSR when the CENDF flag was 1.

Figure 34.33 shows an example of communication end interrupt operation during receive only slave mode on SPI operation (4-wire).

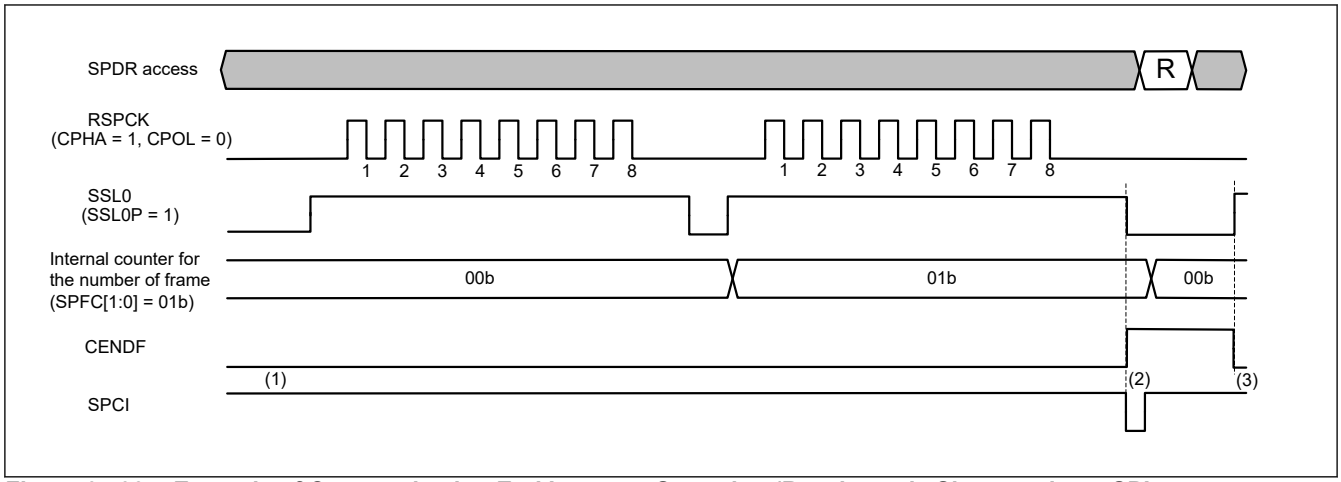

Figure 34.33 Example of Communication End Interrupt Operation (Receive only Slave mode on SPI Operation)

1. The CNEDF flag is 0 and the level of SPCI is 1 before communication start, and these have kept during communication.
2. The CENDF flag will be 1 (Communication End) at the timing of SSL0 negate, when the last frame transmission ends, and then the SPCI interrupt output when the CENDIE bit is 1.
3. The CENDF flag is cleared at the SSL0 assert when the next transmission start. Or the CENDF flag is cleared if the CENDF flag was written 0 after reading the SPCR when the CENDF flag was 1.

34.3.8.4 Transmit-Receive/Transmit in Slave Mode on Clock Synchronous Operation (3-wire)

The communication end interrupt (SPCI) is made and the CENDF flag is set to 1 when both SPTX buffer and transmit shift register are empty in transmit-receive/transmit slave mode on clock synchronous operation (3-wire). The set timing of CENDF flag is same as the last data sampling of the RSPCK (the last odd edge of RSPCK when the SPCMD0.CPHA bit is 0, the last even edge of RSPCK when the SPCMD0.CPHA bit is 1). The communication end interrupt (SPCI) is one PCLKA width and low active.

The CENDF flag will not be cleared even if the SPCR.SPE bit is cleared after CENDF = 1. The CENDF flag will be cleared in one of following tow conditions.

- The SSL0 assert timing of next transmission.
- The CENDF flag was written 0 after reading the SPSR when the CENDF flag was 1.

Figure 34.34 shows an example of communication end interrupt operation during transmig-receive/transmit slave mode on clock synchronous operation (3-wire).

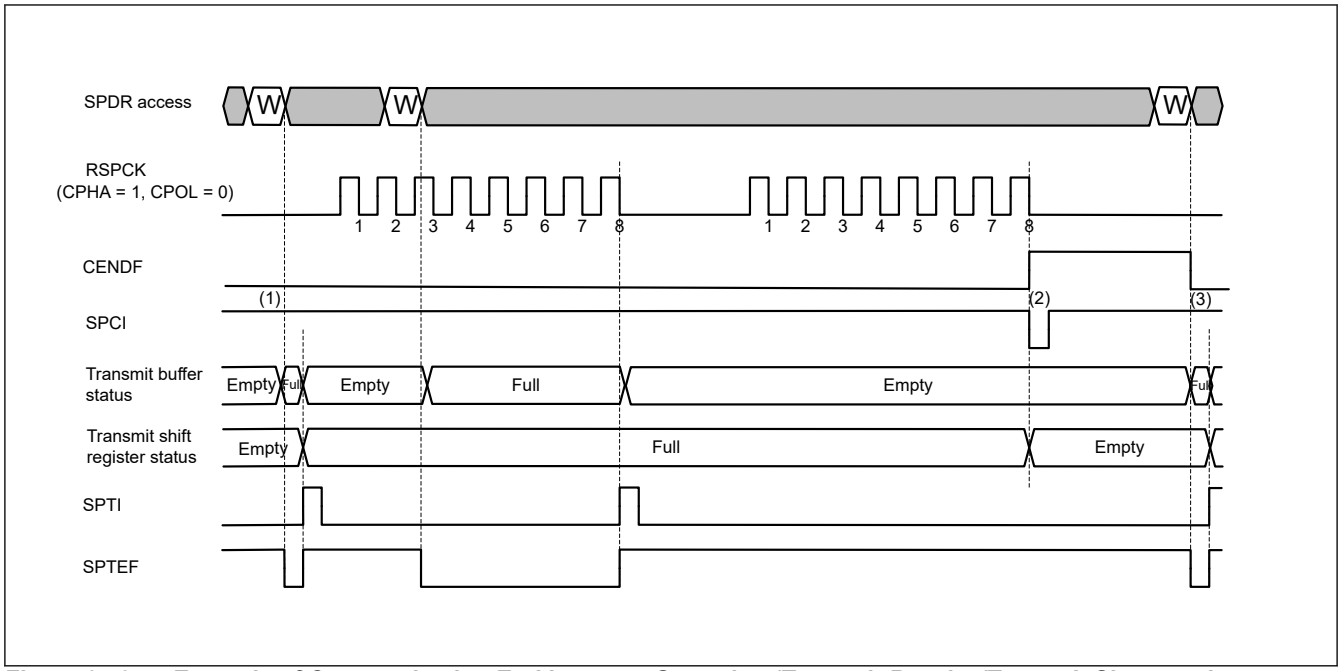

Figure 34.34 Example of Communication End Interrupt Operation (Transmit-Receive/Transmit Slave mode on Clock Synchronous Operation)

1. The CNEDF flag is 0 and the level of SPCI is 1 before communication start, and these have kept during communication.
2. The CENDF flag will be 1 (Communication End) at the last data sampling timing of RSPCK, when both SPTX buffer and transmit shift buffer are empty, and then the SPCI interrupt output when the CENDIE bit is 1.
3. The CENDF flag is cleared when the next transmission data is written to the transmit buffer (SPTX). Or the CENDF flag is cleared if the CENDF flag was written 0 after reading the SPCR when the CENDF flag was 1.

34.3.8.5 Receive Only in Slave Mode on Clock Synchronous Operation (3-wire)

The communication end interrupt (SPCI) is made and the CENDF flag is set to 1 at the last data sampling of the last transmission frame in receive only slave mode on clock synchronous operation (3-wire). The sampling timing is the last odd edge of RSPCK when the SPCMD0.CPHA bit is 0, the last even edge of RSPCK when the SPCMD0.CPHA bit is 1. The number of transmission frame is set by the SPDCR.SPFC[1:0]. The communication end interrupt (SPCI) is one PCLKA width and low active.

The CENDF flag will not be cleared even if the SPCR.SPE bit is cleared after CENDF = 1. The CENDF flag will be cleared in one of following tow conditions.

- The first edge of RSPCK for next transmission.
- The CENDF flag was written 0 after reading the SPSR when the CENDF flag was 1.

Figure 34.35 shows an example of communication end interrupt operation during receive only slave mode on clock synchronous operation.

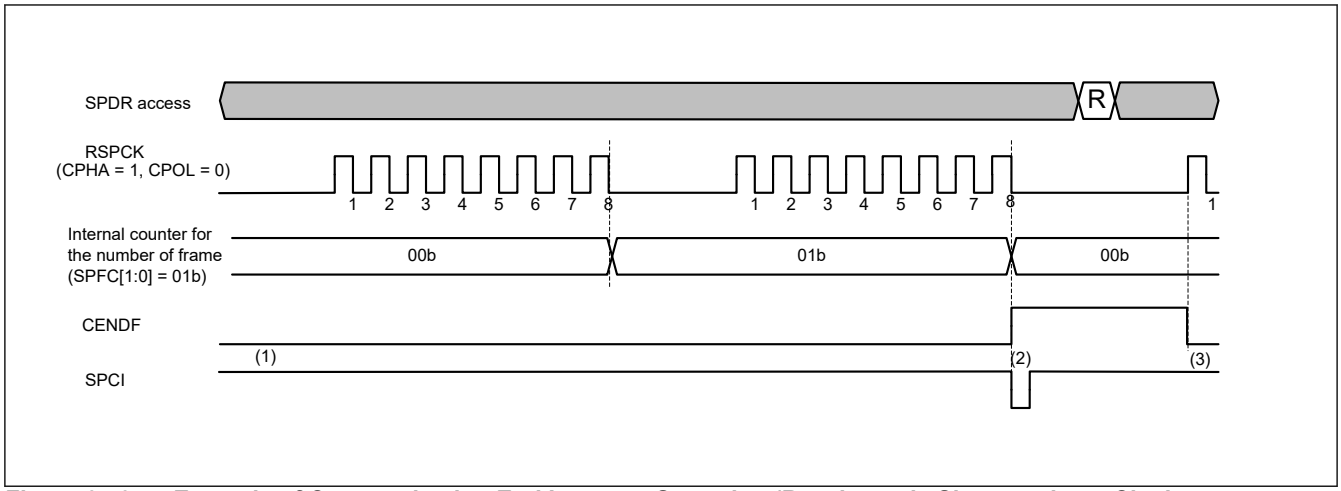

Figure 34.35 Example of Communication End Interrupt Operation (Receive-only Slave mode on Clock Synchronous Operation)

1. The CNEDF flag is 0 and the level of SPCI is 1 before communication start, and these have kept during communication.
2. The CENDF flag will be 1 (Communication End) at the last data sampling timing of RSPCK, when the last frame transmission end. The number of transmission frame is set by the SPDCR.SPFC[1:0]. And then the SPCI interrupt output when the CENDIE bit is 1.
3. The CENDF flag is cleared at the first edge of RSPCK for the next transmission. Or the CENDF flag is cleared if the CENDF flag was written 0 after reading the SPCR when the CENDF flag was 1.

34.3.8.6 Common Operation

In this chapter, the operation common to each mode / area option communication in section 34.3.8.1. Transmit-Receive/ Transmit in Master Mode to section 34.3.8.5. Receive Only in Slave Mode on Clock Synchronous Operation (3-wire) is explained. When the enable of SPI communication end interrupt (CENDIE) is 0, at the time of communication completion, a flag of communication end (CENDF) is set and an event of communication end (sp_elccend) is output, but no interrupt is output. However, if the enable of communication end interrupt (CENDIE) is set to 1 before clearing the flag of communication end (CENDF) while the enable of SPI function (SPE) is 1, the communication end interrupt is output.

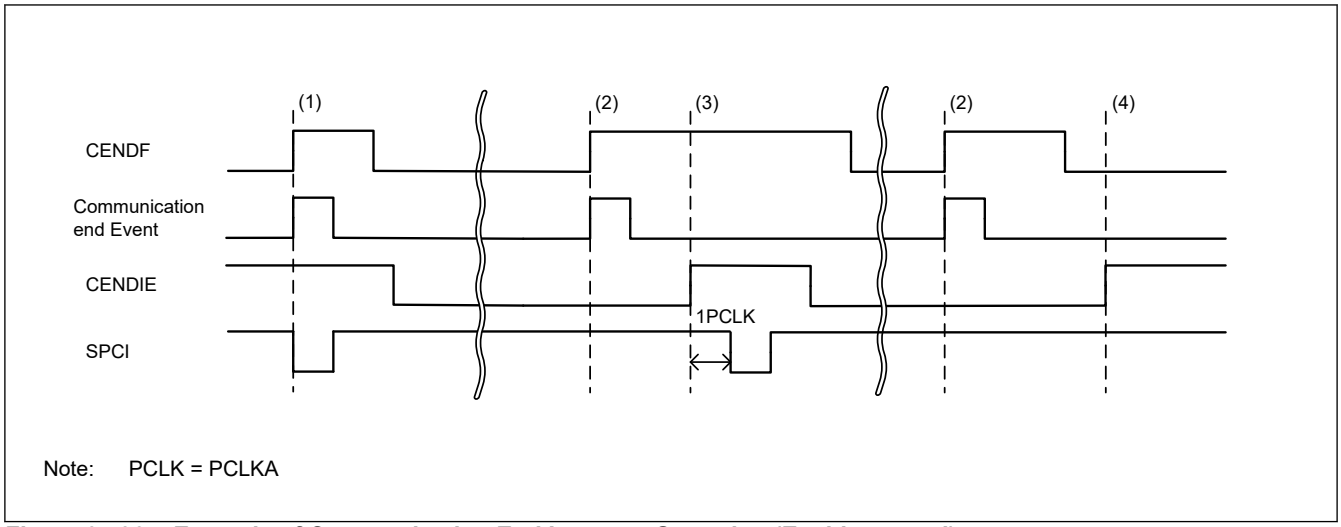

Figure 34.36 Example of Communication End Interrupt Operation (Enable control)

1. When the enable of SPI communication end interrupt (CENDIE) is 1, at the time of communication completion, the following three are the same timing.
   - A flag of communication end (CENDF)
   - An event of communication end (sp_elccend)
   - The communication end interrupt

2. When the enable of SPI communication end interrupt (CENDIE) is 0, at the time of communication completion, the following two are the same timing, but no interrupt.
   - A flag of communication end (CENDF)
   - An event of communication end (sp_elccend)
3. After (2), if the enable of communication end interrupt (CENDIE) is set when the enable of SPI function (SPE) and the flag of communication end (CENDF) are 1, the communication end interrupt is output after 1 PCLKA.
4. After (2), even if the enable of communication end interrupt (CENDIE) is set when the enable of SPI function (SPE) or the flag of communication end (CENDF) is 0, the communication end interrupt is not output.

34.3.9 Error Detection

In normal SPI serial transfers, data written to the transmit buffer of SPDR/SPDR_HA is transmitted, and received data can be read from the receive buffer of SPDR/SPDR_HA. If access is made to SPDR/SPDR_HA, an abnormal transfer might occur, depending on the status of the transmit or receive buffer or the status of the SPI at the beginning or end of serial transfer.

If an abnormal transfer occurs, the SPI detects the event as an underrun error, overrun error, parity error, or mode fault error. Table 34.10 lists the relationship between non-normal transfer operations and the SPI error detection function.

Table 34.10 Relationship between non-normal transfer operations and SPI error detection

Operation	Occurrence condition	SPI operation	Error detection
1	SPDR/SPDR_HA is written when the transmit buffer is full.	• The contents of the transmit buffer are kept • Write data is missing	None
2	SPDR/SPDR_HA is read when the receive buffer is empty.	The contents of the receive buffer and previously received data are output.	None
3	Serial transfer is started in slave mode when the SPI is not able to transmit data.	• Serial transfer is suspended • Transmit or receive data is missing • Driving of the MISOn output signal is stopped • SPI function is disabled	Underrun error
4	Serial transfer terminates when the receive buffer is full.	• Keeps the contents of the receive buffer • Missing receive data	Overrun error
5	An incorrect parity bit is received during full-duplex synchronous serial communication with the parity function enabled in following mode: • Transmit-receive master mode • Transmit-receive slave mode • Receive-only slave mode	The parity error flag is asserted	Parity error
6	The SSLn0 input signal is asserted when the serial transfer is idle in multi-master mode.	• Driving of the RSPCKn, MOSIn, SSLn1 to SSLn3 output signals is stopped • SPI function is disabled	Mode fault error
7	The SSLn0 input signal is asserted during serial transfer in multi-master mode.	• Serial transfer is suspended • Transmit or receive data is missing • Driving of the RSPCKn, MOSIn, SSLn1 to SSLn3 output signals is stopped • SPI function is disabled	Mode fault error
8	The SSLn0 input signal is negated during serial transfer in slave mode.	• Serial transfer is suspended • Transmit or receive data is missing • Driving of the MISOn output signal is stopped • SPI function is disabled	Mode fault error

In operation 1 described in Table 34.10, the SPI does not detect an error. To prevent data omission during writes to SPDR/SPDR_HA, the writes to SPDR/SPDR_HA must be executed using a transmit buffer empty interrupt request (when the SPSR.SPTEF flag is 1).

Similarly, the SPI does not detect an error in operation 2. To prevent extraneous data from being read, SPDR/SPDR_HA read must be executed with an SPI receive buffer full interrupt request (when the SPSR.SPRF flag is 1).

For information on the other errors, see the following sections:

- Underrun error, indicated in operation 3, see section 34.3.9.4. Underrun errors
- Overrun error, indicated in operation 4, see section 34.3.9.1. Overrun errors
- Parity error, indicated in operation 5, see section 34.3.9.2. Parity errors
- Mode fault error, indicated in operations 6 to 8, see section 34.3.9.3. Mode fault errors
- For the transmit and receive interrupts, see section 34.3.7. Transmit Buffer Empty and Receive Buffer Full Interrupts.

34.3.9.1 Overrun errors

If a serial transfer ends when the receive buffer of SPDR/SPDR_HA is full, the SPI detects an overrun error and sets the SPSR.OVRF flag to 1. When the OVRF flag is 1, the SPI does not copy data from the shift register to the receive buffer, so the data prior to the error occurrence is retained in the receive buffer. To set the OVRF flag to 0, write 0 to the OVRF flag after the CPU reads SPSR with the OVRF flag set to 1.

Figure 34.37 shows an example of operation of the OVRF and SPRF flags. The SPSR and SPDR_HA accesses shown in Figure 34.37 indicate the condition of accesses to the SPSR and SPDR_HA register, where W denotes a write cycle, and R a read cycle. In this example, the SPI performs an 8-bit serial transfer when SPCMDm.CPHA bit is 1 and the SPCMDm.CPOL bit is 0. The numbers given for RSPCKn in the waveform represent the number of RSPCK cycles, such as the number of transferred bits.

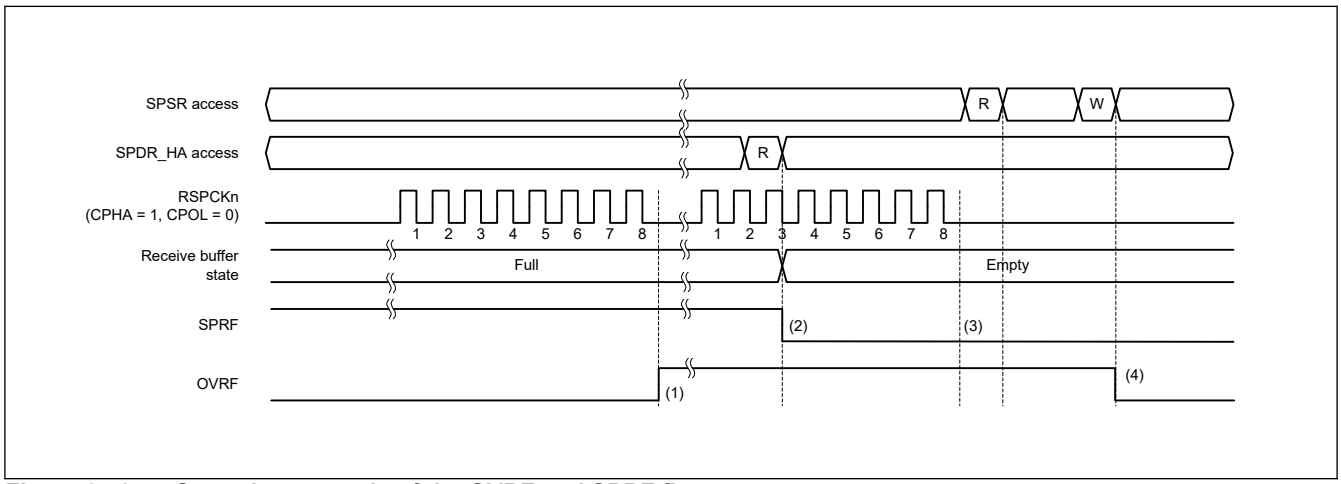

Figure 34.37 Operation example of the OVRF and SPRF flags

The operation of the flags at timings (1) to (4) in Figure 34.37 is as follows:

1. If a serial transfer terminates with the SPRF flag set to 1 (receive buffer full), the SPI detects an overrun error, and sets the OVRF flag to 1. The SPI does not copy the data in the shift register to the receive buffer. Even when the SPPE bit is 1, parity errors are not detected.
2. When SPDR/SPDR_HA is read, the SPI outputs the data in the receive buffer. The SPRF flag is then set to 0. The receive buffer becoming empty does not set the OVRF flag to 0.
3. If the serial transfer ends with the OVRF flag set to 1 (overrun error occurred), the SPI does not copy data in the shift register to the receive buffer (the SPRF flag does not set to 1). A receive buffer full interrupt is not generated. Even when the SPPE bit is 1, parity errors are not detected. In an overrun error state when the SPI does not copy the received data from the shift register to the receive buffer, on termination of the serial transfer, the SPI determines that the shift register is empty. This enables data transfer from the transmit buffer to the shift register.
4. If 0 is written to the OVRF flag after SPSR is read when the OVRF flag is 1, the OVRF flag clears is set to 0.

The occurrence of an overrun can be checked either by reading SPSR or by using an SPI error interrupt and reading SPSR. When executing a serial transfer, you must ensure that overrun errors are detected early, for example by reading SPSR immediately after SPDR/SPDR_HA/SPDR_BY is read.

If an overrun error occurs and the OVRF flag sets to 1, normal reception operations cannot be performed until the OVRF flag is set to 0.

When the RSPCK auto-stop function is enabled (SPCR2.SCKASE = 1) in master mode, an overrun error does not occur. Figure 34.38 and Figure 34.39 show the clock stop waveform when a serial transfer continues while the receive buffer is full in master mode.

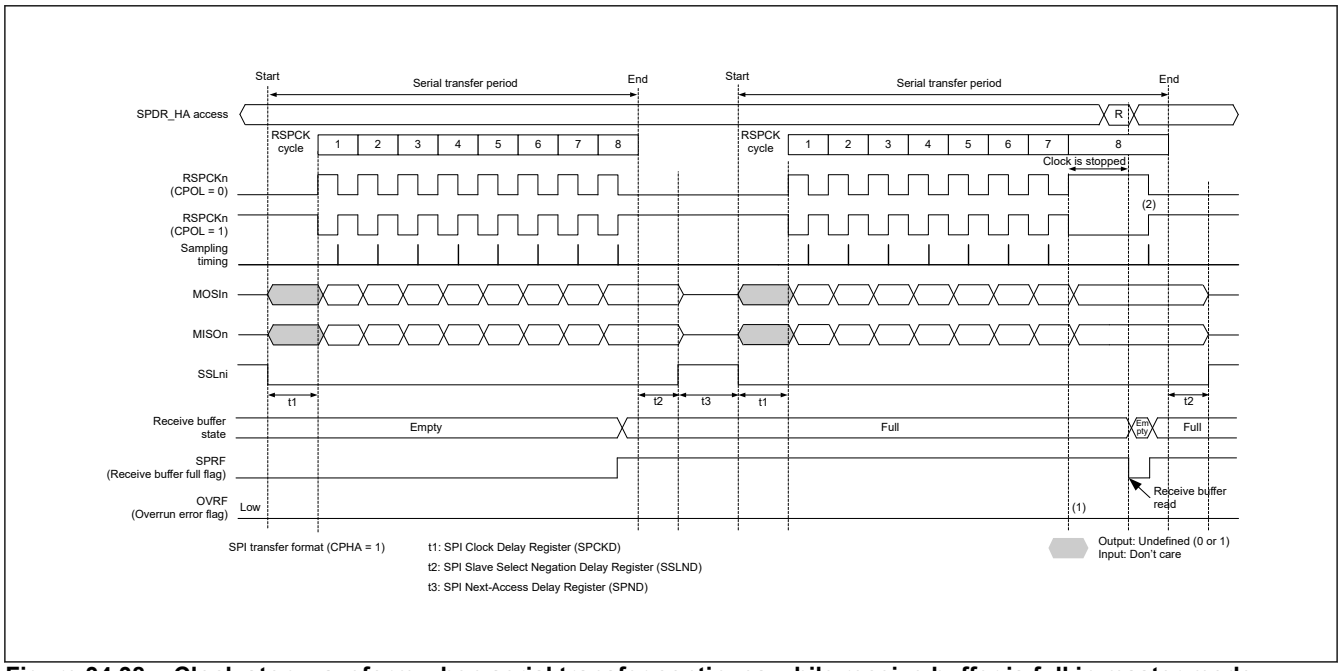

Figure 34.38 Clock stop waveform when serial transfer continues while receive buffer is full in master mode (CPHA = 1)

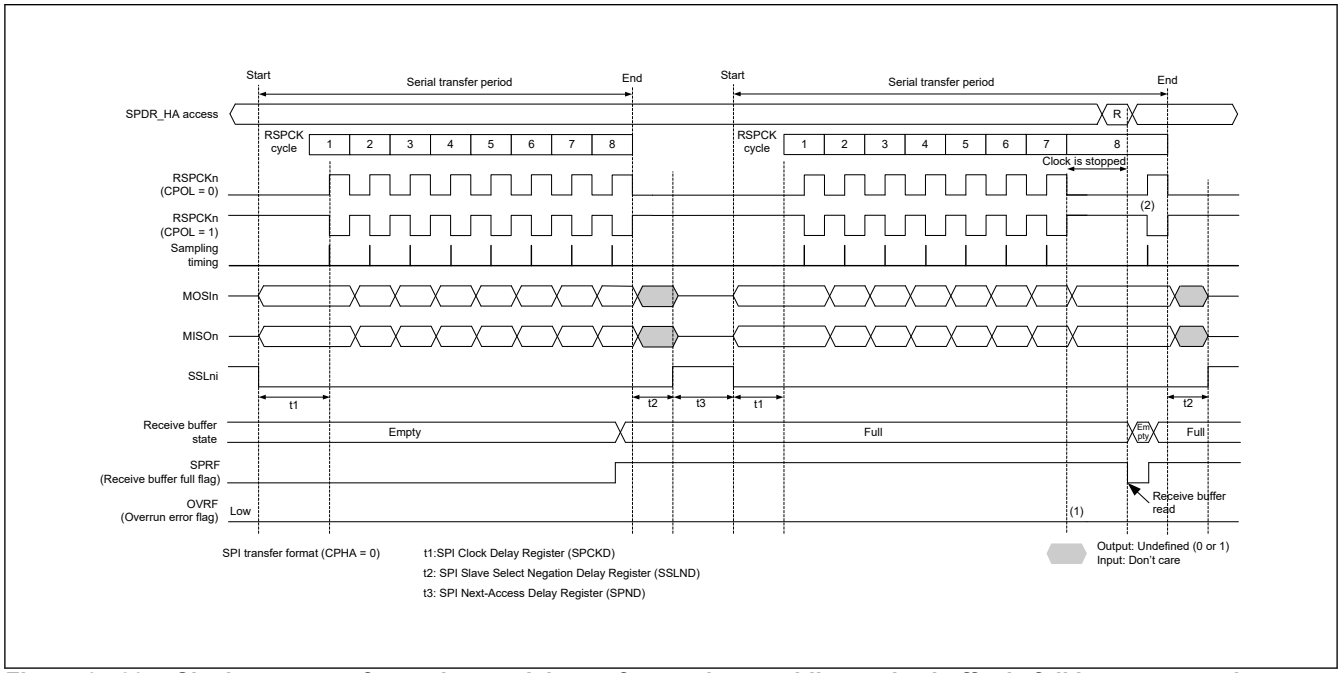

Figure 34.39 Clock stop waveform when serial transfer continues while receive buffer is full in master mode (CPHA = 0)

The operation of the flags at timings (1) and (2) in Figure 34.38 and Figure 34.39 is as follows:

1. When the receive buffer is full, an overrun error does not occur because the RSPCK clock is stopped.
2. If SPDR/SPDR_HA is read while the clock is stopped, data in the receive buffer can be read. The RSPCK clock restarts after reading the receive buffer (after the SPSR.SPRF flag is set to 0).

Overrun error does not occur when RSPCK automatic stop function is enabled for transfer with no delay of between frames during burst transfer in master mode. Figure 34.40 and Figure 34.41 show the clock stop waveform, when there is no delay between frames at burst transfer and the serial transfer continues in the reception buffer full state.

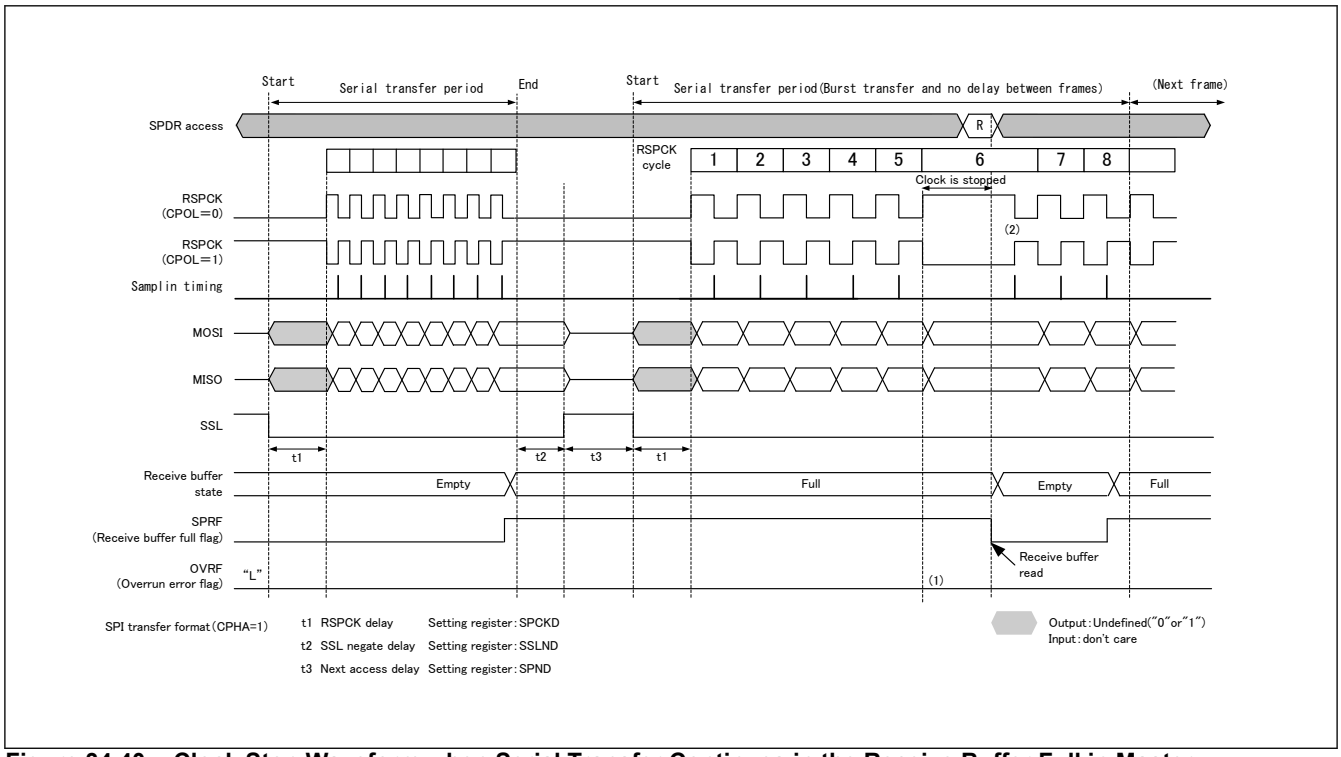

Figure 34.40 Clock Stop Waveform when Serial Transfer Continues in the Receive Buffer Full in Master Mode (at burst transfer and no delay between frames CPHA = 1)

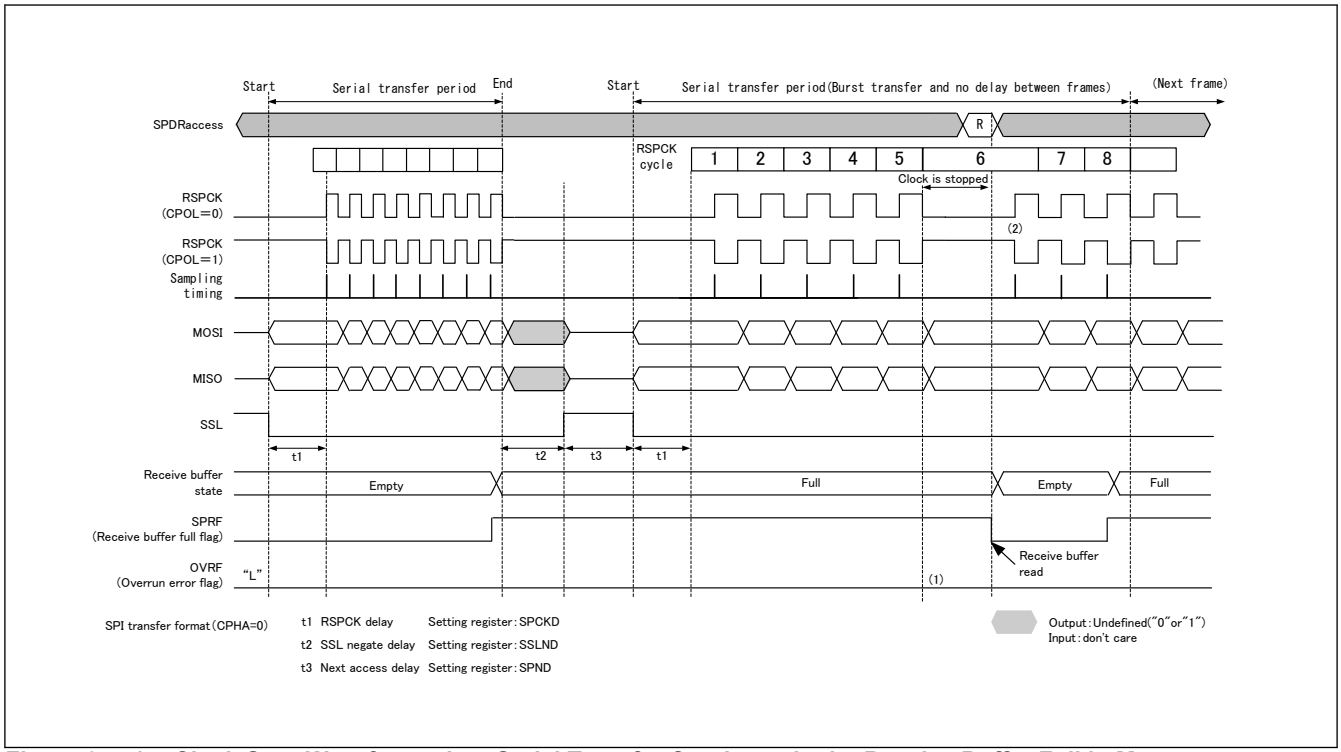

Figure 34.41 Clock Stop Waveform when Serial Transfer Continues in the Receive Buffer Full in Master Mode (at burst transfer and no delay between frames CPHA = 0)

The following describes operation of flags at timings (1) and (2) in the figure above.

1. While the receive buffer is full, the RSPCK clock is deactivated and no overrun error occurs.
2. Receive buffer data can be read by reading SPDR during clock stop. After the receive buffer data has been read (after the SPSR.SPRF flag has been cleared to 0), the RSPCK clock restarts.

34.3.9.2 Parity errors

When full-duplex synchronous serial communications is performed with the SPCR.TXMD bit set to 0 and the SPCR2.SPPE bit set to 1, when serial transfer ends, the SPI checks whether there are parity errors. On detecting a parity error in the received data, the SPI sets the SPSR.PERF flag to 1. Because the SPI does not copy data in the shift register to the receive buffer when the SPSR.OVRF flag is set to 1, parity error detection is not performed for the received data. To set the PERF flag to 0, write 0 to the PERF flag after the SPSR register is read with the PERF flag set to 1.

Figure 34.42 shows an example of operation of the OVRF and PERF flags. The SPSR access shown in Figure 34.42 indicates the condition of access to the register, where W denotes a write cycle, and R a read cycle. In this example, full-duplex serial communication is performed while the SPCR2.SPPE bit is 1. The SPI performs an 8-bit serial transfer when SPCMDm.CPHA bit is 1 and the SPCMDm.CPOL bit is 0. The numbers given for RSPCKn in the waveform represent the number of RSPCK cycles, such as the number of transferred bits.

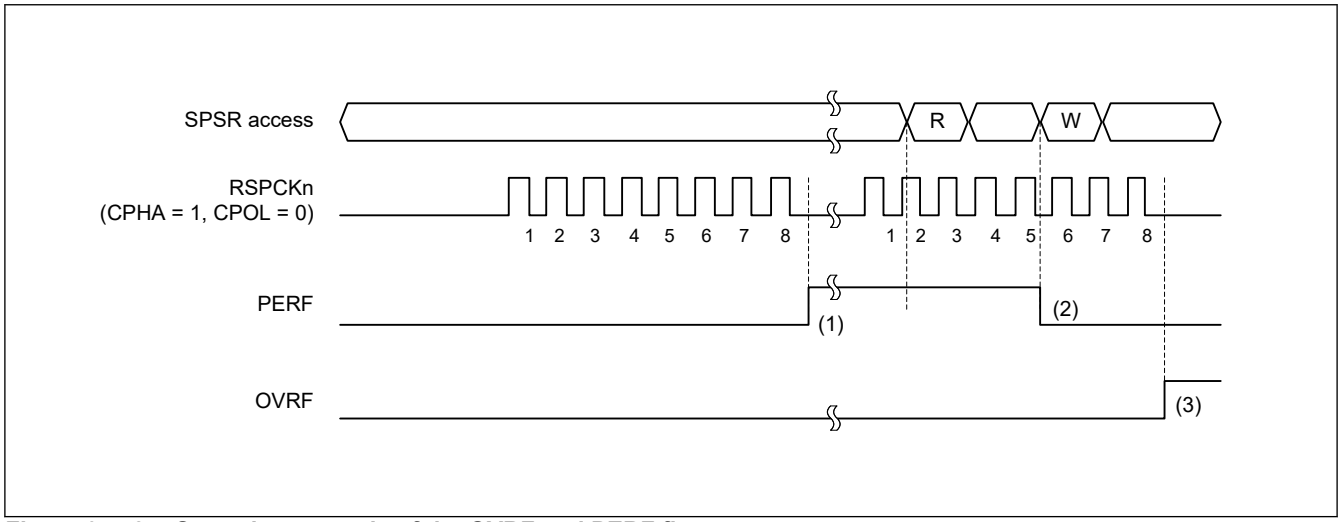

Figure 34.42 Operation example of the OVRF and PERF flags

The operation of the flags at timings (1) to (3) in Figure 34.42 is as follows:

1. If a serial transfer terminates with the SPI not detecting an overrun error, the SPI copies the data in the shift register to the receive buffer. The SPI checks the received data at this time and sets the PERF flag to 1 if a parity error is detected.
2. If 0 is written to the PERF flag after the SPSR register is read when the PERF flag is 1, the PERF flag is set to 0.
3. When the SPI detects an overrun error and serial transfer is terminated, the data in the shift register is not copied to the receive buffer. The SPI does not perform parity error detection at this time.

Parity errors can be checked for by either reading the SPSR register or using an SPI error interrupt and reading the SPSR register. When executing a serial transfer, such checks are required to ensure early detection of parity errors. When the SPI is used in master mode, the pointer value to the SPCMDm register at the occurrence of the error can be checked by reading the SPSSR.SPECM[2:0] bits (Only SPI0).

34.3.9.3 Mode fault errors

The SPI operates in multi-master mode when the SPCR.MSTR bit is 1, the SPCR.SPMS bit is 0, and the SPCR.MODFEN bit is 1. If the active level is input for the SSLn0 input signal of the SPI in multi-master mode, the SPI detects a mode fault error regardless of the status of the serial transfer, and sets the SPSR.MODF flag to 1. On detecting the mode fault error, the SPI copies the value of the pointer to SPCMDm to the SPDCR.SPFC[1:0] bits. The active level of the SSLn0 signal is determined by the SSLP.SSL0P bit.

When the MSTR bit is 0, the SPI operates in slave mode. The SPI detects a mode fault error if the MODFEN bit of the SPI in slave mode is 1, and the SPMS bit is 0, and if the SSLn0 input signal is negated during the serial transfer period (from the time the driving of valid data is started to the time the final valid data is fetched).

On detecting a mode fault error, the SPI stops the driving of the output signals and clears the SPCR.SPE bit to 0 (see section 34.3.10. Initializing the SPI). For multi-master configuration, detection of a mode fault error is used to stop the driving of output signals and the SPI function, which allows the master to be released.

The occurrence of a mode fault error can be checked either by reading SPSR or by using an SPI error interrupt and reading SPSR. Detecting mode-fault errors without using the SPI error interrupt requires polling of SPSR. When using the SPI in master mode, the value of the pointer to the SPCMDm register at the occurrence of the error can be checked by reading the SPSSR.SPECM[2:0] bits.

When the MODF flag is 1, writing 1 to the SPE bit is ignored by the SPI. To enable the SPI function after the detection of a mode fault error, the MODF flag must be set to 0.

34.3.9.4 Underrun errors

While the SPI is operating in slave mode (SPCR.MSTR bit = 0) and the Extended Communication Mode Select bit (ETXMD) in the SPI Control Register 3 (SPCR3) is set to 0, if serial transfer is started before transmit data output is ready with the SPCR.SPE bit set to 1 (SPI function enabled), the SPI detects an underrun error and sets the SPSR.MODF and SPSR.UDRF flags to 1.

On detecting an underrun error, the SPI stops the driving of output signals and clears the SPCR.SPE bit to 0 (see section 34.3.10. Initializing the SPI).

The occurrence of underrun errors can be checked either by reading SPSR or by using an SPI error interrupt and reading SPSR. Detecting underrun errors without using the SPI error interrupt requires polling of SPSR.

When the MODF flag is 1, writing 1 to the SPE bit is ignored by the SPI. To enable the SPI function after the detection of an underrun error, the MODF flag must be set to 0.

34.3.10 Initializing the SPI

If 0 is written to the SPCR.SPE bit or if the SPI sets the SPE bit to 0 because it detected a mode fault error or an underrun error, the SPI disables the SPI function and initializes some of the module functions. When a system reset is generated, the SPI initializes all of the module functions. This section describes initialization by clearing of the SPCR.SPE bit and by a system reset.

34.3.10.1 Initialization by clearing of the SPCR.SPE bit

When the SPCR.SPE bit is set to 0, the SPI initializes by:

- Suspending any serial transfer that is being executed
- Stopping the driving of output signals (Hi-Z) in slave mode
- Initializing the internal state of the SPI
- Initializing the transmit buffer of the SPI (the SPSR.SPTEF flag sets to 1)

Initialization by clearing of the SPE bit does not initialize the control bits of the SPI. For this reason, the SPI can be started in the same transfer mode in use prior to initialization when the SPE bit is set to 1 again.

The SPSR.CENDF, SPSR.SPRF, SPSR.OVRF, SPSR.MODF, SPSR.PERF, and SPSR.UDRF flags are not initialized, and the value of the SPI Sequence Status Register (SPSSR) is not initialized. Therefore, even after the SPI is initialized, data from the receive buffer can be read to check the communication completion status and the error status during an SPI transfer.

The transmit buffer is initialized to an empty state (the SPSR.SPTEF flag sets to 1). Therefore, if the SPCR.SPTIE bit is set to 1 after SPI initialization, a transmit buffer empty interrupt is generated. To disable any transmit buffer empty interrupts when the SPI is initialized, write 0 to the SPTIE bit simultaneously while writing 0 to the SPE bit.

34.3.10.2 Initialization by system reset

A system reset completely initializes the SPI by initializing all SPI control bits, status bits, and data registers, in addition to meeting the requirements described in section 34.3.10.1. Initialization by clearing of the SPCR.SPE bit.

34.3.11 SPI Operation

34.3.11.1 Master mode operation

The only difference between single- and multi-master mode operation is the use of mode fault error detection (see section 34.3.9. Error Detection). In single-master mode, the SPI does not detect mode fault errors whereas in multi-master mode, it does. This section explains operations that are common to both modes.

(1) Starting a serial transfer

The SPI updates the data in the transmit buffer (SPTX) when data is written to the SPI Data Register (SPDR/SPDR_HA) with the SPI transmit buffer empty, data for the next transfer is not set, and the SPSR.SPTEF flag is 0. When the shift register is empty after the number of frames set in the SPDCR.SPFC[1:0] bits are written to the SPDR/SPDR_HA/ SPDR_BY, the SPI copies data from the transmit buffer to the shift register and starts serial transfer. On copying transmit data to the shift register, the SPI changes the status of the shift register to full. On termination of the serial transfer, it changes the status of the shift register to empty. The status of the shift register cannot be referenced.

The polarity of the SSLni output pins depends on the SSLP register settings. For details on the SPI transfer format, see section 34.3.5. Transfer Formats.

(2) Terminating a serial transfer

Regardless of the SPCMDm.CPHA bit setting, the SPI terminates the serial transfer after transmitting an RSPCKn edge associated with the final sampling timing. If free space is available in the receive buffer (SPRX) (the SPSR.SPRF flag is 0), on termination of the serial transfer, the SPI copies data from the shift register to the receive buffer of the SPDR/SPDR_HA register.

The final sampling timing varies depending on the bit length of transfer data. In master mode, the SPI data length depends on the SPCMDm.SPB[3:0] bit settings. The polarity of the SSLni output pin depends on the SSLP register settings. For details on the SPI transfer format, see section 34.3.5. Transfer Formats.

(3) Sequence control

The transfer format used in master mode is determined by the SPSCR, SPCMDm, SPBR, SPCKD, SSLND, and SPND registers.

The SPSCR register determines the sequence configuration for serial transfers that are executed by the SPI in master mode. The following items are set in the SPCMDm register:

- SSLni pin output signal value
- MSB- or LSB-first
- Data length
- Some of the bit rate settings
- RSPCK polarity and phase
- Whether SPCKD is to be referenced
- Whether SSLND is to be referenced
- Whether SPND is to be referenced

SPBR holds some of the bit rate settings, including SPCKD (SPI clock delay), SSLND (SSL negation delay), and SPND (next-access delay).

Based on the sequence length assigned in SPSCR, the SPI makes up a sequence comprised of a part or all of the SPCMDm register. The SPI contains a pointer to the SPCMDm register that makes up the sequence. The value of this pointer can be checked by reading the SPSSR.SPCP[2:0] bits. When the SPCR.SPE bit is set to 1 and the SPI function is enabled, the SPI loads the pointer to the commands in SPCMD0, and incorporates the SPCMD0 settings into the transfer format at the beginning of serial transfer. The SPI increments the pointer each time the next-access delay period for a data transfer ends. On completion of the serial transfer that corresponds to the final command in the sequence, the SPI sets the pointer to SPCMD0, and in this way the sequence is executed repeatedly.

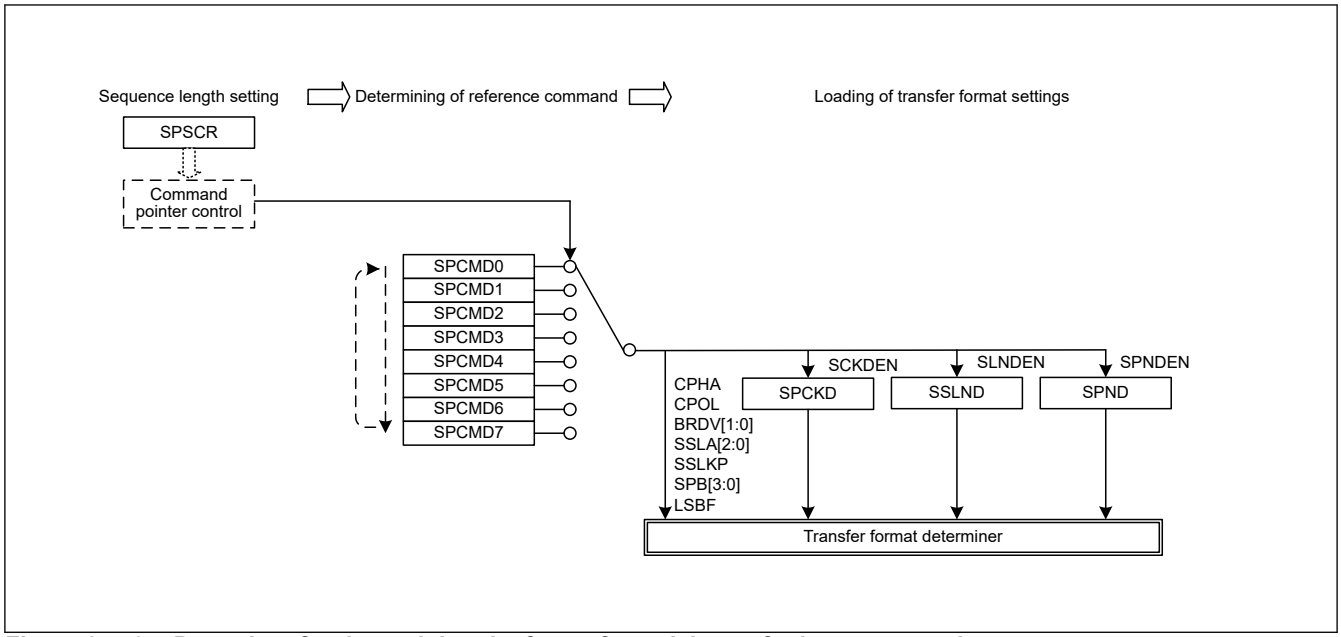

Figure 34.43 Procedure for determining the form of a serial transfer in master mode

In this section, a frame is the combination of the data in SPDR/SPDR_HA and the settings in SPCMDm.

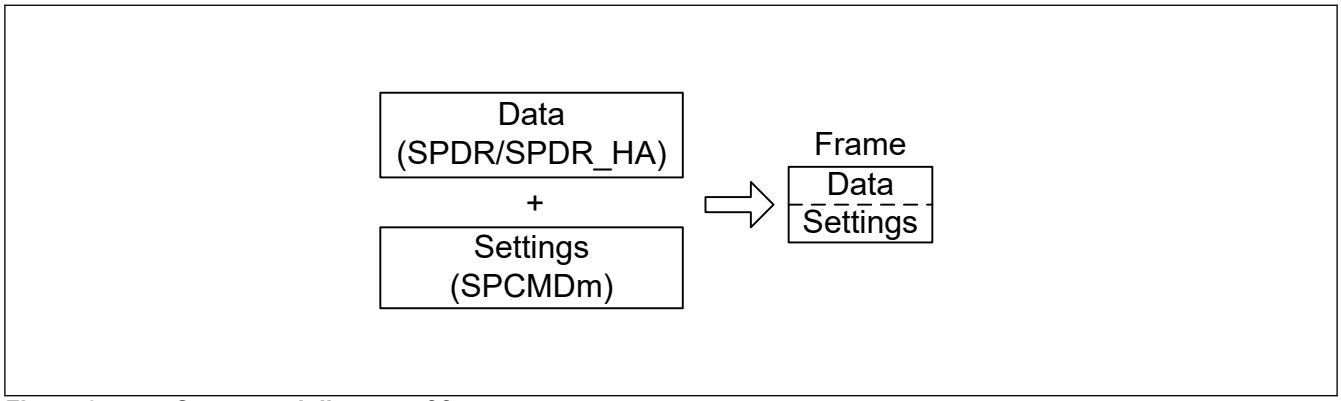

Figure 34.44 Conceptual diagram of frames

Figure 34.45 shows the correspondence between the commands and the transmit and receive buffers in the sequence of operations specified by the settings in Table 34.4.

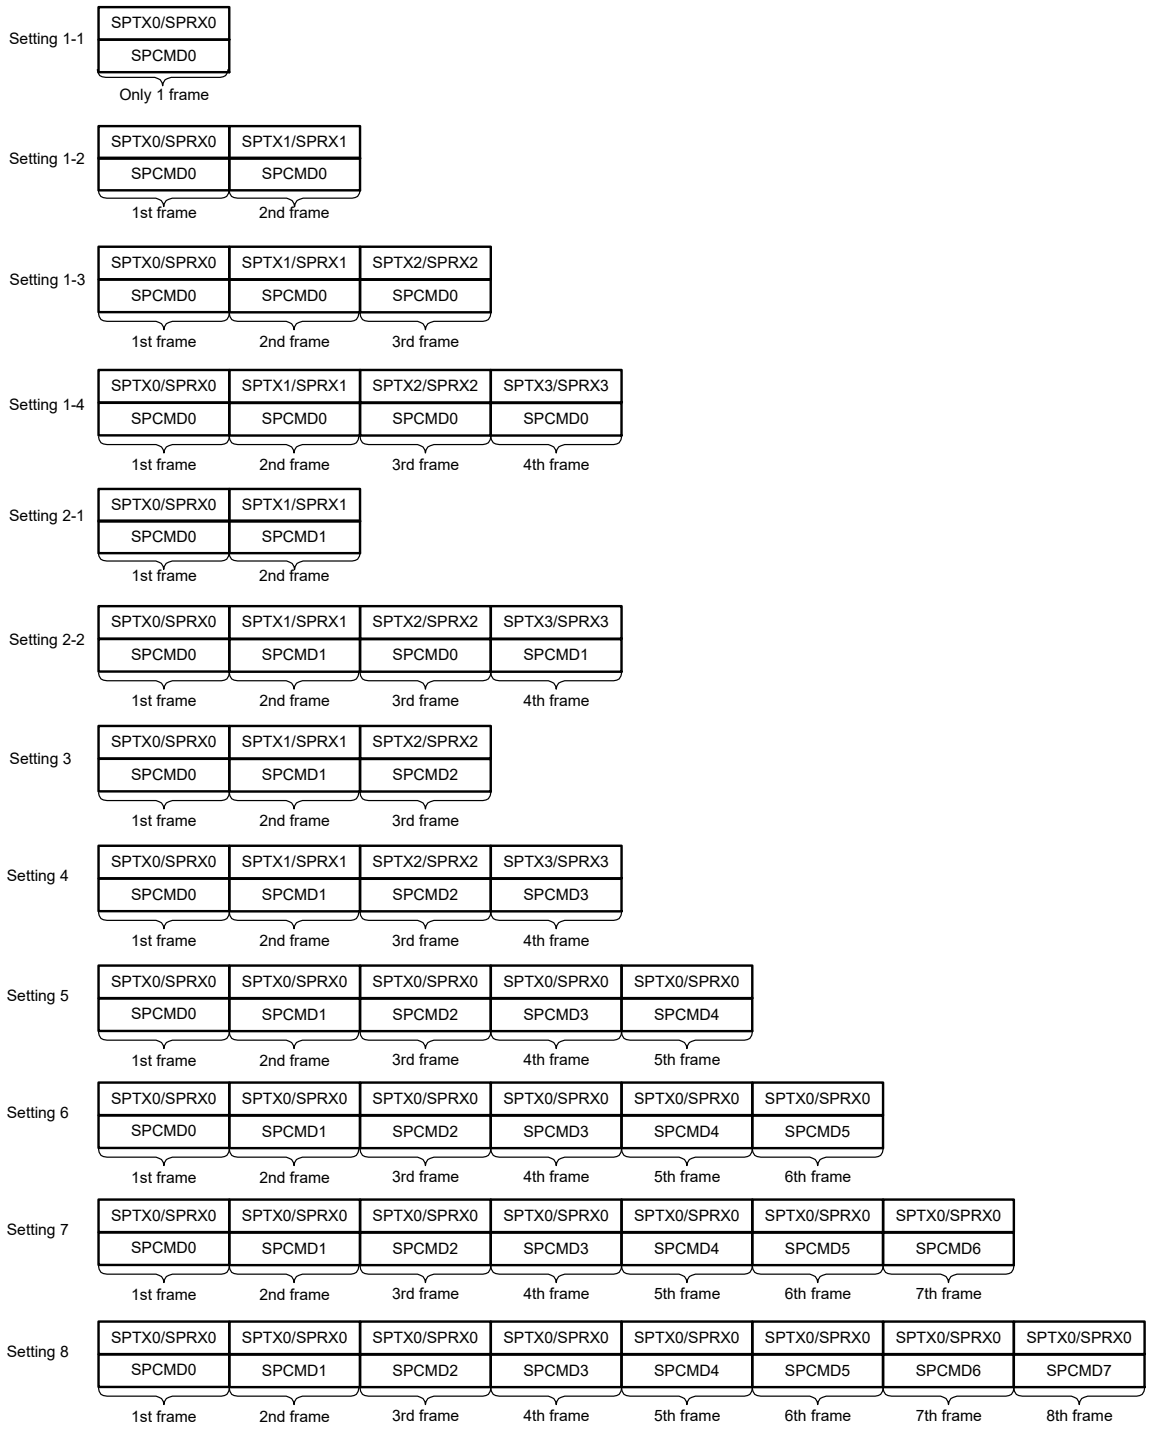

Figure 34.45 Correspondence between SPI Command Register and transmit and receive buffers in sequence operations

(4) Burst transfers

If the SPCMDm.SSLKP bit that the SPI references during the current serial transfer is 1, the SPI maintains the SSLni signal level during the serial transfer until the beginning of the SSLni signal assertion for the next serial transfer. If the SSLni

signal level for the next serial transfer is the same as the SSLni signal level for the current serial transfer, the SPI can execute continuous serial transfers while keeping the SSLni signal assertion status (burst transfer).

- When Between Burst Transfer Frames Delay Select bit (BFDS) of SPI control register 3 (SPCR3) is 0.

Figure 34.46 shows an example of an SSLni signal operation for a burst transfer that is implemented using the SPCMD0 and SPCMD1 register settings. This section describes SPI operations (1) to (8) shown in Figure 34.46.

Note: The polarity of the SSLni output signal depends on the SSLP register settings.

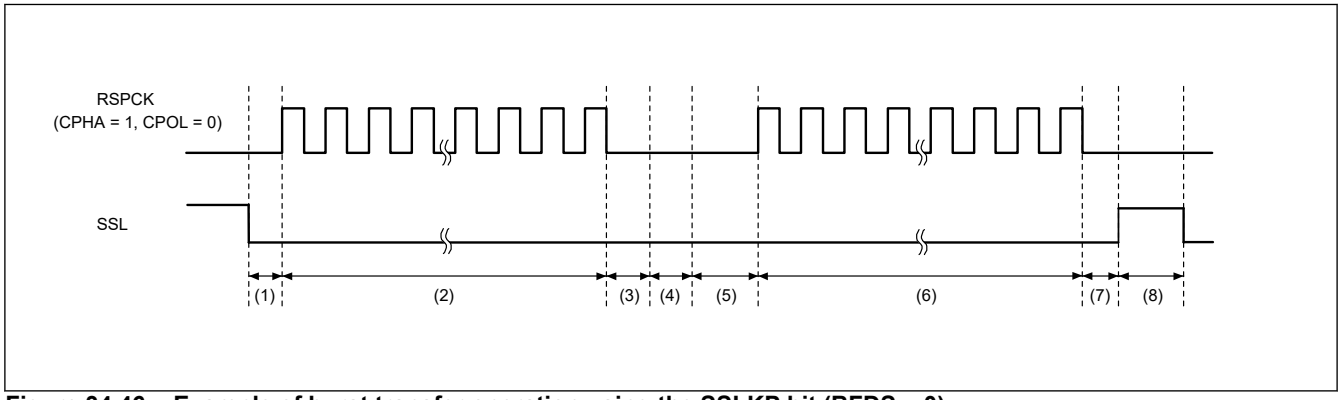

Figure 34.46 Example of burst transfer operation using the SSLKP bit (BFDS = 0)

The SPI operation at times (1) to (8) in the figure is as follows:

1. Based on the SPCMD0 settings, the SPI asserts the SSLni signal and inserts RSPCK delays.
2. The SPI executes serial transfers in accordance with the SPCMD0 settings.
3. The SPI inserts an SSL negation delay.
4. Because the SPCMD0.SSLKP bit is 1, the SPI keeps the SSLni signal value specified in SPCMD0. This period is sustained at a minimum for a period equal to the next-access delay in SPCMD0. If the shift register is empty after the passage of the minimum period, this period is sustained until the transmit data is stored in the shift register for the next transfer.
5. Based on the SPCMD1 settings, the SPI asserts the SSLni signal and inserts RSPCK delays.
6. The SPI executes serial transfers in accordance with the SPCMD1 settings.
7. Insert SSL negate delay.
8. Because the SPCMD1.SSLKP bit is 0, the SPI negates the SSLni signal. In addition, a next-access delay is inserted in accordance with SPCMD1.

If the SSLni signal output settings in the SPCMDm register where 1 is assigned to the SSLKP bit are different from the SSLni signal output settings in the SPCMDm register to be used in the next transfer, the SPI switches the SSLni signal status to SSLni signal assertion as shown in (5) in Figure 34.46. This corresponds to the command for the next transfer.

Note: If such an SSLni signal switching occurs, the slaves that drive the MISOn signal compete, and collision of signal levels might occur.

The SPI in master mode references the SSLni signal operation within the module when the SSLKP bit is not used. When the SPCMDm.CPHA bit is 0, the SPI can accurately start serial transfers by using the SSLni signal assertion for the next transfer that is detected internally.

- When Between Burst Transfer Frames Delay Select bit (BFDS) of SPI control register 3 (SPCR3) is 1.

Figure 34.47 shows an example of SSL signal operation when burst transfer is achieved by using the settings of SPCMD0 and SPCMD1. The following describes SPI operations of (1) to (6) shown in Figure 34.47. The SSL output signal polarity depends on the set SPI slave select polarity register (SSLP) value.

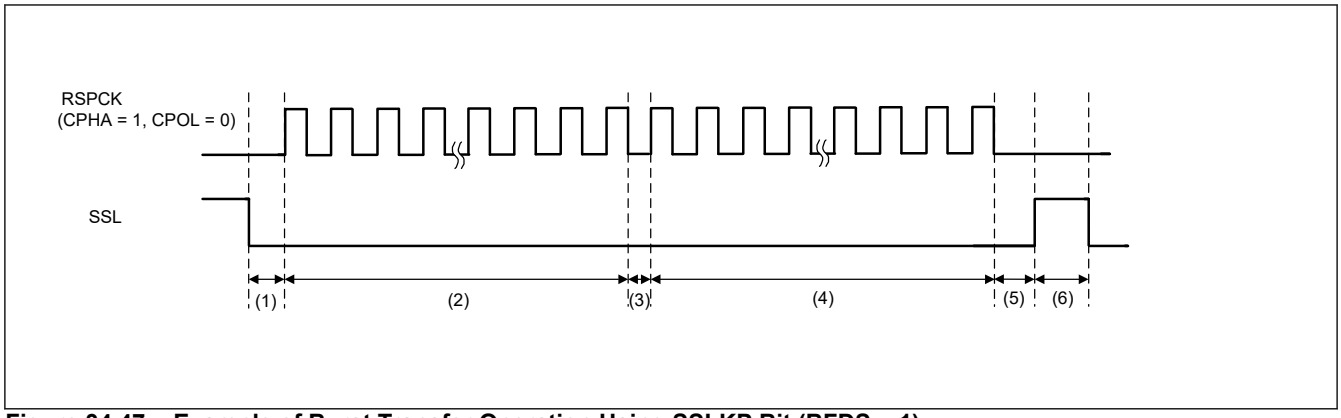

Figure 34.47 Example of Burst Transfer Operation Using SSLKP Bit (BFDS = 1)

1. Assert the SSL signal and insert an RSPCK delay according to SPCMD0. The RSPCK delay is inserted only the first frame of burst transmission.
2. Perform serial transfer according to SPCMD0. Wait last clock until the next transmit data is stored in the shift register, if the shift register is empty during RSPCK negate period between frames.
3. The value of SSL signal according to SPCMD0 was hold, because the SPCMD0.SSLKP bit is 1. RSPCK negate period between frames is 0.5RSPCK, if the shift register is not empty.
4. Perform serial transfer according to SPCMD1.
5. Insert SSL negate delay for the last frame.
6. The SSL signal is negated because the SSLKP bit in SPCMD1 is 0. Furthermore, the next-access delay is inserted according to SPCMD1.

(5) RSPCK delay (t1)

The RSPCK delay value of the SPI in master mode depends on the SPCMDm.SCKDEN bit setting and the SPCKD.SCKDL[2:0] bits setting. The SPI determines the SPCMDm register to be referenced during a serial transfer by pointer control, and determines an RSPCK delay using the SPCMDm.SCKDEN bit and SPCKD.SCKDL[2:0] bits, as listed in Table 34.11. For a definition of RSPCK delay, see section 34.3.5. Transfer Formats.

RSPCK delay insert to only the first frame of burst transmission, when transmit without “Between Burst Transfer Frames Delay”. (The SPCMD.SSLKP bit is 1 and the SPCR3.BFDS bit is 1.)

Table 34.11 Relationship between the SPCMDm.SCKDEN bit, SPCKD.SCKDL[2:0] bits, and RSPCK delay

SPCMDm.SCKDEN bit	SPCKD.SCKDL[2:0] bits	RSPCK delay
0	000b to 111b	1 RSPCK
1	000b	1 RSPCK
	001b	2 RSPCK
	010b	3 RSPCK
	011b	4 RSPCK
	100b	5 RSPCK
	101b	6 RSPCK
	110b	7 RSPCK
	111b	8 RSPCK

(6) SSL negation delay (t2)

The SSL negation delay value of the SPI in master mode depends on the SPCMDm.SLNDEN bit setting and the SSLND.SLNDL[2:0] bits setting. The SPI determines the SPCMDm register to be referenced by pointer control during a serial transfer, and determines an SSL negation delay using the SPCMDm.SLNDEN bit and SSLND.SLNDL[2:0] bits, as listed in Table 34.12. For a definition of SSL negation delay, see section 34.3.5. Transfer Formats.

An SSL negation delay is inserted to only the last frame of the burst transmission, that is, transmit without “between burst transfer frames delay”. (SPCMD.SSLKP bit is 1 and SPCR3.BFDS bit is 1).

Table 34.12 Relationship between the SPCMDm.SLNDEN bit, SSLND.SLNDL[2:0] bits, and SSL negation delay

SPCMDm.SLNDEN bit	SSLND.SLNDL[2:0] bits	SSL negation delay
0	000b to 111b	1 RSPCK
1	000b	1 RSPCK
	001b	2 RSPCK
	010b	3 RSPCK
	011b	4 RSPCK
	100b	5 RSPCK
	101b	6 RSPCK
	110b	7 RSPCK
	111b	8 RSPCK

(7) Next-access delay (t3)

The next-access delay value of the SPI in master mode depends on the SPCMDm.SPNDEN bit setting and the SPND.SPNDL[2:0] bits setting. The SPI determines the SPCMDm register to be referenced during serial transfer by pointer control, and then determines a next-access delay during serial transfer using the SPCMDm.SPNDEN bit and SPND.SPNDL[2:0] bits, as listed in Table 34.13. For a definition of next-access delay, see section 34.3.5. Transfer Formats.

A next-Access delay is inserted to only the last frame of the burst transmission, that is, transmit without “between burst transfer frames delay”. (SPCMD.SSLKP bit is 1 and SPCR3.BFDS bit is 1).

Table 34.13 Relationship between the SPCMDm.SPNDEN bit, SPND.SPNDL[2:0] bits, and next-access delay

SPCMDm.SPNDEN bit	SPND.SPNDL[2:0] bits	Next-access delay
0	000b to 111b	1 RSPCK + 2 PCLKA
1	000b	1 RSPCK + 2 PCLKA
	001b	2 RSPCK + 2 PCLKA
	010b	3 RSPCK + 2 PCLKA
	011b	4 RSPCK + 2 PCLKA
	100b	5 RSPCK + 2 PCLKA
	101b	6 RSPCK + 2 PCLKA
	110b	7 RSPCK + 2 PCLKA
	111b	8 RSPCK + 2 PCLKA

(8) Initialization flow

Figure 34.48 shows an example of SPI initialization flow when the SPI is in master mode. For information on how to set up the Interrupt Controller Unit (ICU), DMAC and I/O ports, see the descriptions given in the individual blocks.

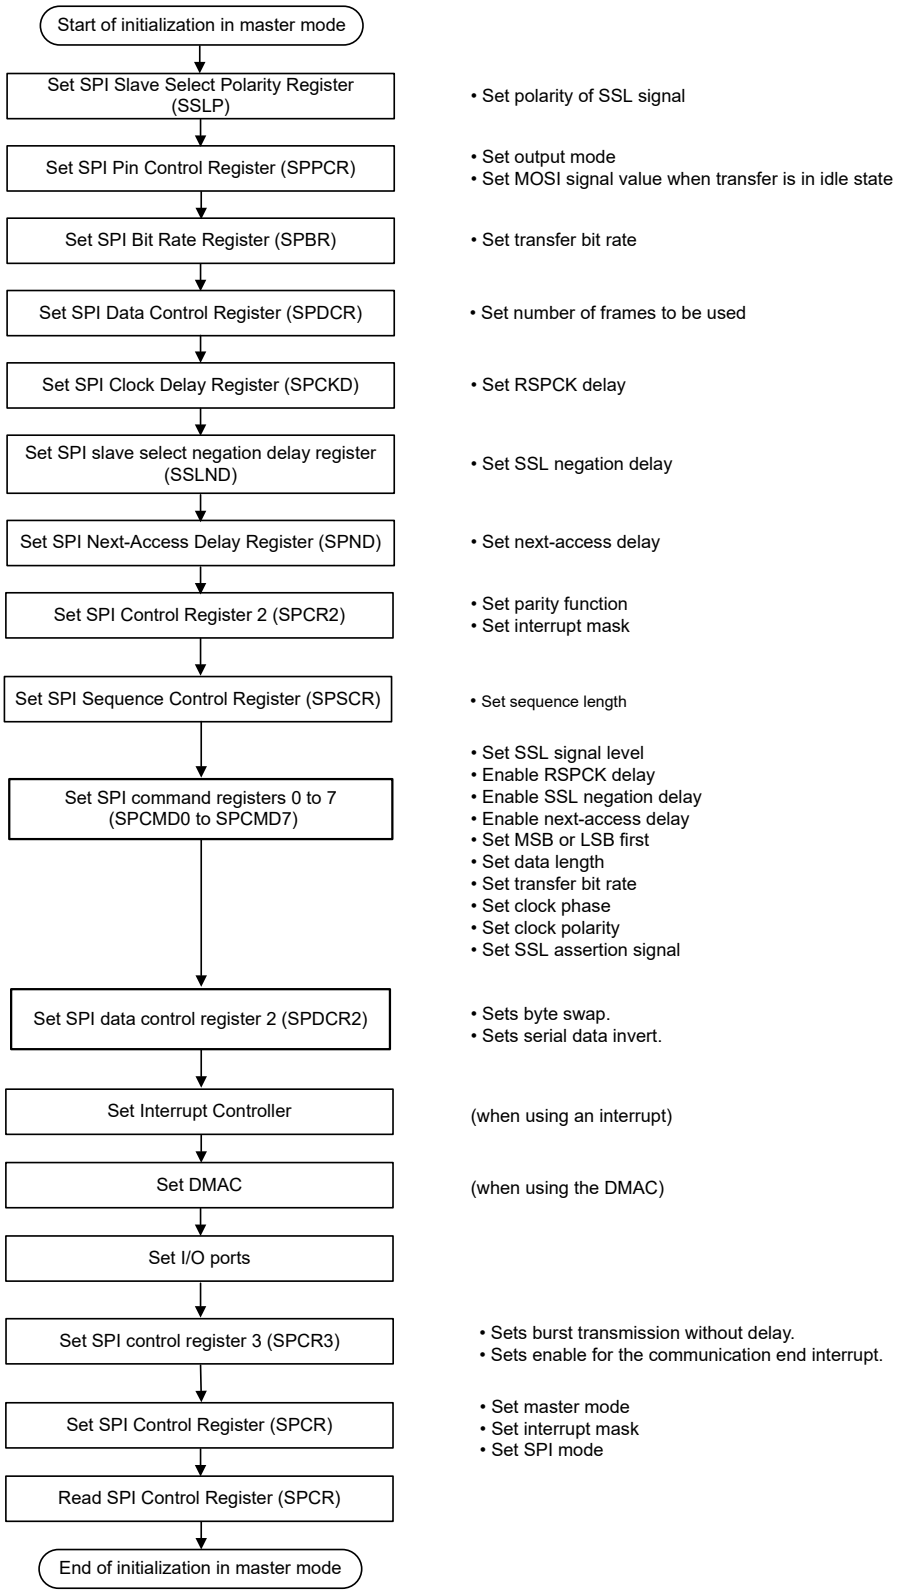

Figure 34.48 Example of initialization flow in master mode for SPI operation

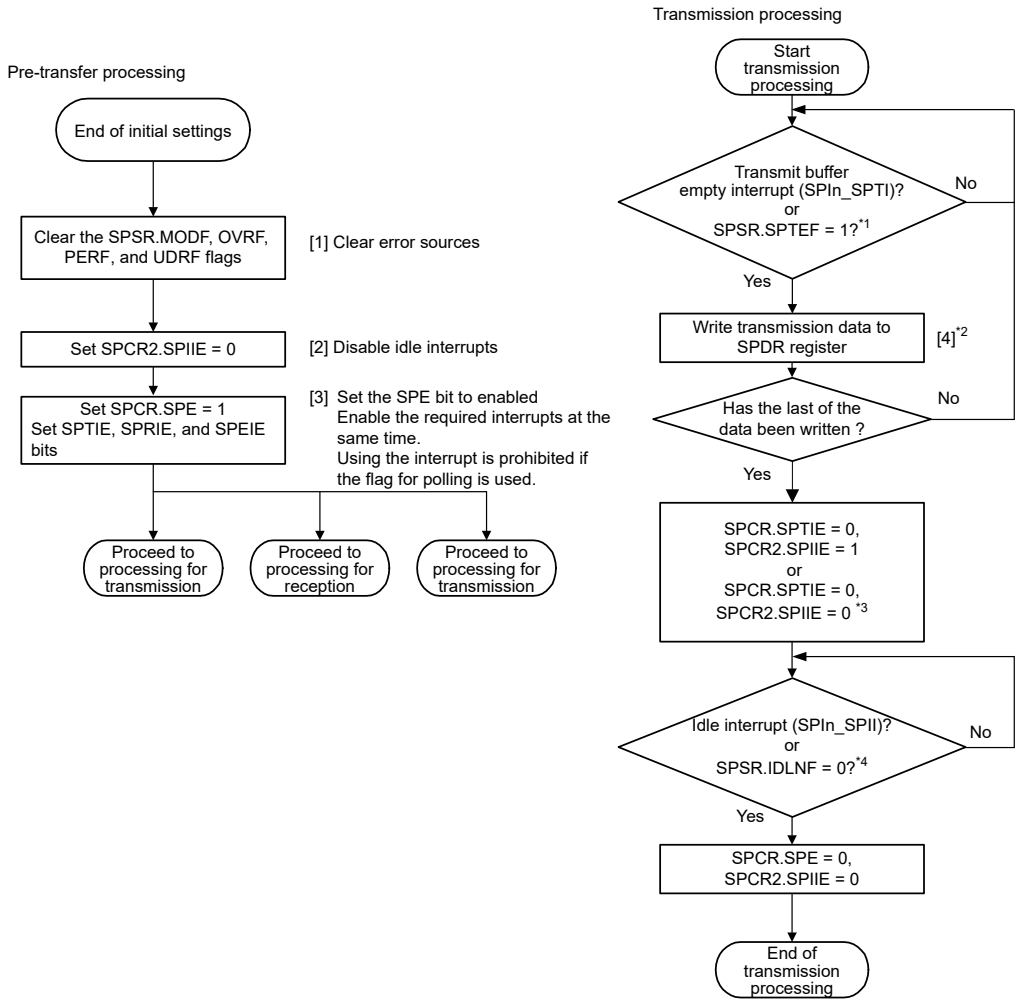
(9) Software processing flow

Figure 34.49 to Figure 34.51 show examples of the software processing flow.

Transmit processing flow

When transmitting data, with the SPIi_SPII interrupt enabled, the CPU is notified of the completion of data transmission after the last data write for transmission.



Note 1. Before writing data for transmission to SPDR/SPDR_HA/SPDR_BY, check that the transmit buffer is empty by reading the SPSR.SPTEF flag, if the flag for polling is used.
Note 2. Setting SPCR2.SPIIE and SPCR3.CENDIE to 0 is prohibited if the flag for polling is used.
Note 3. Wait more than 1 PCLKA, after writing data for transmission to SPDR register, and before starting to poll SPSR.IDLNF flag or SPSR.CENDF, if the flag for polling is used.
Note 4. SPDR = SPDR/SPDR_HA/SPDR_BY
Access when interrupt handling routine is executed once to the number of frames set in SPDCR.SPFC[1:0]

Figure 34.49 Transmission flow in master mode

Receive processing flow

The SPI has receive only operation in slave mode.

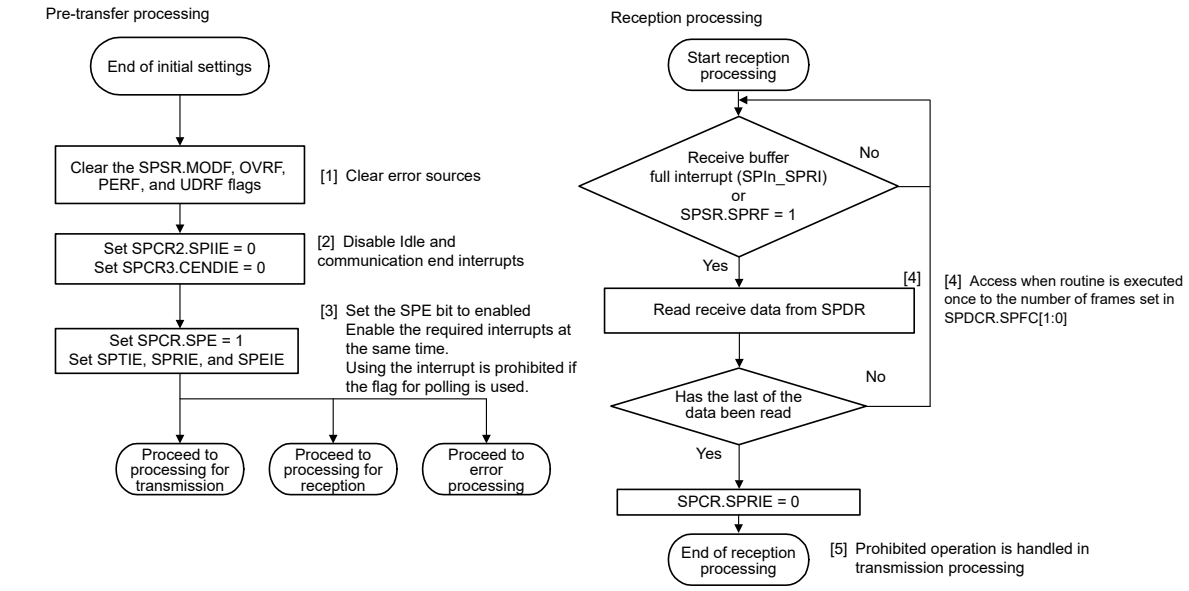


Figure 34.50 Reception flow in master mode

Error processing flow

The SPI detects the following errors:

- Mode fault error
- Underrun error
- Overrun error
- Parity error

When a mode fault error is generated, the SPCR.SPE bit is automatically cleared, stopping operations for transmission and reception. For errors from other sources, the SPCR.SPE bit is not cleared and operations for transmission and reception continue. Therefore, Renesas recommends clearing the SPCR.SPE bit to stop operations for errors other than mode fault errors. Not doing so leads to updating of the SPSSR.SPECM[2:0] bits.

When an error is detected using an interrupt, clear the ICU.IELSRn.IR flag in the error processing routine. If this is not done, the ICU.IELSRn.IR flag might continue to indicate the SPIi_SPTI or SPIi_SPRI interrupt request. If the SPIi_SPRI interrupt request is indicated, read the receive buffer and initialize the sequencer in the SPI.

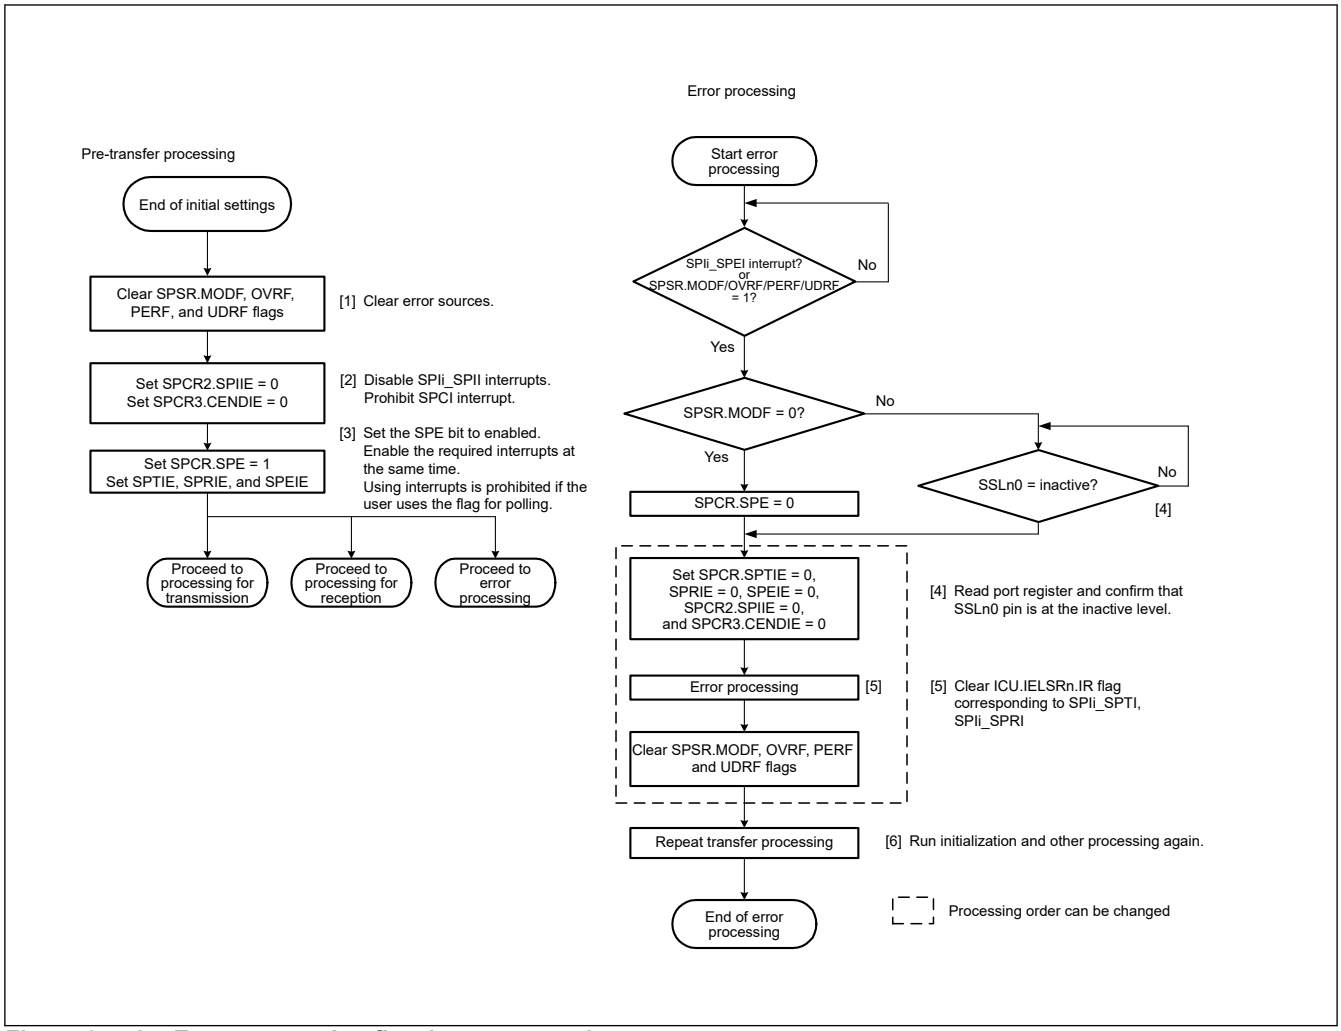

Figure 34.51 Error processing flow in master mode

34.3.11.2 Slave mode operation

(1) Starting a serial transfer

When the SPCMD0.CPHA bit is 0, if the SPI detects an SSLn0 input signal assertion, it must drive valid data to the MISOn output signal. For this reason, when the CPHA bit is 0, the assertion of the SSLn0 input signal triggers the start of a serial transfer.

When the CPHA bit is 1, if the SPI detects the first RSPCKn edge in an SSLn0 signal asserted condition, it must drive valid data to the MISOn output signal. For this reason, when the CPHA bit is 1, the first RSPCKn edge in an SSLn0 signal asserted condition triggers the start of a serial transfer.

Regardless of the CPHA bit setting, the SPI drives the MISOn output signal on SSLn0 signal assertion. The data that is output by the SPI is either valid or invalid, depending on the CPHA bit setting.

For details on the SPI transfer format, see section 34.3.5. Transfer Formats. The polarity of the SSLn0 input signal depends on the SSLP.SSL0P setting.

(2) Terminating a serial transfer

Regardless of the SPCMD0.CPHA bit setting, the SPI terminates the serial transfer after detecting an RSPCKn edge corresponding to the final sampling timing. When free space is available in the receive buffer (the SPSR.SPRF flag is 0), on termination of serial transfer, the SPI copies received data from the shift register to the receive buffer of the SPDR/ SPDR_HA register. On termination of a serial transfer, the SPI changes the status of the shift register to empty, regardless of the receive buffer state. A mode fault error occurs if the SPI detects an SSLn0 input signal negation from the beginning of serial transfer to the end of serial transfer (see section 34.3.9. Error Detection).

The final sampling timing changes depending on the bit length of transfer data. In slave mode, the SPI data length is determined by the SPCMD0.SPB[3:0] bits setting. The polarity of the SSLn0 input signal is determined by the SSLP.SSL0P bit setting. For details on the SPI transfer format, see section 34.3.5. Transfer Formats.

(3) Notes on single-slave operations

If the SPCMD0.CPHA bit is 0, the SPI starts serial transfers when it detects the assertion edge for an SSLn0 input signal. In the configuration shown in Figure 34.7, if the SPI is used in single-slave mode, the SSLn0 signal is fixed at an active state. Therefore, when the CPHA bit is set to 0, the SPI cannot correctly start a serial transfer. For the SPI to correctly execute transmit and receive operations in slave mode when the SSLn0 input signal is fixed at an active state, the CPHA bit must be set to 1. Do not fix the SSLn0 input signal if there is a requirement for setting the CPHA bit to 0.

(4) Burst transfer

If the SPCMD0.CPHA bit is 1, continuous serial transfer (burst transfer) can be executed while retaining the assertion state for the SSLn0 input signal. When the CPHA bit is 1, the serial transfer period is the period from the first RSPCKn edge to the sampling timing for the reception of the final bit in an SSLn0 signal active state. Even when the SSLn0 input signal remains at the active level, the SPI can accommodate burst transfers, because it can detect the start of an access.

When the CPHA bit is 0, the second and subsequent serial transfers during burst transfer cannot be executed correctly.

(5) Initialization flow

Figure 34.52 shows an example of initialization flow for SPI operation when the SPI is in slave mode. For a description of how to set up the ICU, DTC, and I/O ports, see the descriptions given in the individual blocks.

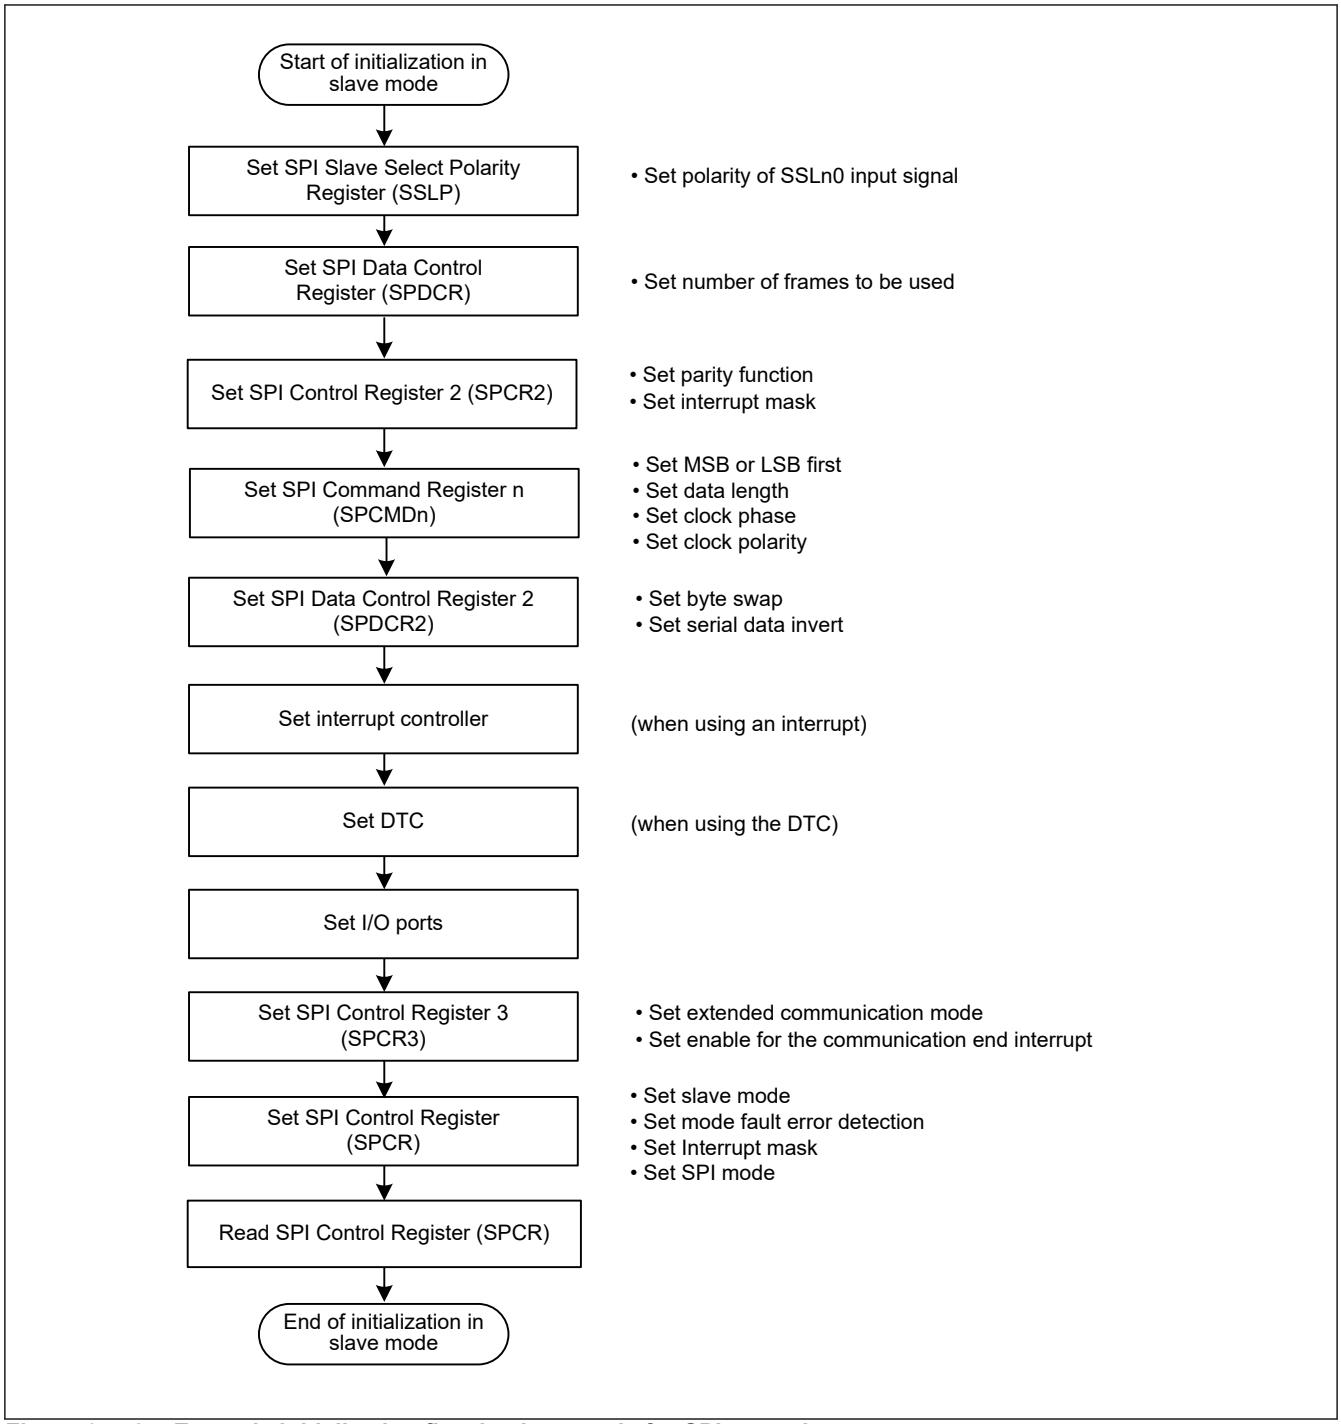

Figure 34.52 Example initialization flow in slave mode for SPI operation

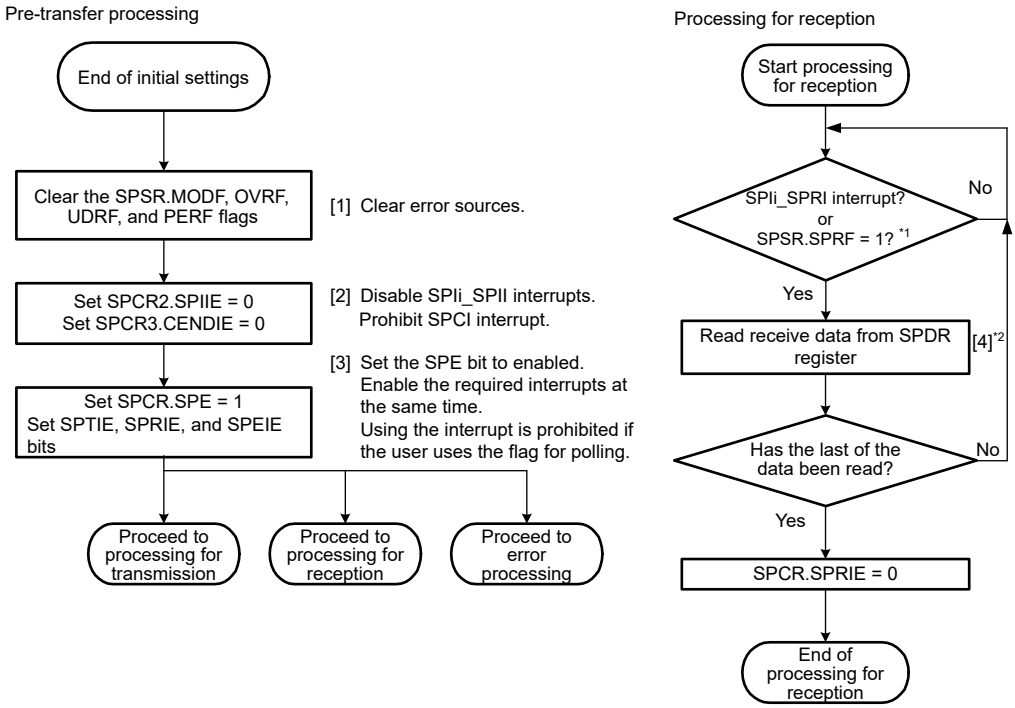
(6) Software processing flow

Figure 34.53 to Figure 34.55 show examples of the flow of software processing.

Transmit processing flow

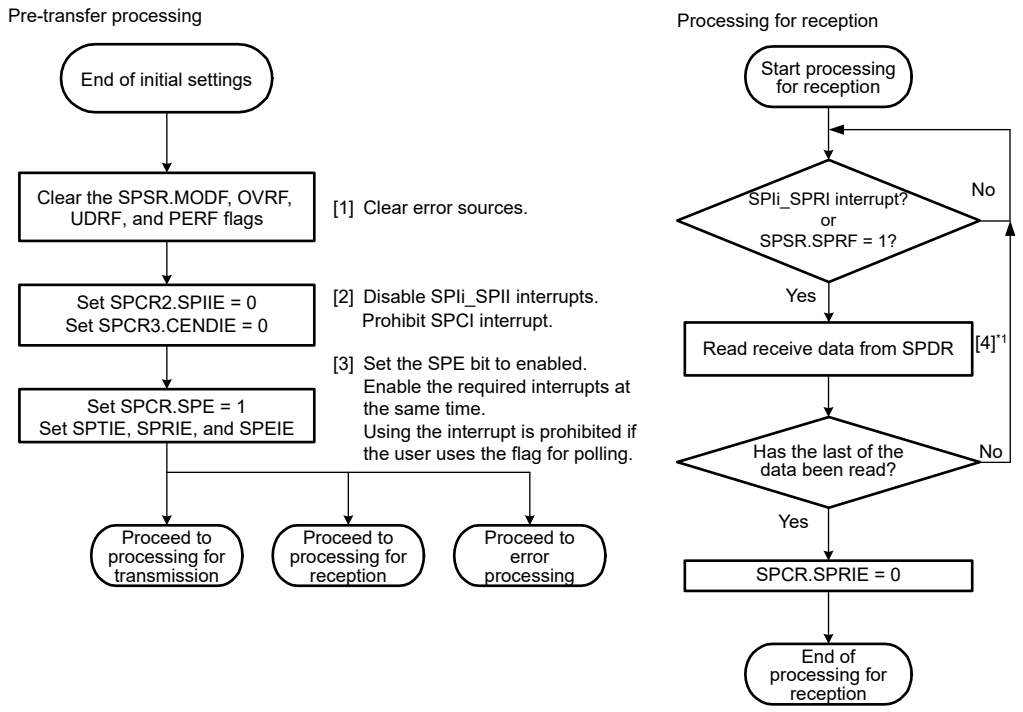


Note 1. Before writing data for transmission to SPDR register, check the transmit buffer empty interrupt by reading SPSR.SPTEF flag, if the flag for polling is used.
Note 2. SPDR = SPDR/SPDR_HA/SPDR_BY
Access when interrupt handling routine is executed once to the number of frames set in SPDCR.SPFC[1:0] bits

Figure 34.53 Transmission flow in slave mode

Receive processing flow

The SPI does not handle receive-only operation, so processing for transmission is required.



Note 1. Before writing data for transmission to the SPDR register, check that the transmit buffer is empty by reading the SPSR.SPTEF flag, if the flag for polling is used.
Note 2. SPDR = SPDR/SPDR_HA/SPDR_BY
Access when interrupt handling routine is executed once to the number of frames set in SPDCR.SPFC[1:0] bits

Figure 34.54 Reception flow in slave mode

Error processing flow

In slave mode operation, even when a mode fault error is generated, the SPSR.MODF flag can be cleared regardless of the state of the SSLn0 pin.

When an error is detected by using an interrupt, clear the ICU.IELSRn.IR flag in the error processing routine. If this is not done, the ICU.IELSRn.IR flag might continue to indicate the SPIi_SPTI or SPIi_SPRI interrupt request. If the SPIi_SPRI interrupt request is indicated, read the receive buffer and initialize the sequencer in the SPI.

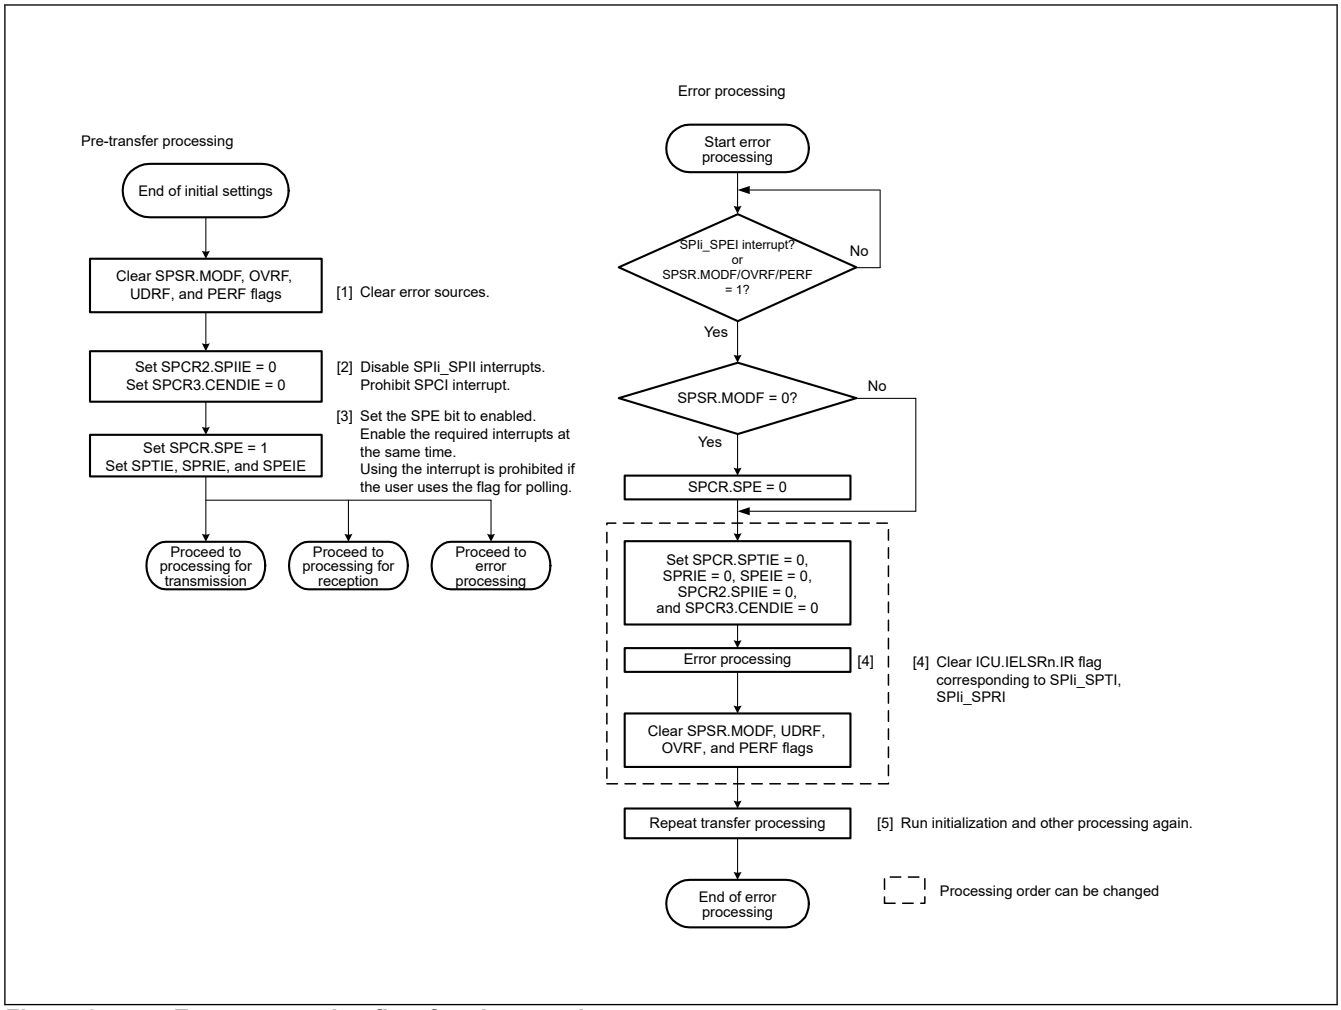


Figure 34.55 Error processing flow for slave mode

34.3.12 Clock Synchronous Operation

Setting the SPCR.SPMS bit to 1 selects clock synchronous operation of the SPI. In clock synchronous operation, the SSLni pin is not used, and the RSPCKn, MOSIn, and MISOn pins handle communications. All SSLni pins are available as I/O port pins.

Although clock synchronous operation does not require the use of the SSLni pin, operation of the module is the same as in SPI operation. In both master mode and slave mode operations, communications can be performed with the same flow as in SPI operation. However, mode fault errors are not detected, because the SSLni pin is not used.

Additionally, do not perform operation if clock synchronous operation is enabled when the SPCMDm.CPHA bit is set to 0 in slave mode (SPCR.MSTR = 0).

34.3.12.1 Master mode operation

(1) Starting serial transfer

The SPI updates the data in the transmit buffer (SPTX) of SPDR/SPDR_HA when data is written to the SPDR/SPDR_HA register with the transmit buffer empty, the data for the next transfer not set and the SPSR.SPTEF flag is 1. When the shift register is empty after the number of frames set in the SPDCR.SPFC[1:0] bits are written to the SPDR/SPDR_HA, the SPI copies data from the transmit buffer to the shift register and starts serial transmission. On copying transmit data to the shift register, the SPI changes the status of the shift register to full, and on termination of serial transfer, it changes the status of the shift register to empty. The status of the shift register cannot be referenced.

Transfer in clock synchronous operation is conducted without the SSLn0 output signal. For details on the SPI transfer format, see section 34.3.5. Transfer Formats.

(2) Terminating serial transfer

The SPI terminates the serial transfer after transmitting an RSPCKn edge corresponding to the sampling timing. If free space is available in the receive buffer (the SPSR.SPRF flag is 0), on termination of serial transfer, the SPI copies data from the shift register to the receive buffer of the SPI Data Register (SPDR/SPDR_HA).

The final sampling timing varies depending on the bit length of transfer data. In master mode, the SPI data length depends on the SPCMDm.SPB[3:0] bits setting. Transfer in clock synchronous operation is conducted without the SSLn0 output signal. For details on the SPI transfer format, see section 34.3.5. Transfer Formats.

(3) Sequence control

The transfer format used in master mode is determined by the SPSCR, SPCMDm, SPBR, SPCKD, SSLND, and SPND registers. Although the SSLni signals are not output in clock synchronous operation, these settings are valid.

The SPSCR register determines the sequence configuration for serial transfers that are executed by the SPI in master mode. The following parameters are specified in the SPCMDm register:

- SSLni output signal value
- MSB or LSB first
- Data length
- Some of the bit rate settings
- RSPCKn polarity and phase
- Whether SPCKD is to be referenced
- Whether SSLND is to be referenced
- Whether SPND is to be referenced

SPBR holds some of the bit rate settings such as SPCKD, an SPI clock delay value, SSLND, an SSL negation delay, and SPND, a next-access delay value.

Based on the sequence length that is assigned to SPSCR, the SPI makes up a sequence comprised of a part or all of SPCMDm register. The SPI contains a pointer to the SPCMDm register that makes up the sequence. The value of this pointer can be checked by reading the SPSSR.SPCP[2:0] bits. When the SPCR.SPE bit is set to 1 and the SPI function is enabled, the SPI loads the pointer to the commands in SPCMD0 register, and incorporates the SPCMD0 register setting into the transfer format at the beginning of serial transfer. The SPI increments the pointer each time the next-access delay period for a data transfer ends. On completion of the serial transfer that corresponds to the final command comprising the sequence, the SPI sets the pointer to the SPCMD0 register, and in this manner the sequence is executed repeatedly.

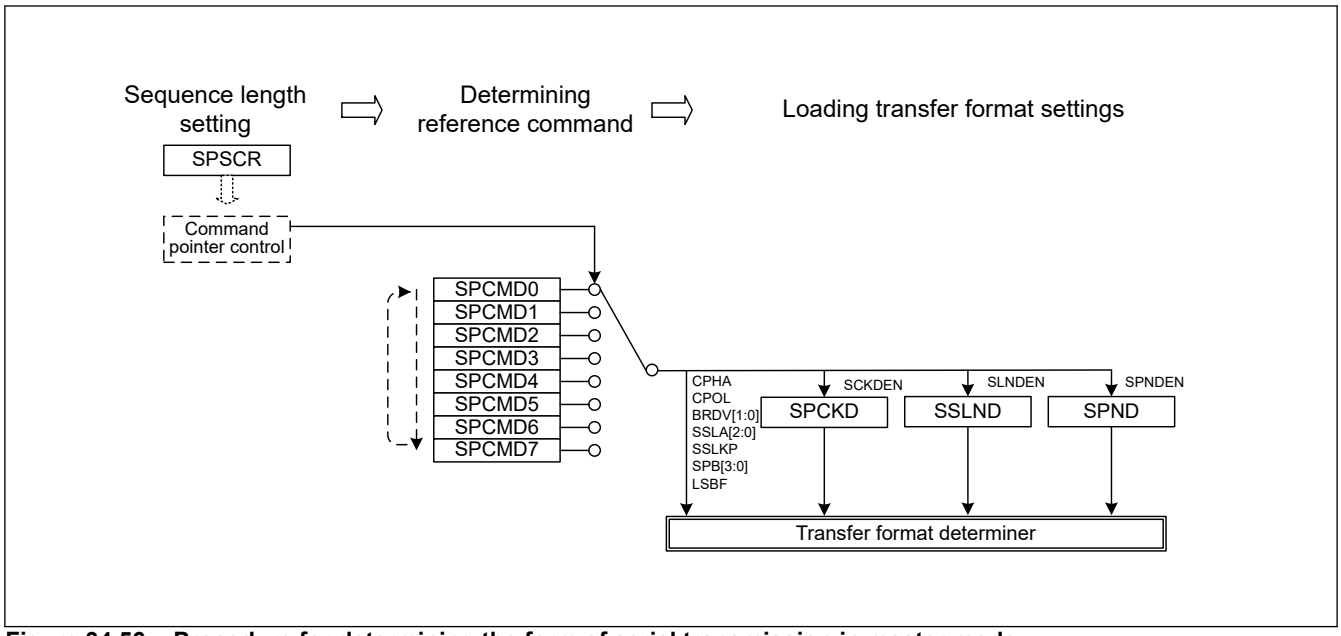

Figure 34.56 Procedure for determining the form of serial transmission in master mode

In this section, a frame is the combination of the data (SPDR/SPDR_HA) and the settings (SPCMDm).

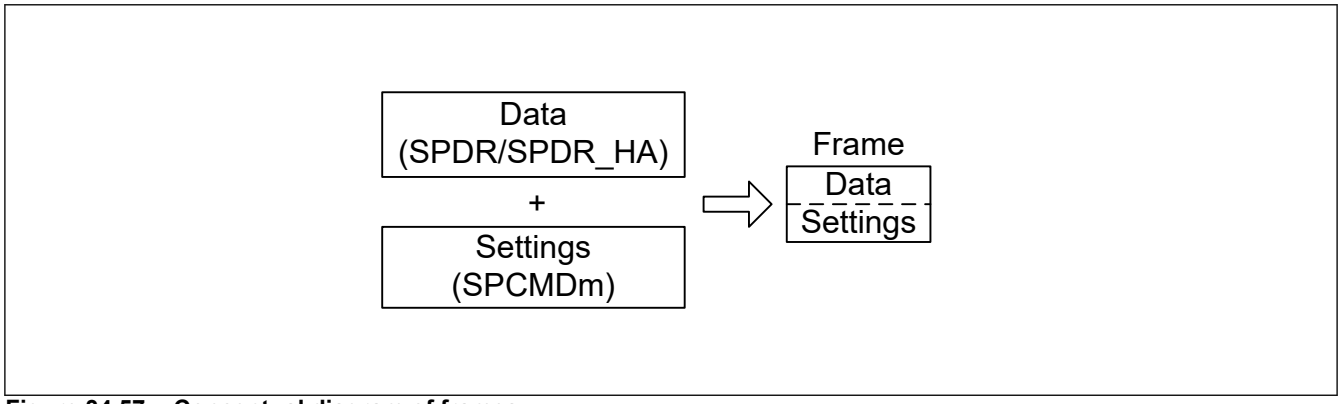

Figure 34.57 Conceptual diagram of frames

Figure 34.58 shows the relationship between the command and the transmit and receive buffers in the sequence of operations specified by the settings in Table 34.4.

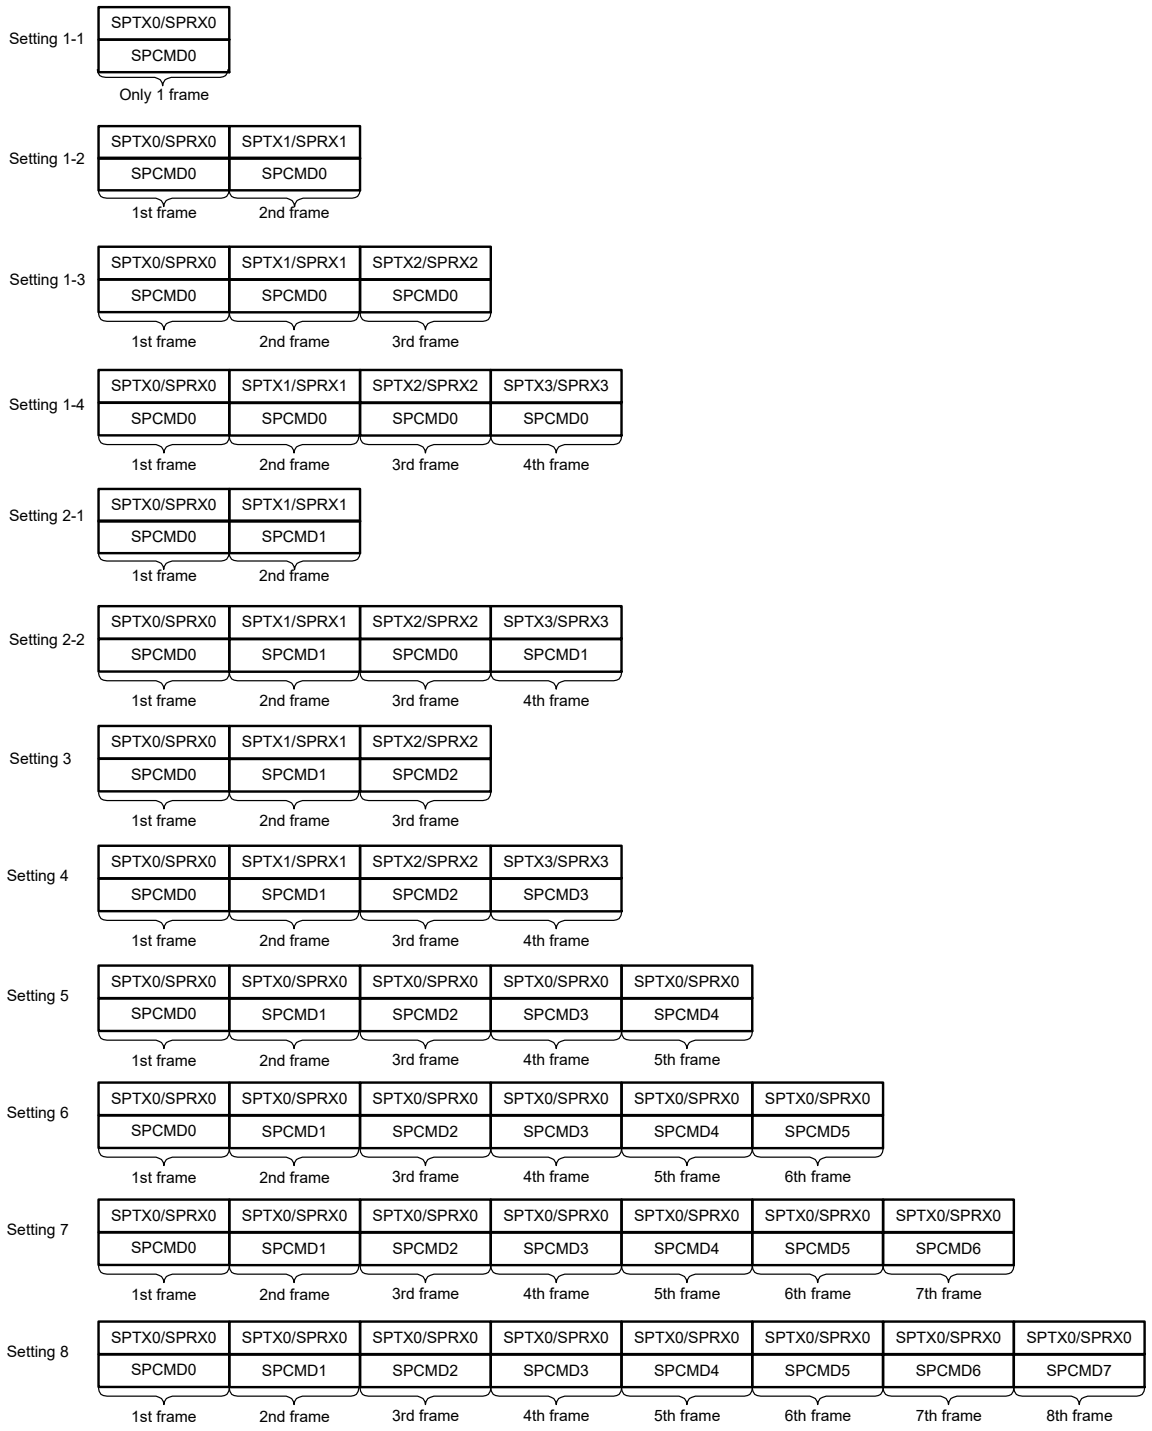

Figure 34.58 Correspondence between SPI Command Register and transmit and receive buffers in sequence operations

(4) Initialization flow

Figure 34.59 shows an example of initialization flow for clock synchronous operation when the SPI is used in master mode. For information on how to set up the ICU, DMAC or DTC, and I/O ports, see the descriptions given in the individual blocks.

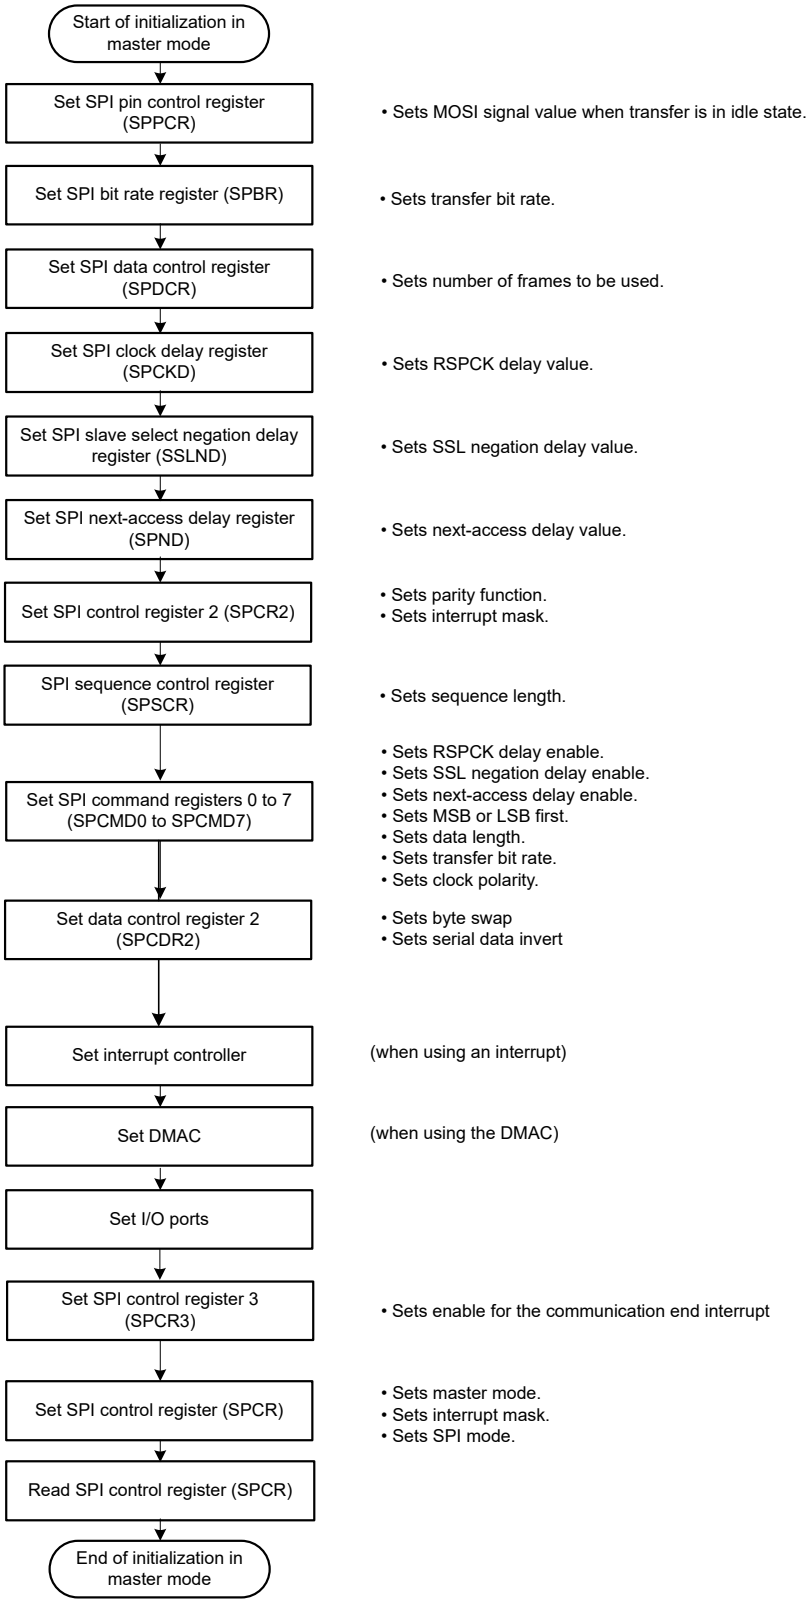

Figure 34.59 Example of initialization flow in master mode for clock synchronous operation

(5) Software processing flow

Software processing during clock synchronous master operation is the same as that for SPI master operation. For details, see (9) Software processing flow in section 34.3.11.1. Master mode operation. Mode fault errors do not occur in clock synchronous operation.

34.3.12.2 Slave mode operation

(1) Starting serial transfer

When the SPCR.SPMS bit is 1, the first RSPCKn edge triggers the start of a serial transfer in the SPI, and the SPI drives the MISOn output signal. The SSL0 input signal is not used in clock synchronous operation. For details on the SPI transfer format, see section 34.3.5. Transfer Formats.

(2) Terminating serial transfer

The SPI terminates the serial transfer after detecting an RSPCKn edge corresponding to the final sampling timing. When free space is available in the receive buffer (the SPSR.SPRF flag is 0), on termination of serial transfer, the SPI copies received data from the shift register to the receive buffer of the SPDR/SPDR_HA register. On termination of a serial transfer, the SPI changes the status of the shift register to empty regardless of the receive buffer.

The final sampling timing changes depending on the bit length of transfer data. In slave mode, the SPI data length depends on the SPCMD0.SPB[3:0] bits setting. For details on the SPI transfer format, see section 34.3.5. Transfer Formats.

(3) Initialization flow

Figure 34.60 shows an example of initialization flow for clock synchronous operation when the SPI is used in slave mode. For a description of how to set up the ICU, DTC, and I/O ports, see the descriptions given in the individual blocks.

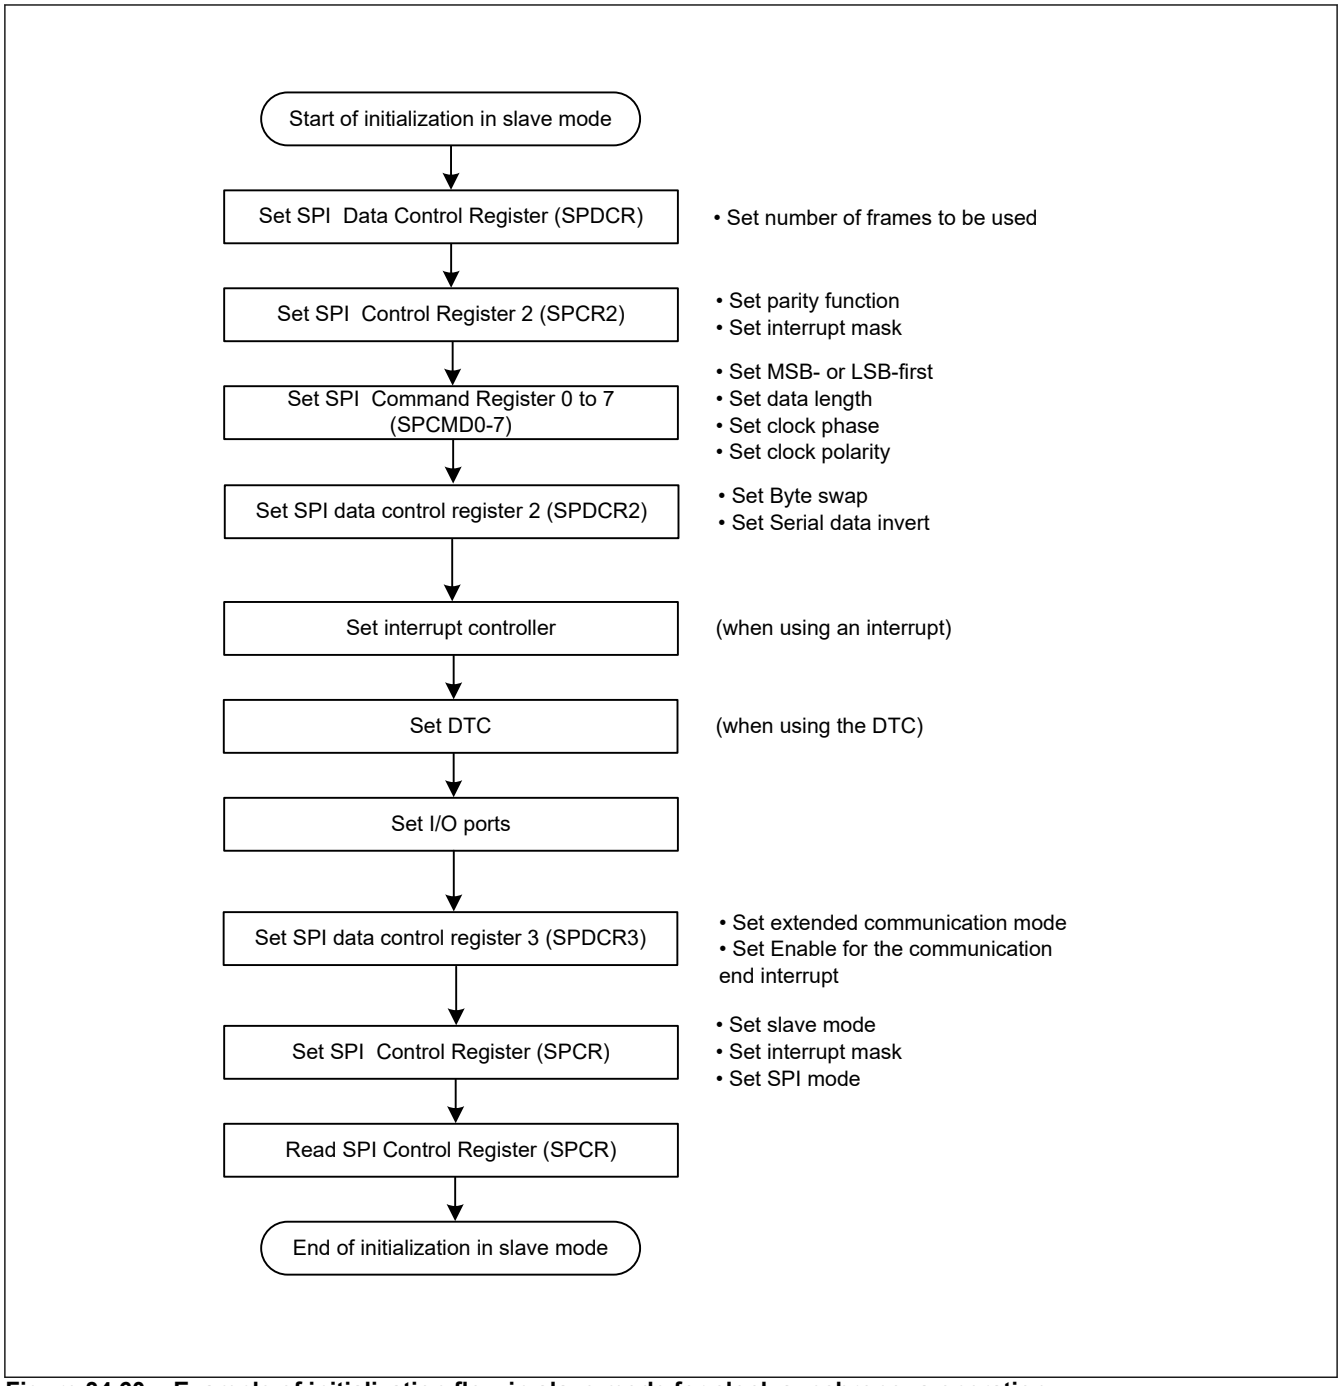

Figure 34.60 Example of initialization flow in slave mode for clock synchronous operation

(4) Software processing flow

Software processing during clock synchronous slave operation is the same as that for SPI slave operation. For details, see (6)Software processing flow. Mode fault errors do not occur in clock synchronous mode.

34.3.13 Loopback Mode

When 1 is written to the SPPCR.SPLP2 bit or SPPCR.SPLP bit, the SPI shuts off the path between the MISOn pin and the shift register if the SPCR.MSTR bit is 1, or between the MOSIn pin and the shift register if the SPCR.MSTR bit is 0, and connects the input and output paths of the shift register, establishing a loopback mode. The SPI does not shut off the path between the MOSIn pin and the shift register if the SPCR.MSTR bit is 1, or between the MISOn pin and the shift register if the SPCR.MSTR bit is 0. This is called loopback mode. When a serial transfer is executed in loopback mode, the transmit data for the SPI or the reversed transmit data becomes the received data for the SPI.

Table 34.14 lists the relationship between the SPLP2 and SPLP bits and the received data. Figure 34.61 shows the configuration of the shift register I/O paths when the SPI in master mode is set to loopback mode (SPPCR.SPLP2 = 0, SPPCR.SPLP = 1).

Table 34.14 SPLP2 and SPLP bit settings and received data

SPPCR.SPLP2 bit	SPPCR.SPLP bit	Received data
0	0	Input data from the MOSIn pin or MISOn pin
0	1	Inverted transmit data
1	0	Transmit data
1	1	Transmit data

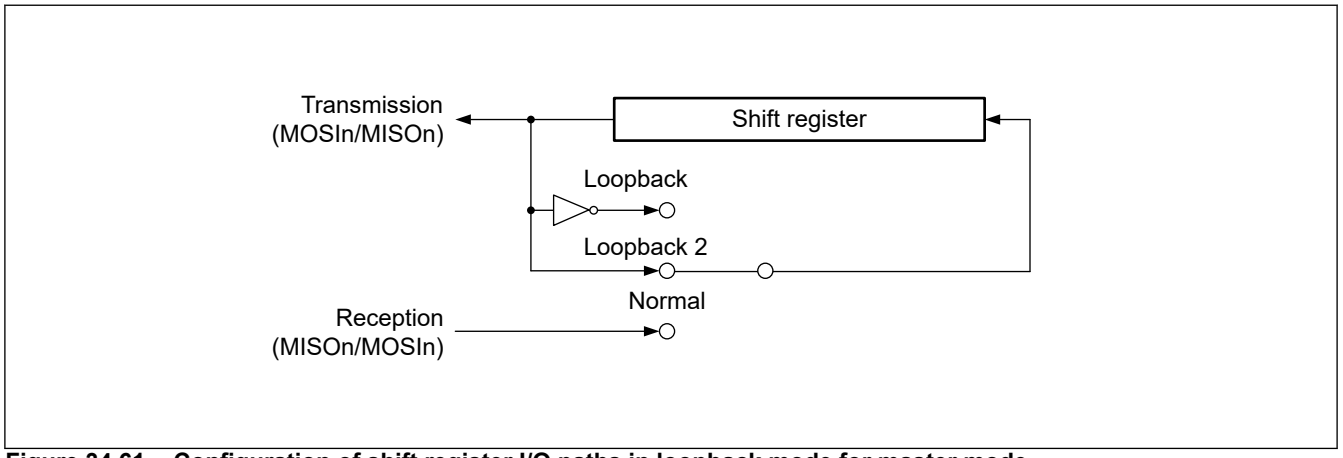

Figure 34.61 Configuration of shift register I/O paths in loopback mode for master mode

34.3.14 Self-Diagnosis of Parity Bit Function

The parity circuit consists of a parity bit adding unit used for transmit data and an error detecting unit used for received data. To detect defects in the parity bit adding unit and error detecting unit, the parity circuit performs self-diagnosis as shown in Figure 34.62.

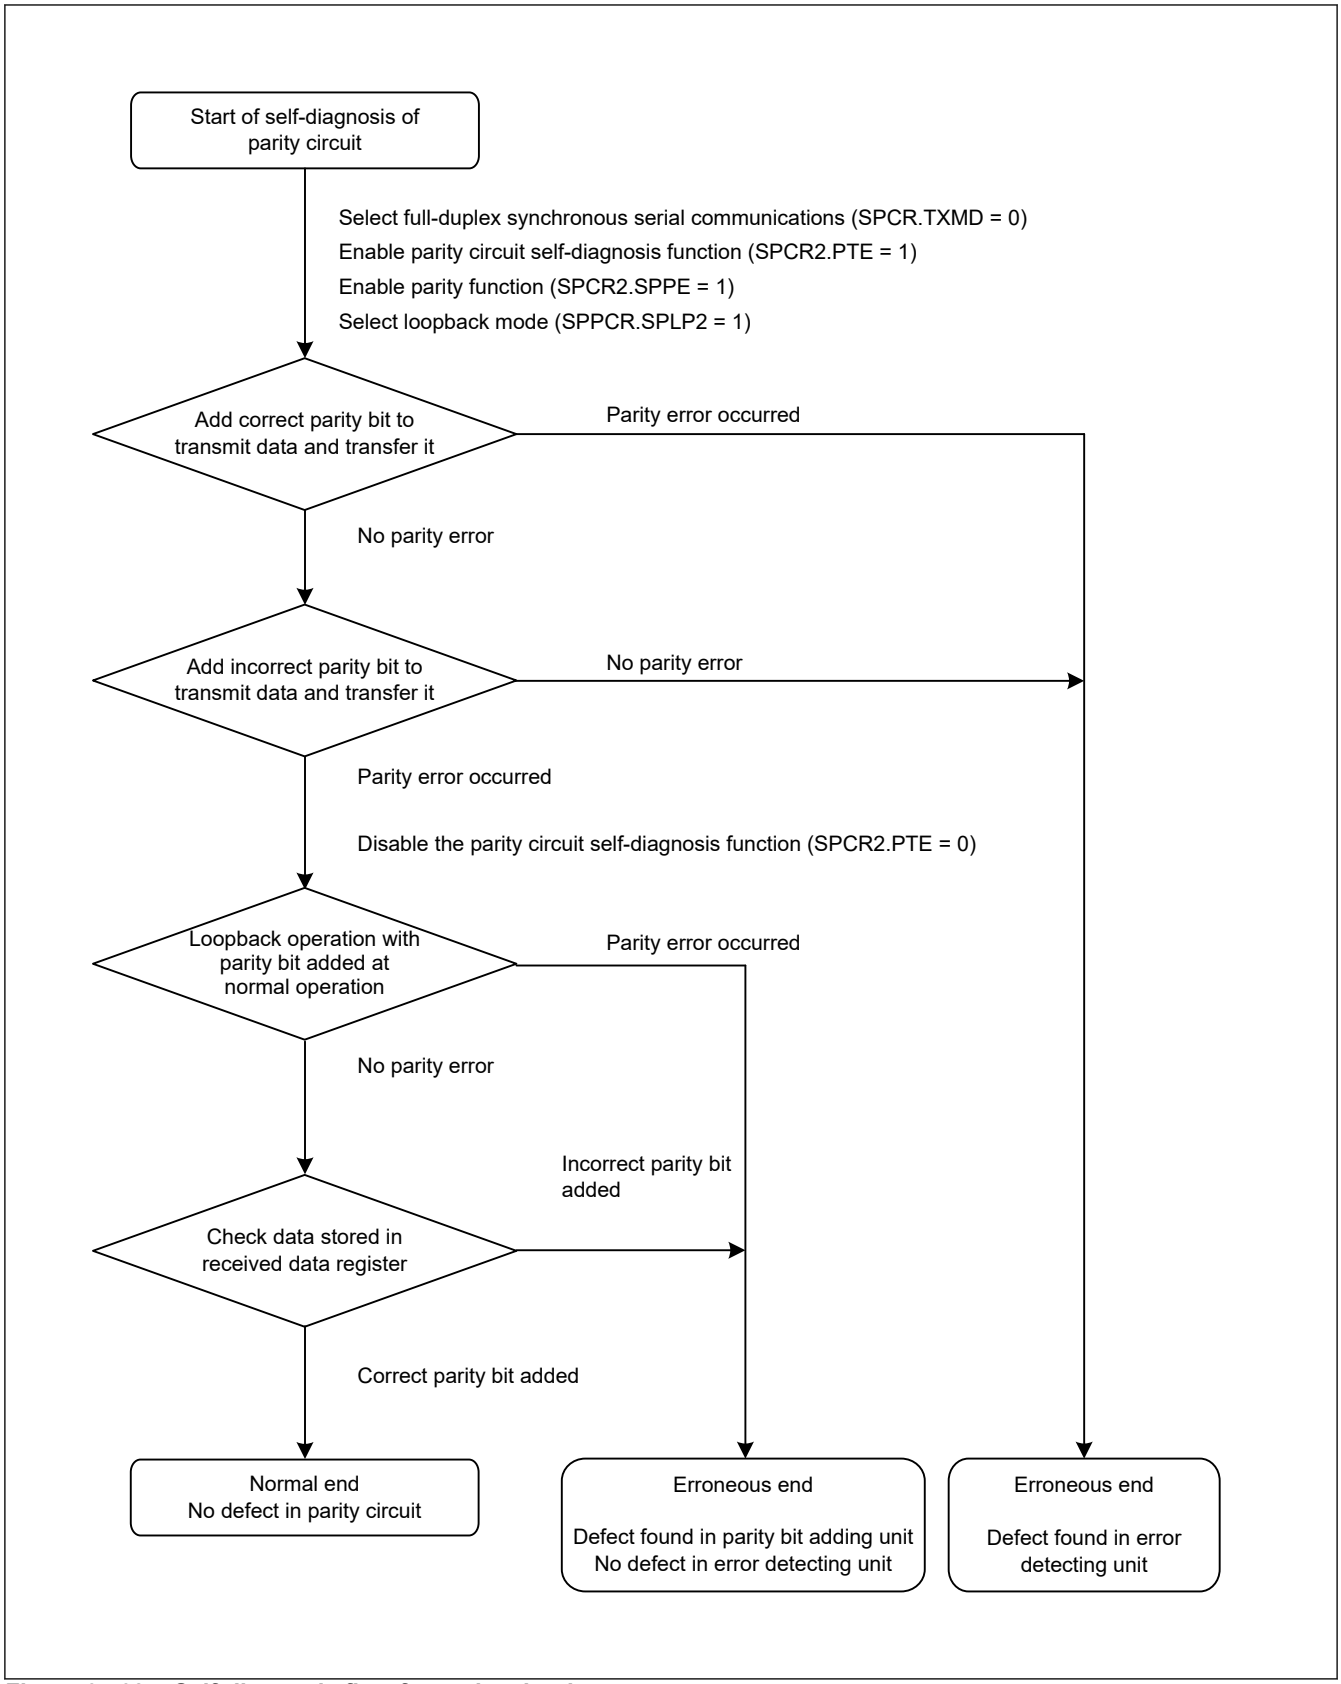

Figure 34.62 Self-diagnosis flow for parity circuit

34.3.15 Interrupt Sources

The SPI has the following interrupt sources:

- Receive buffer full
- Transmit buffer empty
- SPI error (mode-fault, underrun, overrun, or parity error)
- SPI idle
- Communication-end

The DMAC or DTC can be activated by the receive buffer full or transmit buffer empty interrupt to perform data transfer.

Because the vector address for the SPIi_SPEI (SPI error interrupt) is allocated to interrupt requests on mode-fault, underrun, overrun, and parity errors, the actual interrupt source must be determined from the flags. Interrupt sources for the SPI are listed in Table 34.15. An interrupt is generated on satisfaction of one of the interrupt conditions in Table 34.15. Clear the receive buffer full and transmit buffer empty sources through a data transfer.

When using the DMAC or DTC to perform data transmission and reception, you must first set up the DMAC or DTC to be in a transfer-enabled status before setting the SPI. For information on setting up the DMAC or DTC, see section 16, DMA Controller (DMAC) and section 17, Data Transfer Controller (DTC).

If the conditions for generating a transmit buffer empty or receive buffer full interrupt occur while the ICU.IELSRn.IR flag is 1, the interrupt is not output as a request for the ICU but is retained internally (the capacity for retention is one request per source). A retained interrupt request is output when the ICU.IELSRn.IR flag becomes 0. A retained interrupt request is automatically discarded when it is output as an actual interrupt request. The interrupt enable bit (the SPCR.SPTIE or SPCR.SPRIE bit) for an internally retained interrupt request can also be set to 0.

Table 34.15 SPI interrupt sources

Interrupt source	Symbol	Interrupt condition	DTC/DMAC activation
Receive buffer full	SPIi_SPRI	The receive buffer becomes full (SPSR.SPRF flag is 1) while the SPCR.SPRIE bit is 1	Possible
Transmit buffer empty	SPIi_SPTI	The transmit buffer becomes empty (SPSR.SPTEF flag is 1) while the SPCR.SPTIE bit is 1	Possible
SPI error (mode-fault, underrun, overrun, or parity error)	SPIi_SPEI	The SPSR.MODF, OVRF, UDRF or PERF flag sets to 1 while the SPCR.SPEIE bit is 1	Impossible
SPI idle	SPIi_SPII	The SPSR.IDLNF flag sets to 0 while the SPCR2.SPIIE bit is 1	Impossible
Communication-end	SPIi_SPCI	CENDIE = 1 and CENDF = 1	Impossible

34.4 Event Link Controller Event Output

The Event Link Controller (ELC) can produce the following event output signals:

- Receive buffer full event output
- Transmit buffer empty event output
- Mode-fault, underrun, overrun, or parity error event output
- SPI idle event output
- Transmission-completed event output

The event link output signal is output regardless of the interrupt enable bit setting.

34.4.1 Receive Buffer Full Event Output

This event signal is output when received data is transferred from the shift register to the SPDR/SPDR_HA on completion of serial transfer.

34.4.2 Transmit Buffer Empty Event Output

This event signal is output when data for transmission is transferred from the transmit buffer to the shift register and when the value of the SPE bit changes from 0 to 1.

34.4.3 Mode-Fault, Underrun, Overrun, or Parity Error Event Output

This event signal is output when mode-fault, underrun, overrun, or parity error is detected. See section 34.5.4. Constraints on Mode-Fault, Underrun, Overrun, or Parity Error Event Output if using this event signal.

(1) Mode-fault

Table 34.16 lists the conditions for occurrence of a mode-fault event.

Table 34.16 Conditions for mode-fault occurrence

SPI mode	SPCR.MODFEN bit	SSLn0 pin	Remarks
SPI operation (SPMS = 0) Slave (SPCR.MSTR = 0)	1	Not active	Event is output only when the SSLn0 pin is deactivated during transmission

(2) Underrun

This event signal is output in response to an underrun when a serial transfer starts while the transmission data is not ready, and the value of the SPCR.MSTR bit is 0 and the SPCR.SPE bit is 1. Under these conditions, the MODF and UDRF flags are set to 1.

(3) Overrun

This event signal is output in response to an overrun when a serial transfer completes while the receive buffer contains unread data and the value of the SPCR.TXMD bit is 0. Under these conditions, the OVRF flag is set to 1.

(4) Parity error

This event signal is output in response to a parity error detected on completion of a serial transfer while the value of the TXMD bit in SPCR is 0 and the value of the SPPE bit in SPCR2 is 1.

34.4.4 SPI Idle Event Output

(1) In master mode

In master mode, an event is output when the condition for setting the IDLNF flag (SPI idle flag) to 0 is satisfied.

(2) In slave mode

In slave mode, an event is output when the SPCR.SPE bit is set to 0 (SPI is initialized).

34.4.5 Communication End Event Output

In master mode, an event is output when the IDLNF flag (SPI idle flag) changes from 1 to 0. In slave mode, an event occurs with conditions shown in Table 34.17 and Table 34.18

Table 34.17 Communication End Event Generating Conditions (transmit-receive/transmit slave mode)

	Transmit Buffer Status	Shift Register Status	Others
SPI operation (SPMS = 0)	Empty	Empty	SSL0 input is negated
Clock synchronous operation (SPMS = 1)	Empty	Empty	The last even edge of RSPCK of last data was detected (CPHA = 1)

Table 34.18 Communication End Event Generating Conditions (receive only slave mode)

	Others
SPI operation (SPMS = 0)	SSL0 input is negated
Clock synchronous operation (SPMS = 1)	The last even edge of RSPCK of last data was detected (CPHA = 1)

Regardless of master mode or slave mode, no event is output when 0 is written to the SPCR.SPE bit during transmission or when the SPCR.SPE bit is cleared due to a mode fault error or an underrun error.

A communication end event is output at the following timing. The communication end event output timing in master operation is omitted because it is output at the same timing as an idle event.

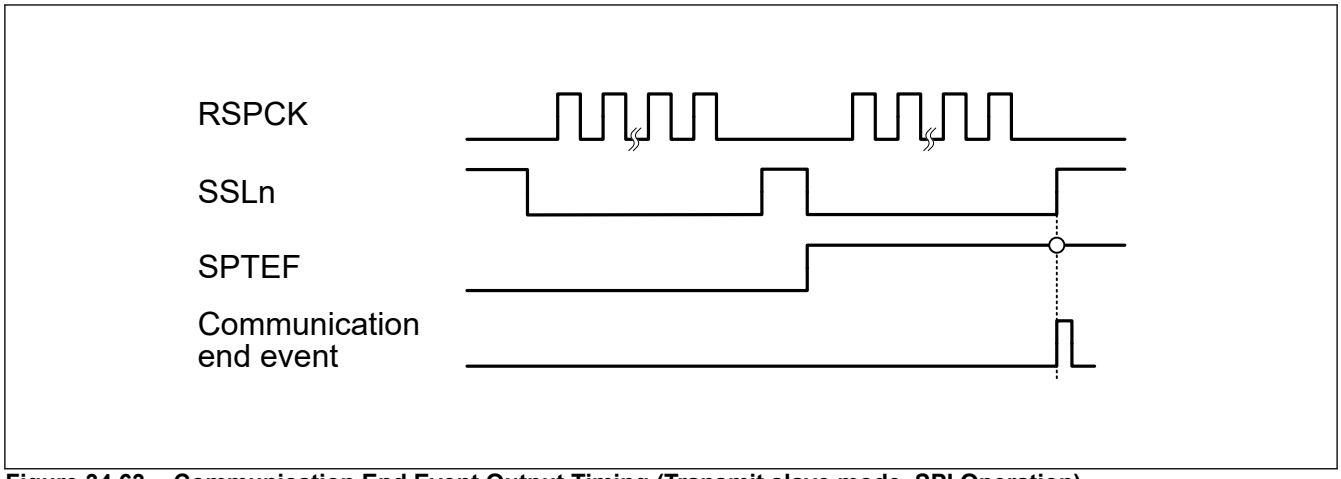

Figure 34.63 Communication End Event Output Timing (Transmit slave mode, SPI Operation)

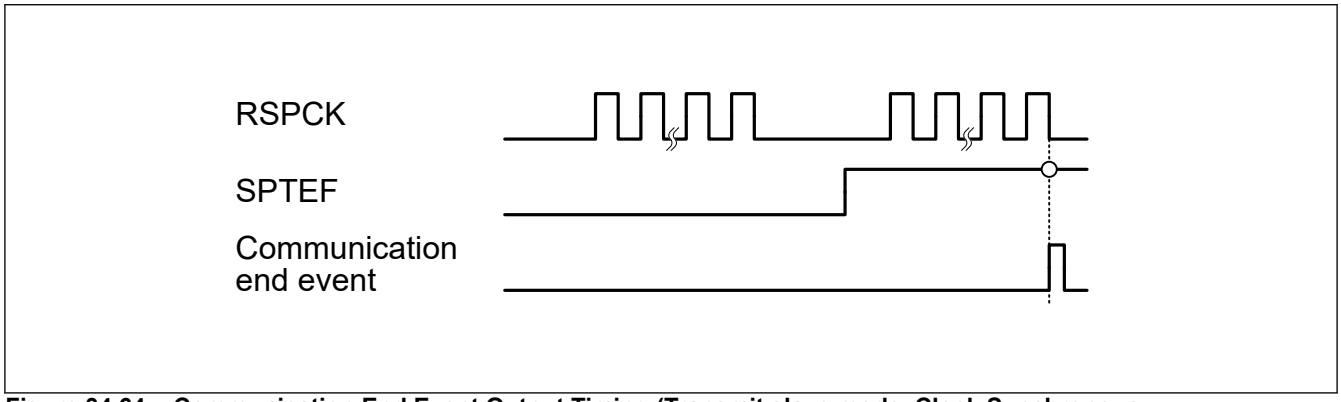

Figure 34.64 Communication End Event Output Timing (Transmit slave mode, Clock Synchronous Operation)

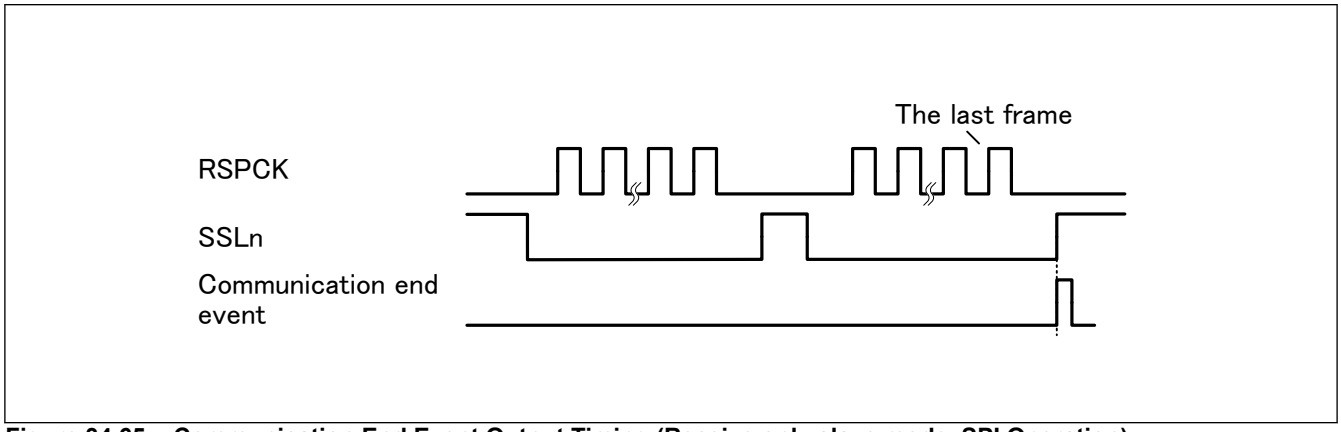

Figure 34.65 Communication End Event Output Timing (Receive only slave mode, SPI Operation)

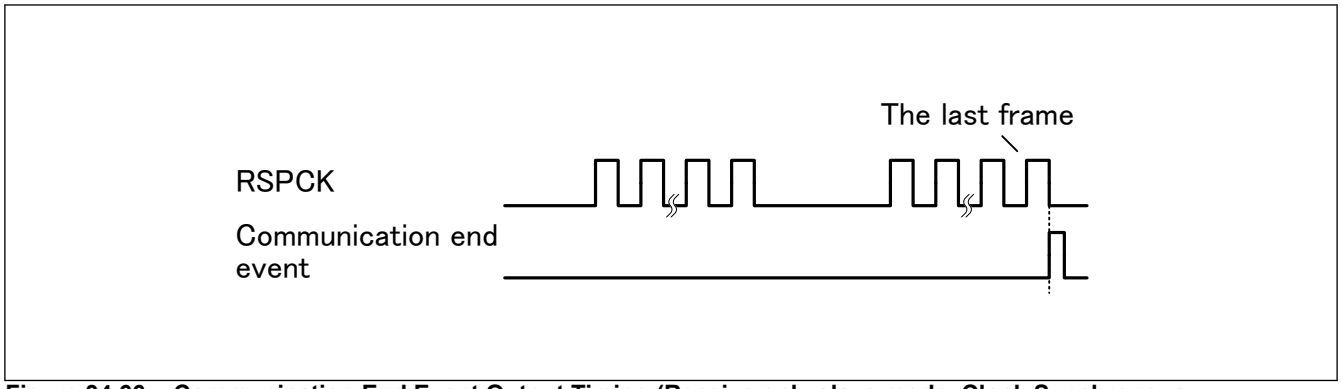

Figure 34.66 Communication End Event Output Timing (Receive only slave mode, Clock Synchronous Operation)

34.5 Usage Notes

34.5.1 Settings for the Module-Stop State

The Module Stop Control Register B (MSTPCRB) can enable or disable the SPI operation. The SPI is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details on the Module Stop Control Register B, see section 10, Low Power Modes.

34.5.2 Constraint on Low-Power Functions

When using the module-stop function and entering a low-power mode other than Sleep mode, set the SPCR.SPE bit to 0 before completing communication.

34.5.3 Constraints on Starting Transfer

If the ICU.IELSRn.IR flag is 1 when transfer starts, the interrupt request is internally retained, which can lead to unanticipated behavior of the ICU.IELSRn.IR flag.

To prevent this, use the following procedure to clear interrupt requests before enabling operations (by setting the SPCR.SPE bit to 1):

1. Confirm that transfer stopped (the SPCR.SPE bit is 0).
2. Set the associated interrupt enable bit (SPCR.SPTIE bit or SPCR.SPRIE bit) to 0.
3. Read the associated interrupt enable bit (SPCR.SPTIE bit or SPCR.SPRIE bit) and confirm that its value is 0.
4. Set the ICU.IELSRn.IR flag to 0.

34.5.4 Constraints on Mode-Fault, Underrun, Overrun, or Parity Error Event Output

Using the mode-fault, underrun, overrun, or parity error event is prohibited if the SPI is in multi-master mode (when the SPCR.SPMS bit is 0, the SPCR.MSTR bit is 1, and the SPCR.MODFEN bit is 1).

34.5.5 Constraints on the SPSR.SPRF and SPSR.SPTEF Flags

If the polling flags, SPRF and SPTEF, are used, using the interrupts is prohibited, and you must set the SPCR.SPRIE and SPCR.SPTIE bits to 0. Either the interrupts or the flags can be used, but not both.

35. Quad Serial Peripheral Interface (QSPI)

35.1 Overview

The QSPI is a memory controller for connecting a serial ROM (nonvolatile memory such as a serial flash memory, serial EEPROM, or serial FeRAM) that has an SPI-compatible interface.

Table 35.1 lists the QSPI specifications, Figure 35.1 shows a block diagram, and Table 35.2 lists the I/O pins.

Table 35.1 QSPI specifications

Parameter	Specifications
Number of channels	1 channel
SPI protocols	• Single SPI protocol, extended SPI protocol to achieve full-duplex communications Note: Standard or fast reading can only be used in single SPI operation. Four-wire communications with the serial flash memory by using the QSSL, QSPCLK, QIO0, and QIO1 pins (QIO0, QSSL, and QSPCLK for output, and QIO1 for input) • Dual SPI protocol to achieve half-duplex communications Four-wire communications with the serial flash memory by using the QSSL, QSPCLK, QIO0, and QIO1 pins (QSSL and QSPCLK for output, and QIO0 and QIO1 for input and output) • Quad SPI protocol to achieve half-duplex communications Six-wire communications with the serial flash memory by using the QSSL, QSPCLK, and QIO0 to QIO3 pins (QSSL and QSPCLK for output, and QIO0 to QIO3 for input and output)
SPI mode	• SPI mode 0: The QSPCLK signal is driven low when the SPI bus is not active. • SPI mode 3: The QSPCLK signal is driven high when the SPI bus is not active.
SPI timing adjustment function	The following settings are possible to suit various types of serial flash memory device: • SPI bus reference cycle (SFMSKC.SFMDV[4:0]) • Duty cycle correction (SFMSKC.SFMDTY) • Adjustment of the number of dummy cycles (SFMSDC.SFMDN[3:0]) • Minimum width at high level for the QSSL signal (SFMSSC.SFMSW[3:0]) • QSSL signal setup time (SFMSSC.SFMSLD) • QSSL signal hold time (SFMSSC.SFMSHD) • Serial data output enable hold time (SFMSMD.SFMOEX)
ROM access mode	• Support for Standard Read, Fast Read, Fast Read Dual Output, Fast Read Dual I/O, Fast Read Quad Output, and Fast Read Quad I/O instructions • Substitutable instruction code • Prefetch function (data are sequentially stored in a buffer after one request without waiting for further requests to read the serial flash memory) • Polling processing • SPI bus cycle extension function • XIP mode (allowing skipping of the reception of an instruction code to read the serial flash memory) Note: ROM access mode is only possible with reading .
Direct communication mode	Flexible support for a wide variety of serial flash memory instructions and functions through software control, including erase, ID read, and power-down control
Interrupt source	Error interrupts
Module-stop function	Module-stop state can be set to reduce power consumption.
TrustZone Filter	Security attribution is always non-secure

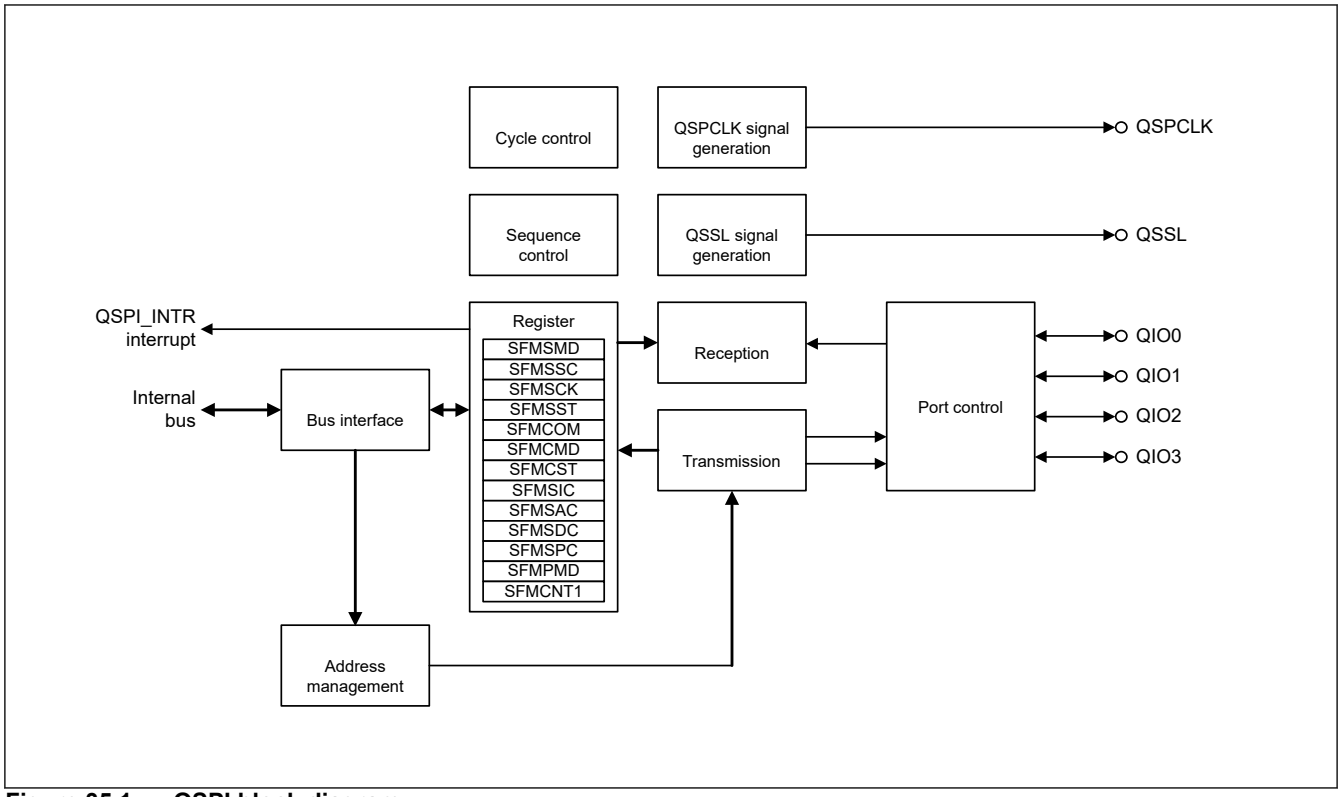

Figure 35.1 QSPI block diagram

Table 35.2 QSPI I/O pins

Function	Pin name	I/O	Description
QSPI	QSPCLK	Output	QSPI clock output pin.
	QSSL	Output	QSPI slave output pin.
	QIO0 to QIO3	I/O	Data0 to Data3

35.2 Register Descriptions

35.2.1 SFMSMD : Transfer Mode Control Register

Base address: QSPI = 0x6400_0000

Offset address: 0x000

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	SFMCCE	—	—	—	SFMOSW	SFMOHW	SFMOEX	SFMMD3	SFMPAE	SFMPFE	SFMSE[1:0]		—	SFMRM[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	SFMRM[2:0]	Serial interface read mode select 0 0 0: Standard Read 0 0 1: Fast Read 0 1 0: Fast Read Dual Output 0 1 1: Fast Read Dual I/O 1 0 0: Fast Read Quad Output 1 0 1: Fast Read Quad I/O Others: Setting prohibited	R/W
3	—	This bit is read as 0. The write value should be 0.	R/W
5:4	SFMSE[1:0]	QSSL extension function select after SPI bus access 0 0: Do not extend QSSL 0 1: Extend QSSL by 33 QSPCLK 1 0: Extend QSSL by 129 QSPCLK 1 1: Extend QSSL infinitely	R/W
6	SFMPFE	Prefetch function select 0: Disable function 1: Enable function	R/W
7	SFMPAE	Function select for stopping prefetch at locations other than on byte boundaries*1 0: Disable function 1: Enable function	R/W
8	SFMMD3	SPI mode select. 0: SPI mode 0 1: SPI mode 3	R/W
9	SFMOEX	Extension select for the I/O buffer output enable signal for the serial interface 0: Do not extend 1: Extend by 1 QSPCLK	R/W
10	SFMOHW	Hold time adjustment for serial transmission 0: Do not extend high-level width of QSPCLK during transmission 1: Extend high-level width of QSPCLK by 1 PCLKA during transmission	R/W
11	SFMOSW	Setup time adjustment for serial transmission 0: Do not extend low-level width of QSPCLK during transmission 1: Extend low-level width of QSPCLK by 1 PCLKA during transmission	R/W
14:12	—	These bits are read as 0. The write value should be 0.	R/W
15	SFMCCE	Read instruction code select 0: Uses automatically generated SPI instruction code*2 1: Use instruction code in the SFMSIC register	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. The QSPI outputs additional one clock without accompanying data reception. For details, see section 35.5.9. Serial Data Receiving Latency.

Note 2. When QSPI accesses serial flash memory, the instruction code is based on the SFMSAC register and SFMSMD register settings. See section 35.6.1. SPI Instructions That Are Automatically Generated.

35.2.2 SFMSSC : Chip Selection Control Register

Base address: QSPI = 0x6400_0000

Offset address: 0x004

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	SFMSLD	SFMSHD	SFMSW[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	1	1	0	1	1	1

Bit	Symbol	Function	R/W
3:0	SFMSW[3:0]	Minimum High-level Width Select for QSSL Signal 0x0: 1 QSPCLK 0x1: 2 QSPCLK 0x2: 3 QSPCLK 0x3: 4 QSPCLK 0x4: 5 QSPCLK 0x5: 6 QSPCLK 0x6: 7 QSPCLK 0x7: 8 QSPCLK 0x8: 9 QSPCLK 0x9: 10 QSPCLK 0xA: 11 QSPCLK 0xB: 12 QSPCLK 0xC: 13 QSPCLK 0xD: 14 QSPCLK 0xE: 15 QSPCLK 0xF: 16 QSPCLK	R/W
4	SFMSHD	QSSL Signal Hold Time 0: QSSL outputs high after 0.5 QSPCLK cycles from the last rising edge of QSPCLK. 1: QSSL outputs high after 1.5 QSPCLK cycles from the last rising edge of QSPCLK.	R/W
5	SFMSLD	QSSL Signal Setup Time 0: QSSL outputs low before 0.5 QSPCLK cycles from the first rising edge of QSPCLK. 1: QSSL outputs low before 1.5 QSPCLK cycles from the first rising edge of QSPCLK.	R/W
31:6	—	These bits are read as 0. The write value should be 0.	R/W

35.2.3 SFMSKC : Clock Control Register

Base address: QSPI = 0x6400_0000

Offset address: 0x008

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	SFMDTY	SFMDV[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0

Bit	Symbol	Function	R/W
4:0	SFMDV[4:0]	Serial interface reference cycle select. (Pay attention to irregularities.) 0x00: 2 PCLKA 0x01: 3 PCLKA (divided by an odd number)*1 0x02: 4 PCLKA 0x03: 5 PCLKA (divided by an odd number)*1 0x04: 6 PCLKA 0x05: 7 PCLKA (divided by an odd number)*1 0x06: 8 PCLKA 0x07: 9 PCLKA (divided by an odd number)*1 0x08: 10 PCLKA 0x09: 11 PCLKA (divided by an odd number)*1 0x0A: 12 PCLKA 0x0B: 13 PCLKA (divided by an odd number)*1 0x0C: 14 PCLKA 0x0D: 15 PCLKA (divided by an odd number)*1 0x0E: 16 PCLKA 0x0F: 17 PCLKA (divided by an odd number)*1 0x10: 18 PCLKA 0x11: 20 PCLKA 0x12: 22 PCLKA 0x13: 24 PCLKA 0x14: 26 PCLKA 0x15: 28 PCLKA 0x16: 30 PCLKA 0x17: 32 PCLKA 0x18: 34 PCLKA 0x19: 36 PCLKA 0x1A: 38 PCLKA 0x1B: 40 PCLKA 0x1C: 42 PCLKA 0x1D: 44 PCLKA 0x1E: 46 PCLKA 0x1F: 48 PCLKA	R/W
5	SFMDTY	Duty ratio correction function select for the QSPCLK signal when devided by an odd number 0: Make no correction 1: Make correction	R/W
31:6	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Set the SFMDTY bit to 1 when PCLKA is to be divided by an odd number.

35.2.4 SFMSST : Status Register

Base address: QSPI = 0x6400_0000

Offset address: 0x00C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	PFOFF	PFFUL	—	PFCNT[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
4:0	PFCNT[4:0]	Number of bytes of prefetched data 0x00: 0 byte 0x01: 1 byte 0x02: 2 bytes 0x03: 3 bytes 0x04: 4 bytes 0x05: 5 bytes 0x06: 6 bytes 0x07: 7 bytes 0x08: 8 bytes 0x09: 9 bytes 0x0A: 10 bytes 0x0B: 11 bytes 0x0C: 12 bytes 0x0D: 13 bytes 0x0E: 14 bytes 0x0F: 15 bytes 0x10: 16 bytes 0x11: 17 bytes 0x12: 18 bytes Others: Reserved	R
5	—	This bit is read as 0.	R
6	PFFUL	Prefetch buffer state 0: Prefetch buffer has free space 1: Prefetch buffer is full	R
7	PFOFF	Prefetch function operating state 0: Prefetch function operating 1: Prefetch function not enabled or not operating	R
31:8	—	These bits are read as 0.	R

35.2.5 SFMCOM : Communication Port Register

Base address: QSPI = 0x6400_0000

Offset address: 0x010

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	SFMD[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	x	x	x	x	x	x	x	x

Bit	Symbol	Function	R/W
7:0	SFMD[7:0]	Port for direct communication with the SPI bus Input and output from this port are converted to an SPI bus cycle in direct communications mode (DCOM = 1). Access to this port is ignored in ROM access mode.	R/W
31:8	—	These bits are read as 0. The write value should be 0.	R/W

35.2.6 SFMCMD : Communication Mode Control Register

Base address: QSPI = 0x6400_0000

Offset address: 0x014

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DCOM
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	DCOM	Mode select for communication with the SPI bus 0: ROM access mode 1: Direct communication mode*1	R/W
31:1	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. SFMCMD.DCOM = 1 must be written when the transaction ends. For details, see section 35.10. Direct Communication Mode.

35.2.7 SFMCST : Communication Status Register

Base address: QSPI = 0x6400_0000

Offset address: 0x018

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	EROMR	—	—	—	—	—	—	COMBSY
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	COMBSY	SPI bus cycle completion state in direct communication 0: No serial transfer being processed 1: Serial transfer being processed	R
6:1	—	These bits are read as 0. The write value should be 0.	R/W
7	EROMR	ROM access detection status in direct communication mode 0: ROM access not detected 1: ROM access detected	R/(W)*1
31:8	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Only 0 can be written to this bit.

35.2.8 SFMSIC : Instruction Code Register

Base address: QSPI = 0x6400_0000

Offset address: 0x020

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	SFMCIC[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

31:26	QSPI_EXT[5:0]	Bank switching address When accessing from 0x60000000 to 0x63FFFFFF, the address bus is set from QSPI_EXT[5:0] to the upper 6 bits of the internal bus address for the address bus. 0x00: QSPI bank 00 0x01: QSPI bank 01 0x02: QSPI bank 02 ⋮ ⋮ 0x3C: QSPI bank 60 0x3D: QSPI bank 61 0x3E: QSPI bank 62 0x3F: Setting prohibited	R/W

35.3 Memory Map

35.3.1 External Bus Space

The locations of a serial flash memory and control register on the address space are determined by the address range of the area set in the configuration.

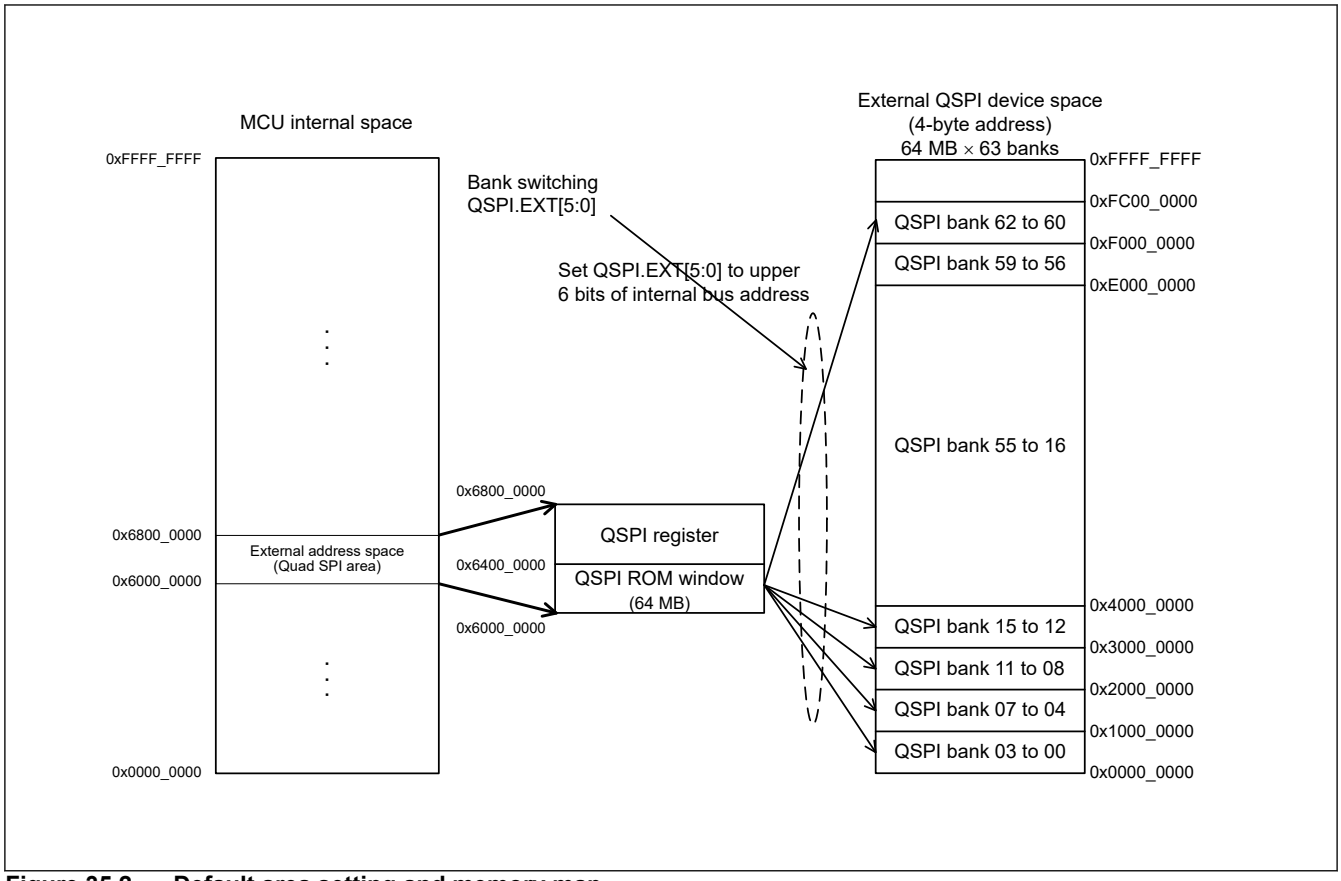

Figure 35.2 Default area setting and memory map

35.3.2 Address Width of the SPI Space and SPI Bus

The SPI space has a 32-bit address width for referencing the serial flash memory. When the SPI space is accessed for a read, an SPI bus cycle starts automatically, and data read from the serial flash is returned.

The address width of the SPI space is fixed at 32 bits. However, the address width of the SPI bus is selectable to 8, 16, 24, or 32 bits in the SFMAS[1:0] bits in the Address Mode Control Register (SFMSAC) register. If 8, 16, or 24 bits is selected as the address width of the SPI bus, only the lower part of the address used to access the SPI space is posted to the serial flash memory through the SPI bus. As a result, the mirror image of the serial flash corresponding to the address width of the SPI bus repeatedly appears in the SPI space.

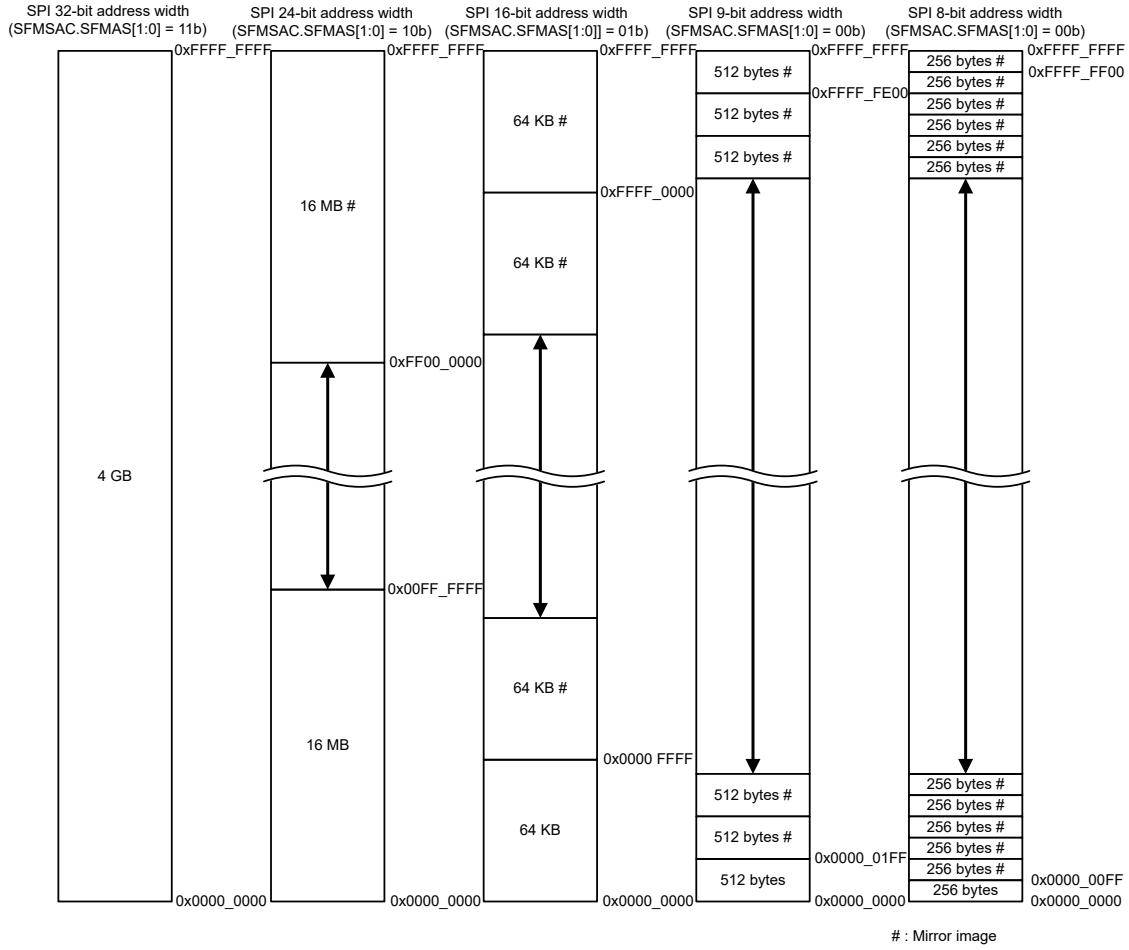

Figure 35.3 Memory map of SPI space

Note: The SPI bus address width is selectable to 8, 16, 24, or 32 bits in the SFMAS[1:0] bits in the SFMSAC register (cases 1 to 3 and 5 in the figure correspond to the respective address widths). When an 8-bit address width is selected, the address information of the ninth bit can be embedded in the Read instruction code. The memory map in case 4 in the figure is for the 9-bit address width. For details on the Read instruction, see section 35.6.2. Standard Read Instruction.

35.4 SPI Bus

35.4.1 SPI Protocol

Single SPI, extended SPI, dual SPI, and quad SPI are supported in addition to the SPI protocol used for serial flash memory connection.

The initial state of the SPI protocol is Single SPI, extended SPI and can be changed with the SFMSPI[1:0] bits in the SPI Protocol Control Register (SFMSPC) register.

The address and data pins used in the Single SPI, extended SPI protocol change depending on the setting of the serial interface read mode select bits SFMRM[2:0] in Transfer Mode Control Register (SFMSMD). Table 35.3 and Table 35.4 list the pins used for instruction code, addresses, and data in each of the SPI protocols.

Note: In read operation, the QSPI outputs additional one clock without accompanying data reception per one SPI bus cycle. For details, see section 35.5.9. Serial Data Receiving Latency.

Table 35.3 List of SPI Protocols (1)

SPI Protocol (SFMSPC.SFMSPI[1:0])	Single SPI Protocol, Extended SPI Protocol					
Serial interface read mode select (SFMSMD.SFMRM[2:0])	Standard read	Fast read	Fast read dual output	Fast read dual I/O	Fast read quad output	Fast read quad I/O
All pins used	QSPCLK, QSSL, QIO0, QIO1	QSPCLK, QSSL, QIO0, QIO1	QSPCLK, QSSL, QIO0, QIO1	QSPCLK, QSSL, QIO0, QIO1	QSPCLK, QSSL, QIO0, QIO1, QIO2, QIO3	QSPCLK, QSSL, QIO0, QIO1, QIO2, QIO3
Pins used for instruction code	QIO0	QIO0	QIO0	QIO0	QIO0	QIO0
Pins used for addresses	QIO0	QIO0	QIO0	QIO0, QIO1	QIO0	QIO0, QIO1, QIO2, QIO3
Pins used for data	QIO0/QIO1	QIO0/QIO1	QIO0, QIO1	QIO0, QIO1	QIO0, QIO1, QIO2, QIO3	QIO0, QIO1, QIO2, QIO3

Note: Single SPI protocol operation is for standard read and fast read. Extended SPI protocol operation is fast read dual output, fast read dual I/O, fast read quad output, and fast read quad I/O.

Table 35.4 List of SPI Protocols (2)

SPI Protocol (SFMSPC.SFMSPI[1:0])	Dual-SPI Protocol		Quad-SPI Protocol	
Serial interface read mode select (SFMSMD.SFMRM[2:0])	Fast read dual output	Fast read dual I/O	Fast read quad output	Fast read quad I/O
All pins used	QSPCLK, QSSL, QIO0, QIO1	QSPCLK, QSSL, QIO0, QIO1	QSPCLK, QSSL, QIO0, QIO1, QIO2, QIO3	QSPCLK, QSSL, QIO0, QIO1, QIO2, QIO3
Pins used for instruction code	QIO0, QIO1	QIO0, QIO1	QIO0, QIO1, QIO2, QIO3	QIO0, QIO1, QIO2, QIO3
Pins used for addresses	QIO0, QIO1	QIO0, QIO1	QIO0, QIO1, QIO2, QIO3	QIO0, QIO1, QIO2, QIO3
Pins used for data	QIO0, QIO1	QIO0, QIO1	QIO0, QIO1, QIO2, QIO3	QIO0, QIO1, QIO2, QIO3

In single SPI protocol and extended SPI protocol, the instruction code is always output from the QIO0 pin. Address and data input/output operations are performed according to the settings in SFMSMD.SFMRM[2:0].

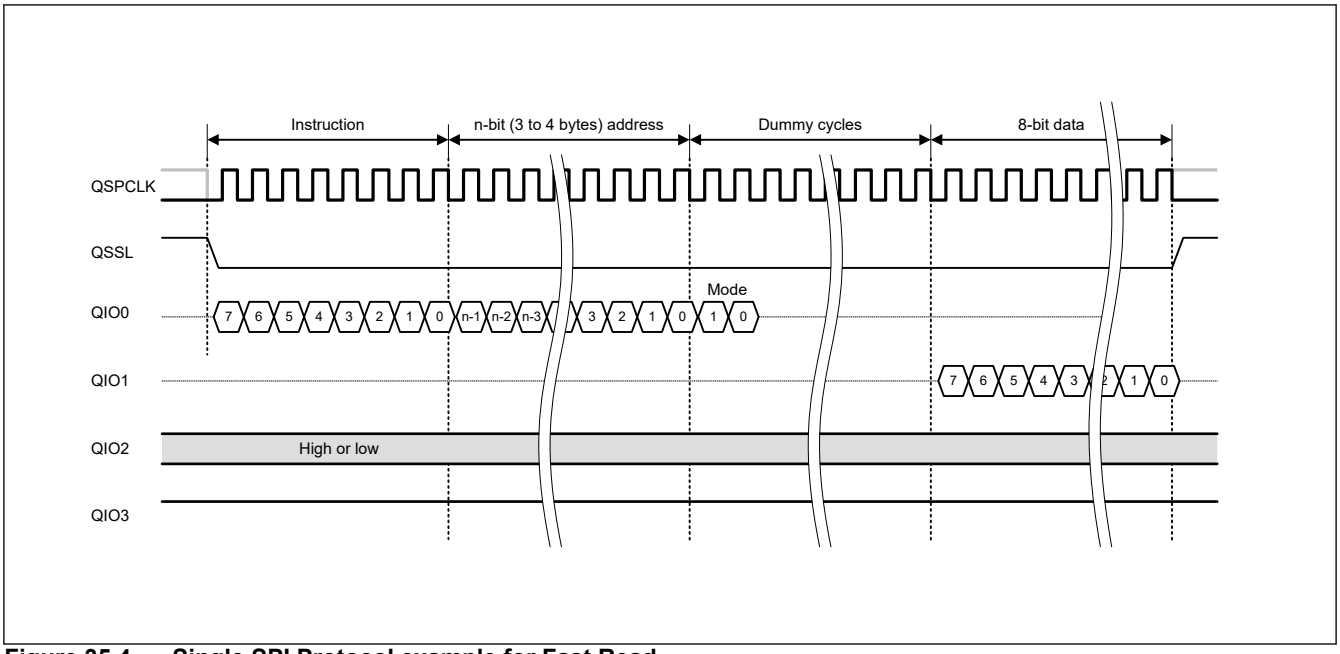

Figure 35.4 Single SPI Protocol example for Fast Read

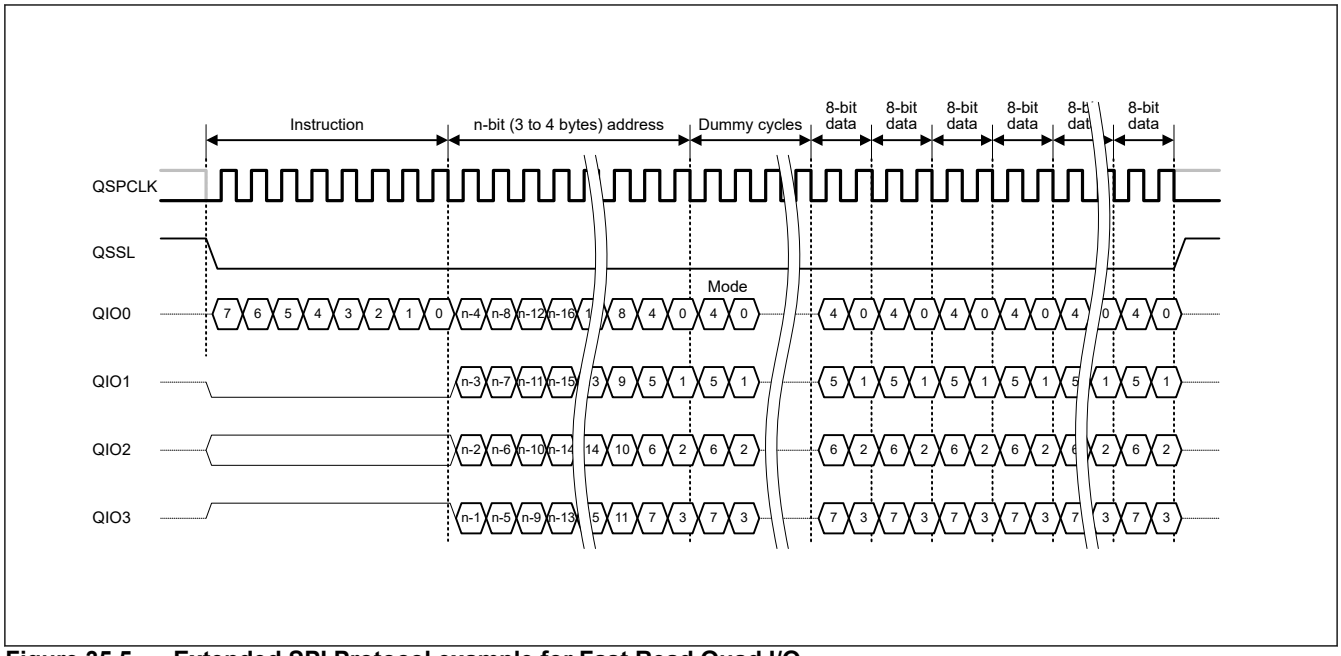

Figure 35.5 Extended SPI Protocol example for Fast Read Quad I/O

The Dual SPI protocol performs I/O operation of all signals such as instruction codes, addresses, and data using two pins, QIO0 and QIO1.

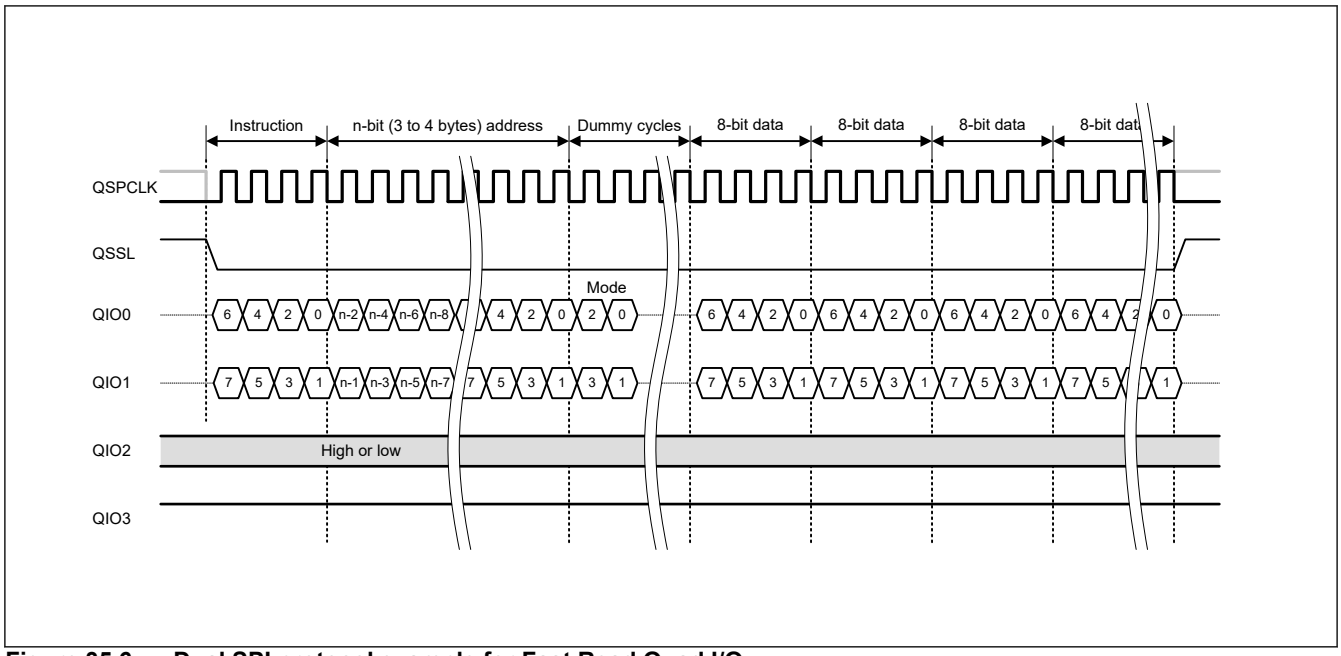

Figure 35.6 Dual SPI protocol example for Fast Read Quad I/O

The Quad SPI protocol performs I/O operation of all signals such as instruction codes, addresses, and data using four pins, QIO0, QIO1, QIO2, and QIO3.

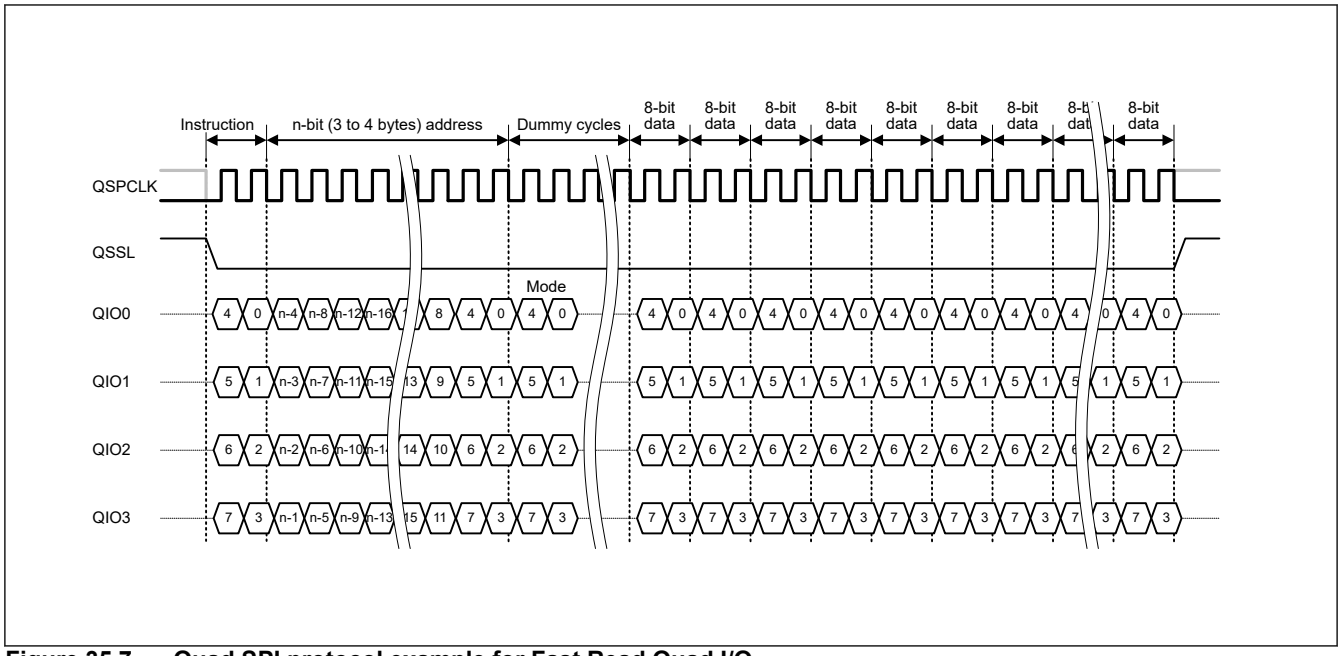

Figure 35.7 Quad SPI protocol example for Fast Read Quad I/O

35.4.2 SPI Mode

Either SPI mode 0 or SPI mode 3 can be selected as the SPI mode by the SFMSMD.SFMMD3 bit. This can be switched by changing the register setting during operation. The difference between SPI modes 0 and 3 is the state of the QSPCLK signal when it is inactive. The standby level of the QSPCLK signal in SPI mode 0 is low, and high in SPI mode 3.

Serial data is output from the QSPI on a falling edge of the serial clock and is read into the serial flash memory on a rising edge of the serial clock. Serial data is output from the serial flash memory on a falling edge of the serial clock and is read into the QSPI on the next falling edge of the serial clock.

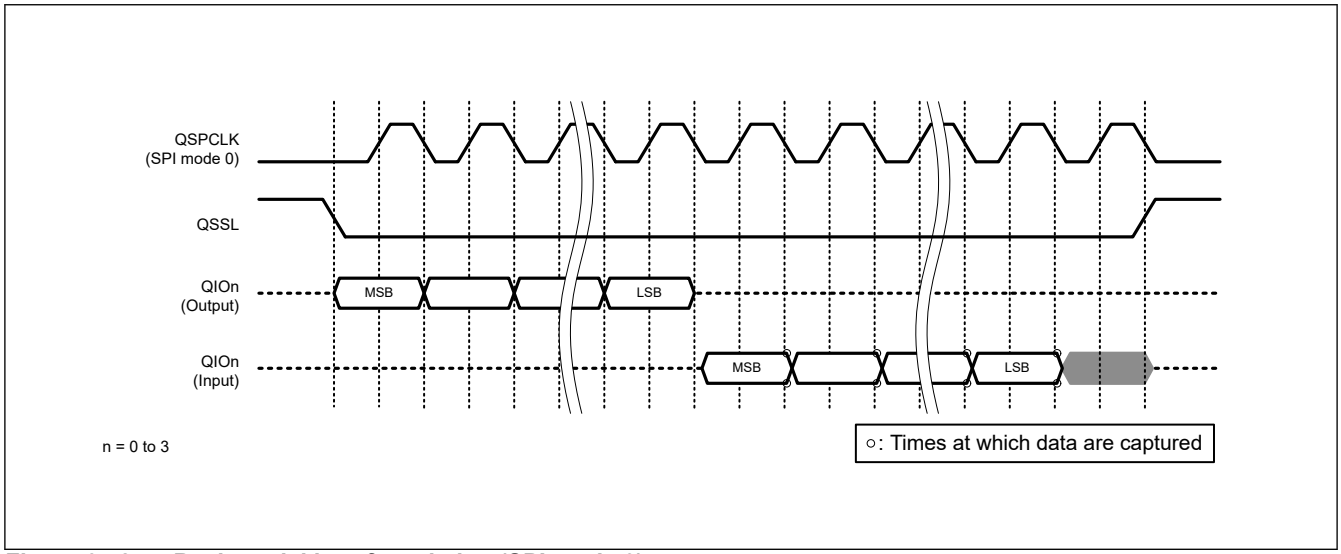

Figure 35.8 Basic serial interface timing (SPI mode 0)

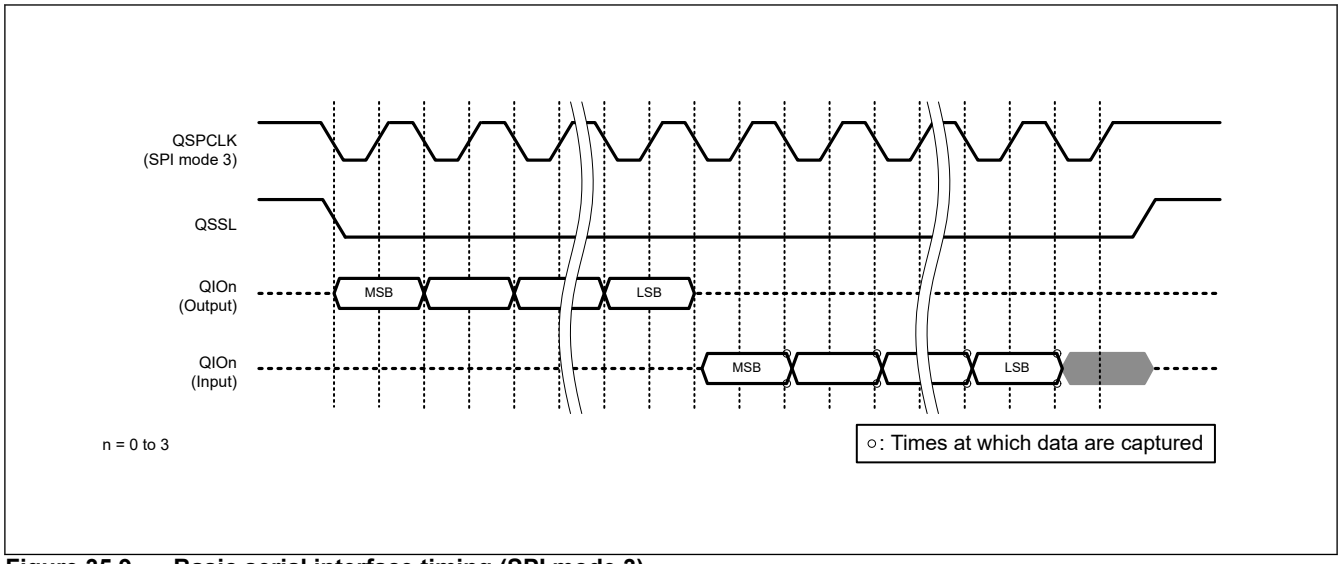

Figure 35.9 Basic serial interface timing (SPI mode 3)

35.5 SPI Bus Timing Adjustment

The timing of the SPI bus signal can be adjusted in the registers. The configured timing is applied to all SPI bus accesses, for both ROM access and direct communication.

35.5.1 SPI Bus Reference Cycles

The SPI bus operates on reference cycles obtained by multiplying PCLKA by an integer. The reference cycles are selectable within the range of PCLKA multiplied by 2 to 48 in the SFMDV[4:0] bits in the Transfer Mode Control Register (SFMSKC) register.

Table 35.5 Relationship among SFMDV[4:0] bits, cycle multiplier, and serial clock frequencies (1 of 2)

SFMDV[4:0]	Cycle multiplier	PCLKA = 100 [MHz]
11111b	48	2.08
11110b	46	2.17
11101b	44	2.27
11100b	42	2.38
11011b	40	2.50
11010b	38	2.63
11001b	36	2.78
11000b	34	2.94
10111b	32	3.13
10110b	30	3.33
10101b	28	3.57
10100b	26	3.85
10011b	24	4.17
10010b	22	4.55
10001b	20	5.00
10000b	18	5.56
01111b	17	5.88
01110b	16	6.25
01101b	15	6.67

Table 35.5 Relationship among SFMDV[4:0] bits, cycle multiplier, and serial clock frequencies (2 of 2)

SFMDV[4:0]	Cycle multiplier	PCLKA = 100 [MHz]
01100b	14	7.14
01011b	13	7.69
01010b	12	8.33
01001b	11	9.09
01000b	10	10.00
00111b	9	11.11
00110b	8	12.50
00101b	7	14.29
00100b	6	16.67
00011b	5	20.00
00010b	4	25.00
00001b	3	33.33
00000b	2	50.00

35.5.2 QSPCLK Signal Duty Ratio

When the reference clock is configured as PCLKA divided by an odd number without duty ratio correction, the duty ratio of the QSPCLK signal will not be 50%. When the reference clock is PCLKA divided by an odd number, be sure to enable the duty ratio correction function (SFMSKC.SFMDTY = 1).

When the reference clock is PCLKA divided by an even number, the SFMDTY setting in the SFMSKC register is ignored.

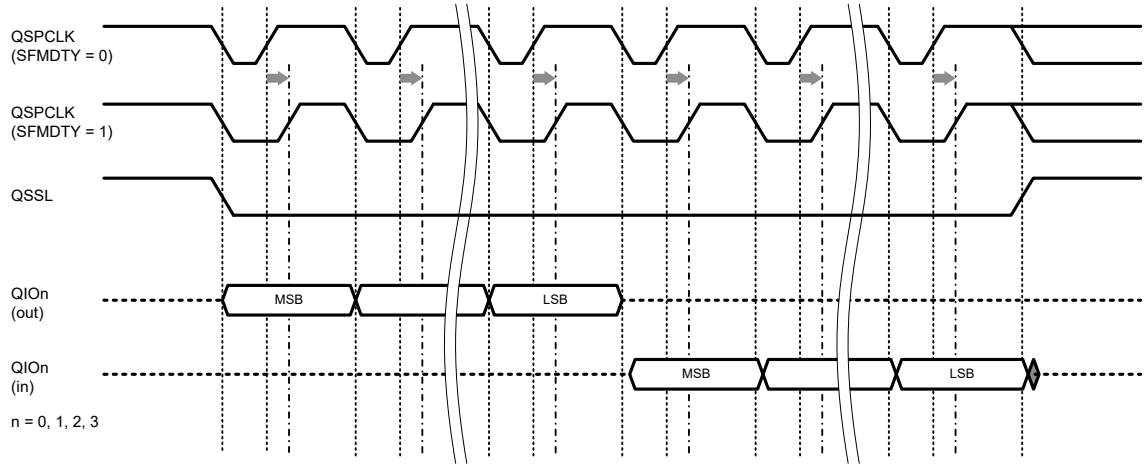

Figure 35.10 Example correction of the QSPCLK signal duty ratio using the SFMDTY bit, when PCLKA is multiplied by 3

35.5.3 Minimum High-Level Width for the QSSL Signal

Between adjacent SPI bus cycles, the QSSL signal must be held high (inactive) for a sufficient time to satisfy the deselect time required by the serial flash memory. The minimum high-level width of the QSSL output signal is selectable as the reference cycle multiplied by an integer from 1 to 16 in the SFMSW[3:0] bits in the Instruction Code Register (SFMSSC) register.

35.5.4 QSSL Signal Setup Time

The QSSL signal setup time that the serial flash memory requires after the QSSL signal is driven active low until the first rising edge of the QSPCLK signal can be configured. The setup time can be selected as 0.5 or 1.5 cycles of QSPCLK in the SFMSLD bit of the SFMSSC register.

Set a value that meets the most constrained timing condition for your application.

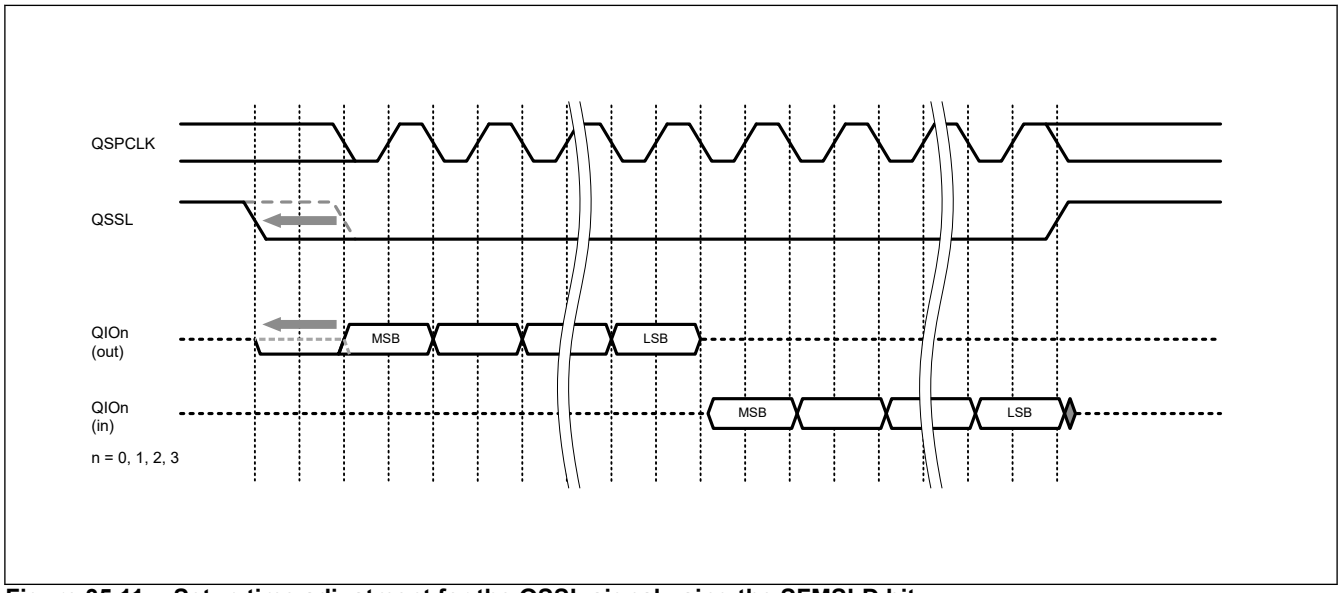

Figure 35.11 Setup time adjustment for the QSSL signal using the SFMSLD bit

35.5.5 QSSL Signal Hold Time

The QSSL signal hold time that the serial flash memory requires until the QSSL signal is driven high after the last rising edge of the QSPCLK signal can be configured. The hold time can be selected as 0.5 or 1.5 cycles of QSPCLK in the SFMSHD bit of the SFMSSC register.

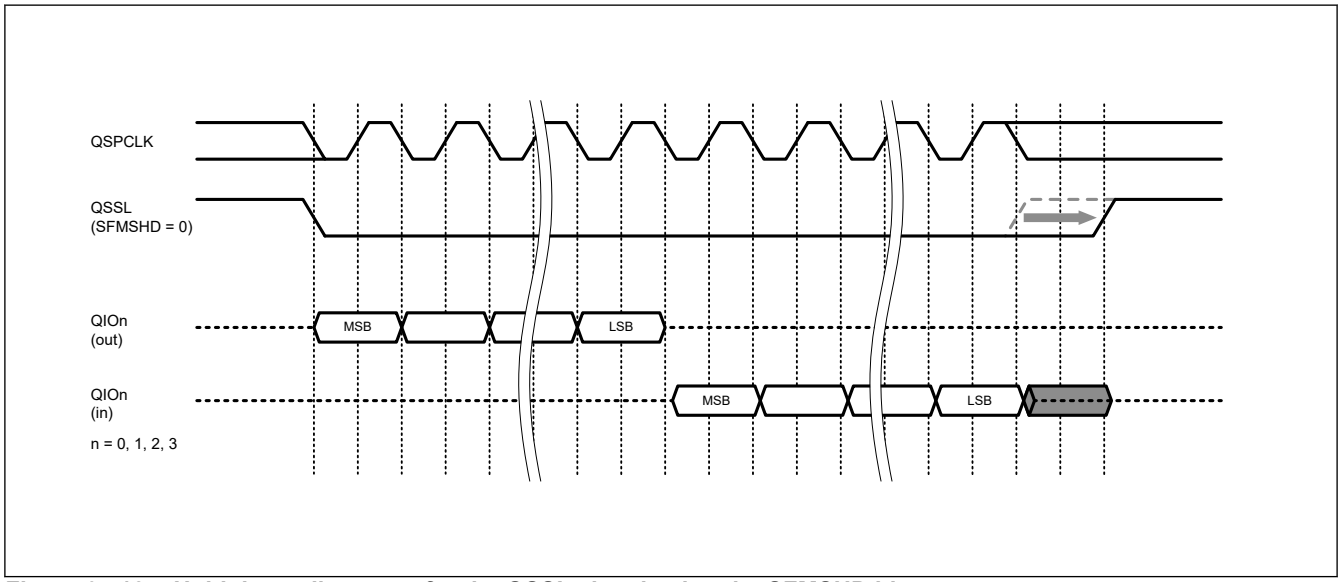

Figure 35.12 Hold time adjustment for the QSSL signal using the SFMSHD bit

35.5.6 Hold Time of the Serial Data Output Enable

The buffer output enable of the QIO0, QIO1, QIO2, or QIO3 pin can be extended by 1 QSPCLK using the SFMOEX bit in the SFMSMD register.

For a standard read instruction, it is extended immediately after an address code. For other read instructions, it is extended after two cycles of mode data (XIP mode control) of the serial flash memory in dummy cycles.

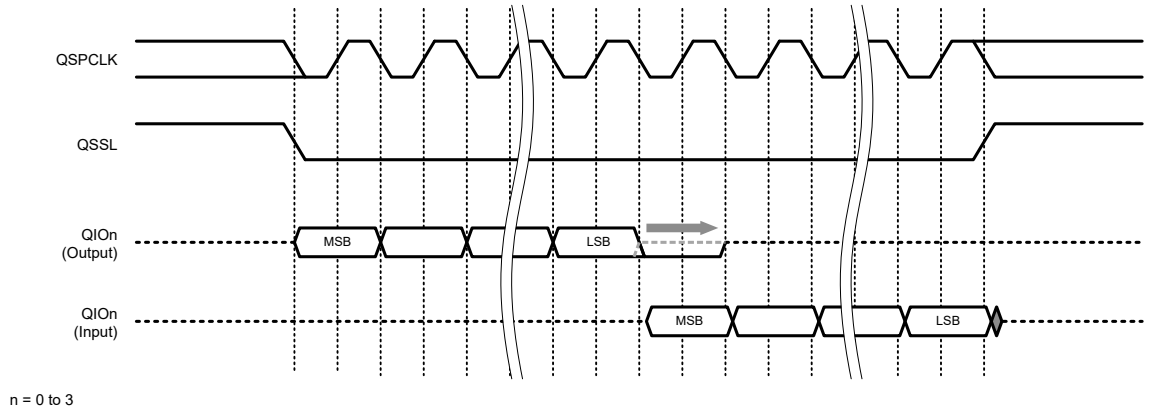

Figure 35.13 Hold time adjustment for output enable using the SFMOEX bit (Standard Read)

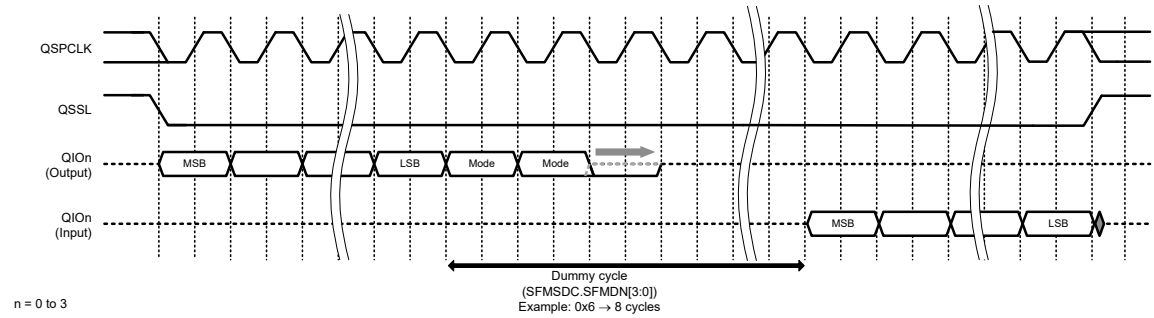

Figure 35.14 Hold Time Adjustment of Output Enabling Using the SFMOEX Bit (Fast Read)

35.5.7 Setup Time for Serial Data Output

When a command or address is transmitted to the serial flash memory, the setup time begins on serial data output and ends when the QSPCLK signal rises. If this setup time is insufficient, it can be extended by 1 PCLKA using the SFMOSW bit in the SFMSMD register. When SFMOSW is 1, the low-level width of QSPCLK during serial data transmission is extended by 1 PCLKA while data is being output from the QSPI. This function has no effect on serial data reception.

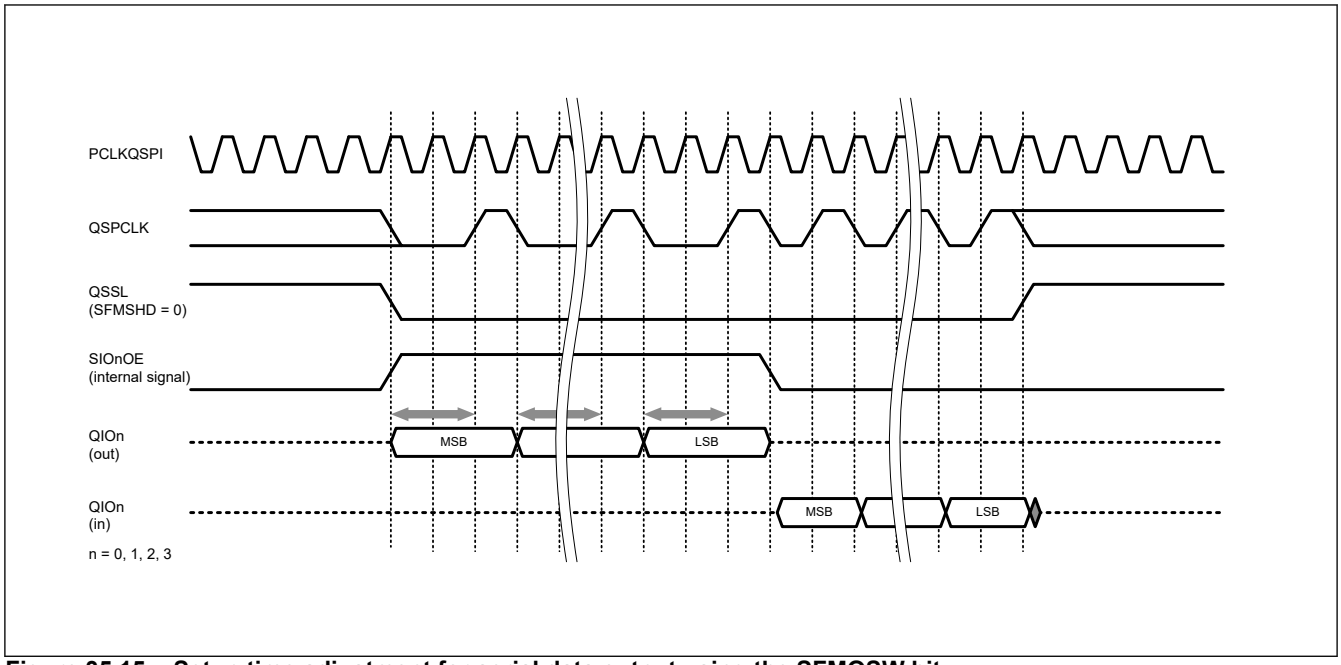

Figure 35.15 Setup time adjustment for serial data output using the SFMOSW bit

35.5.8 Hold Time for Serial Data Output

When a command or address is transmitted to the serial flash memory, the hold time begins on the rising edge of QSPCLK and ends when the serial data makes another transmission. If this hold time is insufficient, it can be extended by 1 PCLKA using the SFMOHW bit in the SFMSMD register. When SFMOSW is 1, the high-level width of QSPCLK during serial data transmission is extended by 1 PCLKA while data is being output from the QSPI. This function has no effect on serial data reception.

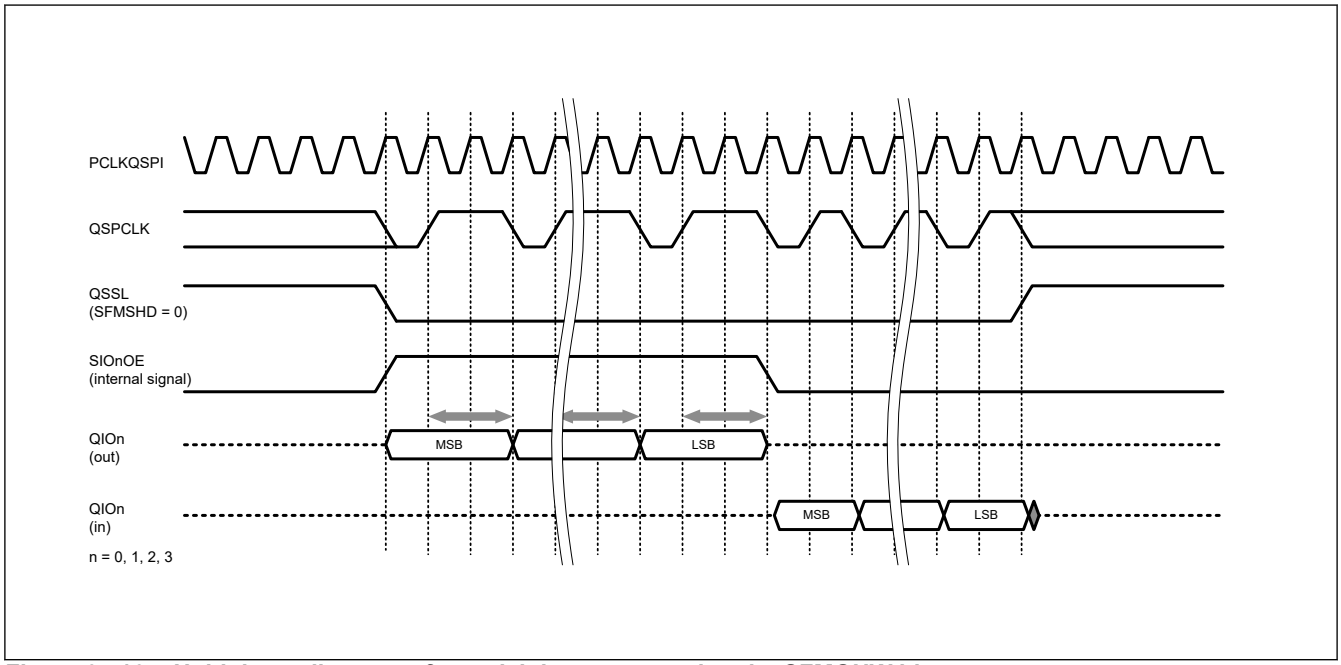

Figure 35.16 Hold time adjustment for serial data output using the SFMOHW bit

35.5.9 Serial Data Receiving Latency

The serial flash outputs data in synchronization with the falling edge of the QSPCLK signal. The QSPI receives that data in synchronization with the falling edge of the subsequent QSPCLK signal. The delay from when the serial flash starts outputting data until the QSPI receives that data is called the receiving latency. The QSPI adds a latency adjustment cycle immediately before the first data reception cycle in the SPI bus cycle. From the serial flash side, this is seen as an increase

in the number of data reception cycles. This added latency adjustment cycle is not generated in the SPI bus cycle without accompanying data reception.

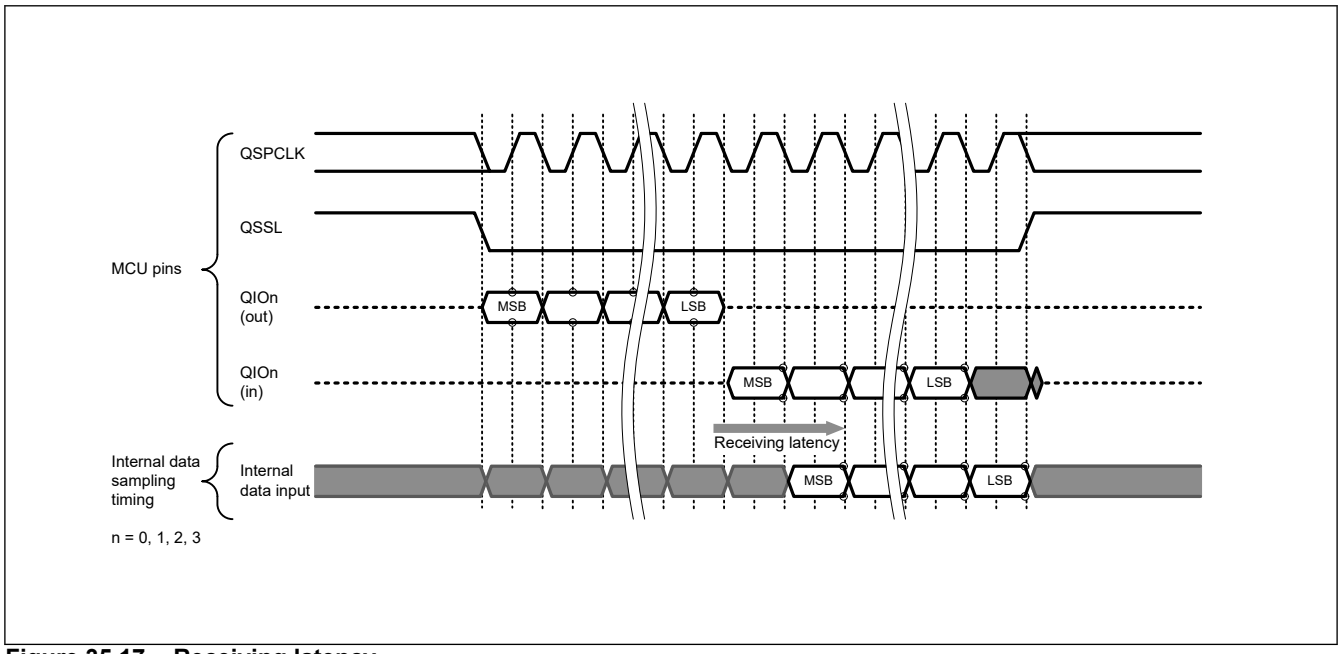

Figure 35.17 Receiving latency

35.6 SPI Instruction Set Used for Serial Flash Memory Access

35.6.1 SPI Instructions That Are Automatically Generated

When the serial flash memory is accessed, an SPI bus cycle using the instructions described in Table 35.6 to Table 35.10 is automatically generated based on the settings in the SFMSAC register and in the SFMSMD register.

Table 35.6 SPI instructions automatically generated when SFMAS[1:0] = 00b

SPI instruction	Instruction code	Address bytes	Dummy cycles	Data bytes	Remarks
Standard Read	0x03*1	1	—	1 to ∞	SFMRM[2:0] = 000b, A8 = 0
	0x0B*1	1	—	1 to ∞	SFMRM[2:0] = 000b, A8 = 1

Note 1. If the SFMSMD.SFMCCE bit is set to 1, the SFMCIC[7:0] bits in the Instruction Code Register (SFMSIC) setting is used as an instruction code.

Table 35.7 SPI instructions automatically generated when SFMAS[1:0] = 01b

SPI instruction	Instruction code	Address bytes	Dummy cycles	Data bytes	Remarks
Standard Read	0x03*1	2	—	1 to ∞	SFMRM[2:0] = 000b

Note 1. If the SFMSMD.SFMCCE bit is set to 1, the SFMSIC.SFMCIC[7:0] setting is used as an instruction code.

Table 35.8 SPI instructions automatically generated when SFMAS[1:0] = 10b (1 of 2)

SPI instruction	Instruction code	Address bytes	Dummy cycles	Data bytes	Remarks
Standard Read	0x03*1	3	—	1 to ∞	SFMRM[2:0] = 000b
Fast Read	0x0B*1	3	8*2	1 to ∞	Selectable: SFMRM[2:0] = 001b
Fast Read Dual Output	0x3B*1	3	8*2	1 to ∞	Selectable: SFMRM[2:0] = 010b
Fast Read Dual I/O	0xBB*1	3	4*2	1 to ∞	Selectable: SFMRM[2:0] = 011b
Fast Read Quad Output	0x6B*1	3	8*2	1 to ∞	Selectable: SFMRM[2:0] = 100b

Table 35.8 SPI instructions automatically generated when SFMAS[1:0] = 10b (2 of 2)

SPI instruction	Instruction code	Address bytes	Dummy cycles	Data bytes	Remarks
Fast Read Quad I/O	0xEB*1	3	6*2	1 to ∞	Selectable: SFMRM[2:0] = 101b

Note 1. If the SFMSMD.SFMCCE bit is set to 1, the SFMSIC.SFMCIC[7:0] setting is used as an instruction code.
Note 2. The number of dummy cycles is configurable by using SFMDN[3:0] bits in the Dummy Cycle Control Register (SFMSDC).

Table 35.9 SPI instructions automatically generated when SFMAS[1:0] = 11b and SFM4BC = 0

SPI instruction	Instruction code	Address bytes	Dummy cycles	Data bytes	Remarks
Standard Read	0x03*1	4	—	1 to ∞	SFMRM[2:0] = 000b
Fast Read	0x0B*1	4	8*2	1 to ∞	Selectable: SFMRM[2:0] = 001b
Fast Read Dual Output	0x3B*1	4	8*2	1 to ∞	Selectable: SFMRM[2:0] = 010b
Fast Read Dual I/O	0xBB*1	4	4*2	1 to ∞	Selectable: SFMRM[2:0] = 011b
Fast Read Quad Output	0x6B*1	4	8*2	1 to ∞	Selectable: SFMRM[2:0] = 100b
Fast Read Quad I/O	0xEB*1	4	6*2	1 to ∞	Selectable: SFMRM[2:0] = 101b

Note 1. If the SFMSMD.SFMCCE bit is set to 1, the SFMSIC.SFMCIC[7:0] setting is used as an instruction code.
Note 2. The number of dummy cycles is configurable by using the SFMSDC.SFMDN[3:0] bits.

Table 35.10 SPI instructions automatically generated when SFMAS[1:0] = 11b and SFM4BC = 1

SPI instruction	Instruction code	Address bytes	Dummy cycles	Data bytes	Remarks
Standard Read	0x13*1	4	—	1 to ∞	SFMRM[2:0] = 000b
Fast Read	0x0C*1	4	8*2	1 to ∞	Selectable: SFMRM[2:0] = 001b
Fast Read Dual Output	0x3C*1	4	8*2	1 to ∞	Selectable: SFMRM[2:0] = 010b
Fast Read Dual I/O	0xBC*1	4	4*2	1 to ∞	Selectable: SFMRM[2:0] = 011b
Fast Read Quad Output	0x6C*1	4	8*2	1 to ∞	Selectable: SFMRM[2:0] = 100b
Fast Read Quad I/O	0xEC*1	4	6*2	1 to ∞	Selectable: SFMRM[2:0] = 101b

Note 1. If the SFMSMD.SFMCCE bit is set to 1, the SFMSIC.SFMCIC[7:0] setting is used as an instruction code.
Note 2. The number of dummy cycles is configurable by using the SFMSDC.SFMDN[3:0] bits..

35.6.2 Standard Read Instruction

The standard Read instruction is a common read instruction supported by most serial flash memory. When an SPI bus cycle starts, the QSSL signal (serial flash memory select) is asserted, and the instruction code (0x03 or 0x13)*1 is output. Next, an address with a width of 1 to 4 bytes, specified in the SFMAS[1:0] bits in the SFMSAC register, is transmitted. Data is then received.

This standard Read instruction is selected in the initial QSPI settings.

Note 1. Many 4-KB serial flash memory devices have an address field not larger than 1 byte (A7-A0) to minimize the overhead and to receive A8 information from bit 3 of the Read instruction code. To support these devices, the QSPI only outputs A8 (address bit 8) to bit [3] of the standard Read instruction code when an address width of 1 byte is specified (SFMAS[1:0] = 00). This means that 0x0B might be output instead of 0x03 as the standard Read instruction code. This code duplicates the Fast Read instruction code. However, for most of the 2-KB or smaller serial flash memory, with an address width of 1 byte, bit 3 of a command is designed to be excluded from decoding as a don't-care bit, so such a Read instruction code is recognized correctly as the standard Read instruction code. In rare cases, some serial flash memory allow bit 3 to be decoded. When such a serial flash memory is connected, configure your application to avoid access resulting in A8 = 1.

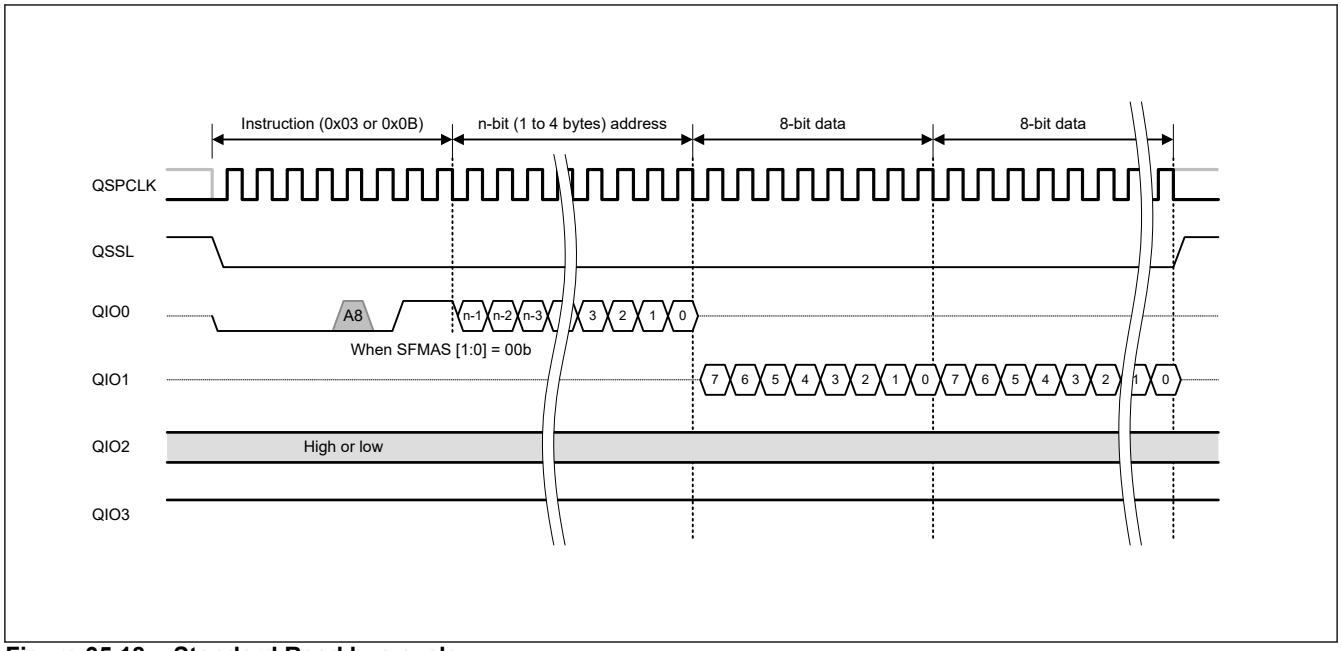

Figure 35.18 Standard Read bus cycle

35.6.3 Fast Read Instruction

The Fast Read instruction is a read instruction that supports a higher communication clock speed than the standard Read instruction. When an SPI bus cycle starts, the QSSL signal is asserted, and the instruction code (0x0B or 0x0C) is output. Next, an address with a width of 1 to 4 bytes specified by the SFMSAC.SFMAS [1: 0] bits is transmitted, a dummy cycle specified by the SFMSDC register is generated, then the data is received.

The first two dummy cycles are used to select the XIP mode. When the XIP mode is selected, the same instruction used this time is applied to the next SPI bus cycle, and the instruction code is not output the next SPI bus cycle. For details on the XIP mode, see section 35.8. XIP Control.

Switching to the Fast Read instruction is controlled in the SFMSMD register.

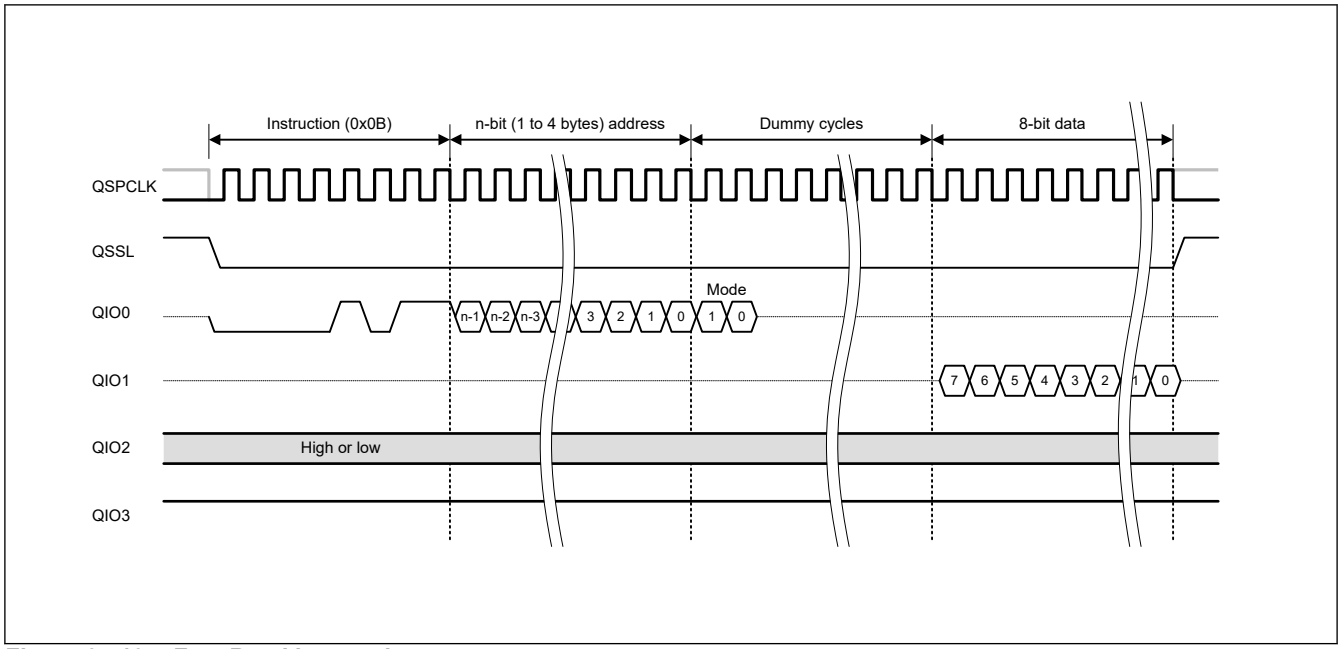

Figure 35.19 Fast Read bus cycle

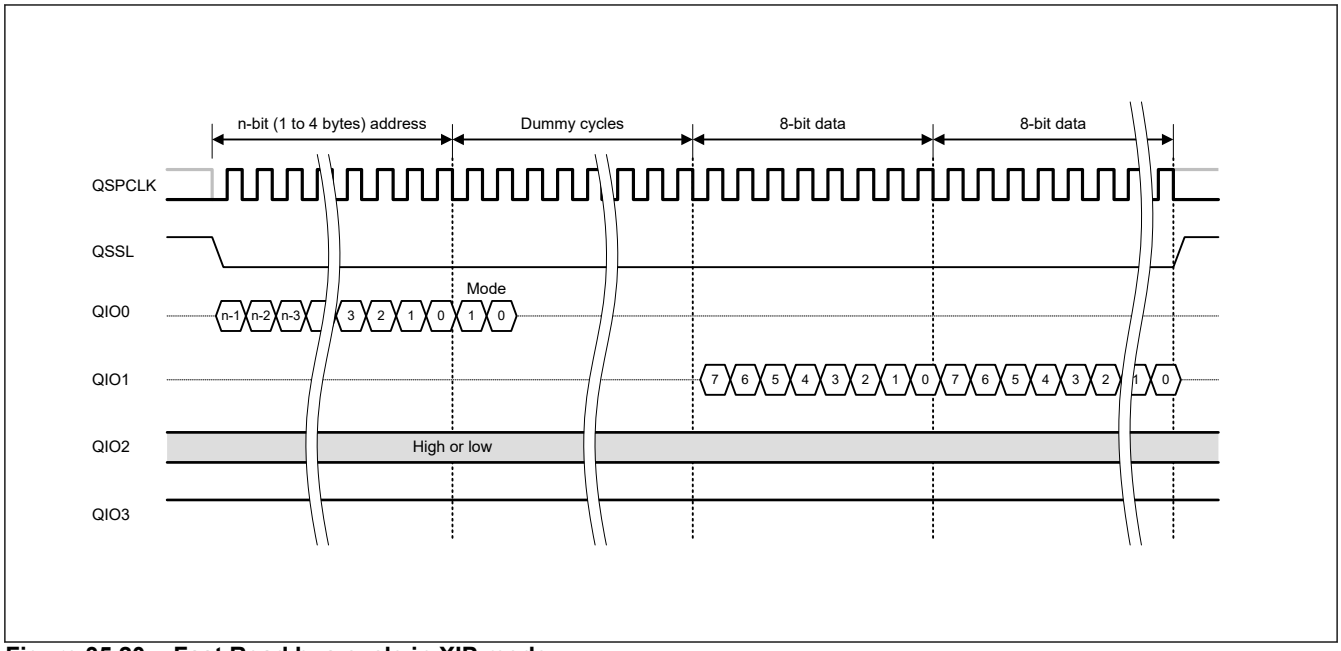

Figure 35.20 Fast Read bus cycle in XIP mode

Note: To use the Fast Read instruction, a serial flash memory that supports Fast Read transfers is required.

35.6.4 Fast Read Dual Output Instruction

The Fast Read Dual Output instruction is a read instruction that uses two signal lines to receive data. When the SPI bus cycle starts, the QSSL signal is asserted. The instruction code (0x3B or 0x3C) and an address with a width of 1 to 4 bytes, specified by the SFMSAC.SFMAS [1: 0] bits are transmitted from the QIO0 pin in the extended SPI protocol, and transmitted from the QIO0 and QIO1 pins in the Dual-SPI protocol. Next, a certain number of dummy cycles, specified in the SFMSDC register, is generated. Data is then received through the QIO0 and QIO1 pins. Even bit data is received from the QIO0 pin and odd bit data is received from the QIO1 pin.

The first two dummy cycles are used to select the XIP mode. When the XIP mode is selected, the same instruction used this time is applied to the next SPI bus cycle, and the instruction code is not output the next SPI bus cycle. For details on the XIP mode, see section 35.8. XIP Control.

Switching to Fast Read Dual Output is controlled in the SFMSMD register.

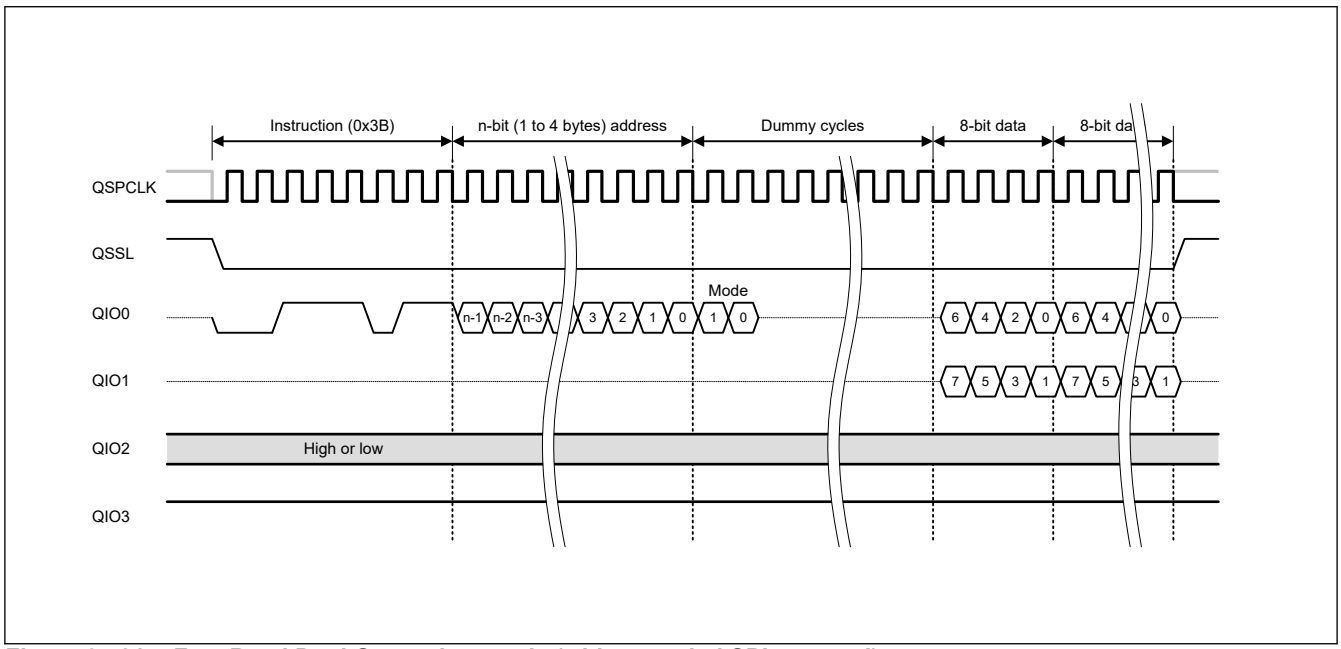

Figure 35.21 Fast Read Dual Output bus cycle (with extended SPI protocol)

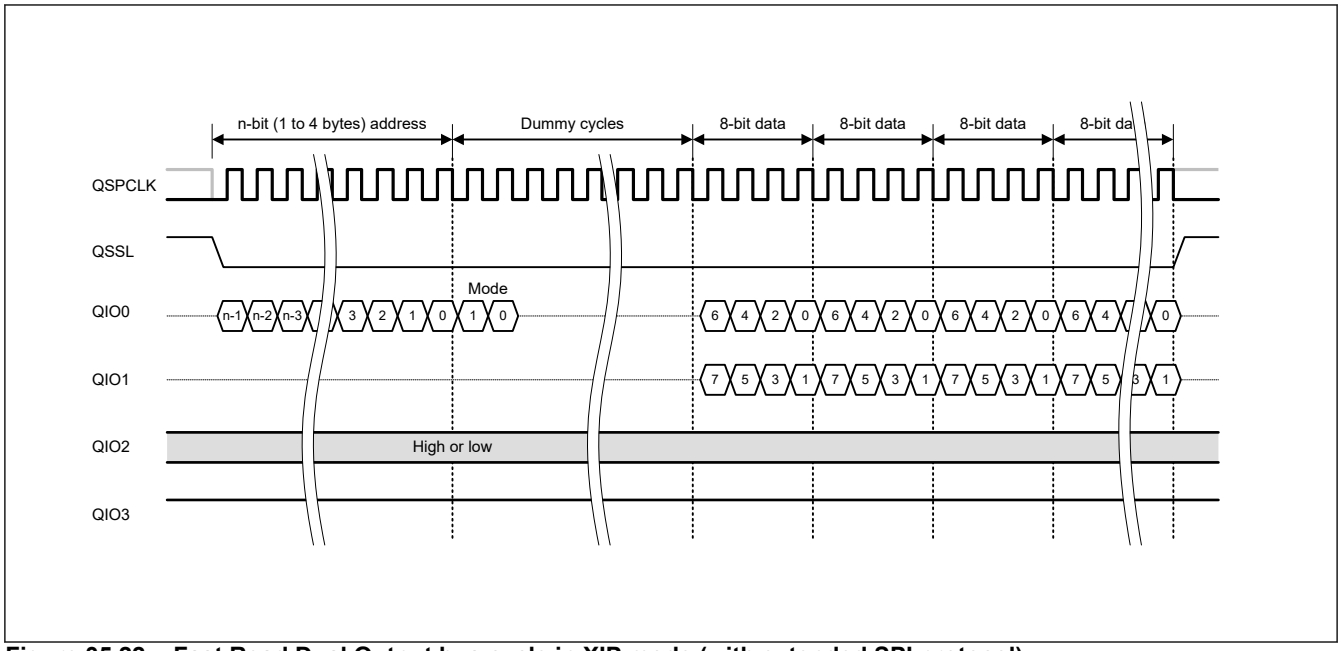

Figure 35.22 Fast Read Dual Output bus cycle in XIP mode (with extended SPI protocol)

Note: To use the Fast Read Dual Output instruction, a serial flash memory that supports Fast Read Dual Output transfers is required.

35.6.5 Fast Read Dual I/O Instruction

The Fast Read Dual I/O instruction is a read instruction that uses two signal lines to transmit an address and receive data. When the SPI bus cycle starts, the QSSL signal is asserted, and the instruction code (0xBB / 0xBC) is transmitted from QIO0 pin in the extended SPI protocol and from QIO0, and QIO1 pins in the Dual SPI protocol. Next, an address with a width of 1 to 4 bytes, specified in the SFMAS[1:0] bits in the SFMSAC register, is transmitted through the QIO0 and QIO1 pins, and a certain number of dummy cycles, specified in the SFMSDC register, is generated. Data is then is received through the QIO0 and QIO1 pins. Address and dummy cycle transmission and data reception are performed through the QIO0 pin for even bits and through the QIO1 pin for odd bits.

The first two dummy cycles are used to select the XIP mode. When the XIP mode is selected, the same instruction used this time is applied to the next SPI bus cycle, and the instruction code is not output the next SPI bus cycle. For details on the XIP mode, see section 35.8. XIP Control.

Switching to Fast Read Dual I/O is controlled in the SFMSMD register.

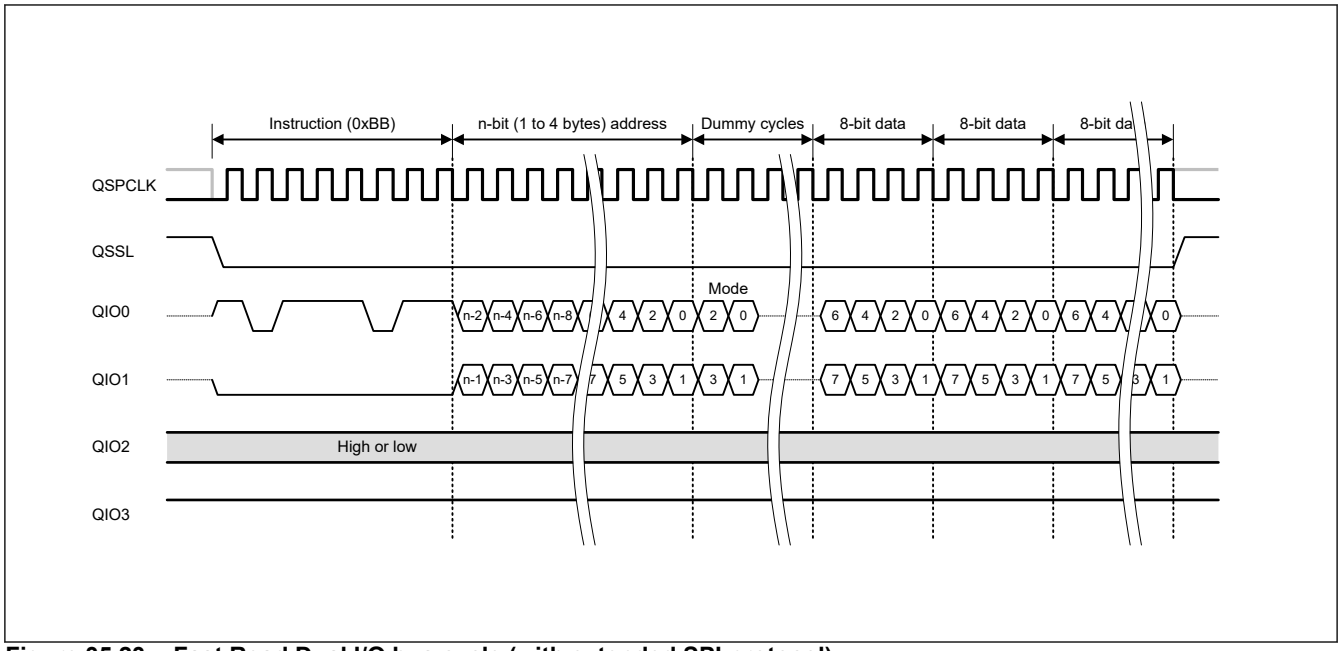

Figure 35.23 Fast Read Dual I/O bus cycle (with extended SPI protocol)

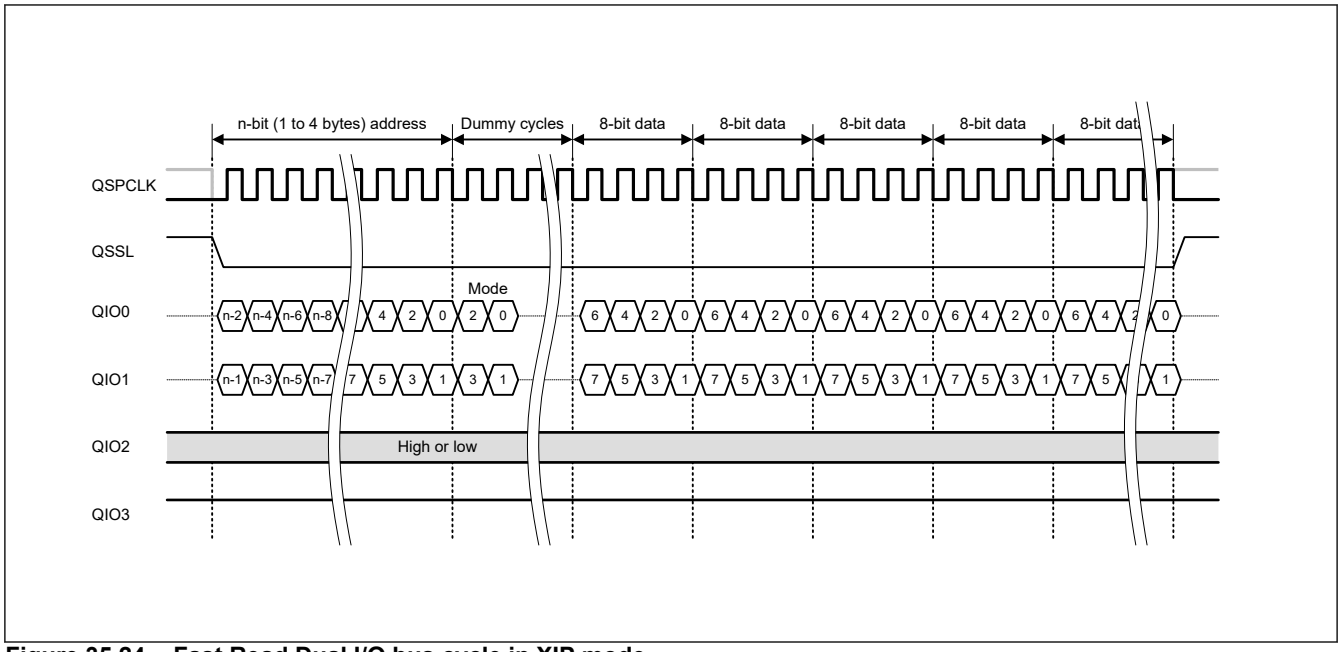

Figure 35.24 Fast Read Dual I/O bus cycle in XIP mode

Note: To use the Fast Read Dual I/O instruction, a serial flash memory that supports Fast Read Dual I/O transfers is required.

35.6.6 Fast Read Quad Output Instruction

The Fast Read Quad Output instruction is a read instruction that uses four signal lines to receive data. When the SPI bus cycle starts, the QSSL signal is asserted. The instruction code (0x6B or 0x6C) and an address with a width of 1 to 4 bytes, specified in the SFMAS[1:0] bits in the SFMSAC register, are output from the QIO0 pin. Next, a certain number of dummy cycles, specified in the SFMDN[3:0] bits in the SFMSMD register, are generated. Data is then received through the QIO0, QIO1, QIO2, and QIO3 pins.

The first two dummy cycles are used to select the XIP mode. When the XIP mode is selected, the same instruction used this time is applied to the next SPI bus cycle, and the instruction code is not output the next SPI bus cycle. For details on the XIP mode, see section 35.8. XIP Control.

Switching to Fast Read Quad Output is controlled in the SFMSMD register.

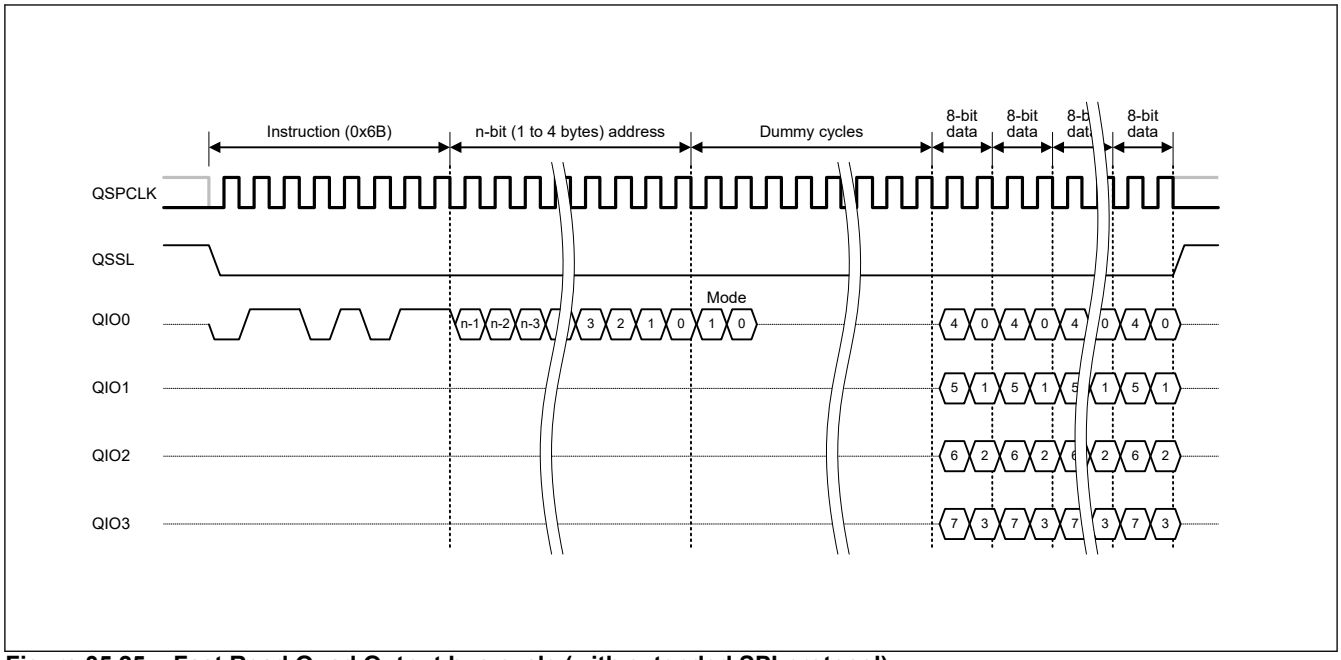

Figure 35.25 Fast Read Quad Output bus cycle (with extended SPI protocol)

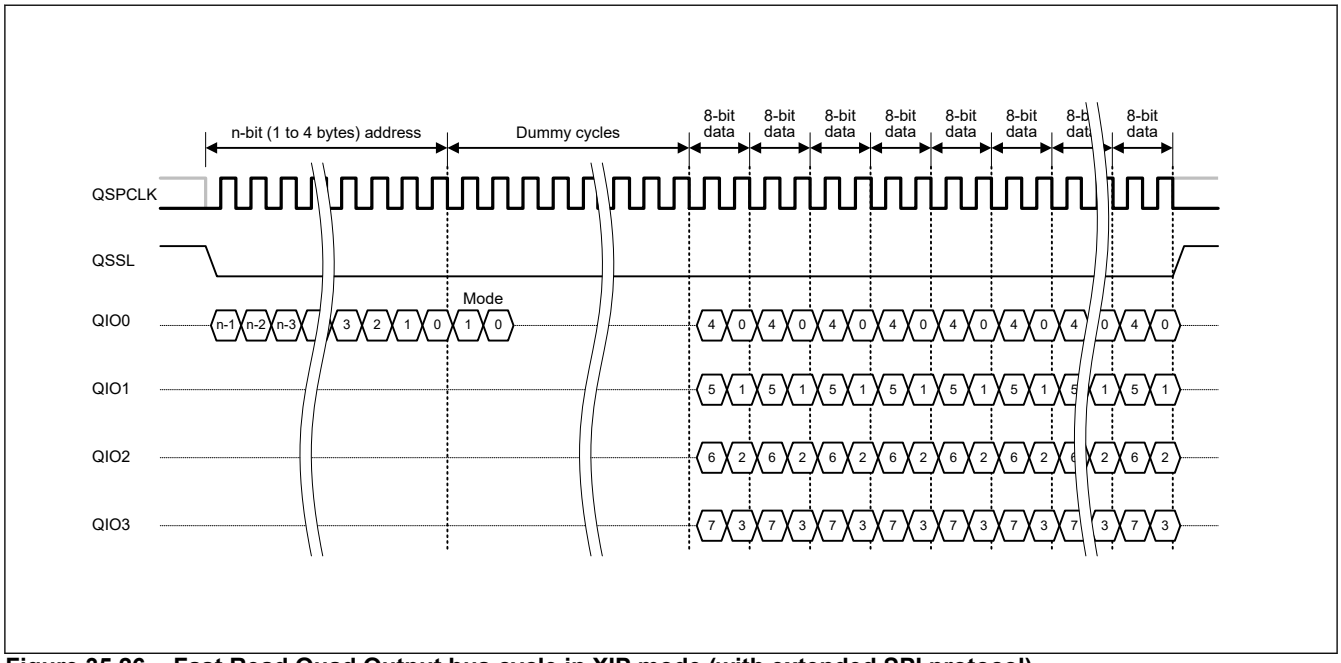

Figure 35.26 Fast Read Quad Output bus cycle in XIP mode (with extended SPI protocol)

Note: To use Fast Read Quad Output, a serial flash memory that supports Fast Read Quad Output transfer is required.

35.6.7 Fast Read Quad I/O Instruction

The Fast Read Quad I/O instruction is a read instruction that uses four signal lines to transmit an address and receive data. When the SPI bus cycle starts, the QSSL signal is asserted, and the instruction code (0xEB / 0xEC) is transmitted from QIO0 pin in the extended SPI protocol and from QIO0, QIO1, QIO2, and QIO3 pins in the Quad-SPI protocol. Next, an address with a width of 1 to 4 bytes, specified in the SFMAS[1:0] bits in the SFMSAC register, is transmitted through the QIO0, QIO1, QIO2, and QIO3 pins, and a certain number of dummy cycles, specified in the SFMDN[3:0] bits in the SFMSMD register, is generated. Data is then received through the QIO0, QIO1, QIO2, and QIO3 pins.

The first two dummy cycles are used to select the XIP mode. When the XIP mode is selected, the same instruction used this time is applied to the next SPI bus cycle, and the instruction code is not output the next SPI bus cycle. For details on the XIP mode, see section 35.8. XIP Control.

Switching to Fast Read Quad I/O is controlled in the SFMSMD register.

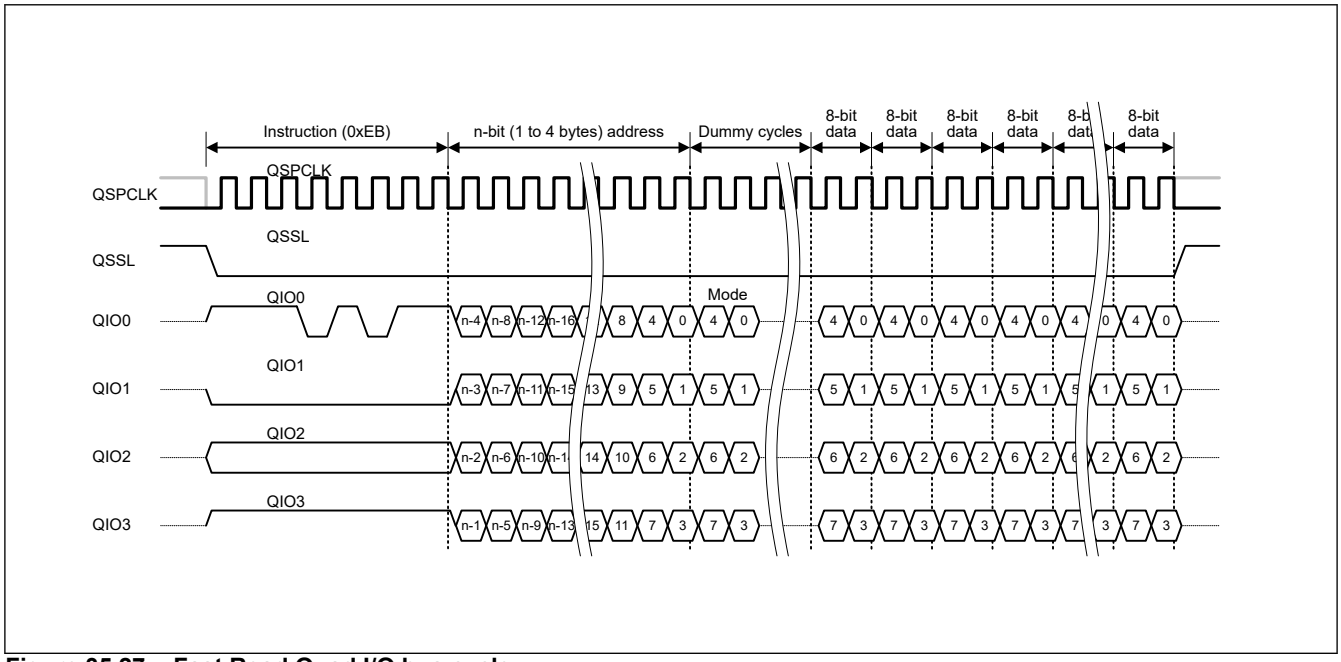

Figure 35.27 Fast Read Quad I/O bus cycle

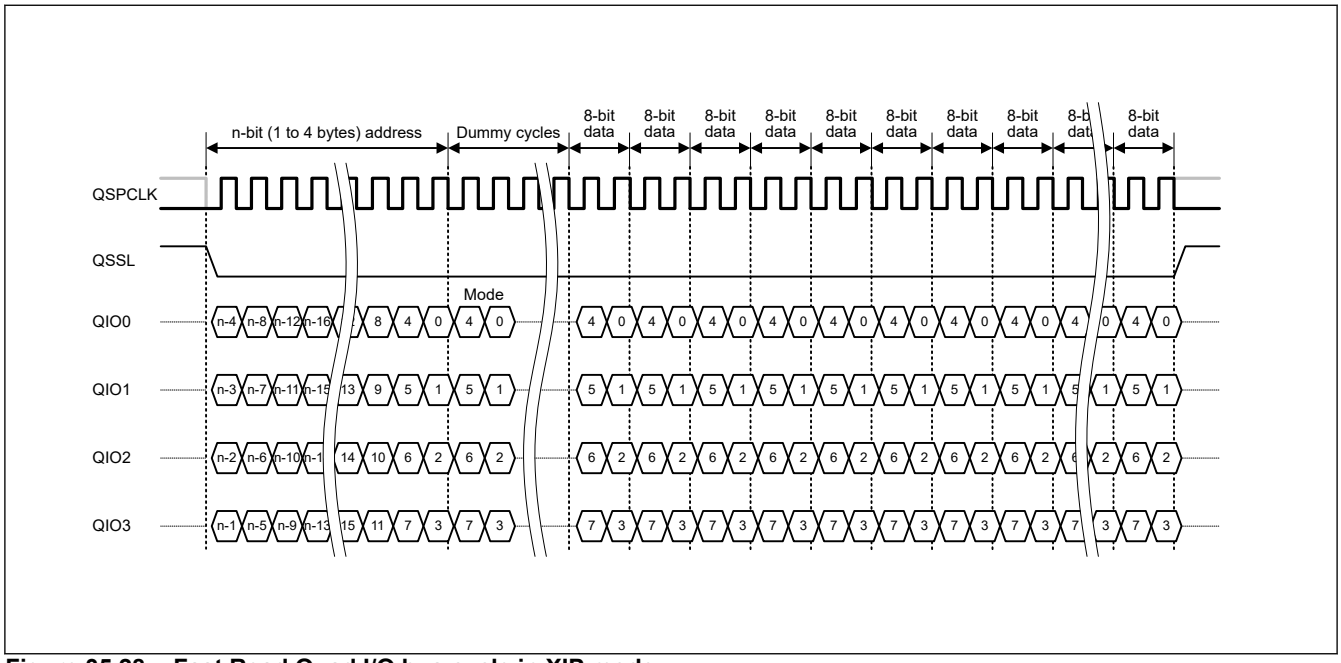

Figure 35.28 Fast Read Quad I/O bus cycle in XIP mode

Note: To use the Fast Read Quad I/O instruction, a serial flash memory that supports Fast Read Quad I/O transfers is required.

35.6.8 Enter 4-Byte Mode Instruction

The Enter 4-Byte Mode instruction sets the serial flash address width to 4 bytes. When the SPI bus cycle starts, the serial flash select signal is asserted, and the instruction code (0xB7) is output.

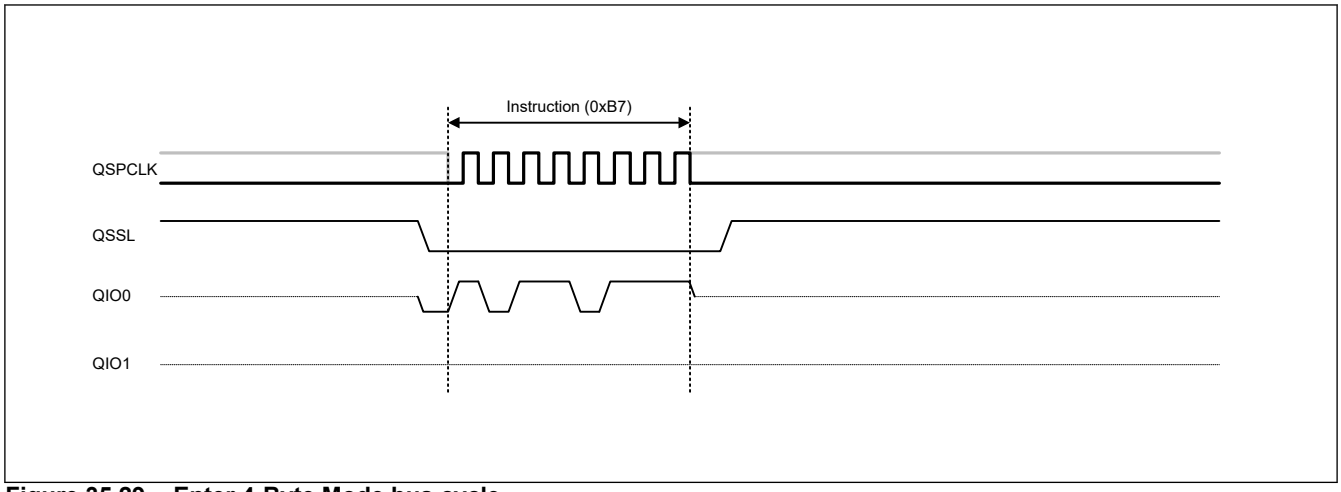

Figure 35.29 Enter 4-Byte Mode bus cycle

Note: The Enter 4-Byte Mode instruction is issued regardless of whether the serial flash is in 3- or 4-byte mode.

35.6.9 Exit 4-Byte Mode Instruction

The Exit 4-Byte Mode instruction sets the serial flash address width to 3 bytes. When the SPI bus cycle starts, the serial flash select signal is asserted, and the instruction code (0xE9) is output.

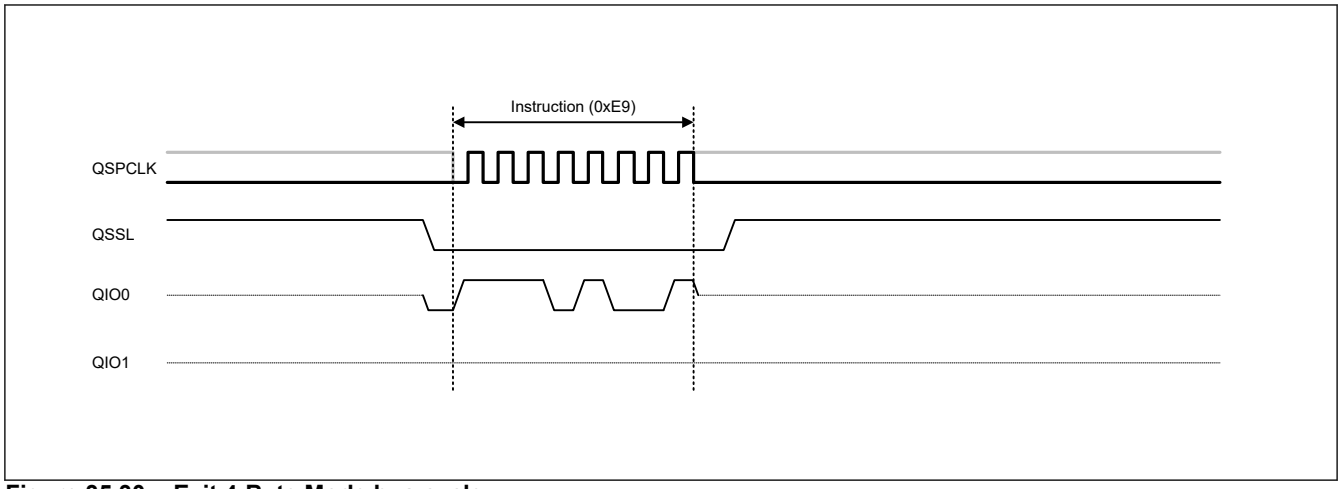

Figure 35.30 Exit 4-Byte Mode bus cycle

Note: The Exit 4-Byte Mode instruction is issued regardless of whether the serial flash is in 3- or 4-byte mode.

35.6.10 Write Enable Instruction

The Write Enable instruction enables changing of the serial flash address width. When the SPI bus cycle starts, the serial flash select signal is asserted, and the instruction code (0x06) is output.

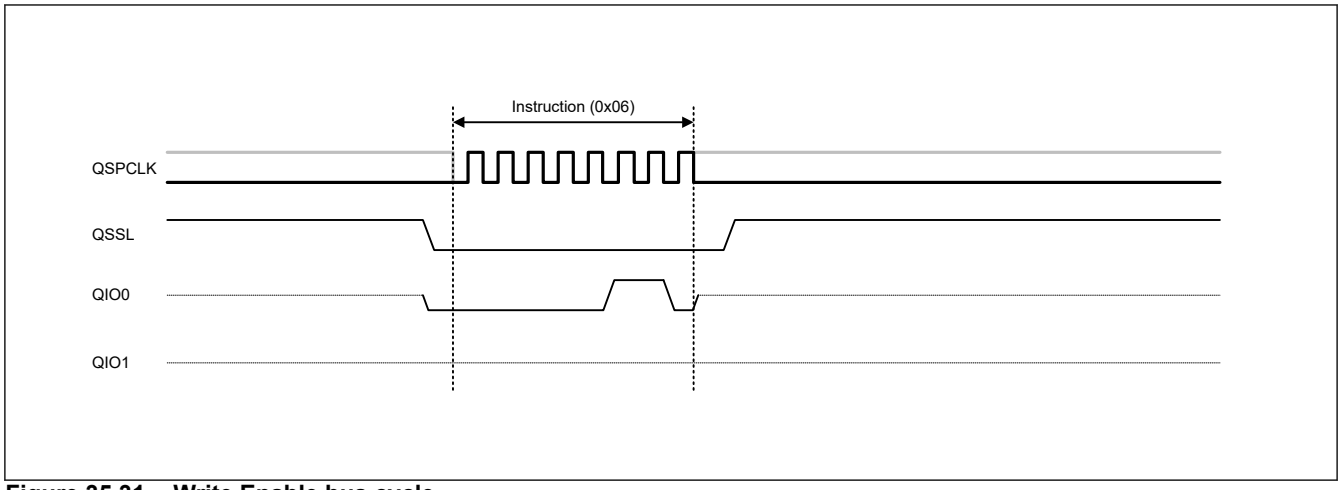

Figure 35.31 Write Enable bus cycle

35.7 SPI Bus Cycle Arrangement

35.7.1 Serial Flash Memory Read Based on Individual Conversion

ROM read bus cycles are individually converted to SPI bus cycles on a one-to-one basis. When a ROM read bus cycle is detected, the QSSL signal is asserted, and an SPI bus cycle starts. When the data receiving is finished from the serial flash memory, the QSSL signal is negated and the SPI bus cycle is complete.

When the next ROM read bus cycle is detected, the QSSL signal set by the SFMSSC.SFMSW[3: 0] bits is asserted again, then the next SPI bus cycle starts.

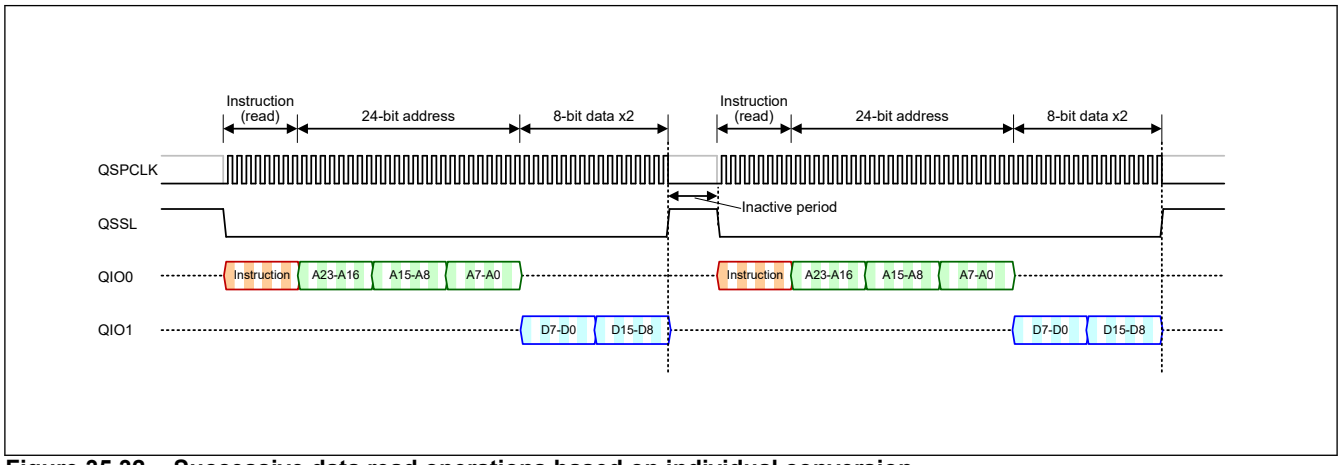

Figure 35.32 Successive data read operations based on individual conversion

35.7.2 Serial Flash Memory Read Using the Prefetch Function

In operations such as CPU instruction execution and block data transfer, data is often read in ascending order from contiguous addresses. Serial flash memory provides the ability to repeat data reception without reissuing an instruction code and address. To work with this function, the QSPI has a prefetch function for continuous data reception. However, if the CPU issues a flash read request for discontinuous flash addresses, SPI bus cycles are separated from each other, disabling the prefetch function.

To enable the prefetch function of the QSPI, set the SFMPFE bit in the SFMSMD register to 1. When the prefetch function is enabled, data is received continuously and stored in the prefetch buffer of the QSPI, without waiting for another flash read request. When the CPU issues a flash read request, an address check is made. If an address match is confirmed, the data in the buffer is passed to the CPU. If an address mismatch is detected, the data in the buffer is discarded and a new SPI bus cycle is issued.

The buffer for prefetching is 18 bytes long. When this buffer is full, the SPI bus cycle is ended. When the buffer data is read to create free space, a new SPI bus cycle is automatically started to resume prefetching.

The prefetch function allows for efficient transfer operations when data is read in ascending order from contiguous addresses, as in instruction fetch and block data transfer.

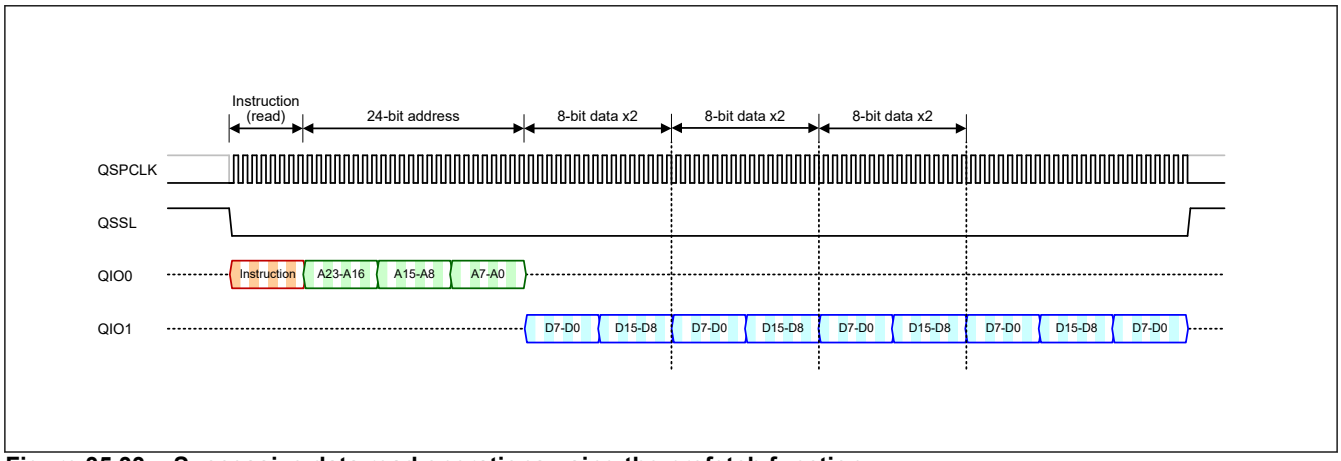

Figure 35.33 Successive data read operations using the prefetch function

35.7.3 Halt of Prefetching

If a serial flash memory read request for discontinuous addresses is issued when continuous data is being received by the prefetch function, the transfer of continuous data being made is halted and a new SPI bus cycle is started. Usually, such a halt of serial transfer occurs on data reception byte boundaries. However, if the SFMPAE bit in the SFMSMD register is set to 1, the halt can occur on locations other than byte boundaries.

35.7.4 Direct Specification of Prefetch Destination

When the prefetch function is enabled (SFMSMD.SFMPFE = 1), when writing to the QSPI window area occurs, after the writing is completed, prefetching starts from the write start address. Writes to serial flash memory cannot be performed.

Combining this function with described in section 35.7.5. Prefetch State Polling, can reduce the load on the internal bus when data is read from a low-speed serial flash memory.

Note: Writing to the QSPI window area with a data size of 2 bytes or more causes a hardfault.

35.7.5 Prefetch State Polling

A read by CPU from a low-speed serial flash memory causes the CPU system bus to be occupied until completion of the SPI reception bus cycle. The prefetch state polling function is provided to reduce this load.

The PFOFF bit in the Status Register (SFMSST) register indicates the state of the prefetch function, and the PFCNT[4:0] bits in the SFMSST register indicate the number of data bytes already prefetched. Place the polling program in the SRAM of this device.

```
//
// copy 1K byte (32bit x 256 word) data from serial flash to internal SRAM
//
unsigned long *sptr; // pointer for the serial flash
unsigned long *dptr; // pointer for the destination
int i;

SFMSMD |= 0x0040; // set SFMPFE bit to enable prefetch
*( (volatile unsigned char *) sptr ) = 0; // make the TAG valid to start prefetch

for ( i = 0 ; i < 256 ; i++ ){
while ( ( SFMSST & 0x00FF ) < 0x04 ){}; // waiting for 4-byte data to be received
*(dptr++) = *(sptr++);
}
```

Note: When executing a polling program, place the program outside of the serial flash memory. If the polling program is executed when the program is placed on the serial flash memory, the prefetch target frequently switches to an instruction code. This eliminates the effect of polling, and an infinite loop can result because the prefetch buffer is not filled.

35.7.6 SPI Bus Cycle Extension Function

If the SFMSE[1:0] bits in the SFMSMD register are set to a value other than 00b, the QSPI waits for the next flash read. At this time, the QSPCLK signal stops, the QSSL signal is kept active low even after data is obtained from the serial flash memory, and the SPI bus cycle is suspended.

If the address of the next flash read is contiguous in ascending order, the toggling of the QSPCLK signal is restarted to continue reception of subsequent data. If the address of the next flash read is not contiguous in ascending order, the QSSL signal is driven high once to end the SPI bus cycle being suspended. A new SPI bus cycle is then started.

When data is read intermittently from ascending order contiguous addresses, this function enables an efficient transfer operation to be performed by reducing the overhead for instruction code and address transmission.

The SPI bus cycle extension time is selectable in the SFMSE[1:0] bits in the SFMSMD register. When the specified extension time elapses, the QSSL signal returns to the high level to automatically end the SPI bus cycle being suspended. If the SFMSE[1:0] bits are set to 11b, QSSL is extended infinitely. This increases the power consumption of the serial flash memory.

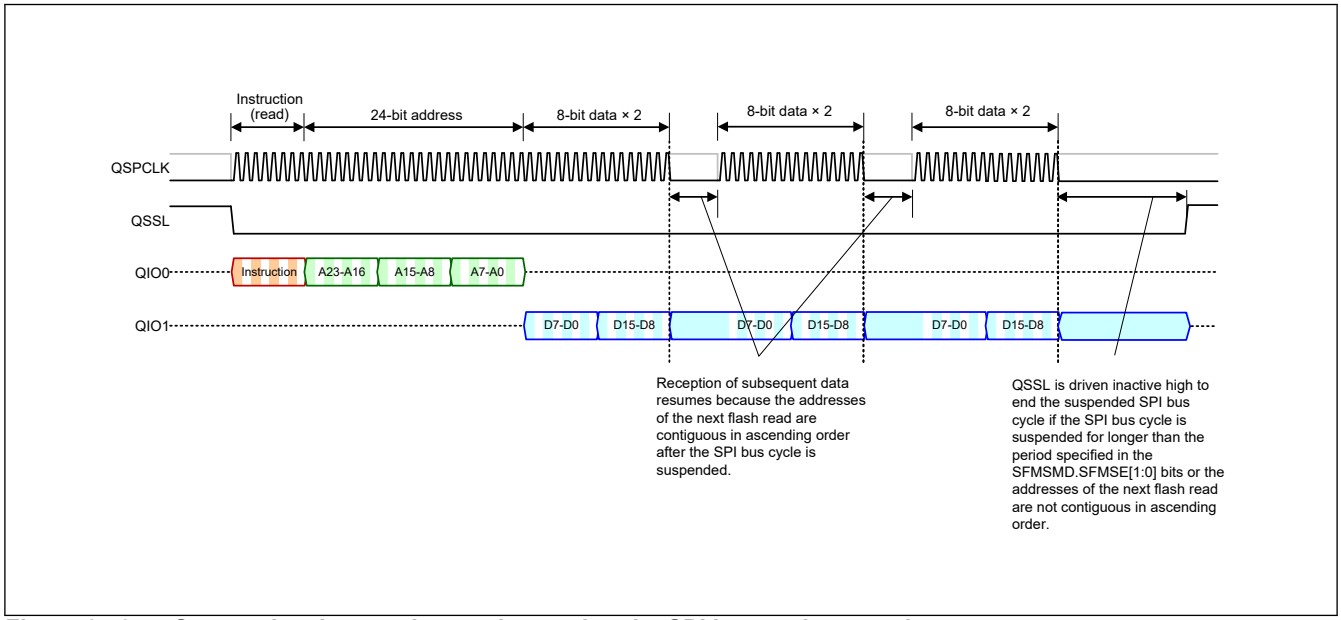

Figure 35.34 Successive data read operations using the SPI bus cycle extension

35.8 XIP Control

Some serial flash memory devices allow latencies to be reduced by skipping instruction code reception for flash reads. This instruction code skip function is selected in mode data received during the dummy cycle period of the previous serial bus cycle.

In the dummy cycle of the Fast Read instructions, the QSPI controls the XIP mode of the serial flash memory by using the serial data signal to send the mode data set in the SFMXD[7:0] bits in the SFMSDC register during the first 2 cycles, as shown in Figure 35.35.

The mode data to enable the XIP mode differs for each serial flash memory. Accordingly, set the appropriate mode data in the SFMXD[7:0] bits.

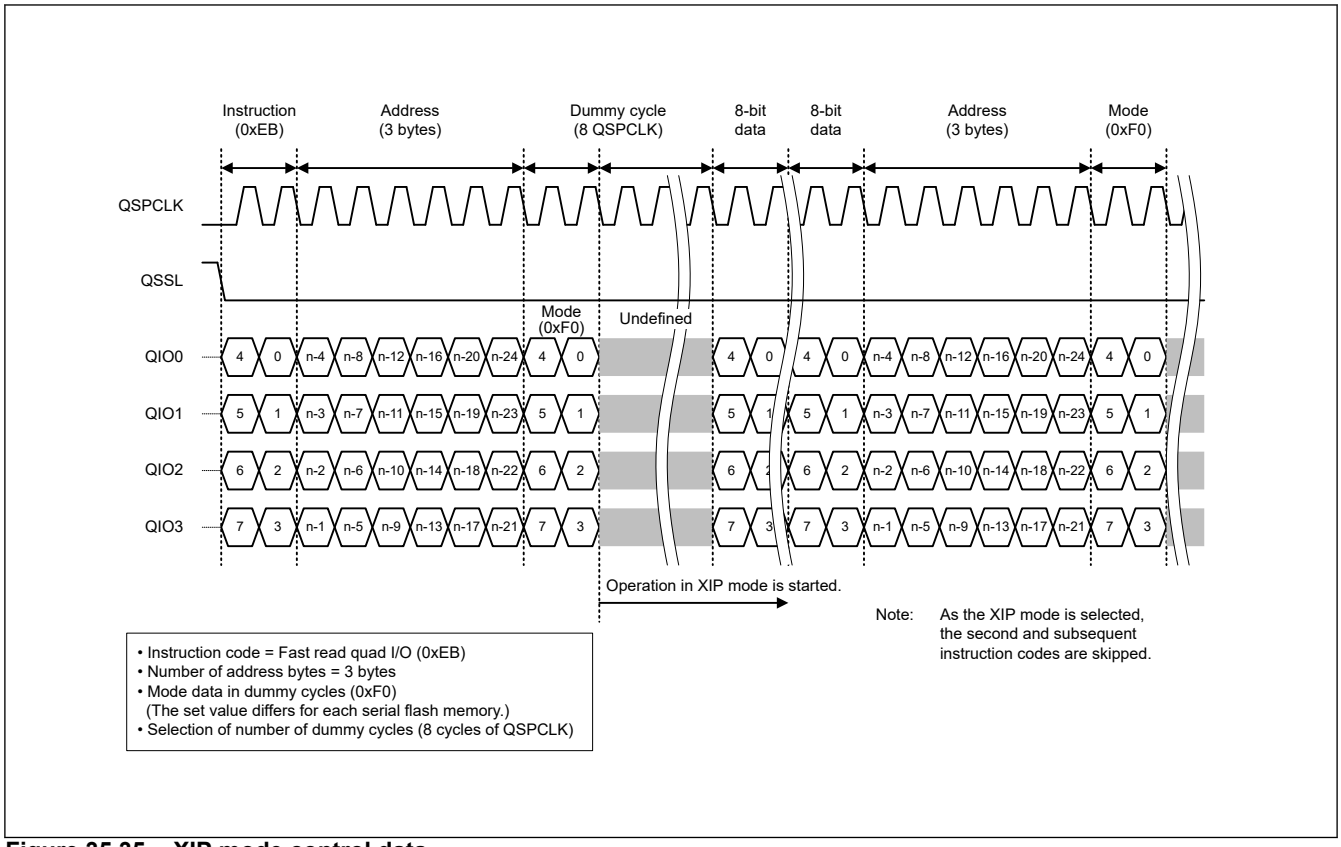

Figure 35.35 XIP mode control data

35.8.1 Setting XIP Mode

To start XIP mode in serial flash memory, perform the following register settings:

- Set a mode data value in the SFMXD[7:0] bits in the SFMSDC register.*1
- Set the SFMXEN bit in the SFMSDC register to 1.

In the dummy cycle of the first fast read cycle after these registers are set, the mode data value set in the register is transferred. From that point, XIP mode is enabled in the serial flash memory. To confirm the current XIP mode status, read the SFMXST flag in the SFMSDC register.

Note 1. In the SFMXD[7:0] bits in the SFMSDC register, set the mode data that follows the specifications for the actual serial flash memory.

The following figure shows an example of the XIP mode setting procedure.

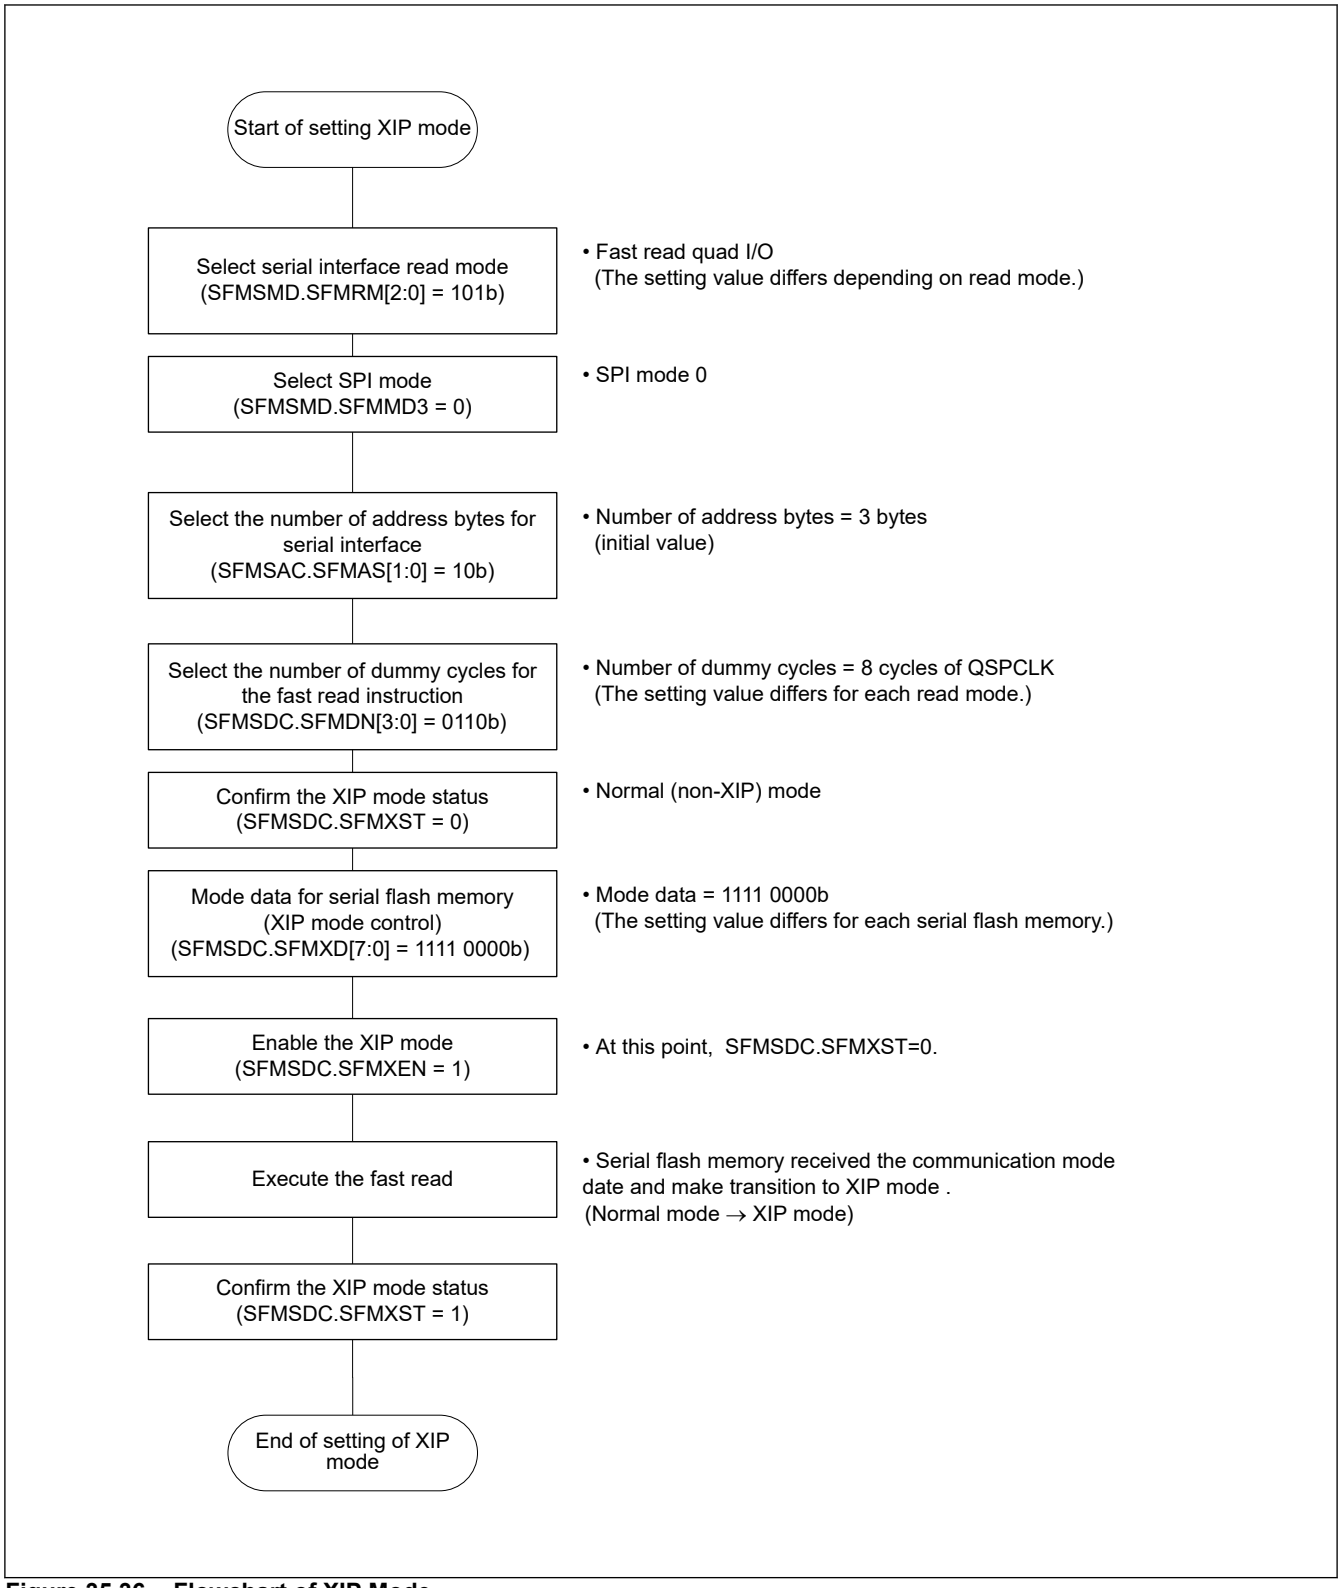

Figure 35.36 Flowchart of XIP Mode

35.8.2 Releasing the XIP Mode

To release XIP mode in serial flash memory, perform the following register setting:

- Set the mode data value to disable XIP mode in SFMSDC.SFMXD [7: 0] bits*1
- Set the SFMXEN bit in the SFMSDC register to 0.

In the dummy cycle of the first fast read cycle after this register is set, The mode data value that disables the XIP mode set in the register is transferred. From that point, XIP mode is disabled in the serial flash memory. To confirm the current XIP mode status, read the SFMXST flag in the SFMSDC register.

Note 1. Set the mode data in the SFMSDC.SFMXD [7: 0] bits according to the specifications of the serial flash memory.

Figure 35.37 shows an example of the procedure for releasing XIP mode.

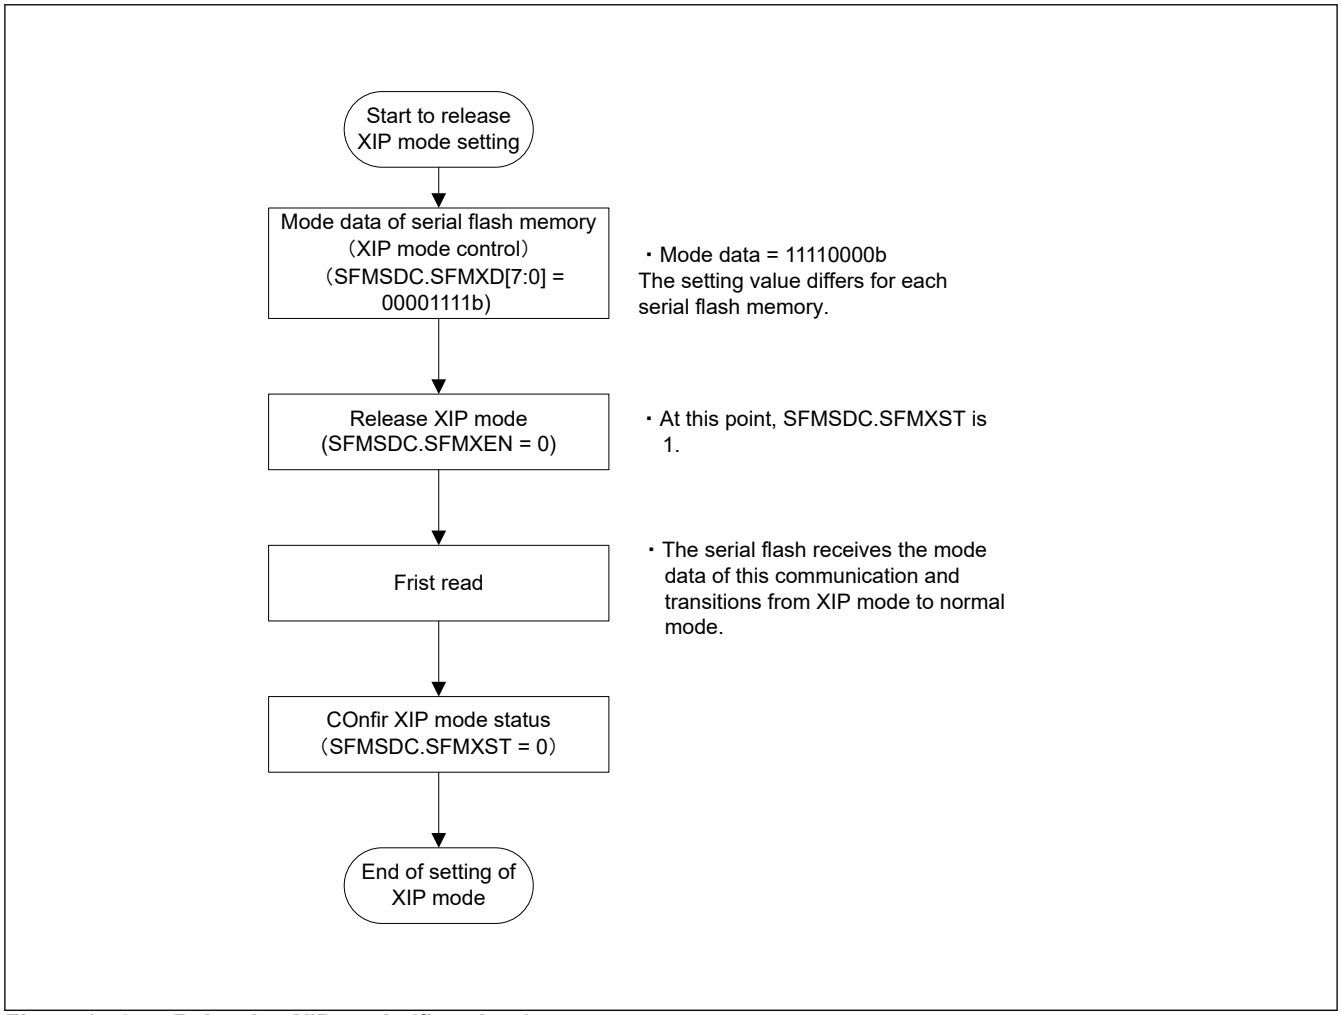

Figure 35.37 Releasing XIP mode (flowchart)

35.9 QIO2 and QIO3 Pin States

The QIO2 and QIO3 pin states depend on the serial interface read mode specified in the SFMRM[2:0] bits in the SFMSMD register.

Table 35.11 QIO2 and QIO3 pin states (1 of 2)

SFMSMD.SFMRM[2:0] bits	QIO2 pin state*1	QIO3 pin state*2	Remarks
111	Setting prohibited		
110			
101	Input or output as serial data signal (The pin is in the Hi-Z state when it is inactive.)	Input or output as serial data signal (The pin is in the Hi-Z state when it is inactive.)	Fast Read Quad I/O
100			Fast Read Quad Output

Table 35.11 QIO2 and QIO3 pin states (2 of 2)

SFMSMD.SFMRM[2:0] bits	QIO2 pin state*1	QIO3 pin state*2	Remarks
011	Output SFMWPL bit variable of the Port Control Register (SFMPMD) (initial value is low level)	Output high level	Fast Read Dual I/O
010			Fast Read Dual Output
001			Fast Read
000			Standard Read (Initial State)

Note 1. The serial flash memory can also use the QIO2 pin for the write protect (WP) function. The WP function prohibits writes to the status registers. (The function is available in mode other than Quad-SPI mode.)

Note 2. The serial flash memory can also use the QIO3 pin for the HOLD or RESET function.
The hold function places the I/O pin in an inactive state without deselecting the chip. (The function is available in mode other than Quad-SPI mode.)
The reset function resets the serial flash memory. (The function is available when the QSSL pin function is disabled or in a mode in which the QIO3 pin is not used.)

35.10 Direct Communication Mode

35.10.1 About Direct Communication

The QSPI can read the serial flash memory contents by automatically converting from reading the QSPI window area to SPI bus cycles. However, serial flash memory have many different functions in addition to memory data read, including ID information read, erase, programming, and status information read. There is no standardized instruction set for using these functions, and more functions are being added rapidly by different vendors to different devices. Therefore, to support these functions, the software can create any required SPI bus cycle by communicating directly with serial flash memory.

35.10.2 Using Direct Communication Mode

To communicate directly with serial flash memory, transition to direct communication mode by setting the DCOM bit in the Communication Mode Control Register (SFMCMD) register to 1. While direct communications mode is selected, the read operation to the serial flash memory by the QSPI window is invalid.

Note: If the QSPI is set to the XIP mode, you must terminate the XIP mode before starting direct communication mode.

35.10.3 Generating the SPI Bus Cycle during Direct Communication

The SPI bus cycle in direct communications starts on the first access to the SFMCOM register, and after a series of input / output operations are executed via the SFMCOM register, the bus cycle ends when 1 is written to the SFMCMD register. At that point, a write to the SFMCOM port is converted to a one-byte transmission to the SPI bus, and a read from the SFMCOM register is converted to a one-byte reception from the SPI bus.

During the period from the first access to the SFMCOM register to the last write operation to the SFMCMD register, the QSSL signal is held active to notify the serial flash memory that a series of SPI bus cycles is in progress.

Note: In direct communication mode, all writes to registers other than SFMCMD and SFMCOM (including SFMSMD, SFMSSC, SFMSKC, SFMSST, SFMCST, SFMSIC, SFMSAC, SFMSDC, SFMSPC, and SFMPMD) are disabled.

Figure 35.38 to Figure 35.40 show direct communication program examples, and Figure 35.41 shows ID read direct communication timing examples.

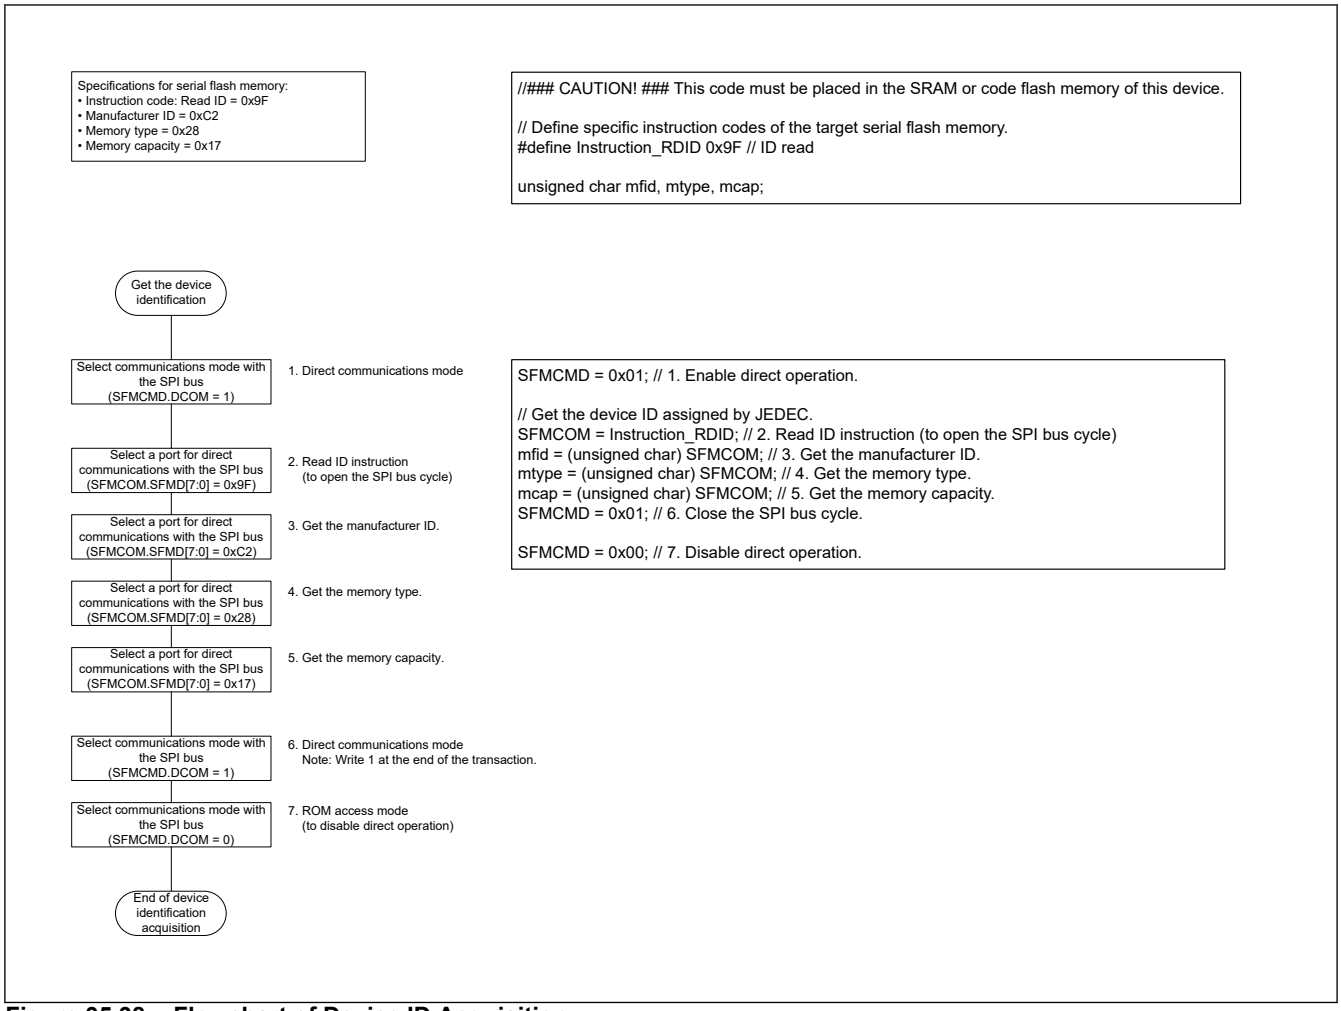

Figure 35.38 Flowchart of Device ID Acquisition

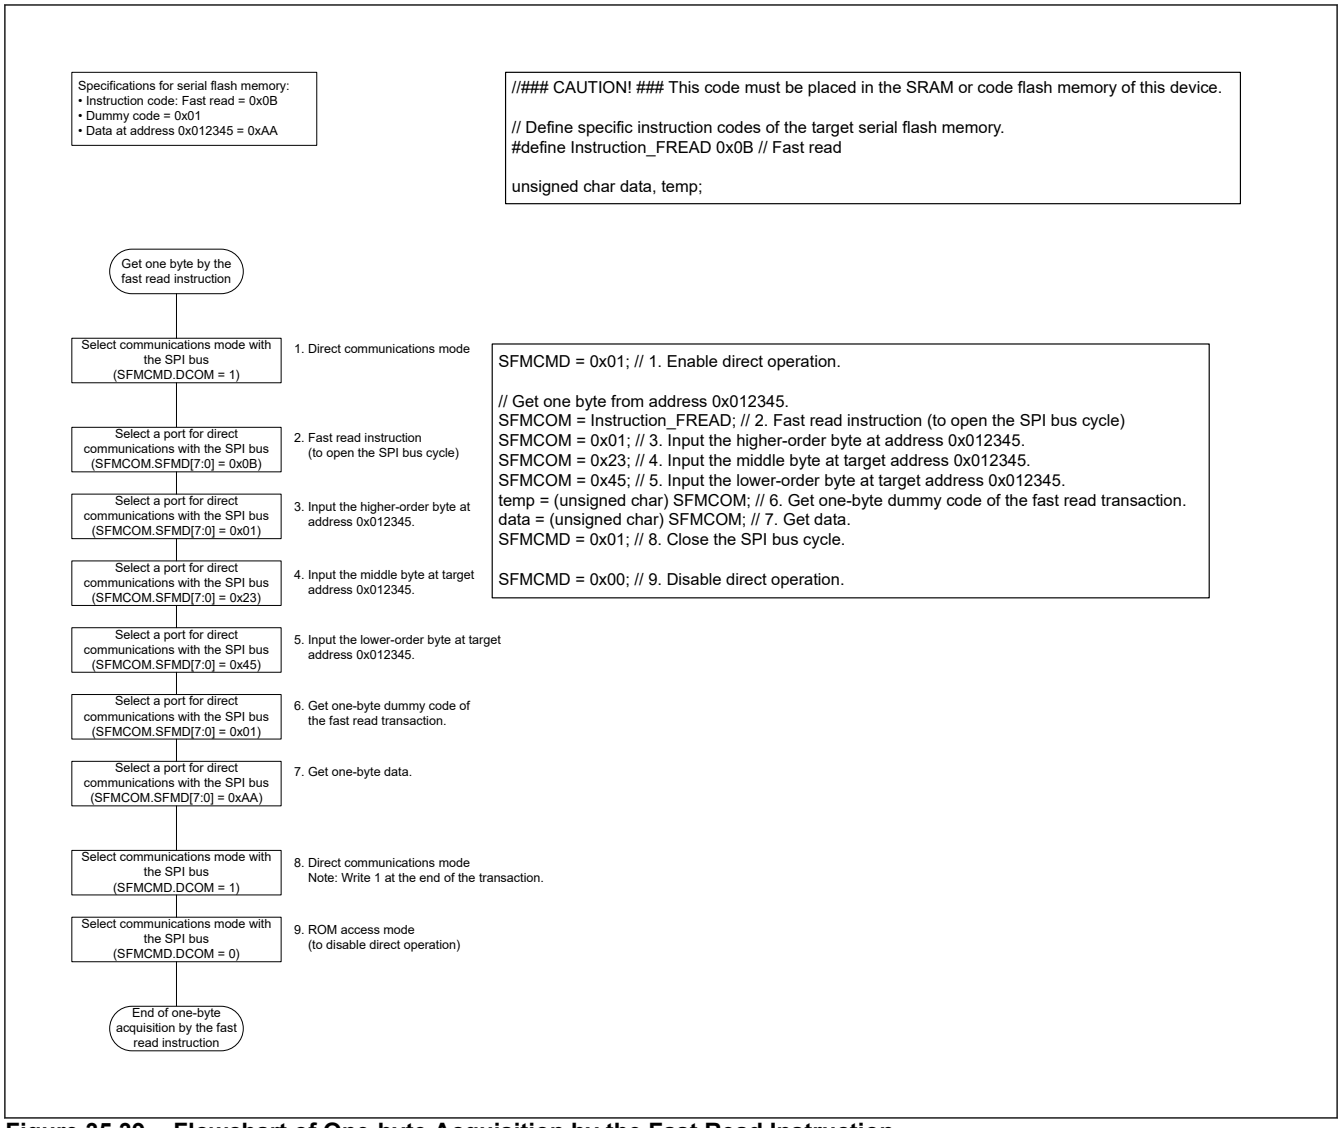

Figure 35.39 Flowchart of One-byte Acquisition by the Fast Read Instruction

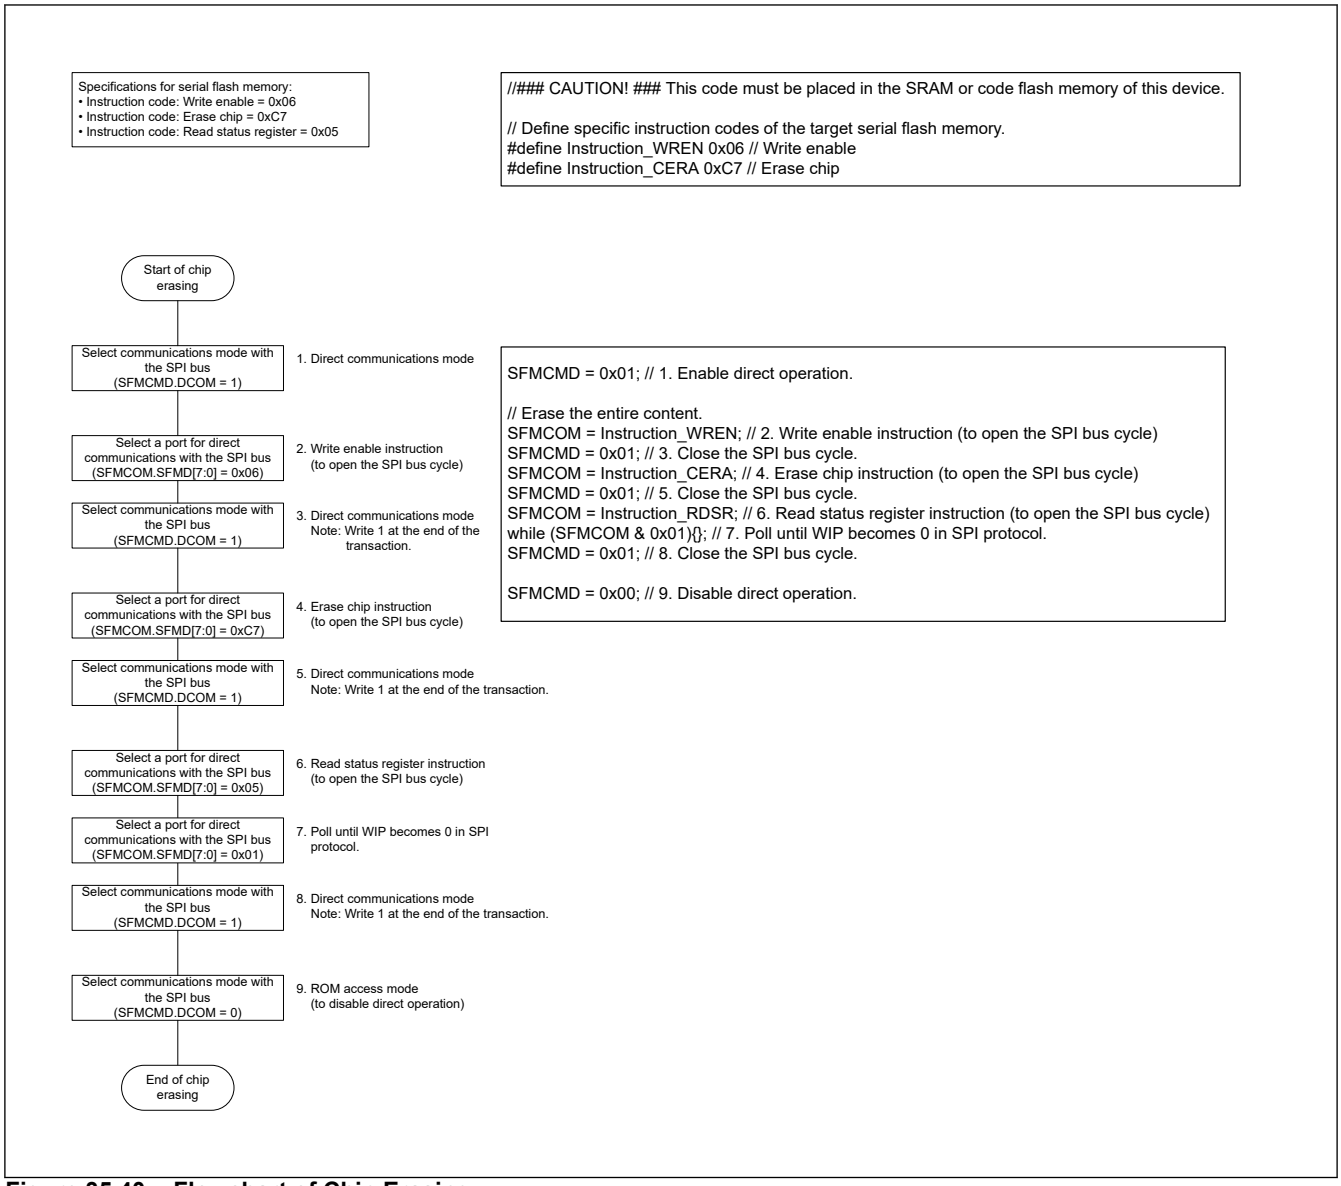

Figure 35.40 Flowchart of Chip Erasing

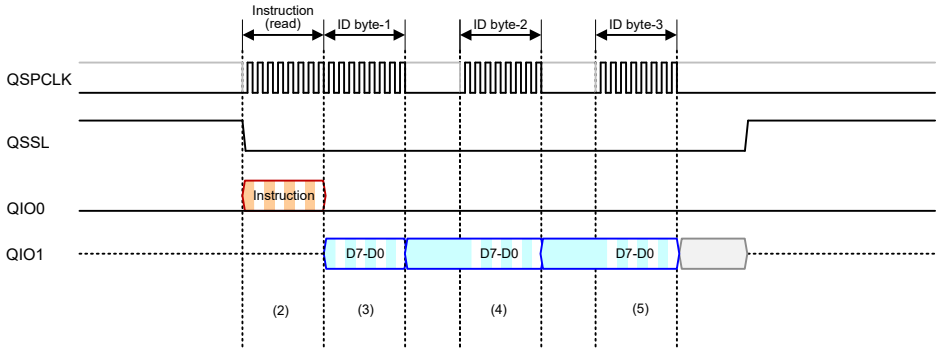

Note: (1) SFMCMD = 0x01; // Enable direct operation. Get the device ID assigned by JEDEC.
(2) SFMCOM = Instruction_RDID; // Read ID instruction (to open the transaction)
(3) mfid = (unsigned char) SFMCOM; // Get the manufacturer ID from ID byte 1.
(4) mtype = (unsigned char) SFMCOM; // Get the memory type from ID byte 2.
(5) mcap = (unsigned char) SFMCOM; // Get the memory capacity from ID byte 3.
(6) SFMCMD = 0x01; // Close the transaction.
(7) SFMCMD = 0x00; // Disable direct operation.

The timings (1), (6) and (7) for enabling or disabling direct communications mode are omitted in the figure.

Figure 35.41 Example of direct communication timing for ID read

Note: When the Single SPI Protocol, Extended SPI Protocol is used in direct communication mode, the standard Read or Fast Read instruction must be used to reference the contents of the serial flash memory. The QSPI does not support Fast Read Dual Output, Fast Read Dual I/O, Fast Read Quad Output, or Fast Read Quad I/O transfers in this configuration. When these Fast Read operations are required, use ROM access memory.

35.11 Interrupts

When ROM read access is detected in direct communication mode, the SFMCST.EROMR flag is set to 1 and QSPI generates an interrupt request. Interrupt requests are retained until the EROMR flag is cleared by a 0 write. For details, see section 13, Interrupt Controller Unit (ICU).

35.12 Usage Note

35.12.1 Settings for the Module-Stop Function

QSPI operation can be disabled or enabled using Module Stop Control Register B (MSTPCRB). The QSPI is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

35.12.2 Procedure for Changing Settings in Multiple Control Registers

The settings of the QSPI control registers can be modified dynamically during system operation. However, when the settings of multiple control registers are changed sequentially, an SPI bus cycle might occur before all of the registers are updated. The register setting sequence must be designed so that the SPI bus timing specifications are satisfied at all stages of register setting modification.

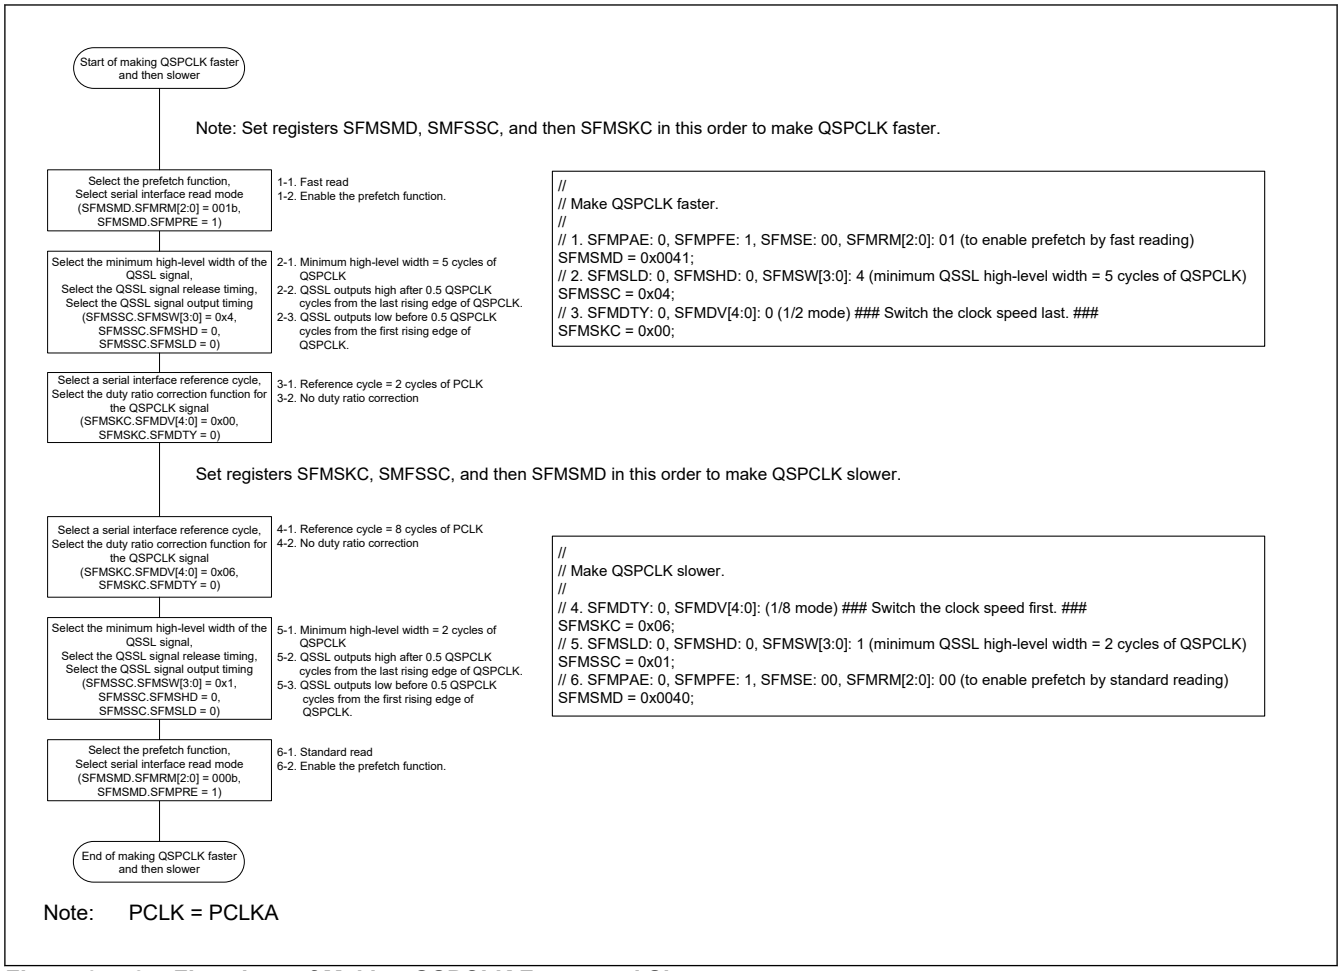

Figure 35.42 Flowchart of Making QSPCLK Faster and Slower

36. Octa Serial Peripheral Interface (OSPI)

The Octa Serial Peripheral Interface (OSPI) module is a memory controller for connecting OctaFlash™ and OctaRAM™.

The OSPI is compliant with JEDEC standard JESD251, Profile 1.0.

Note: OctaFlash™ and OctaRAM™ are trademarks of Macronix International Co., Ltd.

36.1 Overview

36.1.1 Features

- Macronix Serial Multi I/O (MXSMIO®) Octa Peripheral Interface (OPI) for high-end consumer applications is supported.
- Flash device compliant with JEDEC standard JESD251, Profile 1.0 is supported.
- One each of an OctaFlash device and an OctaRAM device compliant with the OPI specifications are connectable.
- A chip select signal is assigned to each memory device (OM_CS0: OctaRAM; OM_CS1: OctaFlash).*1
- Supported device interfaces
  - SPI: Serial peripheral interface (OctaFlash, SPI mode)
  - SOPI: Single Octa I/O (8 bits) (OctaFlash, single data rate)
  - DOPI: Double Octa I/O (8 bits) (OctaFlash and OctaRAM, double data rate)
- 3-byte and 4-byte OctaFlash address commands are supported.
- 4-byte OctaRAM address commands are supported.
- The read-while-write (RWW) operation is supported.
- 1LC and 2LC (latency count) OctaRAM devices are supported.
- The error corrected signal (ECS) is available, and ECC errors can be detected (for OctaFlash only).
- Interrupt source: Error interrupts.
- Fastboot mode is not supported.
- Direct access (memory-mapped reading and writing) to memory devices in separate flash and RAM address spaces is supported.

Note 1. Only one of the memory devices can operate (be read or written to) at a time.

36.1.2 Block diagram

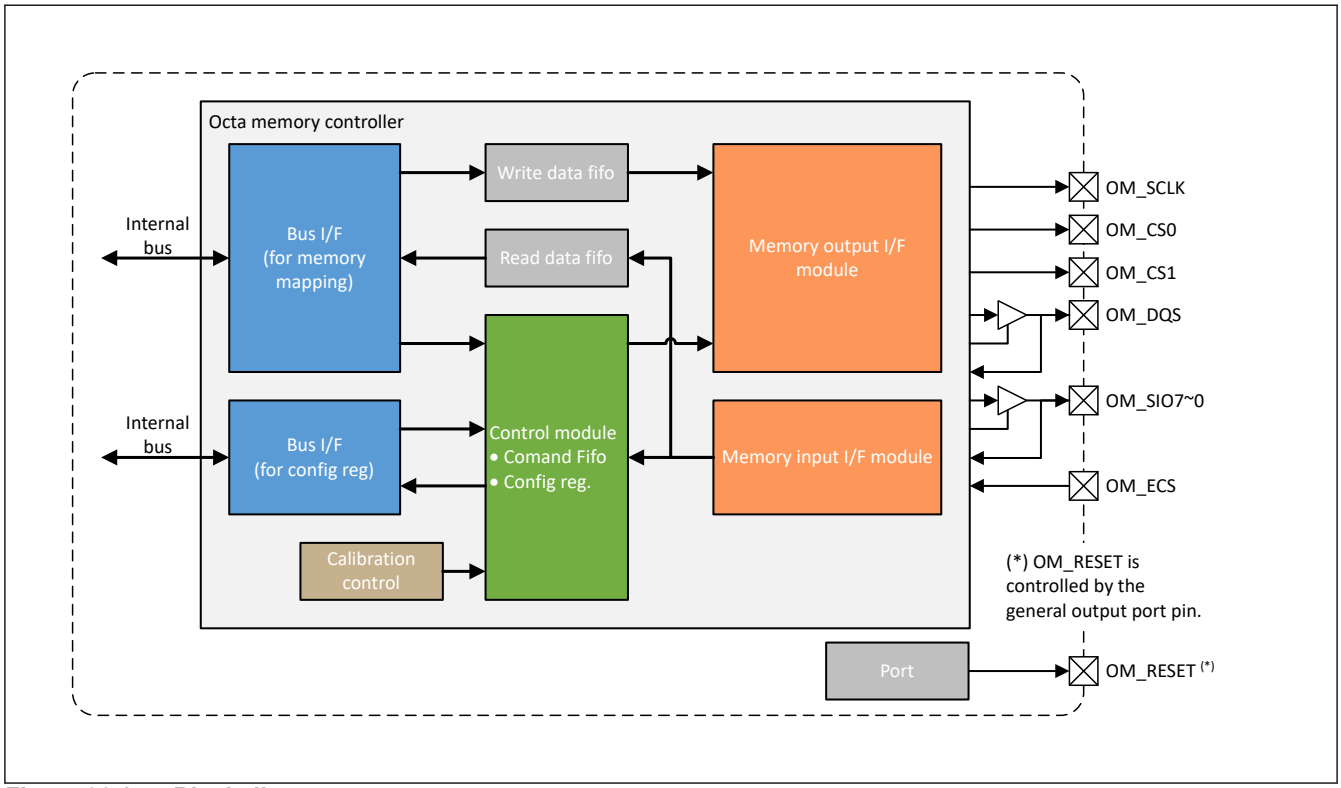

Figure 36.1 Block diagram

36.1.3 Input/Output Pins

Table 36.1 shows the pin configuration to connect chip pins.

Table 36.1 Configuration of Memory Controller Pins to connect Chip pins

Pin name	I/O	Function
OM_SCLK	Output	Clock output (OCTACLK divided by 2)
OM_CS0	Output	Chip select signal for an OctaRAM device
OM_CS1	Output	Chip select signal for an OctaFlash device
OM_DQS	I/O	Read data strobe/write data mask signal
OM_SIO7 to OM_SIO0	I/O	Data input/output
OM_RESET	Output	Reset signal for both OctaFlash and OctaRAM devices
OM_ECS	Input	ECC error detection signal from the external memory

36.1.4 Device Interface

The device interface is compatible with OctaFlash/OctaRAM interface.

When reading data from memory or programming data to memory, the bit order is changed in accordance with the I/O mode. The bit order is shown below:

Table 36.2 Bit order in accordance with I/O mode (1 of 2)

I/O mode	Bit order (MSB)
Read data from device	
1 I/O (SPI)	OM_SIO1 input
8 I/O (SOPI)	OM_SIO7 to OM_SIO0 input

Table 36.2 Bit order in accordance with I/O mode (2 of 2)

I/O mode	Bit order (MSB)
8 I/O (DOPI)	OM_SIO7 to OM_SIO0 input. Order of data {D1, D0}, {D3, D2}, … or {D0, D1}, {D2, D3}, …, according to setting for memory to be connected.
Program/Write data to device	
1 I/O (SPI)	OM_SIO0 output
8 I/O (SOPI)	OM_SIO7 to OM_SIO0 output
8 I/O (DOPI)	OM_SIO7 to OM_SIO0 output. Order of data {D1, D0}, {D3, D2}, …or {D0, D1}, {D2, D3}, …, according to setting for memory to be connected.

36.2 Register Descriptions

Table 36.3 shows the register configuration.

There are memory-map and configuration modes for accessing the OctaFlash/RAM memory.

In the memory-map mode, the OSPI automatically sends the command for read or write. In the configuration mode, the controller sends commands and data.

Table 36.3 OSPI register configuration

Register Name	Symbol	R/W	Initial Value	Address	Access Size
Device command register	DCR	R/W	0x00000000	0x400A_6000	32
Device address register	DAR	R/W	0x00000000	0x400A_6004	32

36.2.1 DCR : Device Command Register

Base address: OSPI = 0x400A_6000

Offset address: 0x00

Bit position:	31																15							8	7							0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DVCMD1[7:0]								DVCMD0[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	DVCMD0[7:0]	Device Command data Sets the data to be transferred as a command to the device. If DCSR.CMDLEN[2:0] = 1, the controller will send DCR[7:0] as the 1st byte to memory. If DCSR.CMDLEN[2:0] = 2, the controller will send DCR[7:0] as the 2nd byte to memory.	R/W
15:8	DVCMD1[7:0]	Device Command data Sets the data to be transferred as a command to the device. If DCSR.CMDLEN[2:0] = 2, the controller will send DCR[15:8] as the 1st byte to memory	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

DCR sets the device commands for controller operation.

36.2.2 DAR : Device Address Register

Base address: OSPI = 0x400A_6000

Offset address: 0x04

Bit position:	31							24	23							16	15							8	7							0
Bit field:	DVAD3[7:0]								DVAD2[7:0]								DVAD1[7:0]								DVAD0[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	DVAD0[7:0]	Device Address data 0 Set the device address data. When DCSR.ADLEN[2:0] = 3, set as the third byte. When DCSR.ADLEN[2:0] = 4, set as the fourth byte.	R/W
15:8	DVAD1[7:0]	Device Address data 1 Set the device address data. When DCSR.ADLEN[2:0] = 3, set as the second byte. When DCSR.ADLEN[2:0] = 4, set as the third byte.	R/W
23:16	DVAD2[7:0]	Device Address data 2 Set the device address data. When DCSR.ADLEN[2:0] = 3, set as the first byte. When DCSR.ADLEN[2:0] = 4, set as the second byte.	R/W
31:24	DVAD3[7:0]	Device Address data 3 Set the device address data. When DCSR.ADLEN[2:0] = 4 only, set as the first byte.	R/W

DAR sets the device address for controller operation.

36.2.3 DCSR : Device Command Setting Register

Base address: OSPI = 0x400A_6000

Offset address: 0x08

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	PREN	ACDA	DOPI	ADLEN[2:0]			DAOR	CMDLEN[2:0]			ACDV	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	DMLEN[7:0]								DALEN[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	DALEN[7:0]	Transfer data length setting Sets the length of data to be transferred in bytes. Set a value less than 0x5. When [7:0] is 0, there are no transmission data to memory and reception data from memory.	R/W
15:8	DMLEN[7:0]	Dummy cycle setting Sets the length of dummy cycle in OM_SCLK units.	R/W
18:16	—	These bits are read as 0. The write value should be 0.	R
19	ACDV	Access Device setting Sets the device to be accessed. 0: Send commands to device 0. 1: Send commands to device 1.	R/W
22:20	CMDLEN[2:0]	Transfer command length setting Sets the length of the command to be transferred in bytes.	R/W
23	DAOR	Data order setting Sets the byte order of data during read and write operations. 0: byte0, byte1, byte2, byte3 1: byte1, byte0, byte3, byte2	R/W
26:24	ADLEN[2:0]	Transfer address length setting Sets the length of the address to be transferred in bytes.	R/W
27	DOPI	DOPI single byte setting Sets the amount of data transfer per one clock cycle in DOPI mode. 0: Each cycle has two bytes data. (normal DOPI mode) 1: Each cycle has one byte data. (The byte data changes at the rising edge of the clock and does not change at the falling edge of the clock.)	R/W
28	ACDA	Data Access Control Set data access or register access 1. the address bit0 will be forced to 0 in DOPI mode. 2. If DAR[0] of the lead type command is 1, byte 0 from the device will be dropped in DOPI mode. 3. The AXI read data will be arranged according to the DAR. For example: When DAR[1:0] = 1, the first valid data is stored in RDATA[15:8]. 4. The AXI write data is used according to the DAR in DOPI mode. For example: If the target device is Flash Memory and DAR[1:0] = 1, the first byte sent to the flash memory is forced to 0xff. If the target device is RAM and DAR[1: 0] = 1, the first byte sent to RAM is masked by DQSM. 5. When the target device is RAM, the address sent to the memory changes according to RAM specification. 0: Register access Do not arrange the transfer data. 1: Data access	R/W
29	PREN	Preamble bit enable for OctaRAM 0: No check preamble bit from OctaRAM 1: Check preamble bit from OctaRAM	R/W

Bit	Symbol	Function	R/W
31:30	—	These bits are read as 0. The write value should be 0.	R

DCSR sets device commands.

36.2.4 DSR0 : Device Size Register 0

Base address: OSPI = 0x400A_6000

Offset address: 0x0C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	DV0TYP[1:0]		DV0SZ[29:16]													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	DV0SZ[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
29:0	DV0SZ[29:0]	Device 0 size setting Set a 30-bit value for the size of memory connected as device 0. Settings larger than 8 MB for OctaRAM is prohibited. Example 0x00800000: 8-MB memory	R/W
31:30	DV0TYP[1:0]	Device 0 type setting 0 0: Flash on device 0 0 1: RAM on device 0 1 0: No connection on device 0 1 1: Forbidden	R/W

DSR0 specifies the type of memory to be accessed as device 0 and the size of the RAM. It is recommended that device 0 is set to RAM because the address space of CS1 is larger than CS0.

36.2.5 DSR1 : Device Size Register 1

Base address: OSPI = 0x400A_6000

Offset address: 0x10

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	DV1TYP[1:0]		DV1SZ[29:16]													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	DV1SZ[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
29:0	DV1SZ[29:0]	Device 1 size setting Set a 30-bit value for the size of memory connected as device 1. Examples: 0x10000000: 256-MB memory 0x08000000: 128-MB memory 0x01000000: 16-MB memory 0x00800000: 8-MB memory	R/W

Bit	Symbol	Function	R/W
31:30	DV1TYP[1:0]	Device 1 type setting 0 0: Flash on device 1 0 1: RAM on device 1 1 0: No connection on device 1 1 1: Forbidden	R/W

DSR1 specifies the type of memory to be accessed as device 1 and the size of the flash memory. It is recommended that device 1 is set to flash because the address space of CS1 is larger than that of CS0.

36.2.6 MDTR : Memory Delay Trim Register

Base address: OSPI = 0x400A_6000

Offset address: 0x14

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	DQSEDOPI[3:0]				DV1DEL[7:0]							
Value after reset:	0	0	0	0	0	1	1	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	DQSESOPI[3:0]				DQSERAM[3:0]				DV0DEL[7:0]							
Value after reset:	1	0	0	1	0	1	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	DV0DEL[7:0]	Device 0 delay setting These bits specify the delay cycles to be inserted on the input strobe signal (OM_DQS) to adjust the timing for latching data during read access to device 0 in the SOPI or DOPI mode.	R/W
11:8	DQSERAM[3:0]	OM_DQS enable counter Setting for DOPI mode [RAM].	R/W
15:12	DQSESOPI[3:0]	OM_DQS enable counter Setting for SOPI mode [Flash].	R/W
23:16	DV1DEL[7:0]	Device 1 delay setting These bits specify the delay cycles to be inserted on the input strobe signal (OM_DQS) to adjust the timing for latching data during read access to device 1 in the SOPI or DOPI mode.	R/W
27:24	DQSEDOPI[3:0]	OM_DQS enable counter Setting for DOPI mode [Flash].	R/W
31:28	—	These bits are read as 0. The write value should be 0.	R/W

MDTR sets the timing adjustment of memory access.

For the information about the auto-calibration, see section 36.3. Operation.

During a read operation with the OM_DQS clock input (in the SOPI or DOPI mode), the OM_DQS clock transitions from the high-impedance state to the input state (for receiving a value of 0 from the external device) after the command and address phases are completed. To obtain valid data, adjust the DQS enable counter and delay cycles.

OM_DQS enable counter setting (OM_SCLK units)

0000: 1 clock cycle

0001: 2 clock cycles

0010: 3 clock cycles

0011: 4 clock cycles

⋮

1111: 16 clock cycles

OM_DQS enable counter setting examples

Table 36.4 OctaRAM

Number of dummy cycles	DOPI Pre-cycle On	DOPI Pre-cycle Off
3	3 to 4	3 to 5
4	3 to 5	3 to 6
5	3 to 6	3 to 7
6	3 to 7	3 to 8
7	3 to 8	3 to 9
8	3 to 9	3 to 10

Table 36.5 OctaFlash

Number of dummy cycles*1	SOPI Pre-cycle On	DOPI Pre-cycle On	DOPI Pre-cycle Off
4	9	6	6 to 7
6	9 to 11	6 to 8	6 to 9
8	9 to 13	6 to 10	6 to 11
10	9 to 15	6 to 12	6 to 13
12	9 to 15	6 to 14	6 to 15
14	9 to 15	6 to 15	6 to 15
16	9 to 15	6 to 15	6 to 15
18	9 to 15	6 to 15	6 to 15
20	9 to 15	6 to 15	6 to 15

Note 1. Some read register commands of OctaFlash is always 4 cycles regardless of dummy cycle setting of configuration register.

These two tables list cases of DQS delay.

If DQS delay cycle is not within this range, see section 36.6. OM_DQS Enable Counter, and recalculate the correct range.

36.2.7 ACTR : Auto-Calibration Timer Register

Base address: OSPI = 0x400A_6000

Offset address: 0x18

Bit position:	31																												0
Bit field:	CTP[31:0]																												
Value after reset:	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	CTP[31:0]	Automatic calibration cycle time setting Sets performing cycle for the automatic calibration with 32 bits. Automatic calibration cycle time (ns) = CTP[31:0] × OM_SCLK / 2 When automatic calibration is enabled (CDSR.ACMODE[1:0] = 0x1) and the value of the internal timer is equal to that of this register, automatic calibration will start.	R/W

The ACTR register is a register that sets the cycle at which automatic calibration is executed.

36.2.8 ACAR0 : Auto-Calibration Address Register 0

Base address: OSPI = 0x400A_6000

Offset address: 0x1C

Bit position:	31																												0
Bit field:	CAD0[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	CAD0[31:0]	Automatic calibration address Sets the address of the write and read destination to perform the automatic calibration of device 0.	R/W

ACAR0 sets the address of the write/read destination to be performed the automatic calibration of device 0.

36.2.9 ACAR1 : Auto-Calibration Address Register 1

Base address: OSPI = 0x400A_6000

Offset address: 0x20

Bit position:	31																												0
Bit field:	CAD1[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	CAD1[31:0]	Automatic calibration address Sets the address of the write and read destination to perform the automatic calibration of device 1.	R/W

ACAR1 sets the address of the write/read destination to be performed the automatic calibration of device 1.

36.2.10 DRCSTR : Device Memory Map Read Chip Select Timing Setting Register

Base address: OSPI = 0x400A_6000

Offset address: 0x34

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	DVRDLO1[1:0]		DVRDHI1[2:0]			DVRDCMD1[2:0]			CTR1	CTRW1[6:0]						
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	DVRDLO0[1:0]		DVRDHI0[2:0]			DVRDCMD0[2:0]			CTR0	CTRW0[6:0]						
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
6:0	CTRW0[6:0]	Device 0 single continuous read waiting cycle setting in PCLKA units When single continuous read mode of Device 0 is enabled, OM_CS0 is fixed to Low for the clock cycle to be set by CTRW0 from the previous read operation. If the number of clock cycles exceeds the value to be set in these bits before the next read operation is performed, OM_CS0 is returned to High, and the single continuous read will finish.	R/W

Bit	Symbol	Function	R/W
7	CTR0	Device 0 single continuous read mode setting When the OSPI receives single read with increment address, multiple single read is executed in one CS asserted period (see section 36.5.2. Single continuous read operation). This bit must be 0 in SPI mode. 0: Single continuous read mode is disabled for device 0. 1: Single continuous read mode is enabled for device 0.	R/W
10:8	DVRDCMD0[2:0]	Device 0 Command execution interval setting*1 Indicates the timing between command to command for the device 0. Timing definition from OM_CS0 high to the next OM_CS0 low 0 0 0: 2 clock cycles 0 0 1: 5 clock cycles 0 1 0: 7 clock cycles 0 1 1: 9 clock cycles 1 0 0: 11 clock cycles 1 0 1: 13 clock cycles 1 1 0: 15 clock cycles 1 1 1: 17 clock cycles	R/W
13:11	DVRDHI0[2:0]	Device 0 select signal pull-up timing setting*1 Indicates the timing, from the end of read operation to the select signal is pulled up. Timing definition from the last OM_SCLK low to OM_CS0 high 0 0 0: Setting prohibit 0 0 1: Setting prohibit 0 1 0: Setting prohibit 0 1 1: Setting prohibit (DOPI mode) 5 clock cycles (Other mode) 1 0 0: Setting prohibit (DOPI mode) 6 clock cycles (Other mode) 1 0 1: 6.5 clock cycles (DOPI mode) 7 clock cycles (Other mode) 1 1 0: 7.5 clock cycles (DOPI mode) 8 clock cycles (Other mode) 1 1 1: 8.5 clock cycles (DOPI mode) 9 clock cycles (Other mode)	R/W
15:14	DVRDLO0[1:0]	Device 0 select signal pull-down timing setting*1 Indicates the timing between the select signal pull-down to the read operation for the device 0. Timing definition from OM_CS0 low to the first OM_SCLK high 0 0: Setting prohibit 0 1: 2.5 clock cycles (DOPI mode) 3 clock cycles (Other mode) 1 0: 3.5 clock cycles (DOPI mode) 4 clock cycles (Other mode) 1 1: 4.5 clock cycles (DOPI mode) 5 clock cycles (Other mode)	R/W
22:16	CTRW1[6:0]	Device 1 single continuous read waiting cycle setting in PCLKA units When single continuous read mode of Device 1 is enabled, OM_CS1 is fixed to Low for the clock cycle to be set by CTRW1 from the previous read operation. If the number of clock cycles exceeds the value to be set in these bits before the next read operation is performed, OM_CS1 is returned to High, and the single continuous read will finish.	R/W
23	CTR1	Device 1 single continuous read mode setting When the OSPI receives single read with increment address, multiple single read is executed in one CS asserted period (see section 36.5.2. Single continuous read operation). This bit must be 0 in SPI mode. 0: Single continuous read mode is disabled for device 1. 1: Single continuous read mode is enabled for device 1.	R/W

Bit	Symbol	Function	R/W
26:24	DVRDCMD1[2:0]	Device 1 Command execution interval*1 Indicates the timing, between command and command for device 1. Timing, until the OM_CS1 signal goes from High to the next Low 0 0 0: 2 clock cycles 0 0 1: 5 clock cycles 0 1 0: 7 clock cycles 0 1 1: 9 clock cycles 1 0 0: 11 clock cycles 1 0 1: 13 clock cycles 1 1 0: 15 clock cycles 1 1 1: 17 clock cycles	R/W
29:27	DVRDHI1[2:0]	Device 1 select signal High timing setting*1 Indicates the timing, from the end of read operation to the select signal is pulled up. Timing definition from the last OM_SCLK low to OM_CS1 high 0 0 0: Setting prohibit 0 0 1: Setting prohibit 0 1 0: Setting prohibit 0 1 1: Setting prohibit (DOPI mode) 5 clock cycles (Other mode) 1 0 0: Setting prohibit (DOPI mode) 6 clock cycles (Other mode) 1 0 1: 6.5 clock cycles (DOPI mode) 7 clock cycles (Other mode) 1 1 0: 7.5 clock cycles (DOPI mode) 8 clock cycles (Other mode) 1 1 1: 8.5 clock cycles (DOPI mode) 9 clock cycles (Other mode)	R/W
31:30	DVRDLO1[1:0]	Device 1 select signal pull-down timing setting*1 Indicates the timing between the select signal pull-down to the read operation for the device 1. Timing definition from OM_CS1 low to the first OM_SCLK high 0 0: Setting prohibited 0 1: 2.5 clock cycles (DOPI mode) 3 clock cycles (Other mode) 1 0: 3.5 clock cycles (DOPI mode) 4 clock cycles (Other mode) 1 1: 4.5 clock cycles (DOPI mode) 5 clock cycles (Other mode)	R/W

Note 1. These clock cycles are values in OCTACLK units. In OM_SCLK units, the clock cycle is 1/2 of the above table.

DRCSTR sets the timing of memory-mapped reading for each device.

36.2.11 DWCSTR : Device Memory Map Write Chip Select Timing Setting Register

Base address: OSPI = 0x400A_6000

Offset address: 0x38

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	DVWLO1[1:0]		DVWHI1[2:0]			DVWCMD1[2:0]			CTW1	CTWW1[6:0]						
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	DVWLO0[1:0]		DVWHI0[2:0]			DVWCMD0[2:0]			CTW0	CTWW0[6:0]						
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
6:0	CTWW0[6:0]	Device 0 single continuous write waiting cycle setting in PCLKA units When single continuous write mode of Device 0 is enabled, OM_CS0 is fixed to Low for the clock cycle to be set by CTWW0 from the previous single write operation. If the number of clock cycles exceeds the value to be set in these bits before the next single write operation is performed, OM_CS0 is returned to High, and the single continuous write will finish.	R/W
7	CTW0	Device 0 single continuous write mode setting When the OSPI receives single write with increment address, multiple single write is executed in one CS asserted period. See section 36.3.3.1. Write Operation about the operation of the single continuous write. 0: Single continuous write mode is disabled for device 0 1: Single continuous write mode is enabled for device 0	R/W
10:8	DVWCMD0[2:0]	Device 0 Command execution interval setting*1 Indicates the timing between command to command for the device 0. Timing definition from OM_CS0 high to the next OM_CS0 low 0 0 0: 2 clock cycles 0 0 1: 5 clock cycles 0 1 0: 7 clock cycles 0 1 1: 9 clock cycles 1 0 0: 11 clock cycles 1 0 1: 13 clock cycles 1 1 0: 15 clock cycles 1 1 1: 17 clock cycles	R/W
13:11	DVWHI0[2:0]	Device 0 select signal pull-up timing setting*1 Indicates the timing, from the end of write operation to the select signal is pulled up. Timing definition from the last OM_SCLK low to OM_CS0 high 0 0 0: 1.5 clock cycles (DOPI mode) 2 clock cycles (Other mode) 0 0 1: 2.5 clock cycles (DOPI mode) 3 clock cycles (Other mode) 0 1 0: 3.5 clock cycles (DOPI mode) 4 clock cycles (Other mode) 0 1 1: 4.5 clock cycles (DOPI mode) 5 clock cycles (Other mode) 1 0 0: 5.5 clock cycles (DOPI mode) 6 clock cycles (Other mode) 1 0 1: 6.5 clock cycles (DOPI mode) 7 clock cycles (Other mode) 1 1 0: 7.5 clock cycles (DOPI mode) 8 clock cycles (Other mode) 1 1 1: 8.5 clock cycles (DOPI mode) 9 clock cycles (Other mode)	R/W
15:14	DVWLO0[1:0]	Device 0 select signal pull-down timing setting*1 Indicates the timing between the select signal pull-down to the write operation for the device 0. Timing definition from OM_CS0 low to the first OM_SCLK high 0 0: Setting prohibit 0 1: 2.5 clock cycles (DOPI mode) 3 clock cycles (Other mode) 1 0: 3.5 clock cycles (DOPI mode) 4 clock cycles (Other mode) 1 1: 4.5 clock cycles (DOPI mode) 5 clock cycles (Other mode)	R/W
22:16	CTWW1[6:0]	Device 1 single continuous write waiting cycle setting in PCLKA units When single continuous write mode of Device 1 is enabled, OM_CS1 is fixed to Low for the clock cycle to be set by CTWW1 from the previous single write operation. If the number of clock cycles exceeds the value to be set in these bits before the next single write operation is performed, OM_CS1 is returned to High, and the single continuous write will finish.	R/W
23	CTW1	Device 1 single continuous write mode setting When the OSPI receives single write with increment address, multiple single write is executed in one CS asserted period. See section 36.3.3.1. Write Operation about the operation of the single continuous write. 0: Single continuous write mode is disabled for device 1 1: Single continuous write mode is enabled for device 1	R/W

Bit	Symbol	Function	R/W
26:24	DVWCMD1[2:0]	Device 1 Command execution interval setting*1 Indicates the timing between command to command for the device 1. Timing definition from OM_CS1 high to the next OM_CS1 low 0 0 0: setting prohibited 0 0 1: 5 clock cycles 0 1 0: 7 clock cycles 0 1 1: 9 clock cycles 1 0 0: 11 clock cycles 1 0 1: 13 clock cycles 1 1 0: 15 clock cycles 1 1 1: 17 clock cycles	R/W
29:27	DVWHI1[2:0]	Device 1 select signal pull-up timing setting*1 Indicates the timing, from the end of write operation to the select signal is pulled up. Timing definition from the last OM_SCLK low to OM_CS1 high 0 0 0: 1.5 clock cycles (DOPI mode) 2 clock cycles (Other mode) 0 0 1: 2.5 clock cycles (DOPI mode) 3 clock cycles (Other mode) 0 1 0: 3.5 clock cycles (DOPI mode) 4 clock cycles (Other mode) 0 1 1: 4.5 clock cycles (DOPI mode) 5 clock cycles (Other mode) 1 0 0: 5.5 clock cycles (DOPI mode) 6 clock cycles (Other mode) 1 0 1: 6.5 clock cycles (DOPI mode) 7 clock cycles (Other mode) 1 1 0: 7.5 clock cycles (DOPI mode) 8 clock cycles (Other mode) 1 1 1: 8.5 clock cycles (DOPI mode) 9 clock cycles (Other mode)	R/W
31:30	DVWLO1[1:0]	Device 1 select signal pull-down timing setting*1 Indicates the timing between the device 1 select signal pull-down to the write operation. Timing definition from OM_CS1 low to the first OM_SCLK high 0 0: Setting prohibit 0 1: 2.5 clock cycles (DOPI mode) 3 clock cycles (Other mode) 1 0: 3.5 clock cycles (DOPI mode) 4 clock cycles (Other mode) 1 1: 4.5 clock cycles (DOPI mode) 5 clock cycles (Other mode)	R/W

Note 1. These clock cycles are values in internal clock units. In OM_SCLK units, the clock cycle is 1/2 of the above table.

DWCSTR sets the timing of memory-mapped writing for each device.

36.2.12 DCSTR : Device Chip Select Timing Setting Register

Base address: OSPI = 0x400A_6000

Offset address: 0x3C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	DVSELLO[1:0]		DVSELHI[2:0]			DVSELCMD[2:0]			—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	—	These bits are read as 0. The write value should be 0.	R

Bit	Symbol	Function	R/W
10:8	DVSELCMD[2:0]	Device Command execution interval setting*1 Indicates the timing between command to command. Timing definition from OM_CS high to the next OM_CS low 0 0 0: 2 clock cycles 0 0 1: 5 clock cycles 0 1 0: 7 clock cycles 0 1 1: 9 clock cycles 1 0 0: 11 clock cycles 1 0 1: 13 clock cycles 1 1 0: 15 clock cycles 1 1 1: 17 clock cycles	R/W
13:11	DVSELHI[2:0]	Device select signal pull-up timing setting*1 Indicates the timing when the select signal is pulled up from the end of the command execution. Timing definition from the last OM_SCLK low to OM_CS high 0 0 0: Setting prohibited 0 0 1: Setting prohibited 0 1 0: Setting prohibited 0 1 1: Setting prohibited (DOPI mode) 5 clock cycles (Other mode) 1 0 0: Setting prohibited (DOPI mode) 6 clock cycles (Other mode) 1 0 1: 6.5 clock cycles (DOPI mode) 7 clock cycles (Other mode) 1 1 0: 7.5 clock cycles (DOPI mode) 8 clock cycles (Other mode) 1 1 1: 8.5 clock cycles (DOPI mode) 9 clock cycles (Other mode)	R/W
15:14	DVSELLO[1:0]	Device select signal pull-down timing setting*1 Indicates the timing, from the device selection signal is pulled-down to the command execution. Timing definition from OM_CS low to the first OM_SCLK high 0 0: Setting prohibit 0 1: 2.5 clock cycles (DOPI mode) 3 clock cycles (Other mode) 1 0: 3.5 clock cycles (DOPI mode) 4 clock cycles (Other mode) 1 1: 4.5 clock cycles (DOPI mode) 5 clock cycles (Other mode)	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R

Note 1. These clock cycles are values in OCTACLK units. In OM_SCLK units, the clock cycle is 1/2 of the above table.

DCSTR sets the operation timings of each device other than memory-mapped reading and writing.

36.2.13 CDSR : Controller and Device Setting Register

Base address: OSPI = 0x400A_6000

Offset address: 0x40

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	DLFT	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	ACMODE[1:0]		ACME ME1	ACME ME0	—	—	—	—	DV1PC	DV0PC	DV1TTYP[1:0]		DV0TTYP[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	DV0TTYP[1:0]	Device0_transfer_type setting 0 0: SPI mode 0 1: SOPI mode 1 0: DOPI mode 1 1: Setting prohibited	R/W
3:2	DV1TTYP[1:0]	Device1_transfer_type setting 0 0: SPI mode 0 1: SOPI mode 1 0: DOPI mode 1 1: Setting prohibited	R/W
4	DV0PC	Device0_memory precycle setting 0: Disable 1: Enable	R/W
5	DV1PC	Device1_memory precycle setting*1 0: Disable 1: Enable	R/W
9:6	—	These bits are read as 0. The write value should be 0.	R/W
10	ACMEME0	Automatic calibration memory enable setting for device 0 Automatic calibration supports DOPI and SOPI mode. To end DOPI/SOPI mode, disable automatic calibration. 0: Disable 1: Enable	R/W
11	ACMEME1	Automatic calibration memory enable setting for device 1 Automatic calibration supports DOPI and SOPI mode. To end DOPI/SOPI mode, disable automatic calibration. 0: Disable 1: Enable	R/W
13:12	ACMODE[1:0]	Automatic calibration mode The ACMODE bits should be set to disabled, before program/erase access to the OctaFlash device. Automatic calibration is available in the DOPI and SOPI mode. 0 0: Automatic calibration is disabled*2 0 1: Automatic calibration is enabled and modify MDTR 1 0: Automatic calibration immediately is executed for all trim code, but it will not modify MDTR 1 1: Setting prohibited	R/W
30:14	—	These bits are read as 0. The write value should be 0.	R/W
31	DLFT	Deadlock Free Timer Enable*3 Enable the timer to prevent the occurrence of controller deadlock. The timeout status is reset only by a system reset. 0: Enable timer 1: Disable timer	R/W

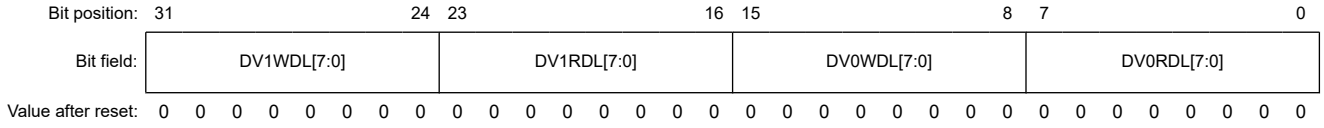
Note 1. This bit should be set 1 in SOPI mode.
Note 2. When automatic calibration is disabled, the device 0 delay and device 1 delay should be manually specified in the memory delay trim register (MDTR) (see section 36.2.6. MDTR : Memory Delay Trim Register).
To determine the device 0 delay and device 1 delay values to be specified in the register, perform automatic calibration in advance and obtain valid delay values from the results.
Note 3. This function is available only when OM_SCLK is 100 MHz. Otherwise, disable the timer.

CDSR controls the automatic calibration, output byte order, precycle setting, and device transfer type of the controller and each device.

36.2.14 MDLR : Memory Map Dummy Length Register

Base address: OSPI = 0x400A_6000

Offset address: 0x44



Bit	Symbol	Function	R/W
7:0	DV0RDL[7:0]	Device 0 Read dummy length setting Set the dummy length when reading to device 0 in OM_SCLK cycles unit.	R/W
15:8	DV0WDL[7:0]	Device 0 Write dummy length setting Set the dummy length when writing to device 0 in OM_SCLK cycles unit.	R/W
23:16	DV1RDL[7:0]	Device 1 Read dummy length setting Set the dummy length when reading to device 1 in OM_SCLK cycles unit.	R/W
31:24	DV1WDL[7:0]	Device 1 Write dummy length setting Set the dummy length when writing to device 1 in OM_SCLK cycles unit.	R/W

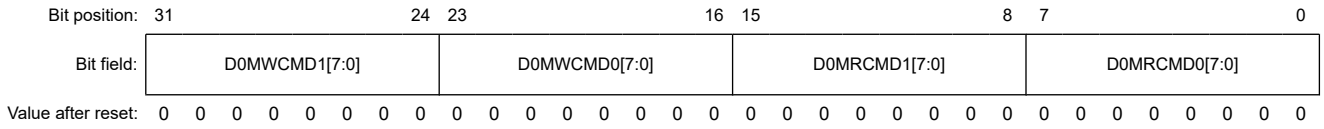
MDLR sets the dummy length for memory map write/read.

Note: When changing the dummy length for the OctaFlash device, modify the setting on the memory and then modify the setting in the DMLEN[7:0] bits in the device command setting register (DCSR) so that the dummy length becomes the same between the memory and OSPI. After that, execute the status read command to confirm the memory status.

36.2.15 MRWCR0 : Memory Map Read/Write Command Register 0

Base address: OSPI = 0x400A_6000

Offset address: 0x48



Bit	Symbol	Function	R/W
7:0	D0MRCMD0[7:0]	Memory map read command 0 setting Set the memory map read command. According to the memory spec to connect the device 0 and transfer type (SPI, SOPI, or DOPI mode), select the write command In SPI mode, the controller will send only command 0. In SOPI and DOPI mode, the controller will send command 1 first and then send command 0. The mode of device 0 is specified by CDSR.DV0TTYP[1:0].	R/W
15:8	D0MRCMD1[7:0]	Memory map read command 1 setting Set the memory map read command. According to the memory spec to connect the device 0 and transfer type (SPI, SOPI, or DOPI mode), select the write command In SPI mode, the controller will not send command 1. In SOPI and DOPI mode, the controller will send command 1 first and then send command 0. The mode of device 0 is specified by CDSR.DV0TTYP[1:0].	R/W

Bit	Symbol	Function	R/W
23:16	D0MWCMD0[7:0]	Memory map write command 0 setting Set the memory map write command. According to the memory spec to connect the device 0 and transfer type (SPI, SOPI, or DOPI mode), select the write command In SPI mode, the controller will send only command 0. In SOPI and DOPI mode, the controller will send command 1 first and then send command 0. The mode of device 0 is specified by CDSR.DV0TTYP[1:0].	R/W
31:24	D0MWCMD1[7:0]	Memory map write command 1 setting Set the memory map write command. According to the memory spec to connect the device 0 and transfer type (SPI, SOPI, or DOPI mode), select the write command In SPI mode, the controller will not send command 1. In SOPI and DOPI mode, the controller will send command 1 first and then send command 0. The mode of device 0 is specified by CDSR.DV0TTYP[1:0].	R/W

MRWCR0 sets the read/write commands for the device 0.

36.2.16 MRWCR1 : Memory Map Read/Write Command Register 1

Base address: OSPI = 0x400A_6000

Offset address: 0x4C

Bit position:	31							24	23							16	15							8	7							0
Bit field:	D1MWCMD1[7:0]								D1MWCMD0[7:0]								D1MRCMD1[7:0]								D1MRCMD0[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	D1MRCMD0[7:0]	Memory map read command 0 setting Set the memory map read command. According to the memory spec to connect the device 1 and transfer type (SPI, SOPI, or DOPI mode), select the write command In SPI mode, the controller will send only command 0. In SOPI and DOPI mode, the controller will send command 1 first and then send command 0. The mode of device 1 is specified by CDSR.DV1TTYP[1:0].	R/W
15:8	D1MRCMD1[7:0]	Memory map read command 1 setting Set the memory map read command. According to the memory spec to connect the device 1 and transfer type (SPI, SOPI, or DOPI mode), select the write command In SPI mode, the controller will not send command 1. In SOPI and DOPI mode, the controller will send command 1 first and then send command 0. The mode of device 1 is specified by CDSR.DV1TTYP[1:0].	R/W
23:16	D1MWCMD0[7:0]	Memory map write command 0 setting Set the memory map write command. According to the memory spec to connect the device 1 and transfer type (SPI, SOPI, or DOPI mode), select the write command In SPI mode, the controller will send only command 0. In SOPI and DOPI mode, the controller will send command 1 first and then send command 0. The mode of device 1 is specified by CDSR.DV1TTYP[1:0].	R/W
31:24	D1MWCMD1[7:0]	Memory map write command 1 setting Set the memory map write command. According to the memory spec to connect the device 1 and transfer type (SPI, SOPI, or DOPI mode), select the write command In SPI mode, the controller will not send command 1. In SOPI and DOPI mode, the controller will send command 1 first and then send command 0. The mode of device 1 is specified by CDSR.DV1TTYP[1:0].	R/W

MRWCR1 sets the read/write commands for the device 1.

36.2.17 MRWCSR : Memory Map Read/Write Setting Register

Base address: OSPI = 0x400A_6000

Offset address: 0x50

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	MWO1	MWCL1[2:0]			MWAL1[2:0]			PREN 1	MRO1	MRCL1[2:0]			MRAL1[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	MWO0	MWCL0[2:0]			MWAL0[2:0]			PREN 0	MRO0	MRCL0[2:0]			MRAL0[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	MRAL0[2:0]	Device 0 read address length setting Set the memory map read address byte length for device 0.	R/W
5:3	MRCL0[2:0]	Device 0 read command length setting Set the write command byte length for device 0.	R/W
6	MRO0	Device 0 read order setting*1 0: Read order is byte0, byte1, byte2, byte3. 1: Read order is byte1, byte0, byte3, byte2.	R/W
7	PREN0	Preamble bit enable for mem0 memory-map read*2 0: No check preamble bit 1: Check preamble bit from OctaFlash (if OctaFlash is connected to device 0)	R/W
10:8	MWAL0[2:0]	Device 0 write address length setting Set the memory map write address byte length for device 0.	R/W
13:11	MWCL0[2:0]	Device 0 write command length setting Set the write command byte length for device 0.	R/W
14	MWO0	Device 0 write order setting*1 0: Write order is byte0, byte1, byte2, byte3. 1: Write order is byte1, byte0, byte3, byte2.	R/W
15	—	This bit is read as 0. The write value should be 0.	R
18:16	MRAL1[2:0]	Device 1 read address length setting Set the memory map read address byte length for device 1.	R/W
21:19	MRCL1[2:0]	Device 1 read command length setting Set the read command byte length for device 1.	R/W
22	MRO1	Device 1 read order setting*1 0: Read order is byte0, byte1, byte2, byte3. 1: Read order is byte1, byte0, byte3, byte2.	R/W
23	PREN1	Preamble bit enable for mem1 memory-map read*2 0: No check preamble bit 1: Check preamble bit from OctaFlash (if OctaFlash is connected to device 1)	R/W
26:24	MWAL1[2:0]	Device 1 write address length setting Set the memory map write address byte length for device 1.	R/W
29:27	MWCL1[2:0]	Device 1 write command length setting Set the number of bytes in the write command for device 1.	R/W
30	MWO1	Device 1 write order setting*1 0: Write order is byte0, byte1, byte2, byte3. 1: Write order is byte1, byte0, byte3, byte2.	R/W
31	—	This bit is read as 0. The write value should be 0.	R

Note 1. This setting is only valid in the DOPI mode. It has no effect in the SOPI or SPI mode.

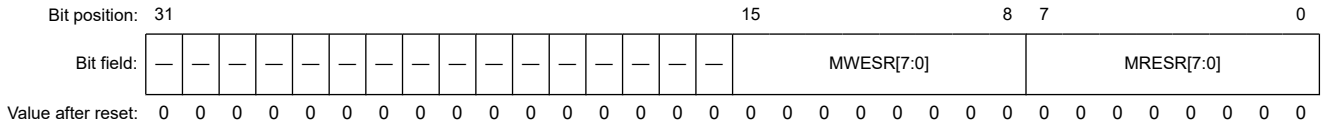
Note 2. Setting this bit to 1 is prohibited, when SPI and SOPI mode.

MRWCSR sets the memory map read/write operations.

36.2.18 ESR : Error Status Register

Base address: OSPI = 0x400A_6000

Offset address: 0x54



Bit	Symbol	Function	R/W
7:0	MRESR[7:0]	Memory map read error status 0x01: ECC error 0x02: Preamble error 0x03: Wait OM_DQS timeout 0x80: Invalid command Others: Reserved	R/W
15:8	MWESR[7:0]	Memory map write error status 0x80: Invalid command Others: Reserved	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

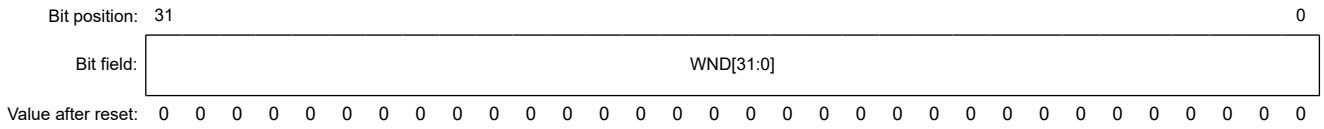
ESR indicates the error status when performing memory map read and write commands.

Note: When ESR register is read by CPU, ESR register is cleared, and the interrupt signal is cleared (if asserted).

36.2.19 CWNDR : Configure Write without Data Register

Base address: OSPI = 0x400A_6000

Offset address: 0x58



Bit	Symbol	Function	R/W
31:0	WND[31:0]	The write value should be 0.	W

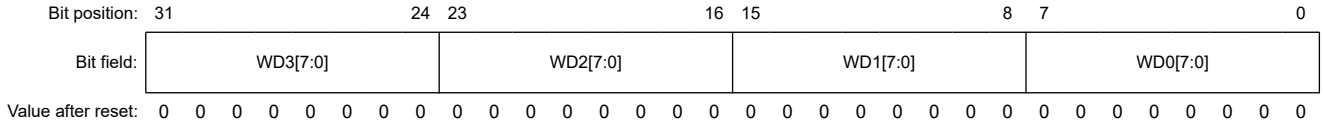
CWNDR is used for write access to configure register of memory. When this register is written to, this module issues a write command without data to memory.

Specify an address in the DAR register, a command in the DCSR register, and command data in the DCR register.

36.2.20 CWDR : Configure Write Data Register

Base address: OSPI = 0x400A_6000

Offset address: 0x5C



Bit	Symbol	Function	R/W
7:0	WD0[7:0]	Write data 0 Set the zeroth byte of the write data.	W
15:8	WD1[7:0]	Write data 1 Set the first byte of the write data.	W
23:16	WD2[7:0]	Write data 2 Set the second byte of the write data.	W
31:24	WD3[7:0]	Write data 3 Set the third byte of the write data.	W

CWDR is used in writing to configure register of memory device. After this register has been written to, it holds the written value, and a write command for that value is issued to the memory device.

Specify the byte order in CDSR, a command in DCSR, an address in DAR, and command data in DCR.

36.2.21 CRR : Configure Read Register

Base address: OSPI = 0x400A_6000

Offset address: 0x60

Bit position:	31							24	23							16	15							8	7							0
Bit field:	RD3[7:0]								RD2[7:0]								RD1[7:0]								RD0[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	RD0[7:0]	Read data 0 Store the zeroth byte of the read data.	R
15:8	RD1[7:0]	Read data 1 Store the first byte of the read data.	R
23:16	RD2[7:0]	Read data 2 Store the second byte of the read data.	R
31:24	RD3[7:0]	Read data 3 Store the third byte of the read data.	R

CRR is used in reading from configure register of memory device.When this register is read, a read command is issued to the device and the value read from the device is stored in this register.

Change the byte order with CDSR. Specify a command in DCSR, an address in DAR, and command data in DCR.

36.2.22 ACSR : Auto-Calibration Status Register

Base address: OSPI = 0x400A_6000

Offset address: 0x64

Bit position:	31																												5	3	2	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ACSR1[2:0]		ACSR0[2:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	ACSR0[2:0]	Auto-calibration status of device 0 0 0 0: Initial state 0 0 1: Reserved 0 1 0: Reserved 0 1 1: Normal end 1 0 0: Error end*1	R/W

Bit	Symbol	Function	R/W
5:3	ACSR1[2:0]	Auto-calibration status of device 1 0 0 0: Initial state 0 0 1: Reserved 0 1 0: Reserved 0 1 1: Normal end 1 0 0: Error end*1	R/W
31:6	—	These bits are read as 0. The write value should be 0.	R/W

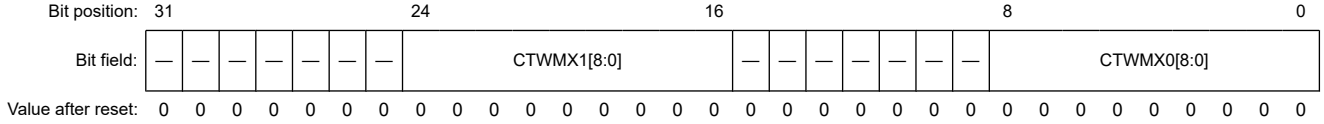
Note 1. Read data in auto-calibration does not match with the preamble pattern.

ACSR provides the auto-calibration status until next auto-calibration.

36.2.23 DCSMXR : Device Chip Select Maximum Period Register

Base address: OSPI = 0x400A_6000

Offset address: 0x7C



Bit	Symbol	Function	R/W
8:0	CTWMX0[8:0]	Indicates the maximum period that OM_CS0 and OM_CS1 are Low in single continuous write of OctaRAM. Period of CTWMX0 cycle + 16 cycles in PCLKA unit to be less than t_{CSM}. For example, CTWMX0 is 0x180, when PCLKA is 100 MHz and t_{CSM} is 4.0 µs. These bits are ignored in OctaFlash.	R/W
15:9	—	These bits are read as 0. The write value should be 0.	R/W
24:16	CTWMX1[8:0]	Indicates the maximum period that OM_CS0 and OM_CS1 are Low in single continuous read of OctaRAM. Period of CTWMX1 cycle + 16 cycles in PCLKA unit to be less than t_{CSM}. For example, CTWMX1 is 0x180, when PCLKA is 100 MHz and t_{CSM} is 4.0 µs. These bits are ignored in OctaFlash.	R/W
31:25	—	These bits are read as 0. The write value should be 0.	R/W

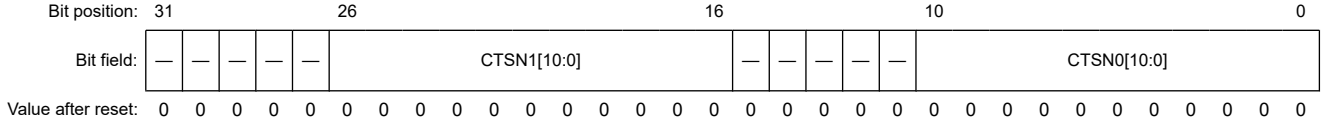
Note: Refer to OctaRAM data sheet about t_{CSM}.

DCSMXR provides the maximum period that OM_CS is Low in single continuous write/read mode of OctaRAM.

36.2.24 DWSCTSR : Device Memory Map Write single continuous translating size Register

Base address: OSPI = 0x400A_6000

Offset address: 0x80



Bit	Symbol	Function	R/W
10:0	CTSN0[10:0]	Indicates the number of bytes to translate in single continuous write of device 0. If these bits are set all 0, the translating length is undefined, the single continuous write is finished, when the period of idle is over the period to be specified by DWCSTR.CTWW0. CTSN0 must be set from 1 to 256, when PCLKA > OCTACLK/2	R/W
15:11	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
26:16	CTSN1[10:0]	Indicates the number of bytes to translate in single continuous write of device 1. If these bits are set all 0, the translating length is undefined, the single continuous write is finished, when the period of idle is over the period to be specified by DWCSTR.CTWW1. CTSN1 must be set from 1 to 256, when PCLKA > OCTACLK/2	R/W
31:27	—	These bits are read as 0. The write value should be 0.	R/W

DWSCTSR provides the translating size of the single continuous write in byte. When the number of single write operations is the value to be set by DWSCTSR, the single continuous write will be finished.

36.3 Operation

36.3.1 Octa Serial Peripheral Interface System Configuration

Figure 36.2 shows an example of connections between OSPI and OctaFlash/OctaRAM.

OM_CS0 should be connected to the OctaRAM device and OM_CS1 should be connected to the OctaFlash device.

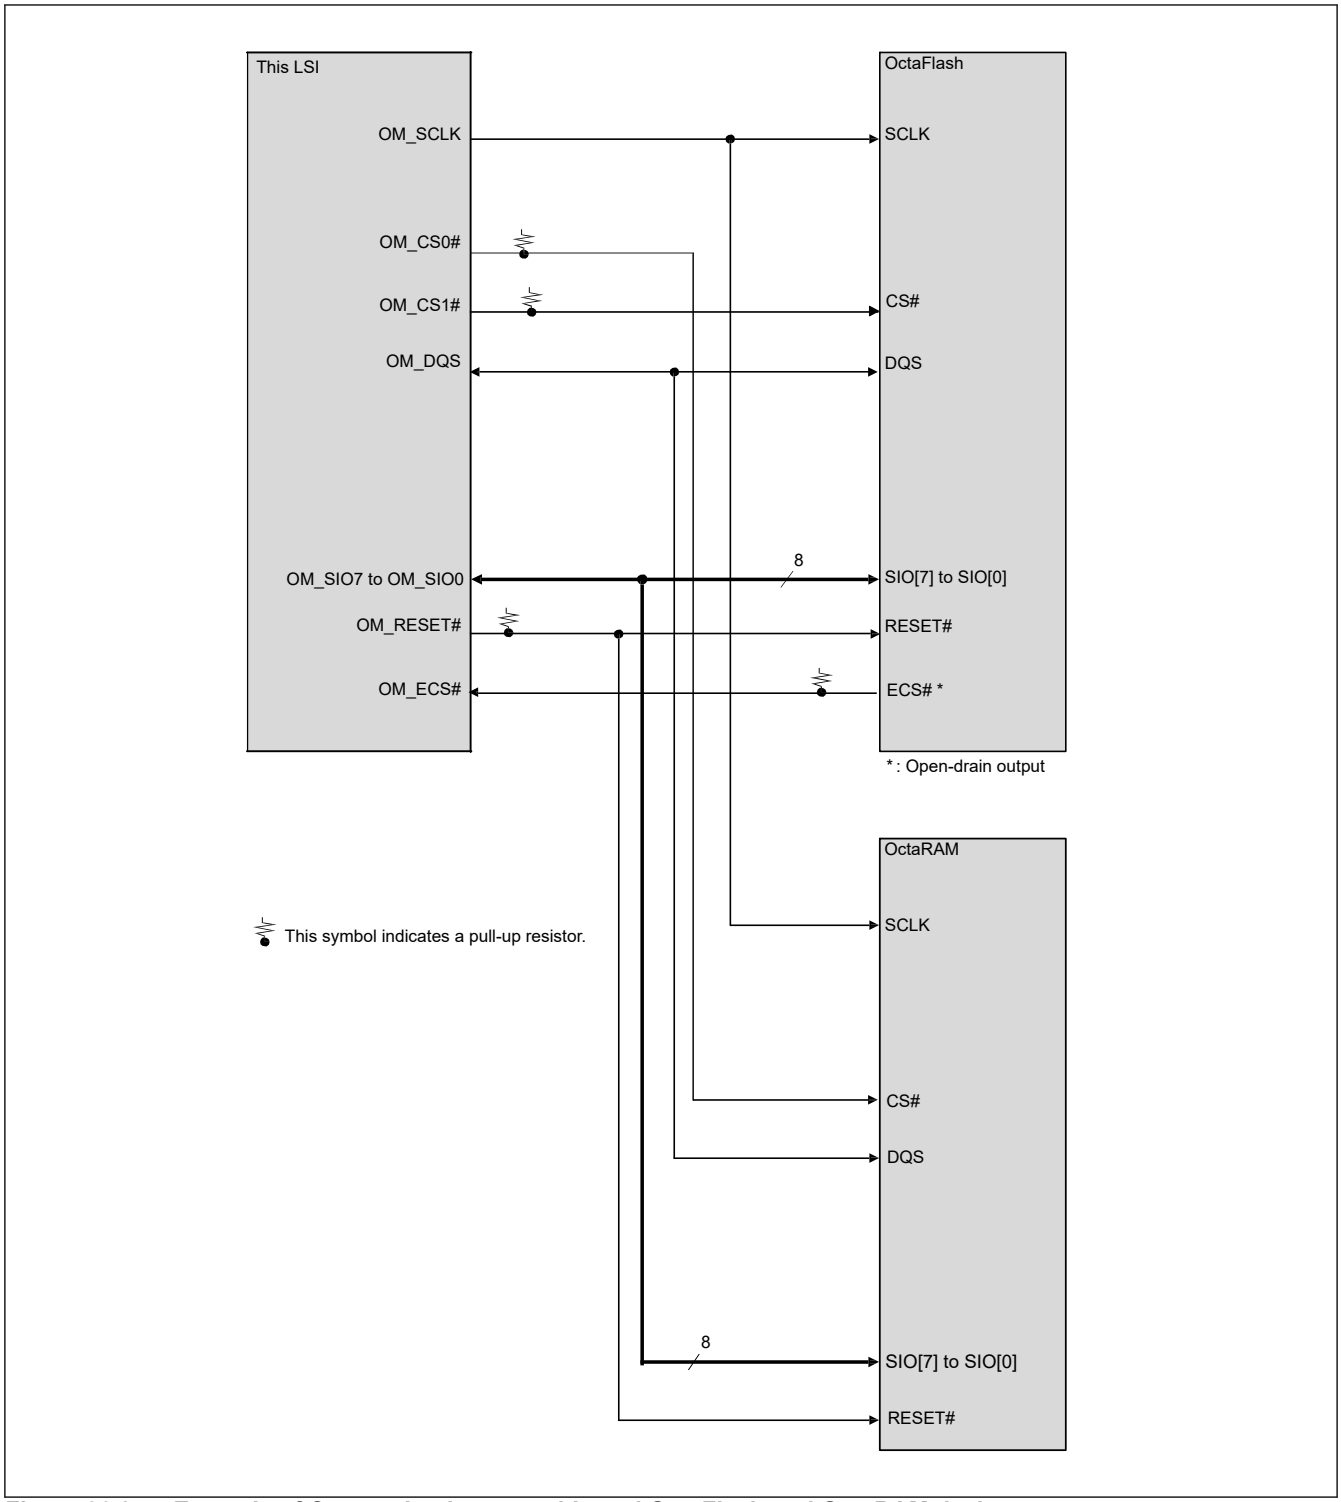


Figure 36.2 Example of Connection between this and OctaFlash and OctaRAM devices.

36.3.2 Address Map

In the memory-map read/write mode, OctaFlash is allocated to the OctaFlash space (0x7000_0000 to 0x7FFF_FFFF), and OctaRAM is allocated to the OctaRAM space (0x6800_0000 to 0x687F_FFFF).

One OctaFlash device and one OctaRAM device can be connected to this LSI, and up to 256 MB can be accessed in OctaFlash device, and up to 8 MB can be accessed in OctaRAM device.

	Internal Address	Maximum Accessible Area
OctaFlash	0x7000_0000 to 0x7FFF_FFFF	Up to 256 MB
OctaRAM	0x6800_0000 to 0x687F_FFFF	Up to 8 MB

36.3.3 Octa Memory Interface

This section describes the Octa memory interface.

36.3.3.1 Write Operation

The OSPI outputs a command and an address and writes one or more data bytes by using lines OM_CS0 /OM_CS1, OM_SCLK, and OM_SIO7 to OM_SIO0.

The write operation for OctaRAM has latency cycles before data is written to memory.

Figure 36.3 to Figure 36.5 show waveforms of the write operation in the OctaFlash interface, and Figure 36.6 shows a waveform of the write operation in the OctaRAM interface.

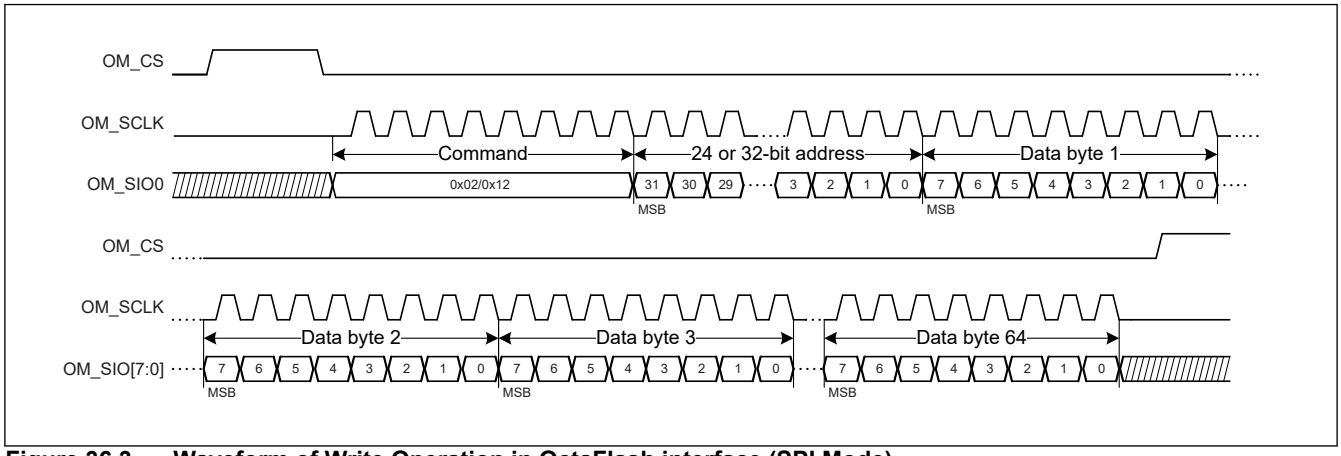

Figure 36.3 Waveform of Write Operation in OctaFlash interface (SPI Mode)

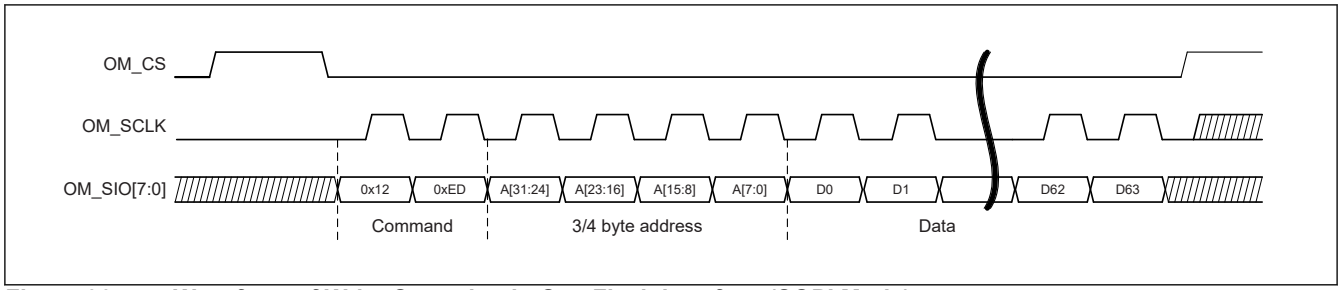

Figure 36.4 Waveform of Write Operation in OctaFlash interface (SOPI Mode)

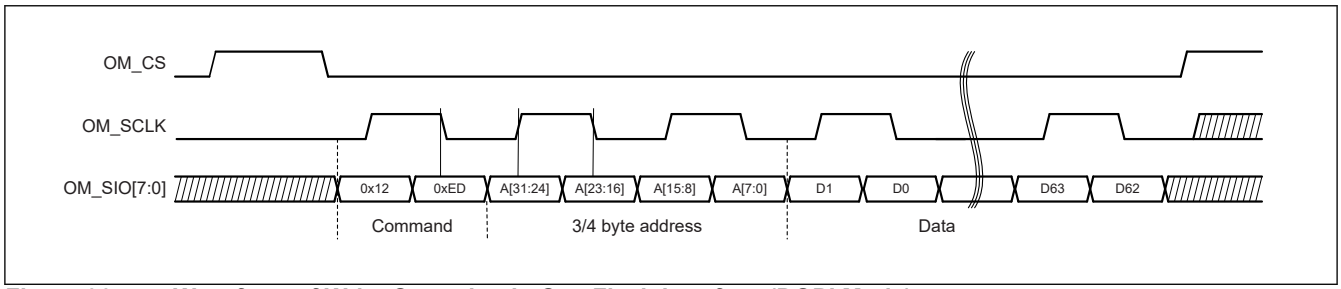

Figure 36.5 Waveform of Write Operation in OctaFlash interface (DOPI Mode)

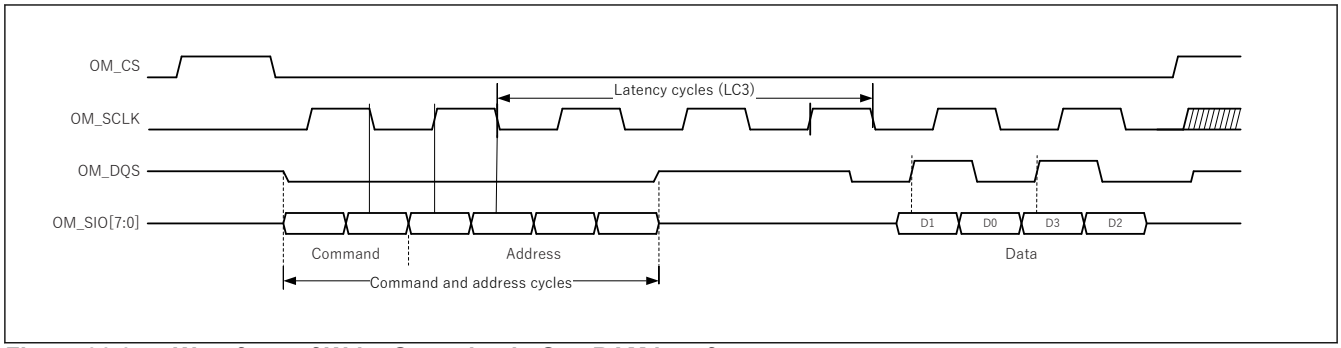

Figure 36.6 Waveform of Write Operation in OctaRAM interface

36.3.3.2 Read Operation

The OSPI outputs a command and an address and reads one or more data bytes by using lines OM_CS0 /OM_CS1, OM_SCLK, and OM_SIO7 to OM_SIO0.

The read operation for OctaFlash and OctaRAM has latency cycles before data is read from memory.

The number of latency cycles should be specified in the memory map dummy length setting register (MDLR) (See section 36.2.14. MDLR : Memory Map Dummy Length Register) in accordance with the setting in the memory device.

In SOPI or DOPI mode, OM_DQS is used. Automatic calibration should be executed before first read OctaFlash or OctaRAM in SOPI or DOPI mode.

Figure 36.7 to Figure 36.9 show waveforms of the read operation in the OctaFlash interface, and Figure 36.10 shows a waveform of the read operation in the OctaRAM interface.

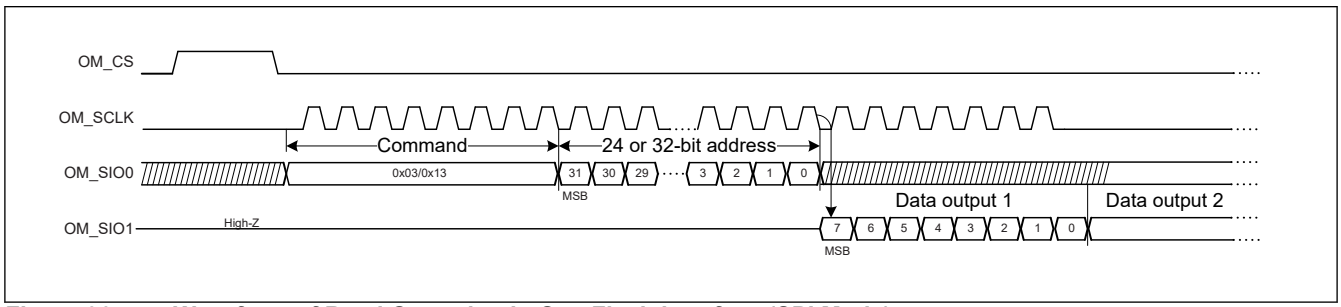

Figure 36.7 Waveform of Read Operation in OctaFlash interface (SPI Mode)

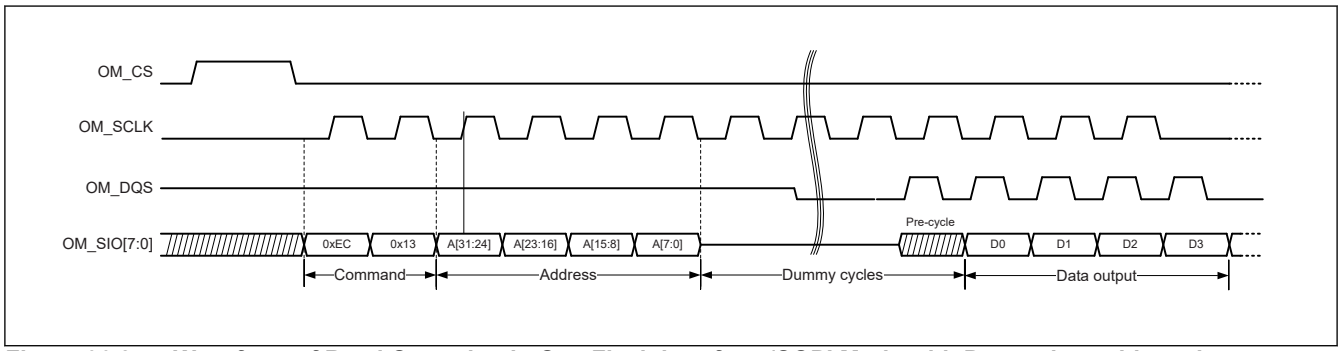

Figure 36.8 Waveform of Read Operation in OctaFlash interface (SOPI Mode with Pre-cycle enable and DQS enable)

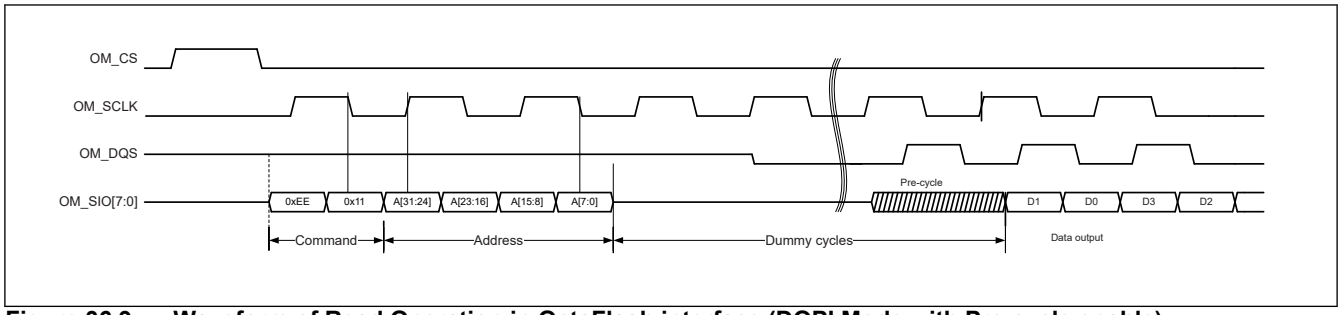

Figure 36.9 Waveform of Read Operation in OctaFlash interface (DOPI Mode with Pre-cycle enable)

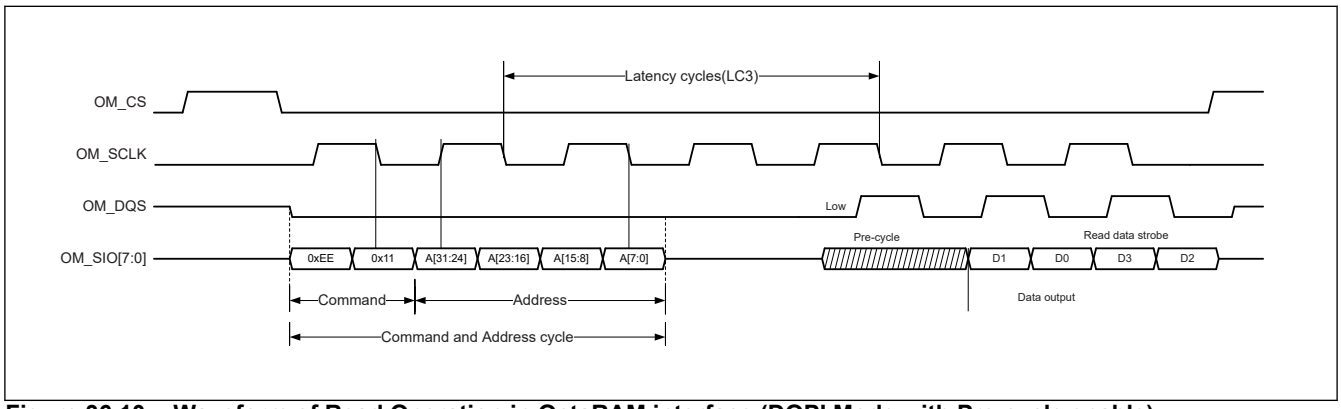

Figure 36.10 Waveform of Read Operation in OctaRAM interface (DOPI Mode with Pre-cycle enable)

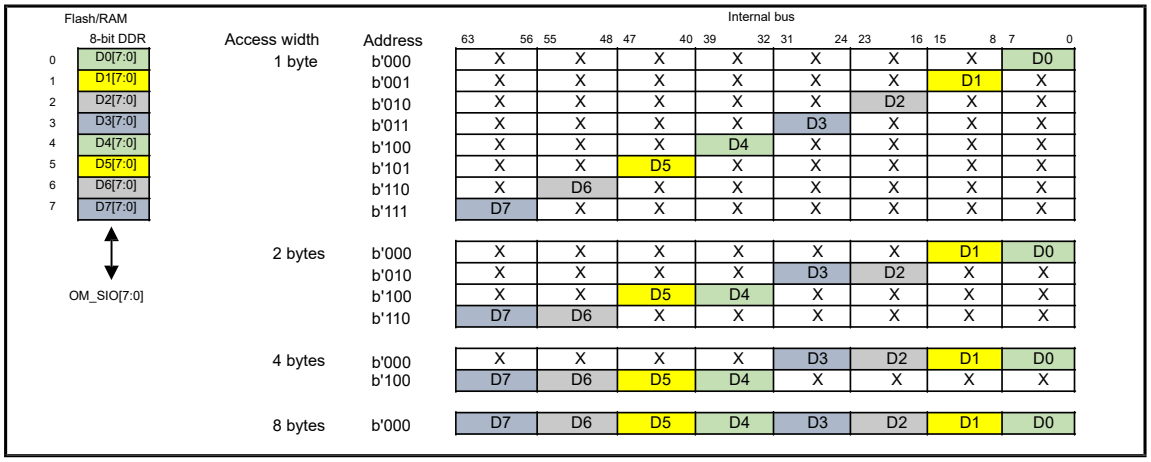
36.3.4 Data Alignment in the OctaFlash and OctaRAMSpaces

Figure 36.11 shows the memory data alignment in the OctaFlash and OctaRAM spaces.

Figure 36.12 shows the data alignment when the configuration register in OctaFlash or OctaRAM is accessed.

When OctaFlash is connected (MRWCSR.MWO0 = 0, MRWCSR.MRO0 = 0) or
OctaRAM is connected (MRWCSR.MWO1 = 0, MRWCSR.MRO1 = 0)



When OctaFlash is connected (MRWCSR.MWO0 = 1, MRWCSR.MRO0 = 1) or
OctaRAM is connected (MRWCSR.MWO1 = 1, MRWCSR.MRO1 = 1)

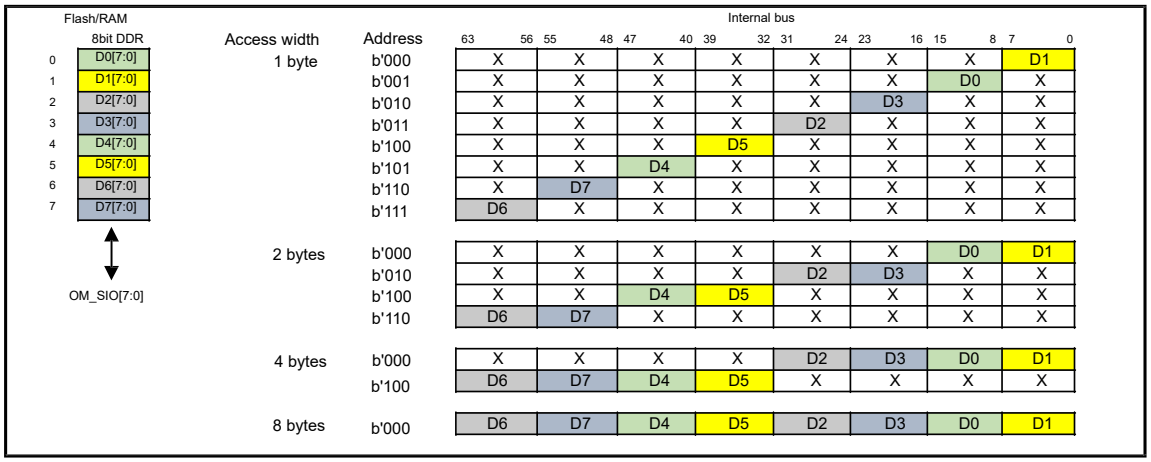


Figure 36.11 Memory Data Alignment in the OctaFlash and OctaRAM Spaces

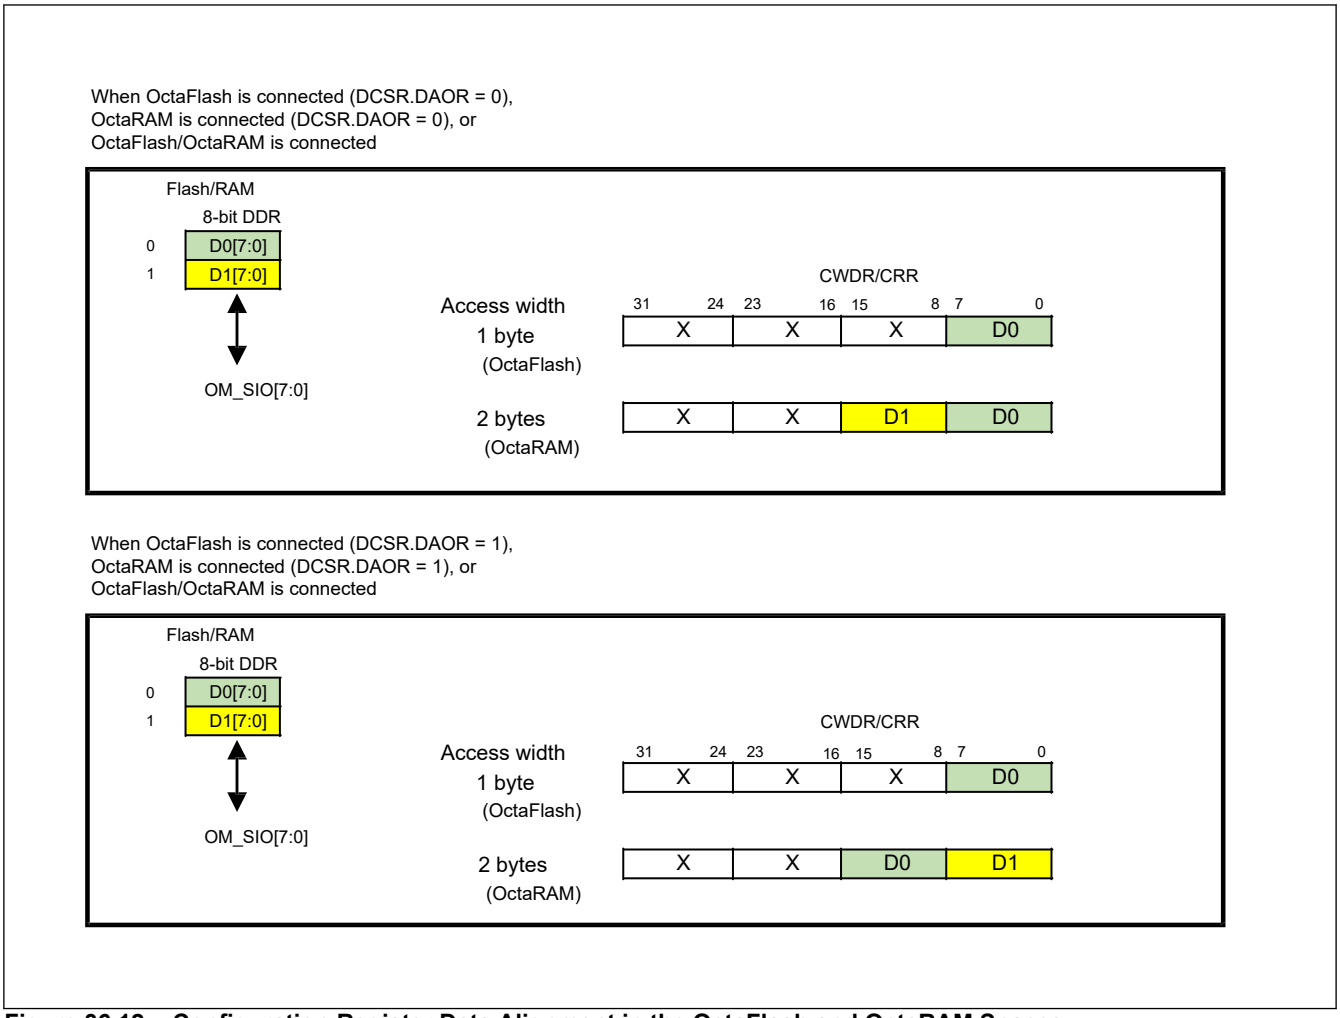

Figure 36.12 Configuration Register Data Alignment in the OctaFlash and OctaRAM Spaces

36.3.5 Byte Mask

This section describes the byte mask function. This function is only available for OctaRAM devices. The OSPI outputs the OM_DQS signal as a write data mask signal during write operation. Write data is masked with the OM_DQS signal driven high. Figure 36.13 shows a waveform of the write operation with the byte mask function enabled.

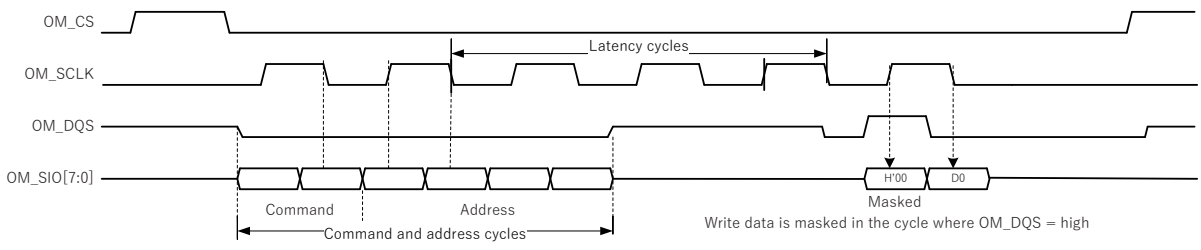

Figure 36.13 Waveform of Write Operation with Byte Mask Enabled

36.3.6 Operation Flows

This section describes the flows of OSPI operations for various purposes.

The following only shows sample settings, and appropriate commands and data should be specified in accordance with the specifications of the target memory device.

The sample settings assume the following environment:

1. Memory connections: OM_CS0 (device 0) to OctaRAM and OM_CS1 (device 1) to OctaFlash
2. OM_SCLK (Octa memory clock) frequency: 100 MHz

36.3.6.1 Initial Settings

Table 36.6 shows an example of initial settings of the OSPI registers.

Table 36.6 Example of initial settings of the OSPI registers

Step	Read/ Write	Address (Register)	Data	Data Length (Bytes)	Description
1	Write	DSR0	0x40800000	4	Specifies the type and size of device 0 The device 0 connects 64 Mbits OctaRAM
2	Write	DSR1	0x08000000	4	Specifies the type and size of device 1 The device 1 connects 1 Gbit OctaFlash
3	Write	MDTR	0x0640A440	4	Adjusts the memory access timing
4	Write	DRCSTR	0x69206920	4	Specifies the read timing for each device
5	Write	DWCSTR	0x41204120	4	Specifies the write timing for each device
6	Write	DCSTR	0x00006A00	4	Specifies the timing of the chip select signals
7	Write	CDSR	0x80000002	4	Sets up the controller functions 1. Auto-calibration is disabled 2. Memory pre-cycle is disabled 3. Transfer type set SPI mode for OctaFlash (devide 1) and DOPI mode for OctaRAM (device 0)
8	Write	MDLR	0x000E0505	4	Specifies the dummy length
9	Write	MRWCR0	0x2000A000	4	Specifies the read and write commands for device 0 Write command: WRCONT of OctaRAM Read command: RDCONT of OctaRAM
10	Write	MRWCR1	0x12EDEE11	4	Specifies the read and write commands for device 1 Write command: PP of OctaFlash Read command: 8DTRD of OctaFlash
11	Write	MRWCSR	0x54545454	4	Sets up the memory-mapped reading and writing 1. The length (bytes) of a command is specified 2. The length (bytes) of an address is specified 3. The order of bytes to be written is specified

36.3.6.2 Basic Operation Settings

This section describes the basic operations of OctaFlash and OctaRAM.

The following only shows sample settings, and appropriate commands and data should be specified in accordance with the specifications of the target memory device.

(1) OctaFlash Operation Settings

Table 36.7 1. Write Enable Settings

Step	Read/ Write	Register	SPI Mode Data	Data Length (Bytes)	OPI Mode Data	Data Length (Bytes)	Description
1	Write	DCR	0x00000006	4	0x000006F9	4	—
2	Write	DCSR	0x00180000	4	0x00280000	4	—
3	Write	CWNDR	Any value	4	Any value	4	—

Table 36.8 2. Read Status Register (1 of 2)

Step	Read/ Write	Register	SPI Mode Data	Data Length (Bytes)	OPI Mode Data	Data Length (Bytes)	Description
1	Write	DCR	0x00000005	4	0x000005FA	4	—

Table 36.8 2. Read Status Register (2 of 2)

Step	Read/ Write	Register	SPI Mode Data	Data Length (Bytes)	OPI Mode Data	Data Length (Bytes)	Description
2	Write	DAR	—	—	0x00000000	4	—
3	Write	DCSR	0x00180001	4	0x0C280401	4	—
4	Read	CRR	0x000000xx	4	0x000000xx	1	The high-order 24 bits are all set to 0s, and the read data is stored in the low-order eight bits.

Table 36.9 3. Read Configuration Register

Step	Read/ Write	Register	SPI Mode Data	Data Length (Bytes)	OPI Mode Data	Data Length (Bytes)	Description
1	Write	DCR	0x00000015	4	0x000015EA	4	—
2	Write	DAR	—	—	0x00000001	4	—
3	Write	DCSR	0x00180001	4	0x0C280401	4	—
4	Read	CRR	0x000000xx	1	0x000000xx	1	The high-order 24 bits are all set to 0s, and the read data is stored in the low-order eight bits.

Table 36.10 4. Write Configuration Register

Step	Read/ Write	Register	SPI Mode Data	Data Length (Bytes)	OPI Mode Data	Data Length (Bytes)	Description
1	Write	DCR	—	—	0x000001FE	4	—
2	Write	DAR	—	—	0x00000001	4	—
3	Write	DCSR	—	—	0x04280001	4	—
4	Write	CWDR	—	—	0x000000xx	1	Set all the high-order 24 bits to 0 and specify the write data in the low-order eight bits.

Note: It is necessary to execute Write Enable instruction before modifying Write Configuration Register and then Write Configuration Register will be set after tW (tW is Write Status/Configuration Register Cycle Time, refer to OctaFlash data sheet).

Table 36.11 5. Read Configuration Register 2

Step	Read/ Write	Register	SPI Mode Data	Data Length (Bytes)	OPI Mode Data	Data Length (Bytes)	Description
1	Write	DCR	0x00000071	4	0x0000718E	4	—
2	Write	DAR	Address	4	Address	4	—
3	Write	DCSR	0x04180001	4	0x0C280401	4	—
4	Read	CRR	0x000000xx	1	0x000000xx	1	The high-order 24 bits are all set to 0s, and the read data is stored in the low-order eight bits.

Table 36.12 6. Write Configuration Register 2

Step	Read/ Write	Register	SPI Mode Data	Data Length (Bytes)	OPI Mode Data	Data Length (Bytes)	Description
1	Write	DCR	0x00000072	4	0x0000728D	4	—
2	Write	DAR	Address	4	Address	4	—
3	Write	DCSR	0x04180001	4	0x04280001	4	—
4	Write	CWDR	0x000000xx	1	0x000000xx	1	Set all the high-order 24 bits to 0s, and specify the write data in the low-order eight bits

Note: It is necessary to execute Write Enable instruction before modifying Write Configuration Register2.

Table 36.13 7. Erase Sector

Step	Read/ Write	Register	SPI Mode Data	Data Length (Bytes)	OPI Mode Data	Data Length (Bytes)	Description
1	Write	DCR	0x00000021	4	0x000021DE	4	—
2	Write	DAR	Address to be erased	4	Address to be erased	4	—
3	Write	DCSR	0x04180000	4	0x04280000	4	—
4	Write	CWNDR	Any value	4	Any value	4	—

Note: For details of the erase sequence, see section 36.3.6.5. Program/Erase of OctaFlash Setting.

(2) OctaRAM Operation Settings

Table 36.14 1. Read Configuration Register

Step	Read/ Write	Register	Data	Data Length (Bytes)	Description
1	Write	DCR	0x0000C000	4	—
2	Write	DAR	0x00040000	4	—
3	Write	DCSR	0x04A00502	4	—
4	Read	CRR	0x0000xxxx	2	The high-order 16 bits are all set to 0s, and the read data is stored in the low-order 16 bits.

Table 36.15 2. Write Configuration Register

Step	Read/ Write	Register	Data	Data Length (Bytes)	Description
1	Write	DCR	0x00004000	4	—
2	Write	DAR	0x00040000	4	—
3	Write	DCSR	0x04A00002	4	—
4	Write	CWDR	0x0000xxxx	2	Set all the high-order 16 bits to 0 and specify the write data in the low-order 16 bits.

36.3.6.3 Modify Settings

If OctaFlash/RAM is operating in the different condition (not default condition), the Config Registers of OctaFlash/RAM and the memory controller must be modified after the initial setting.

(1) Set translate mode

When the translating mode uses whether DOPI, SOPI, or SPI mode in OctaFlash, it is necessary to modify the setting of the Config Register of OctaFlash and memory-controller. Refer to the data sheet of OctaFlash about how to set transfer type. For example, show the sequence to change transfer type in OctaFlash to Table 36.16. When the transfer type is changed from current transfer type, users issue WREN (Write Enable) instruction, successively issue WRCR2 instruction to modify the values of Configuration Register 2 in OctaFlash to change translating mode.

Table 36.16 Example of translating mode setting of OctaFlash (1 of 2)

Step	Read/ Write	Register	SPI Mode Data	Data Length (Bytes)	OPI Mode Data	Data Length (Bytes)	Description
Write Enable (WREN)							
1	Write	DCR	0x00000006	4	0x000006F9	4	—
2	Write	DCSR	0x00180000	4	0x00280000	4	—
3	Write	CWNDR	Any value	4	Any value	4	—
Write Configuration Register2 (WRCR2)							

Table 36.16 Example of translating mode setting of OctaFlash (2 of 2)

Step	Read/ Write	Register	SPI Mode Data	Data Length (Bytes)	OPI Mode Data	Data Length (Bytes)	Description
4	Write	DCR	0x00000072	4	0x0000728D	4	—
5	Write	DAR	0x00000000	4	0x00000000	4	—
6	Write	DCSR	0x04180001	4	0x04280001	4	—
7	Write	CWDR	0x00000001	1	0x00000001	1	in the case of SOPI mode
7	Write	CWDR	0x00000002	1	0x00000002	1	in the case of DOPI mode

The Config Register setting of the memory-controller in DOPI mode specifies to Table 36.17, the setting of SOPI mode specifies to Table 36.18, and the setting of SPI mode specifies to Table 36.19.

Table 36.17 Example of translating mode setting (DOPI mode)

Step	Read/ Write	Address (Register)	Data	Data Length (Bytes)	Description
1	Write	CDSR	0x80001C0A	4	Sets up the controller functions Auto-calibration is enabled Memory pre-cycle is disabled Transfer type of OctaFlash and OctaRAM set DOPI mode
2	Write	MRWCR1	0x12EDEE11	4	Specifies the read and write commands for OctaFlash Write command: PP of OctaFlash Read command: 8DTRD of OctaFlash

Table 36.18 Example of translating mode setting (SOPI mode)

Step	Read/ Write	Address (Register)	Data	Data Length (Bytes)	Description
1	Write	CDSR	0x80001C06	4	Sets up the controller functions Auto-calibration is enabled Memory pre-cycle is disabled Transfer type of OctaFlash set SOPI mode, and OctaRAM set DOPI mode
2	Write	MRWCR1	0x12EDEC13	4	Specifies the read and write commands for OctaFlash Write command: PP of OctaFlash Read command: 8READ of OctaFlash

Table 36.19 Example of translating mode setting (SPI mode)

Step	Read/ Write	Address (Register)	Data	Data Length (Bytes)	Description
1	Write	CDSR	0x80000004	4	Sets up the controller functions Auto-calibration is disabled Memory pre-cycle is disabled Transfer type of OctaFlash set SPI mode, and OctaRAM set DOPI mode
2	Write	MRWCR1	0x00120013	4	Specifies the read and write commands for OctaFlash Write command: PP of OctaFlash Read command: 8READ of OctaFlash

Note: OctaFlash connects the device 1, and OctaRAM connects the device 0.

(2) Set pre-cycle is enabled

When pre-cycle is enabled in OctaFlash/RAM, it is necessary to modify the setting of the Config Register of OctaFlash/RAM and memory-controller. Refer to the data sheet of OctaFlash/RAM about how to be enabled pre-cycle. For example, show the sequence to be enabled pre-cycle in OctaFlash to Table 36.20. When pre-cycle is enabled in OctaFlash, users issue WREN (Write Enable) instruction, and then issue WRCR2 instruction to modify the values of Configuration

Register 2 in OctaFlash to be enabled pre-cycle. For example, show the sequence to be enabled pre-cycle in OctaRAM to Table 36.21 When pre-cycle is enabled in OctaRAM, users write the Configuration Register in OctaRAM.

Table 36.20 Example of setting pre-cycle in OctaFlash

Step	Read/ Write	Register	SPI Mode Data	Data Length (Bytes)	OPI Mode Data	Data Length (Bytes)	Description
Write Enable (WREN)							
1	Write	DCR	0x00000006	4	0x000006F9	4	—
2	Write	DCSR	0x00180000	4	0x00280000	4	—
3	Write	CWNDR	Any value	4	Any value	4	—
Write Configuration Register2 (WRCR2)							
4	Write	DCR	0x00000072	4	0x0000728D	4	—
5	Write	DAR	0x00000200	4	0x00000200	4	—
6	Write	DCSR	0x04180001	4	0x04280001	4	—
7	Write	CWDR	0x00000001	1	0x00000001	1	—

Table 36.21 Example of setting pre-cycle in OctaRAM

Step	Read/ Write	Register	Data	Data Length (Bytes)	Description
1	Write	DCR	0x00004000	4	—
2	Write	DAR	0x00040000	4	—
3	Write	DCSR	0x04A00002	4	—
4	Write	CWDR	0x0000F152	2	pre-cycle is enabled latency counter is 8 clocks (default)

The configuration register of memory controller in DOPI mode specifies Table 36.22 and in SOPI mode specifies Table 36.23.

Table 36.22 Example of setting pre-cycle when OctaFlash is DOPI mode

Step	Read/ Write	Address (Register)	Data	Data Length (Bytes)	Description
1	Write	CDSR	0x80001C3A	4	Sets up the controller functions Auto-calibration is enabled Memory pre-cycle is enabled Transfer type of OctaFlash and OctaRAM set DOPI mode

Table 36.23 Example of setting pre-cycle when OctaFlash is SOPI mode

Step	Read/ Write	Address (Register)	Data	Data Length (Bytes)	Description
1	Write	CDSR	0x80001C36	4	Sets up the controller functions Auto-calibration is enabled Memory pre-cycle is enabled Transfer type of OctaFlash set SOPI mode and OctaRAM set DOPI mode

(3) Set the number of dummy cycle

In the case of operating in 100MHz, the dummy cycle of OctaFlash/RAM should be modified. Following the data-sheet of OctaFlash/RAM, the dummy cycle of OctaFlash is 10 and the dummy cycle (Latency counter) of OctaRAM is 4. For example, show the sequence to change the dummy cycle in OctaFlash to Table 36.24. When the dummy cycle is changed, users issue WREN (Write Enable) instruction, and successively issue WRCR2 instruction to change the dummy cycle in OctaFlash. For example, show the sequence to change the latency counter in OctaRAM to Table 36.25. When the latency

counter is changed, users write the Configuration Register in OctaRAM. The Config Register of the memory-controller specifies Table 36.26.

Table 36.24 Example of changing the dummy cycle in OctaFlash

Step	Read/ Write	Register	SPI Mode Data	Data Length (Bytes)	OPI Mode Data	Data Length (Bytes)	Description
Write Enable (WREN)							
1	Write	DCR	0x00000006	4	0x000006F9	4	—
2	Write	DCSR	0x00180000	4	0x00280000	4	—
3	Write	CWNDR	Any value	4	Any value	4	—
Write Configuration Register2 (WRCR2)							
4	Write	DCR	0x00000072	4	0x0000728D	4	—
5	Write	DAR	0x00000300	4	0x00000300	4	—
6	Write	DCSR	0x04180001	4	0x04280001	4	—
7	Write	CWDR	0x00000005	1	0x00000005	1	—

Table 36.25 Example of changing the latency counter in OctaRAM

Step	Read/ Write	Register	Data	Data Length (Bytes)	Description
1	Write	DCR	0x00004000	4	—
2	Write	DAR	0x00040000	4	—
3	Write	DCSR	0x04A00002	4	—
4	Write	CWDR	0x0000F112	2	pre-cycle is enabled latency counter is 4 clocks

Table 36.26 Example of dummy cycle setting

Step	Read/ Write	Address (Register)	Data	Data Length (Bytes)	Description
1	Write	MDLR	0x000A0404	4	Specifies the dummy length Dummy cycle of OctaFlash is 10 in reading Dummy cycle of OctaRAM is 4 in writing/reading

(4) Set preamble mode is enable

When users use the preamble of OctaFlash, it is necessary to modify the setting of the Config Register of OctaFlash and memory controller. Refer to the data sheet of OctaFlash about how to be enabled preamble. For example, show the sequence to set preamble mode in OctaFlash to Table 36.27. When users set preamble mode, users issue WREN (Write Enable) instruction, and then issue WRCR instruction to set preamble mode. Users need to check out bit0 (WIP) of Status Register in OctaFlash, until this bit (WIP) set 0.

Table 36.27 Example of setting preamble mode in OctaFlash (1 of 2)

Step	Read/ Write	Register	SPI Mode Data	Data Length (Bytes)	OPI Mode Data	Data Length (Bytes)	Description
Write Enable (WREN)							
1	Write	DCR	0x00000006	4	0x000006F9	4	—
2	Write	DCSR	0x00180000	4	0x00280000	4	—
3	Write	CWNDR	Any value	4	Any value	4	—
Write Configuration Register (WRCR)							
4	Write	DCR	—	—	0x000001FE	4	—
5	Write	DAR	—	—	0x00000001	4	—

Table 36.27 Example of setting preamble mode in OctaFlash (2 of 2)

Step	Read/ Write	Register	SPI Mode Data	Data Length (Bytes)	OPI Mode Data	Data Length (Bytes)	Description
6	Write	DCSR	—	—	0x04200001	4	—
7	Write	CWDR	—	—	0x00000017	1	—
Read Status Register (RDSR)							
8	Write	DCR	0x00000005	4	0x000005FA	4	—
9	Write	DAR	—	—	0x00000000	4	—
10	Write	DCSR	0x00180001	4	0x0C280401	4	—
11	Read	CRR	0x000000xx	4	0x000000xx	4	Users must repeat to read Status Register, until the bit0 (WIP) of data to read from Status Register will be 0.

36.3.6.4 Automatic Calibration Setting

The OSPI has an automatic calibration function to prevent acquisition of wrong data due to the variation of voltage and temperature.

Figure 36.14 shows the automatic calibration setting flow for the OctaFlash and OctaRAM devices.

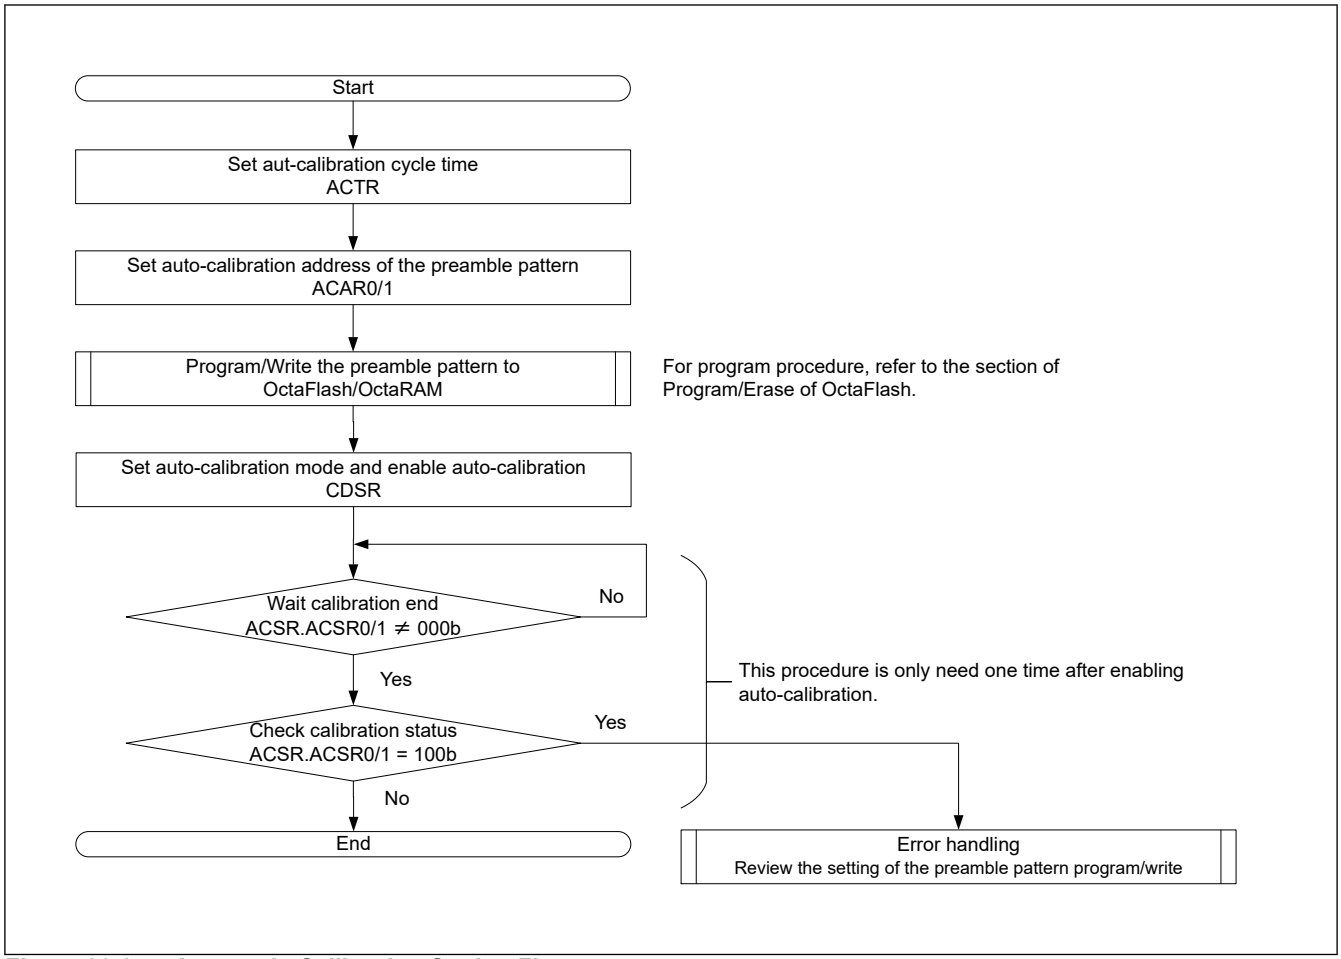

Figure 36.14 Automatic Calibration Setting Flow

For details, see section 36.3.6.2. Basic Operation Settings.

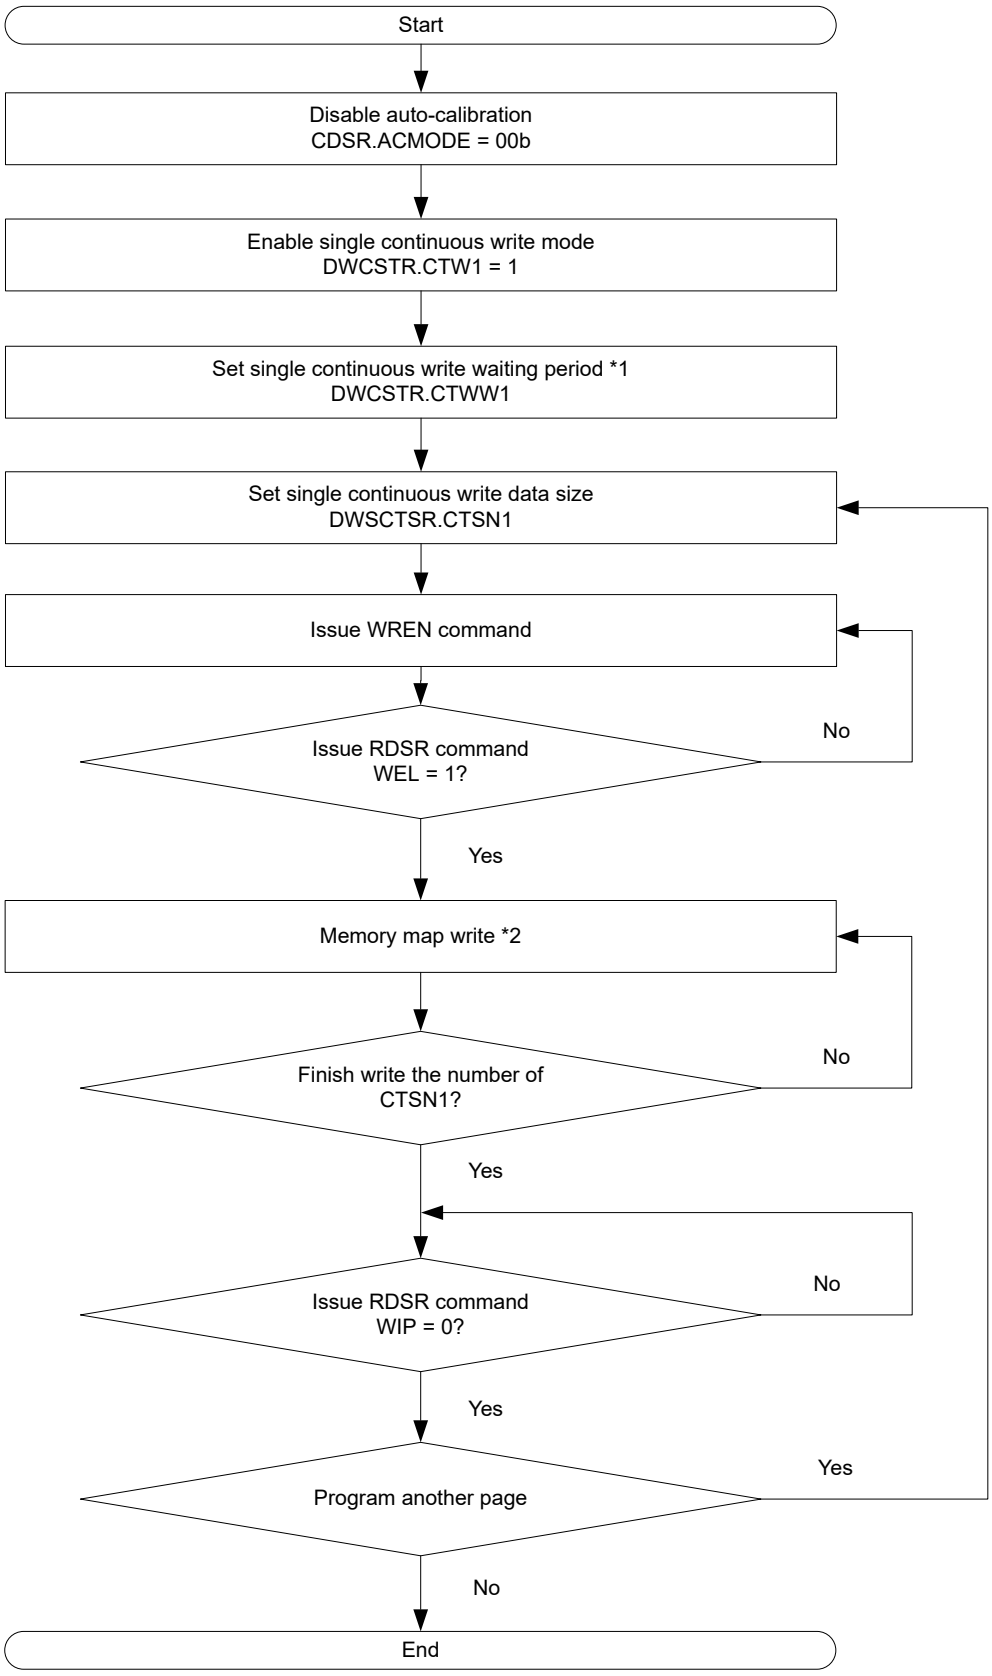
The following preamble pattern should be stored in the setting address of ACAR0 and ACAR1.

- DOPI mode when MRWCSR.MWOn = 0 (n = 0, 1) : 0x00F708F7_FF0000F7_0800FF00_FFFF0000

- DOPI mode when MRWCSR.MWOn = 1 (n = 0, 1) : 0xF700F708_00FFF700_000800FF_FFFF0000
- SOPI mode : 0xF7F700F7_0000FF00

36.3.6.5 Program/Erase of OctaFlash Setting

Figure 36.15 and Figure 36.16 show the procedure for program (write) and erase of OctaFlash. There is a restriction on partial program or double program in OctaFlash, so it should be programmed with a proper size according to the usage of OctaFlash. For details, see OctaFlash datasheet. The program size in one CS asserted period can be specified by enabling single continuous write mode.



Note 1. Set long enough period to ensure the one program size defined by the CTSN1 bits.
Note 2. Not change write access size 8/16/32 bit in one page program.

Figure 36.15 Procedure for program of OctaFlash

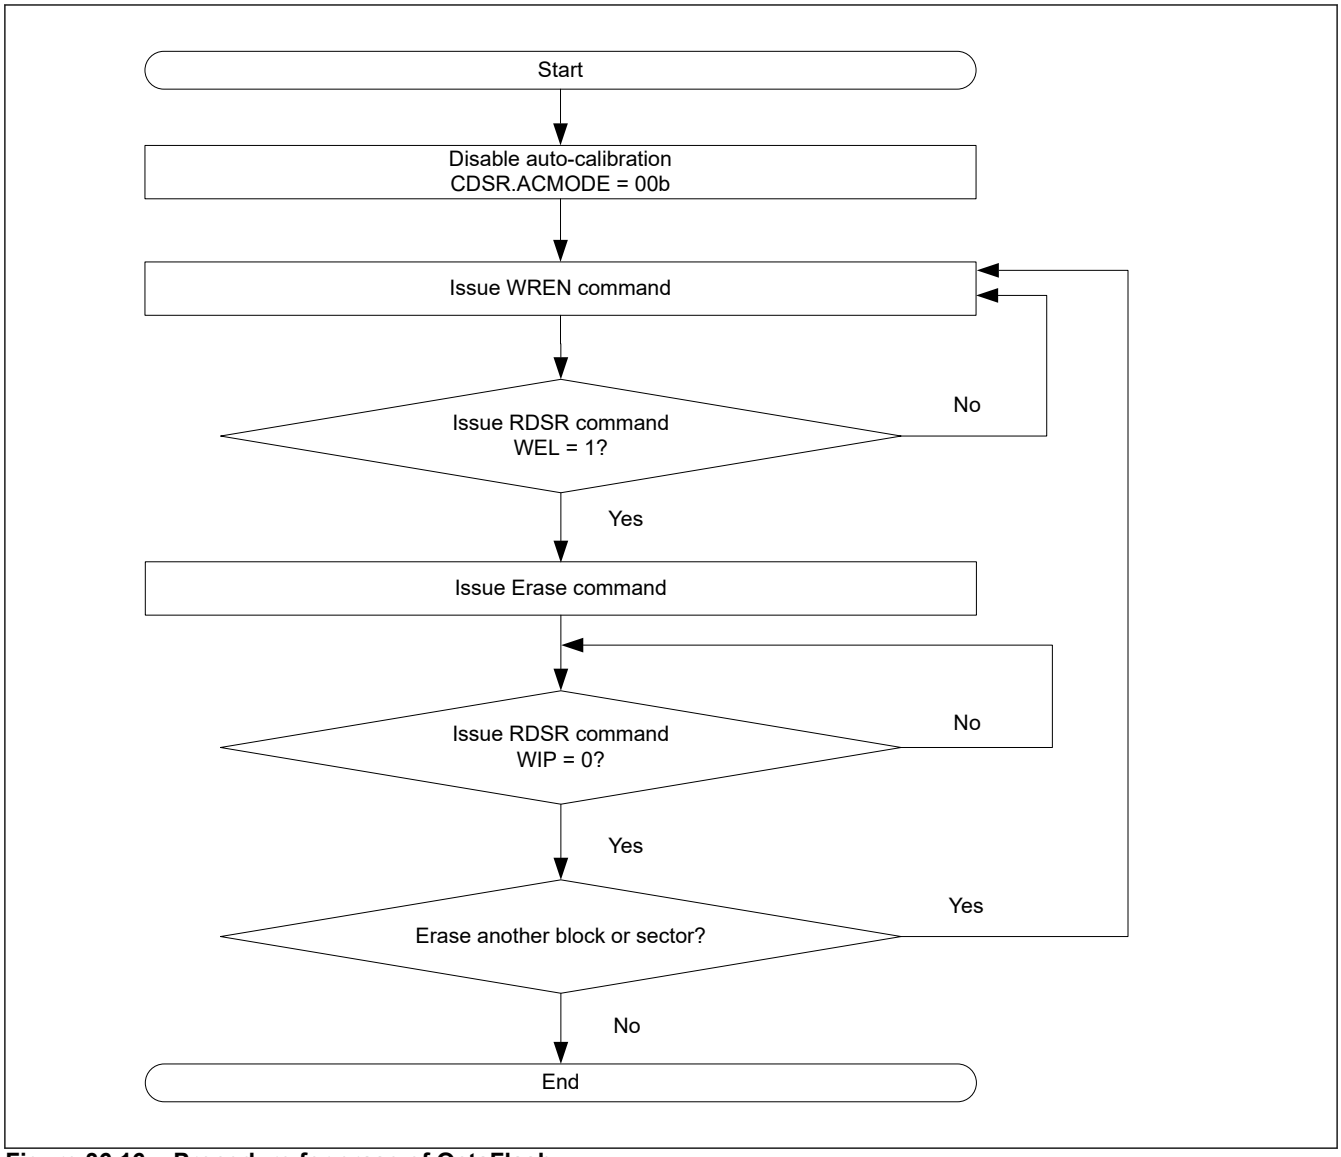


Figure 36.16 Procedure for erase of OctaFlash

36.4 SOPI/DOPI mode, Delay Line Adjustment and OM_DQS Auto-Calibration

36.4.1 SOPI/DOPI mode and OM_DQS

Depending on the characteristic of SOPI/DOPI mode, controller cannot latch data on the rising edge / falling edge of the OM_DQS clock, the delayed OM_DQS is needed to capture data with sufficiency setup/hold time margin.

Figure 36.17 shows delayed OM_DQS (OM_DQS strobe) has good latch position to latch data.

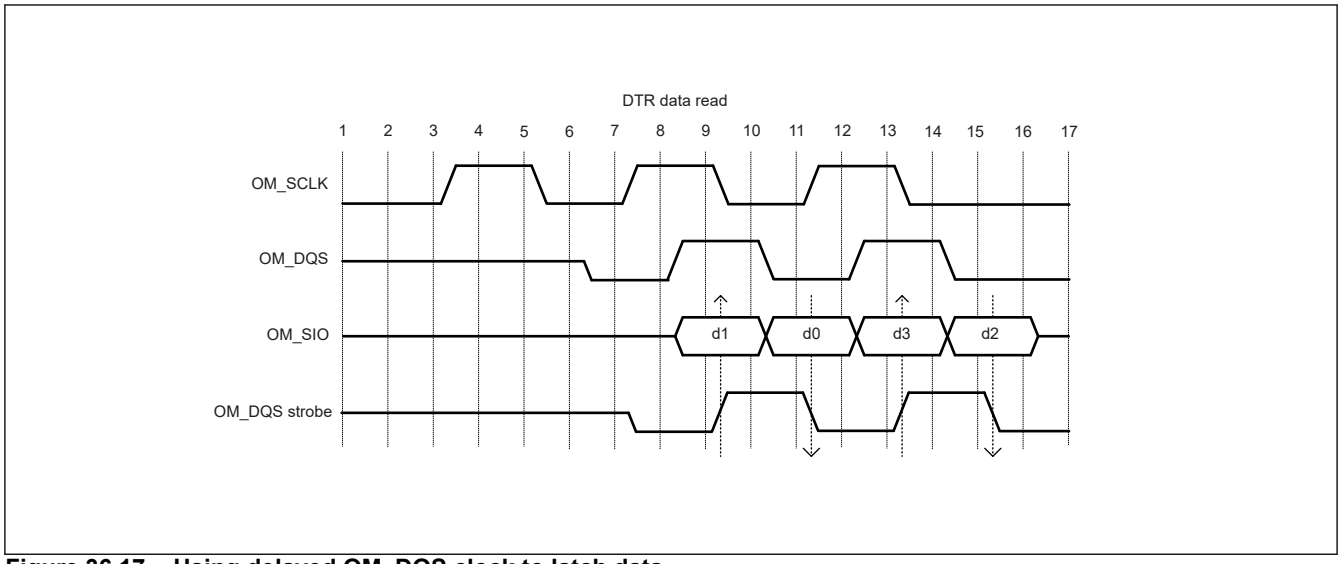

Figure 36.17 Using delayed OM_DQS clock to latch data

36.5 Single continuous write/read mode

Single continuous write/read is a mode to optimize a performance of single access with increment address. When the address is continuous, the OSPI skips to re-send command, address, and dummy cycles to memory device again by keeping OM_CS0/1 low.

Whether single continuous mode effectively optimize a performance depends on master. When master issue single access (not burst) with increment address, single continuous mode effectively optimize a performance. For recommended setting, see Table 36.28.

Table 36.28 Recommended single continuous mode setting when access address is increment

Master	Write/Read	Single continuous mode
CPU	Write	Enable
	Read with S Cache off*1	Enable
	Read with S Cache on*1	Disable
DMAC/DTC	Write	Enable
	Read	Enable
EDMAC	Write	Disable
	Read	Disable

Note 1. For details, see section 14.8. Cache.

36.5.1 Single continuous write operation

Figure 36.18 shows the procedure of single continuous write of OctaRAM. For the procedure of OctaFlash, see the Figure 36.15.

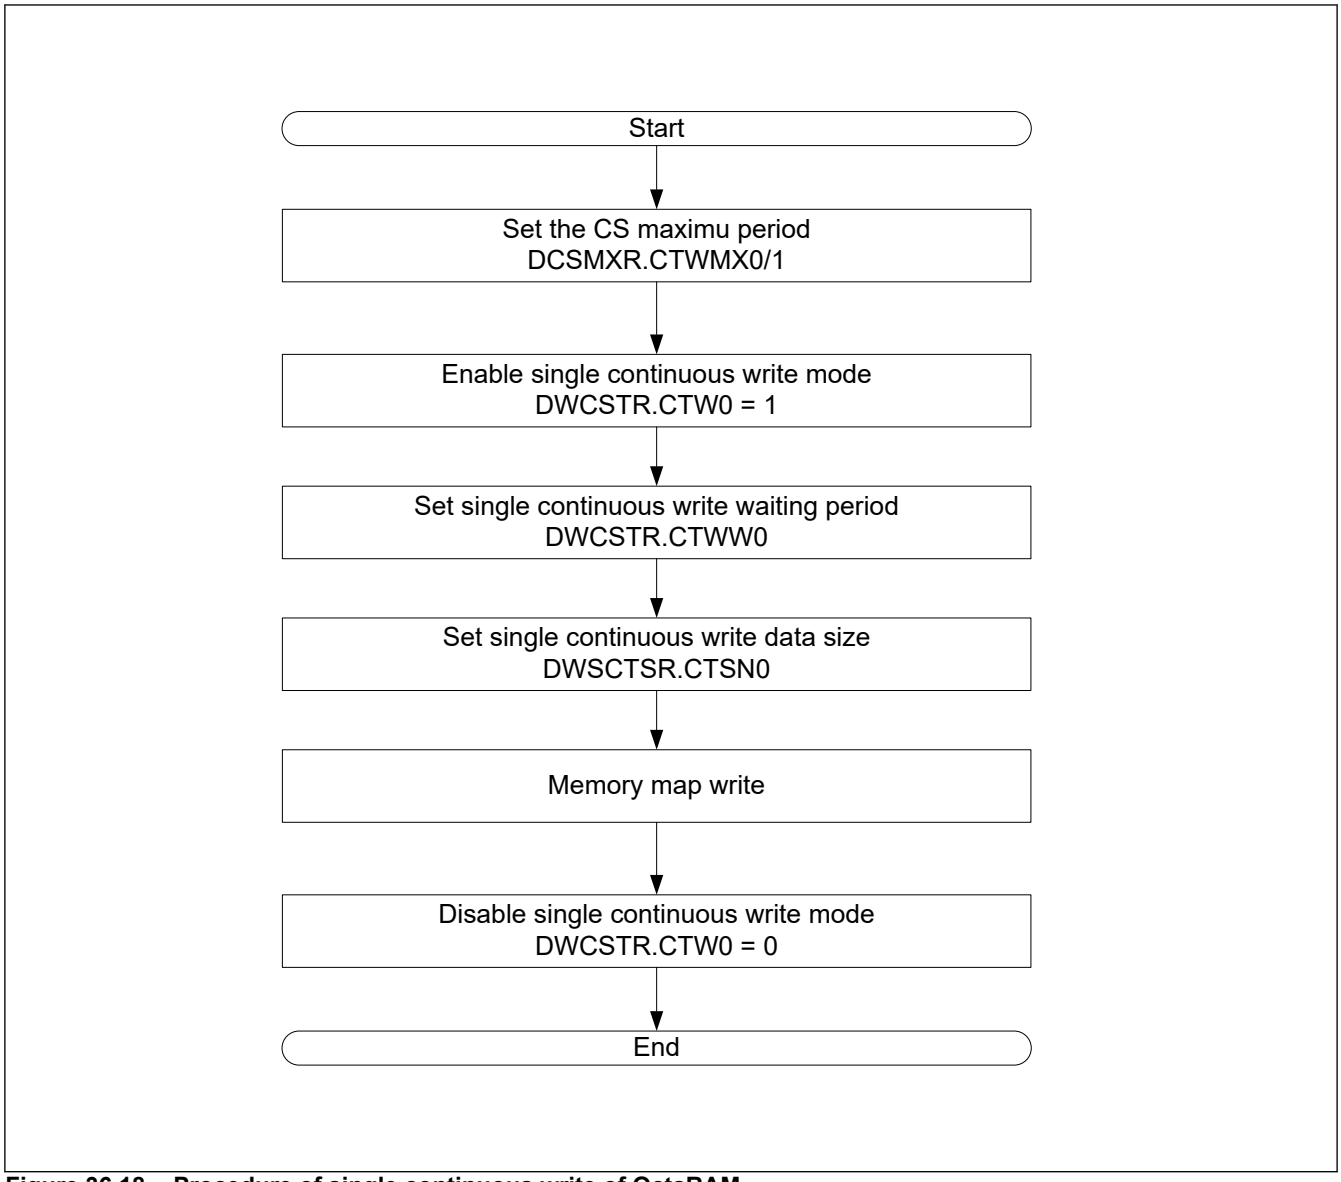

Figure 36.18 Procedure of single continuous write of OctaRAM

When DWCSTR.CTW0/1 is 1 and the OSPI receives a single write, write command will be issued and CS pin will be kept asserted.

When one of the following conditions is satisfied, the current single continuous write will finish and CS pin will be negated.

1. Current access address is not increment.
   The definition of increment address is:
   Current address = Previous address + Previous length
2. Current access attribution is burst (not single).
3. Current access size is different from previous access.*1
4. The OSPI has not received any access for the period specified by DWCSTR.CTWW0/1 bits.
5. Current access is read (not write).
6. CS asserted period has been elapsed the period specified by DCSMXR.CTWMX0/1 bits.*1 *2
7. The number of bytes specified by DWSCTSR.CTSN0/1 bits has been transferred.*3

Note 1. Although once CS pin is negated, next single continuous write will be issued automatically.
Note 2. This condition is for a restriction on CS asserted period in OctaRAM.
This condition is not applied to OctaFlash.
Note 3. When DWSCTSR.CTSN0/1 is set to 0, this condition is never satisfied.

36.5.2 Single continuous read operation

Figure 36.19 shows procedure for single continuous read of OctaRAM and OctaFlash.

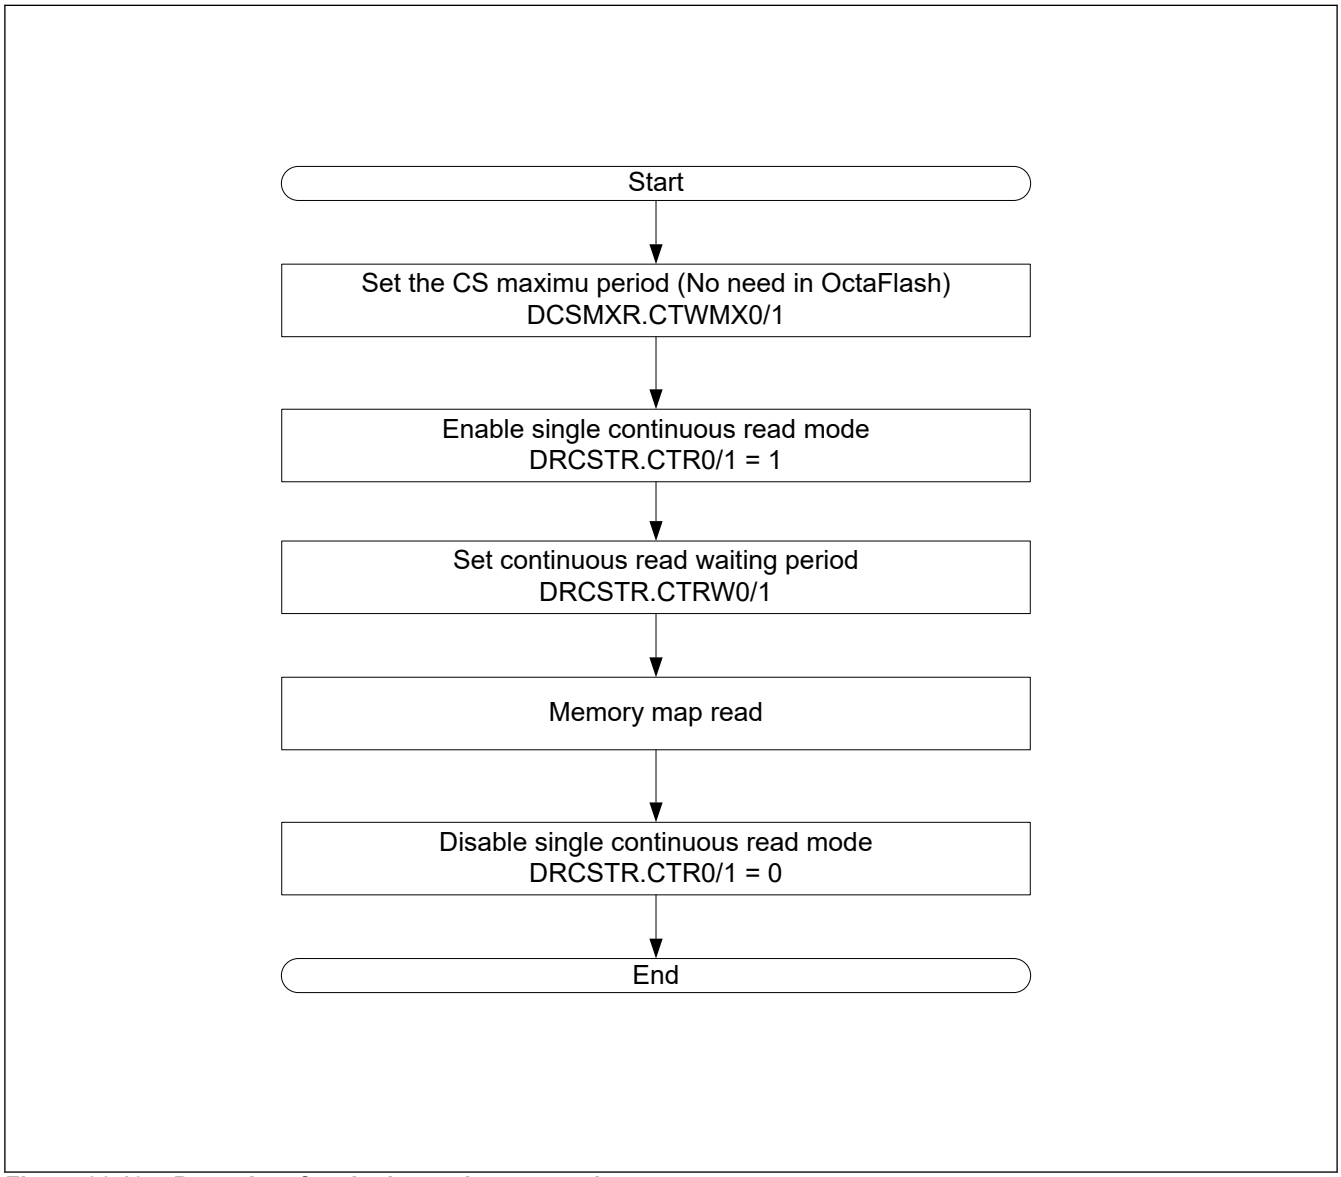

Figure 36.19 Procedure for single continuous read

When DRCSTR.CTR0/1 is 1 and the OSPI receives a single write, read command will be issued and CS pin will be kept asserted.

When one of the following conditions is satisfied, the current single continuous read will finish and CS pin will be negated.

1. Current access address is not increment.

   The definition of increment address is:

   Current address = Previous address + Previous length
2. Current access attribution is burst (not single).
3. Current access size is different from previous access.*1
4. The OSPI has not received any access for the period specified by DRCSTR.CTRW0/1 bits.
5. Current access is write (not read).
6. CS asserted period has been elapsed the period specified by DCSMXR.CTWMX0/1 bits.*1 *2

Note 1. Although once CS pin is negated, next single continuous read will be issued automatically.

Note 2. This condition is for a restriction on CS asserted period in OctaRAM.
This condition is not applied to OctaFlash.

36.6 OM_DQS Enable Counter

During read command operation, the OM_DQS signal is used as the data latch clock by the controller. When the memory device is in the idle state, OM_DQS maintains a high impedance (Hi-Z) state, and asserts low before data is output. This Hi-Z to Low transition may latch wrong data by driving the OM_DQS data latch logic of thecontroller.

Figure 36.20 shows the waveform when OM_DQS maintains a high-impedance (Hi-Z) state and asserts low before data is output.

Avoiding such Hi-Z to Low transitions, this controller can bypass wrong data with Memory delay trim register (MDTR). (MDTR.DQSEDOPI[3:0] for Flash DOPI mode, MDTR.DQSESOPI[3:0] for Flash SOPI mode, and MDTR.DQSERAM[3:0] for RAM mode)

Each configuration can be set from 0 to 15 for each case.

[OctaFlash]

OM_DQS Enable counter (MDTR) minimum value ≥ Command cycle number + Address cycle number*1 + OM_DQS Stable cycle number*2 + 1 (OM_DQS Delay cycle number)

OM_DQS Enable counter (MDTR) maximum value ≤ Command cycle number + Address cycle number*1 + Memory dummy cycle number*3 + Pre-cycle setting*4

[OctaRAM]

OM_DQS Enable counter (MDTR) minimum value ≥ Command cycle number + Address cycle number

OM_DQS Enable counter (MDTR) maximum value ≤ Command cycle number + Address cycle number*1 + Memory dummy cycle number + Pre-cycle setting*4

Note 1. Flash SOPI: Command cycle number + address cycle number = 2 + 4 = 6
Flash DOPI: Command cycle number + address cycle number = 1 + 2 = 3
RAM DOPI: number of command cycles + number of address cycles = 1 + 2 - 1 = 2 (start dummy calculation from the second cycle)
Note 2. OM_DQS Stable cycle number: Maximum value is 2 OM_SCLK (Reference specification of OctaFlash)
Note 3. Refer to OctaFlash minimum dummy cycle number in each command.
For example, dummy cycles of read configuration register is always 4 cycles regardless of dummy cycle setting of Configuration register 2.
Note 4. Pre-cycle setting: OM_DQSpre-cycle on/off
OM_DQS pre-cycle off: Pre-cycle setting = 0
OM_DQS pre-cycle on: Pre-cycle setting = -1

Setting example: Flash DOPI mode, dummy cycle = 4, pre-cycle is off

Minimum value of OM_DQS enable counter (MDTR) ≥ 1 + 2 + 2 + 1 = 6

Maximum value of OM_DQS enable counter (MDTR) ≤ 1 + 2 + 4 + 0 = 7

From the above, setting MDTR .DQSEDOPI[3:0] from 6 to 7 can latch the correct data. If MDTR is too small, wrong data may be latched due to a transition from Hi-Z to Low. If MDTR is too large, no data is latched.

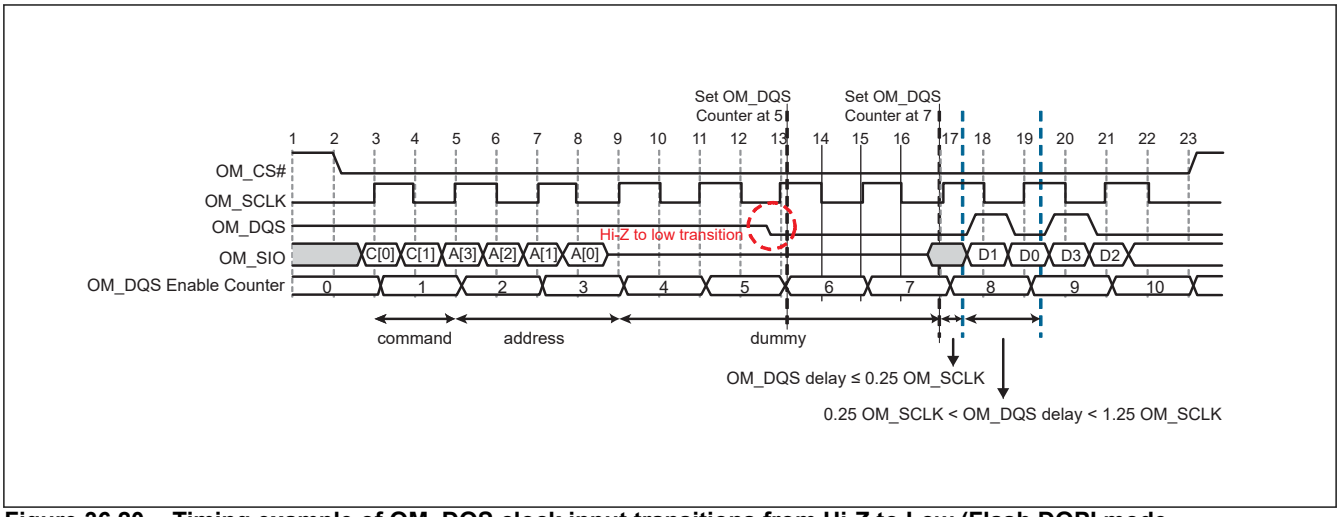

Figure 36.20 Timing example of OM_DQS clock input transitions from Hi-Z to Low (Flash DOPI mode, dummy cycle number = 4, OM_DQS pre-cycle on)

36.7 Interrupt and bus error

The OSPI output the interrupt request and bus error to the CPU in the following conditions.

Table 36.29 Interrupt and bus error sources

Access	Interrupt and bus error sources	Status flag	Interrupt	Bus error
memory-mapped write	Illegal address access	ESR.MWESR = 0x80	✓	✓
	Access during the OSPI is module stop state	—	×	✓
memory-mapped read	Illegal address access or DQS timeout detection in single continuous mode*1	ESR.MRESR = 0x80	✓	✓
	OctaFlash ECC error detection	ESR.MRESR = 0x01	✓	✓
	Preamble error detection	ESR.MRESR = 0x02	✓	✓
	DQS timeout detection*1	ESR.MRESR = 0x03	✓	✓
	Access during the OSPI is module stop state	—	×	✓
Register write	Illegal address access	—	×	✓
Register read	Illegal address access	—	×	✓
CRR register read	DQS timeout detection	—	×	✓

Note 1. After DQS timeout detection, the ESR.MRESR is set to 0x08 only under the condition that first memory map read after reset is executed in single continuous mode. The ESR.MRESR is set to 0x03 under other conditions.

36.8 Usage Note

36.8.1 Setting for the Module-Stop Function

Do not set the MSTP bit of the OSPI to 1 while the OSPI is accessing to the memory devices.

36.8.2 CPU write access attribution

CPU write access attribution to OSPI I/O registers area is recommended to be non-bufferable. Write access attribution is specified by the MPU registers in CPU. For details, see the *ARMv8-M Architecture Reference Manual* (ARM DDI 0553A).

When CPU write access attribution is bufferable, after writing register in memory device or OSPI, confirm that its value has actually changed before memory map read/write.

36.8.3 DQS in SOPI mode

OctaFlash support SOPI mode. In SOPI mode, set DQS enable by the configuration register2 of OctaFlash. The OSPI only support SOPI mode with enabling DQS.

37. CEC Transmission/Reception Circuit (CEC)

37.1 Overview

The CEC transmission/reception circuit can generate and receive CEC signals conforming to the Consumer Electronics Control (CEC) standard, and automatically detect communication statuses by the CEC. CEC transmission/reception can be easily controlled by using these functions.

Table 37.1 lists the CEC specifications and Figure 37.1 shows a block diagram.

Table 37.1 CEC specifications

Parameter	Description
Communication method	Serial communication can be performed that conforms to the Consumer Electronics Control (CEC) standard in the High-Definition Multimedia Interface (HDMI) Ver. 1.4b.
CEC operation clock (f_{CEC})	Selectable from PCLKB/2^5, PCLKB/2^6, PCLKB/2^7, PCLKB/2^8, PCLKB/2^9, PCLKB/2^{10}, CECCLK, and CECCLK/2^8
Interrupt sources	• Data interrupt (INTDA) • Communication complete interrupt (INTCE) • Error interrupt (INTERR) (transmit, ACK, arbitration, timing, underrun, overrun, and bus lock errors)
Other functions	• Communication bit width adjustment function Can be used to set the low-level width and bit width of the start bit and data bit that configure the CEC data frame during transmission. • Count function during signal-free time Can be used to count during the signal-free time (transmission disable period) specified in the CEC standard and set the count period. • Error handling function Can be used to output an error handling pulse by detecting a timing error of the data bit. • Function that restarts reception by detecting the start bit during reception

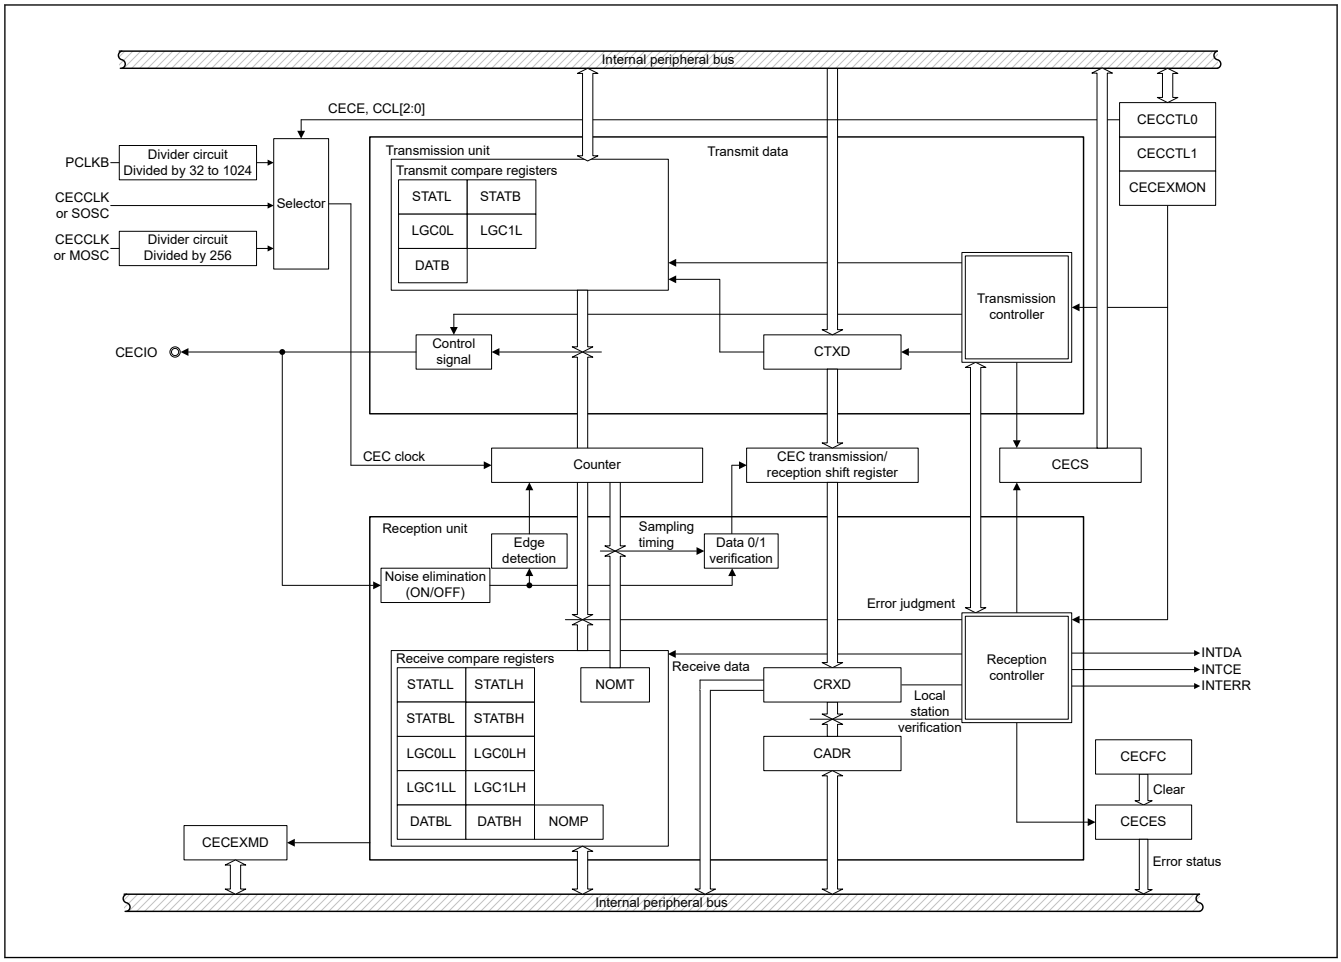

Figure 37.1 CEC block diagram

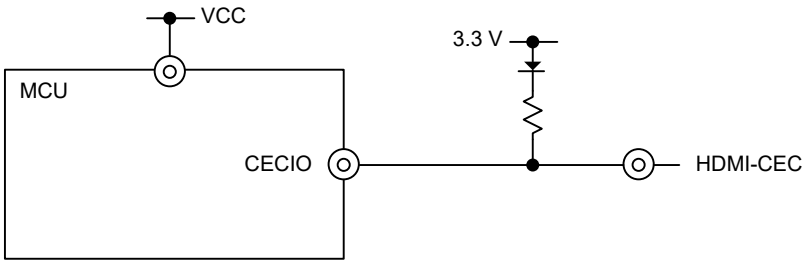
Figure 37.2 shows an example of I/O pin connection to the external circuit. Table 37.2 lists an I/O pin used for the CEC.



Note: When using the CEC transmission/reception function at a value other than VCC = 3.3 V ± 10%, an external circuit is required to meet the CEC standard value.

Figure 37.2 Example of I/O pin connection to external circuit (When using with Vcc = 3.3 ± 10%)

Table 37.2 CEC pin configuration

Pin name	I/O	Function
CECIO	I/O	CEC data communication

37.1.1 Term Description

- Initiator: Device that transmits or is transmitting CEC messages
- Follower: Device that receives or is receiving CEC messages

- Message: All data from the start bit to the operand
- Initiator address: Source address
- Destination address: Destination address
- Direct address communication (direct address message): Communication with one follower
- Broadcast communication (broadcast message): Communication with multiple followers
- Arbitration: Prioritizing devices that output a low level to the CEC line when multiple initiators exist
- Arbitration loss: State in which competing devices are prioritized. At this time, the local station stops transmitting
- Bus free: State in which no communication is performed but transmission can be performed
- Bus busy: During communication
- Error handling: Outputting an error handling pulse (low level with a width of the bit width × 1.5) and transitioning to the communication standby state when a received bit width is shorter than the setting bit width of the data
- ACK/NACK: The logic levels received at the ACK bit timing are as follows:
  ACK: Outputs logical 0
  NACK: Outputs logical 1

(Example) If the initiator outputs logical 1 and the follower outputs logical 0 during an ACK bit period:
Initiator: Transmits a NACK
Follower: Transmits an ACK

Figure 37.3 shows an example of outputting the ACK bit.

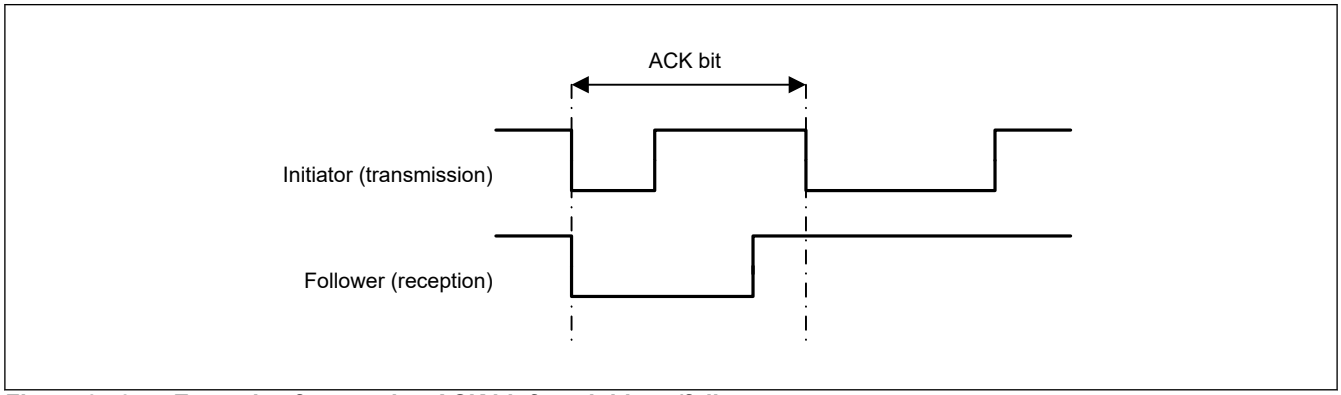


Figure 37.3 Example of outputting ACK bit from initiator/follower

37.2 Register Descriptions

37.2.1 CADR : CEC Local Address Setting Register

Base address: CEC = 0x400A_C000

Offset address: 0x00

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	ADR14	ADR13	ADR12	ADR11	ADR10	ADR09	ADR08	ADR07	ADR06	ADR05	ADR04	ADR03	ADR02	ADR01	ADR00
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	ADR00	Local Address at Address 0 (TV) 0: Does not set as local address. 1: Sets as local address.	R/W

Bit	Symbol	Function	R/W
1	ADR01	Local Address Setting at Address 1 (recording device 1) 0: Does not set as local address. 1: Sets as local address.	R/W
2	ADR02	Local Address Setting at Address 2 (recording device 2) 0: Does not set as local address. 1: Sets as local address.	R/W
3	ADR03	Local Address Setting at Address 3 (tuner 1) 0: Does not set as local address. 1: Sets as local address.	R/W
4	ADR04	Local Address Setting at Address 4 (playback device 1) 0: Does not set as local address. 1: Sets as local address.	R/W
5	ADR05	Local Address Setting at Address 5 (audio system) 0: Does not set as local address. 1: Sets as local address.	R/W
6	ADR06	Local Address Setting at Address 6 (tuner 2) 0: Does not set as local address. 1: Sets as local address.	R/W
7	ADR07	Local Address Setting at Address 7 (tuner 3) 0: Does not set as local address. 1: Sets as local address.	R/W
8	ADR08	Local Address Setting at Address 8 (playback device 2) 0: Does not set as local address. 1: Sets as local address.	R/W
9	ADR09	Local Address Setting at Address 9 (recording device 3) 0: Does not set as local address. 1: Sets as local address.	R/W
10	ADR10	Local Address Setting at Address 10 (tuner 4) 0: Does not set as local address. 1: Sets as local address.	R/W
11	ADR11	Local Address Setting at Address 11 (playback device 3) 0: Does not set as local address. 1: Sets as local address.	R/W
12	ADR12	Local Address Setting at Address 12 (reserved) 0: Does not set as local address. 1: Sets as local address.	R/W
13	ADR13	Local Address Setting at Address 13 (reserved) 0: Does not set as local address. 1: Sets as local address.	R/W
14	ADR14	Local Address Setting at Address 14 (specific use) 0: Does not set as local address. 1: Sets as local address.	R/W
15	—	This bit is read as 0. The write value should be 0.	R/W

Note: To specify address 15 (unregistered) as the CEC local address, clear the ADR00 to ADR14 bits to 0.
Note: Do not rewrite the set value during communication (CECS.BUSST = 1).

The CADR register is a 16-bit register that sets local addresses. This register is valid only during a reception, the ADR00 to ADR14 bits correspond to CEC logical addresses 0 to 14, and up to 15 local addresses can be set. To specify address 15 as the CEC local address, clear the ADR00 to ADR14 bits to 0. A broadcast address always operates as a local address.

For example, when using addresses 0 as local addresses, set the ADR00 bit to 1.

37.2.2 CTXD : CEC Transmission Buffer Register

Base address: CEC = 0x400A_C000

Offset address: 0x40

Bit position:	7	6	5	4	3	2	1	0
Bit field:								
Value after reset:	0	0	0	0	0	0	0	0

The CTXD sequentially transmits 8 bits of data, starting from bit 7 with MSB first. A transmission/reception interrupt request signal (INTDA) is generated at the start timing of the header block and data block. Successive transmission can be performed by writing the next data to the CTXD register before the transmission ends after INTDA is generated.

If an underrun error occurs (UERR = 1), transmission does not continue. An error interrupt is generated and the transmission wait state is entered.

If transmit data is written to this register after a data interrupt (INTDA) is generated during transmission of the last block, the data is invalid.

37.2.3 CRXD : CEC Reception Buffer Register

Base address: CEC = 0x400A_C000

Offset address: 0x41

Bit position:	7	6	5	4	3	2	1	0
Bit field:								
Value after reset:	0	0	0	0	0	0	0	0

The CRXD retains receive data that can be read by reading this register. For every byte of data received, new data is transferred from the CEC Reception Shift register.

If an overrun error occurs (CECES.OERR = 1), the data of the reception buffer register will be overwritten.

37.2.4 CECCTL0 : CEC Control Register 0

Base address: CEC = 0x400A_C000

Offset address: 0x45

Bit position:	7	6	5	4	3	2	1	0
Bit field:	CECE	ACKTEN	CCL[2:0]			TXTRG	CECRXEN	EOM
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	EOM	EOM Setting 0: Continues transmission. 1: Last frame	R/W
1	CECRXEN	Reception Enable Control 0: Disables continuing reception or reports abnormal reception. 1: Enables continuing reception or reports normal reception. Table 37.3 lists the reception status and ACK/NACK timing output.	R/W
2	TXTRG	Transmission Start Trigger 0: No effect 1: Starts CEC transmission.	W

Bit	Symbol	Function	R/W
5:3	CCL[2:0]	CEC Clock Select*1 0 0 0: PCLKB/2^5 0 0 1: PCLKB/2^6 0 1 0: PCLKB/2^7 0 1 1: PCLKB/2^8 1 0 0: PCLKB/2^9 1 0 1: PCLKB/2^{10} 1 1 0: CECCLK (when using SOSC) 1 1 1: CECCLK/2^8 (when using MOSC)	R/W
6	ACKTEN	ACK Bit Timing Error (Bit Width) Check Enable*1 0: Does not detect ACK bit timing errors. 1: Detects ACK bit timing errors.	R/W
7	CECE	CEC Operation Enable Flag 0: Disables CEC operation. 1: Enables CEC operation.	R/W

Note 1. Rewritable only when CEC operation is stopped (CECCTL0.CECE = 0).

CECCTL0 selects enabling operation, starting transmission, and the operating clock.

EOM bit (EOM Setting)

The next frame after 1 is written to this bit is the last frame.

Set the EOM bit before writing transmit data to the transmission buffer register (CTXD).

Writing to the EOM bit and the transmission buffer register (CTXD) should be set after a data interrupt (INTDA) is generated and before the next data interrupt (INTDA) is generated (timing at which the EOM bit transmission is complete). However, this setting is not required when the data interrupt (INTDA) for the last block is generated.

CECRXEN bit (Reception Enable Control)

Setting the CECRXEN bit to 1 enables reception. Set this bit to 1 after determining the local address (setting the CADR register). Do not rewrite the set value during communication (CECS.BUSST = 1).

Table 37.3 Reception status and ACK/NACK timing output from the status of Reception Enable Control Bit

CECRXEN	Reception Enable Control Bit		
1	Reception status		ACK/NACK timing output
	During direct address reception (to local station)	Normal reception	ACK
		Timing error occurrence	NACK
	During broadcast reception	Normal reception	NACK
		Timing error occurrence	ACK
	During direct address reception (to another station)	Not participating in communication (high-impedance)	
0	Reception status		ACK/NACK timing output
	During direct address reception (to local station)	Normal reception	NACK
		Timing error occurrence	NACK
	During broadcast reception	Normal reception	ACK
		Timing error occurrence	ACK
	During direct address reception (to another station)	Not participating in communication (high-impedance)	

TXTRG bit (Transmission Start Trigger)

Setting TXTRG to 1 starts transmission.

This bit is a trigger bit and the read value is 0.

Set CECCTL0.TXTRG to 1 only when CEC operation is enabled (CECCTL0.CECE = 1) and the bus is free (CECS.BUSST = 0). Transmission starts no more than three CEC clock cycles after CECCTL0.TXTRG is set to 1.

CCL[2:0] bit (CEC Clock Select)

The CCL[2:0] bits select the CEC clock. Set the frequency of the CEC clock in the range of 23.4375 to 78.125 kHz. Table 37.4 and Table 37.5 show examples of CEC clock settings.

Table 37.4 Examples of CEC clock settings (1)

CEC clock selected	CEC operation clock (f_{CEC})					
	When PCLKB = 50 MHz	When PCLKB = 40 MHz	When PCLKB = 30 MHz	When PCLKB = 20 MHz	When PCLKB = 10 MHz	When PCLKB = 1 MHz
PCLKB/2^5	set prohibited	set prohibited	set prohibited	set prohibited	set prohibited	31.250 kHz
PCLKB/2^6	set prohibited	set prohibited	set prohibited	set prohibited	set prohibited	set prohibited
PCLKB/2^7	set prohibited	set prohibited	set prohibited	set prohibited	78.125 kHz	set prohibited
PCLKB/2^8	set prohibited	set prohibited	set prohibited	78.125 kHz	39.062 kHz	set prohibited
PCLKB/2^9	set prohibited	78.125 kHz	58.593 kHz	39.062 kHz	set prohibited	set prohibited
PCLKB/2^{10}	48.828 kHz	39.062 kHz	29.296 kHz	set prohibited	set prohibited	set prohibited

Table 37.5 Examples of CEC clock settings (2)

CEC clock selected	CEC operation clock (f_{CEC})
CECCLK	32.768 kHz (SOSC selected)
CECCLK/2^8	31.250 kHz to 78.125 kHz (MOSC selected)

ACKTEN bit (ACK Bit Timing Error (Bit Width) Check Enable)

When ACKTEN is set to 1, timing errors are detected for the bit width (the values specified for DATBL and DATBH), in addition to the low-level width of the ACK bit (the values specified for LGC0LL, LGC0LH, LGC1LL, and LGC1LH). However, the maximum bit width (DATBH) is not checked for the ACK bit of the last frame (EOM = 1) even if ACKTEN is 1.

CECE flag (CEC Operation Enable Flag)

Setting CECE to 1 enables CEC operation. Setting this flag to 0 resets the internal block but does not reset control registers.

37.2.5 CECCTL1 : CEC Control Register 1

Base address: CEC = 0x400A_C000

Offset address: 0x02

Bit position:	7	6	5	4	3	2	1	0
Bit field:	CDFC	CINTMK	BLERRD	STERRD	CESEL[1:0]		SFT[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	SFT[1:0]	Signal-Free Time Data Bit Width Select 0 0: 3-data bit width 0 1: 5-data bit width 1 0: 7-data bit width 1 1: Does not detect signal-free time.	R/W

Bit	Symbol	Function	R/W
3:2	CESEL[1:0]	Communication Complete Interrupt (INTCE) Generation Timing Select*1 0 0: Generates communication complete interrupt once after ACK transmission (reception) of the last frame (EOM = 1) is complete and another time after signal-free time is detected. 0 1: Generates communication complete interrupt after ACK transmission (reception) of the last frame (EOM = 1) is completed. 1 0: Generates communication complete interrupt after signal-free time is detected. 1 1: Setting prohibited	R/W
4	STERRD	Start Bit Error Detection Select*1 0: Does not detect timing errors during start bit reception. 1: Detects timing errors during start bit reception.	R/W
5	BLERRD	Bus Lock Detection Select*1 0: Does not detect sticking of receive data to high or low 1: Detects sticking of receive data to high or low.	R/W
6	CINTMK	CEC Data Interrupt (INTDA) Generation Select*1 0: Does not generate an interrupt when the addresses do not match. 1: Generates an interrupt when the addresses do not match.	R/W
7	CDFC	Digital Filter Select*1 0: Does not use a digital filter. 1: Uses a digital filter.	R/W

Note 1. Rewritable only when CEC operation is stopped (CECCTL0.CECE = 0).

The CECCTL1 register selects a digital filter, data interrupt generation, a start bit error interrupt, and whether to generate a communication complete interrupt and when to generate it.

SFT[1:0] bits (Signal-Free Time Data Bit Width Select)

The bit width of the signal-free time is selected by setting the SFT[1:0] bits in the NOMP register. Rewrite these bits only after confirming that the Signal-Free Time Rewrite Disable Report Flag (CECS.SFTST) is 0.

CESEL[1:0] bits (Communication Complete Interrupt (INTCE) Generation Timing Select)

The timing at which a communication complete interrupt (INTCE) is generated, is selected by setting the CESEL[1:0] bits.

STERRD bit (Start Bit Error Detection Select)

The STERRD bit detects timing errors during start bit reception according to the set value of the STATLL, STATLH, STATBL, or STATBH register by setting this bit to 1.

If a timing error occurred, the start bit for which the error occurred is determined to be disabled and communication standby state is entered.

If the STERRD bit is 0, no timing error is detected. All pulses are determined to be start bits.

BLERRD bit (Bus Lock Detection Select)

The bus lock status of the CEC line can be detected by setting the BLERRD bit to 1. If the next falling edge is not input for a period 2.5 times the 1-data bit width set with the NOMP register in a state where the falling edge of the CEC line is awaited (excluding the communication standby state), an error interrupt (INTERR) is generated the Bus Lock Error Detection Flag (BLERR) is set. Afterward, communication standby state is entered.

CINTMK bit (CEC Data Interrupt (INTDA) Generation Select)

The CINTMK bit selects whether to generate INTDA of the header block when the destination address and local address do not match during a reception or to generate INTCE when communication is complete.

CDFC bit (Digital Filter Select)

The CDFC bit eliminates noise from one CEC clock cycle using a digital filter.

37.2.6 CECS : CEC Communication Status Register

Base address: CEC = 0x400A_C000

Offset address: 0x43

Bit position:	7	6	5	4	3	2	1	0
Bit field:	SFTST	—	—	ITCEF	EOMF	TXST	BUSST	ADRF
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	ADRF	Address Match Detection Flag 0: During communication between other stations, while communication is stopped, or while the local station is transmitting 1: During local reception	R
1	BUSST	Bus Busy Detection Flag 0: Bus-free state 1: Bus-busy state	R
2	TXST	Transmission Status Flag 0: During communication standby state or reception (a follower is operating.) 1: During transmission (an initiator is operating.)	R
3	EOMF	EOM Flag 0: The EOM flag received immediately before is logically 0. 1: The EOM flag received immediately before is logically 1.	R
4	ITCEF	INTCE Generation Source Flag 0: Generates a communication complete interrupt (INTCE) if the signal-free time is counted. 1: Generates INTCE if communication is complete or an error is detected.	R
6:5	—	These bits are read as 0. The write value should be 0.	R/W
7	SFTST	Signal-Free Time Rewrite Disable Report Flag 0: Enables rewriting CECCTL1.SFT[1:0]. 1: Disables rewriting CECCTL1.SFT[1:0].	R

The CECS register indicates the CEC communication status.

ADRF flag (Address Match Detection Flag)

The ADRF flag checks whether communication is addressed to the local station.

[Setting conditions]

- When the local address and reception destination address match
- When a broadcast address is received

[Clearing conditions]

- When CEC operation is stopped (CECCTL0.CECE = 0)
- When reception is completed

BUSST flag (Bus Busy Detection Flag)

The BUSST flag checks the CEC bus state.

[Setting conditions]

- When a fall of the CEC line is detected
- When the status CEC operation is stopped changes to CEC operation is enabled (CECCTL0.CECE is changed from 0 to 1)

[Clearing conditions]

- When CEC operation is stopped (CECCTL0.CECE = 0)

- When the signal-free time has elapsed after communication has ended

TXST flag (Transmission Status Flag)

The TXST flag checks whether transmission is in progress.

EOMF flag (EOM Flag)

The EOMF flag checks the value of the bit received immediately before. The value is updated each time a data interrupt (INTDA) is generated.

ITCEF flag (INTCE Generation Source Flag)

By checking the ITCEF flag after INTCE is generated, it can be determined which case is the interrupt generation source that the signal-free time is counted, communication ends, or an error is detected. This setting is enabled only if CECCTL1.CESEL[1:0] are cleared to 0.

SFTST flag (Signal-Free Time Rewrite Disable Report Flag)

The SFTST flag checks whether rewriting CECCTL1.SFT[1:0] is enabled or disabled.

[Setting condition]

- When a write access to CECCTL1 is performed

[Clearing conditions]

- When CEC operation is stopped (CECCTL0.CECE = 0)
- When the CECCTL1.SFT[1:0] rewrite disable period has elapsed

37.2.7 CECES : CEC Communication Error Status Register

Base address: CEC = 0x400A_C000

Offset address: 0x42

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	BLERR	AERR	TXERR	TERR	ACKERR	UERR	OERR
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	OERR	Overrun Error Detection Flag 0: No overrun error has occurred. 1: An overrun error has occurred.	R
1	UERR	Underrun Error Detection Flag 0: No underrun error has occurred. 1: An underrun error has occurred.	R
2	ACKERR	ACK Error Detection Flag 0: No ACK error has occurred. 1: An ACK error has occurred.	R
3	TERR	Timing Error Detection Flag 0: No timing error has occurred. 1: A timing error has occurred.	R
4	TXERR	Transmission Error Detection Flag*1 0: No transmission error has occurred. 1: A transmission error has occurred.	R
5	AERR	Arbitration Loss Detection Flag 0: No arbitration loss has occurred. 1: An arbitration loss has occurred.	R
6	BLERR	Bus Lock Error Detection Flag 0: No bus lock error has occurred. 1: A bus lock error has occurred.	R

Bit	Symbol	Function	R/W
7	—	This bit is read as 0. The write value should be 0.	R/W

Note 1. Transmission errors are not detected while transmitting the start bit and ACK bit.

CECES indicates whether a bus lock error, arbitration loss, transmission error, timing error, ACK error, underrun error, or overrun error is detected.

OERR flag (Overrun Error Detection Flag)

The OERR flag checks whether an overrun has occurred.

[Setting condition]

- When the next receive operation completes before the receive data stored in the reception buffer register (CRXD) is read

[Clearing condition]

- When 1 is written to CECFC.OCTRG

UERR flag (Underrun Error Detection Flag)

The UERR flag checks whether an underrun has occurred.

[Setting condition]

- When transmit data is not written to the transmission buffer register (CTXD) after a data interrupt (INTDA) is generated and before the next interrupt (INTDA) is generated

[Clearing condition]

- When 1 is written to CECFC.UCTRG

ACKERR flag (ACK Error Detection Flag)

The ACKERR flag checks whether an ACK error has occurred.

[Setting conditions]

- When logical 1 is received at the ACK bit timing during a direct address communication
- When logical 0 is received at the ACK bit timing during a broadcast communication
- When logical 1 is received at the ACK bit timing during a logical address allocation transmission

[Clearing condition]

- When 1 is written to CECFC.ACKCTRG

TERR flag (Timing Error Detection Flag)

The TERR flag checks whether a timing error has occurred.

[Setting condition]

- When a violation is detected in the timing check of the received data

[Clearing condition]

- When 1 is written to CECFC.TCTRG

TXERR flag (Transmission Error Detection Flag)

The TXERR flag checks whether a transmission error has occurred.

[Setting condition]

- When the logic of the transmit and receive data are compared and do not match when the initiator is operating

[Clearing condition]

- When 1 is written to CECFC.TXCTRG

AERR flag (Arbitration Loss Detection Flag)

The AERR flag checks whether arbitration is lost.

[Setting condition]

- When arbitration loss occurs between start bit transmission and initiator address transmission

[Clearing condition]

- When 1 is written to CECFC.ACTRG

BLERR flag (Bus Lock Error Detection Flag)

The BLERR flag checks whether a bus lock error has occurred.

[Setting condition]

- When the next falling edge is not input for a period of 2.5 times the 1-data bit width set by the NOMP register after the falling edge of the CEC reception signal and while the CEC reception signal is fixed to low or high midway through a frame

[Clearing condition]

- When 1 is written to CECFC.BLCTRG

37.2.8 CECFC : CEC Communication Error Flag Clear Trigger Register

Base address: CEC = 0x400A_C000

Offset address: 0x44

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	BLCTRG	ACTRG	TXCTRG	TCTRG	ACKCTRG	UCTRG	OCTRG
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	OCTRG	Overrun Error Detection Flag Clear Trigger*1 0: Does not clear overrun error detection flag. 1: Clears overrun error detection flag.	W
1	UCTRG	Underrun Error Detection Flag Clear Trigger*1 0: Does not clear underrun error detection flag. 1: Clears underrun error detection flag.	W
2	ACKCTRG	ACK Error Detection Flag Clear Trigger*1 0: Does not clear ACK error detection flag. 1: Clears ACK error detection flag.	W
3	TCTRG	Timing Error Detection Flag Clear Trigger*1 0: Does not clear timing error detection flag. 1: Clears timing error detection flag.	W
4	TXCTRG	Transmission Error Detection Flag Clear Trigger*1 0: Does not clear transmission error detection flag. 1: Clears transmission error detection flag.	W
5	ACTRG	Arbitration Loss Detection Flag Clear Trigger*1 0: Does not clear arbitration loss detection flag. 1: Clears arbitration loss detection flag.	W
6	BLCTRG	Bus Lock Error Detection Flag Clear Trigger*1 0: Does not clear bus lock error detection flag. 1: Clears bus lock error detection flag.	W
7	—	This bit is read as 0. The write value should be 0.	R/W

Note 1. The read value is 0.

The CECFC register clears error detection flags written to the communication error status register (CECES). Only the set bits can be cleared by setting 1 to each flag.

37.2.9 STATL : CEC Transmission Start Bit Low Width Setting Register

Base address: CEC = 0x400A_C000

Offset address: 0x06

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	STATL[8:0]								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
8:0	STATL[8:0]	CEC Transmission Start Bit Low Width Setting*1 Low-level width of the start bit during a transmission Low-level width = (set value of STATL[8:0] bits + 1) × CEC clock cycle	R/W
15:9	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Rewritable only when CEC operation is stopped (CECCTL0.CECE = 0).

37.2.10 STATB : CEC Transmission Start Bit Width Setting Register

Base address: CEC = 0x400A_C000

Offset address: 0x04

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	STATB[8:0]								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
8:0	STATB[8:0]	CEC Transmission Start Bit Width Setting*1 Bit width of the start bit during a transmission Bit width = (set value of STATB[8:0] bits + 1) × CEC clock cycle	R/W
15:9	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Rewritable only when CEC operation is stopped (CECCTL0.CECE = 0).

37.2.11 LGC0L : CEC Transmission Logical 0 Low Width Setting Register

Base address: CEC = 0x400A_C000

Offset address: 0x08

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	LGC0L[8:0]								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
8:0	LGC0L[8:0]	CEC Transmission Logical 0 Low Width Setting*1 Low-level width of logical 0 during a transmission Low-level width = (set value of LGC0L[8:0] bits + 1) × CEC clock cycle	R/W
15:9	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Rewritable only when CEC operation is stopped (CECCTL0.CECE = 0).

37.2.12 LGC1L : CEC Transmission Logical 1 Low Width Setting Register

Base address: CEC = 0x400A_C000

Offset address: 0x0A

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	LGC1L[8:0]								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
8:0	LGC1L[8:0]	CEC Transmission Logical 1 Low Width Setting*1 Low-level width of logical 1 during a transmission Low-level width = (set value of LGC1L[8:0] bits + 1) × CEC clock cycle	R/W
15:9	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Rewritable only when CEC operation is stopped (CECCTL0.CECE = 0).

37.2.13 DATB : CEC Transmission Data Bit Width Setting Register

Base address: CEC = 0x400A_C000

Offset address: 0x0C

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	DATB[8:0]								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
8:0	DATB[8:0]	CEC Transmission Data Bit Width Setting*1 Bit width of the data bit during a transmission 1-data bit width = (set value of DATB[8:0] bits + 1) × CEC clock cycle	R/W
15:9	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Rewritable only when CEC operation is stopped (CECCTL0.CECE = 0).

37.2.14 STATLL : CEC Reception Start Bit Minimum Low Width Setting Register

Base address: CEC = 0x400A_C000

Offset address: 0x10

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	STATLL[8:0]								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
8:0	STATLL[8:0]	CEC Reception Start Bit Minimum Low Width Setting*1 Minimum value of the low-level width of the start bit during a reception Low-level width = (set value of STATLL[8:0] bits + 1) × CEC clock cycle	R/W
15:9	—	These bits are read as 0. The write value should be 0.	R/W

Note: The value of this register is not used when the timing of the start bit is not checked (CECCTL1.STERRD = 0) and restarting reception on start detection is not enabled (CECEXMOD.RERCVEN = 0). The set value is invalid.

Note 1. Rewritable only when CEC operation is stopped (CECCTL0.CECE = 0).

37.2.15 STATLH : CEC Reception Start Bit Maximum Low Width Setting Register

Base address: CEC = 0x400A_C000

Offset address: 0x12

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	STATLH[8:0]								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
8:0	STATLH[8:0]	CEC Reception Start Bit Maximum Bit Width Setting*1 Maximum value of the low-level width of the start bit during R/W a reception Low-level width = (set value of STATLH[8:0] bits + 1) × CEC clock cycle	R/W
15:9	—	These bits are read as 0. The write value should be 0.	R/W

Note: The value of this register is not used when the timing of the start bit is not checked (CECCTL1.STERRD = 0) and restarting reception on start detection is not enabled (CECEXMOD.RERCVEN = 0). The set value is invalid.

Note 1. Rewritable only when CEC operation is stopped (CECCTL0.CECE = 0).

37.2.16 STATBL : CEC Reception Start Bit Minimum Bit Width Setting Register

Base address: CEC = 0x400A_C000

Offset address: 0x14

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	STATBL[8:0]

15:9	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Rewritable only when CEC operation is stopped (CECCTL0.CECE = 0).

37.2.22 DATBL : CEC Reception Data Bit Minimum Bit Width Setting Register

Base address: CEC = 0x400A_C000

Offset address: 0x20

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	DATBL[8:0]								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
8:0	DATBL[8:0]	CEC Reception Data Bit Minimum Bit Width Setting*1 Minimum value of the bit width of the data bit during a reception Bit width = (set value of DATBL[8:0] bits + 1) × CEC clock cycle	R/W
15:9	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Rewritable only when CEC operation is stopped (CECCTL0.CECE = 0).

37.2.23 DATBH : CEC Reception Data Bit Maximum Bit Width Setting Register

Base address: CEC = 0x400A_C000

Offset address: 0x22

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	DATBH[8:0]								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
8:0	DATBH[8:0]	CEC Reception Data Bit Maximum Bit Width Setting*1 Maximum value of the bit width of the data bit during a reception Bit width = (set value of DATBH[8:0] bits + 1) × CEC clock cycle	R/W
15:9	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Rewritable only when CEC operation is stopped (CECCTL0.CECE = 0).

37.2.24 NOMT : CEC Reception Data Sampling Time Setting Register

Base address: CEC = 0x400A_C000

Offset address: 0x0E

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	NOMT[8:0]								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
8:0	NOMT[8:0]	CEC Reception Data Sampling Time Setting*1, *2 Sampling time of received data Sampling time = (set value of NOMT[8:0] bits + 1) × CEC clock cycle	R/W
15:9	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Rewritable only when CEC operation is stopped (CECCTL0.CECE = 0).
Note 2. Set this register within a period of LGC1LH < NOMT < LGC0LL.

37.2.25 NOMP : CEC Data Bit Reference Width Setting Register

Base address: CEC = 0x400A_C000

Offset address: 0x24

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	NOMP[8:0]								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
8:0	NOMP[8:0]	CEC Data Bit Reference Width Setting*1 1-data bit width Bit width = (set value of NOMP[8:0] bits + 1) × CEC clock cycle	R/W
15:9	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Rewritable only when CEC operation is stopped (CECCTL0.CECE = 0).

This 1-data bit width is used when counting the number of bits for errors handling, signal-free time, and bus locking detection.

37.2.26 CECEXMD : CEC Extension Mode Register

Base address: CEC = 0x400A_C000

Offset address: 0x28

Bit position:	7	6	5	4	3	2	1	0
Bit field:	RCVINTDSEL	—	RERCVEN	LERPLEN	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	—	These bits are read as 0. The write value should be 0.	R/W
4	LERPLEN	Pulse Output Function Enable by Long Bit Width Error*1 0: Detects only a long bit width error. 1: Detects a long bit width error and outputs an error handling pulse.	R/W

Bit	Symbol	Function	R/W
5	RERCVEN	Start Detection Reception Restart Enable*1 0: Does not restart reception when the start bit is detected during reception. 1: Restarts reception when the start bit is detected during reception.	R/W
6	—	This bit is read as 0. The write value should be 0.	R/W
7	RCVINTDSEL	INTDA Reception Interrupt Timing Change*1 0: EOM timing (9th bit of data) 1: ACK timing (10th bit of data)	R/W

Note 1. Rewritable only when CEC operation is stopped (CECCTL0.CECE = 0).

This register is used to control enabling of error handling when a long bit error is detected, restarting of reception by detecting a start bit, and selecting of the timing for generating reception interrupts.

37.2.27 CECEXMON : CEC Extension Monitor Register

Base address: CEC = 0x400A_C000

Offset address: 0x2A

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	ACKF	CECLNMON
Value after reset:	0	0	0	0	0	0	0	x

Bit	Symbol	Function	R/W
0	CECLNMON	CEC Line Monitor*1 0: Low level 1: High level	R
1	ACKF	ACK Flag*2 The value of the received ACK bit can be read. The value is updated at the timing of ACK reception regardless of transmission/reception or address match/mismatch during reception. However, the value is not updated if an error is detected before an ACK is received. The value is updated when an ACK is received at the next communication.	R
7:2	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. When using the value of the CECEXMON.CECLNMON bit, determine the value after matching two or three times.
Note 2. When using the CECEXMON.ACKF bit, the relationship between the read timing and the read value changes depending on the value of the CECEXMD.RCVINTDSEL bit.

This register can be used to read the CEC line and the ACK flag.

CECLNMON bit (CEC Line Monitor)

The CEC pin state can be read by reading this bit. When using the value of this bit, determine the value after a match of two or three times.

ACKF flag (ACK Flag)

The value of the received ACK bit can be read by reading this bit. When using this bit, the relationship between the read timing and the read value changes depending on the value of the CECEXMD.RCVINTDSEL bit.

Figure 37.4 shows the ACKF flag update timing and reception interrupt generation timing.

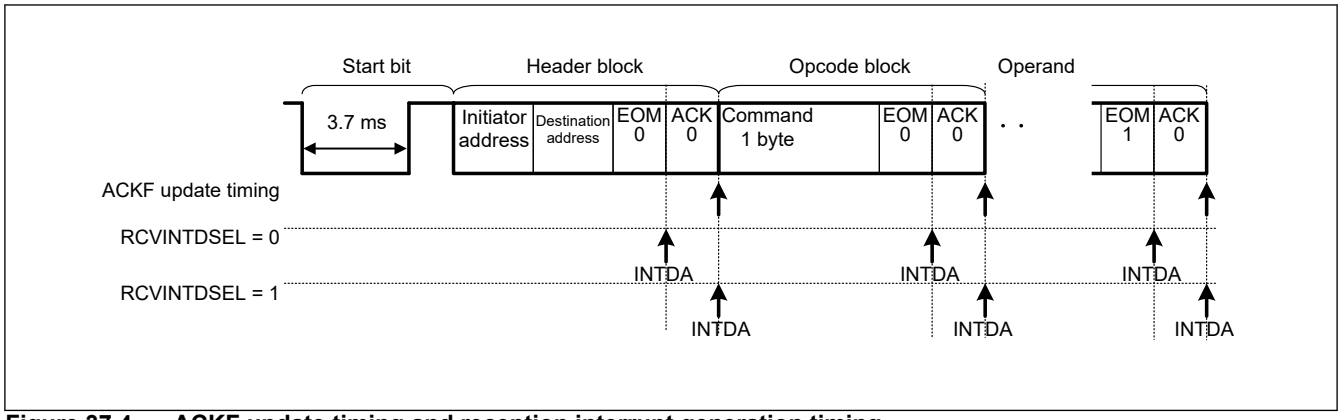

Figure 37.4 ACKF update timing and reception interrupt generation timing

When reading the ACKF bit while RCVINTDSEL = 0, the received ACK state can be read by reading this bit when a 1-bit wait time has elapsed after a reception interrupt is generated. If this bit is read after a reception interrupt is generated, the ACK of the previously received data is read.

When reading the ACKF bit while RCVINTDSEL = 1, read this bit after a reception interrupt is generated. The ACK of the newest received data can be read.

37.3 Operation

37.3.1 Operation of CEC Transmission/Reception Circuit

37.3.1.1 CEC Transmission/Reception Data Format

Figure 37.5 shows the basic CEC communication format. A CEC data frame consists of a start bit, a header block, data block 1 (opcode), and data block 2 (operand). The three blocks other than the start bit consist of 10 bits.

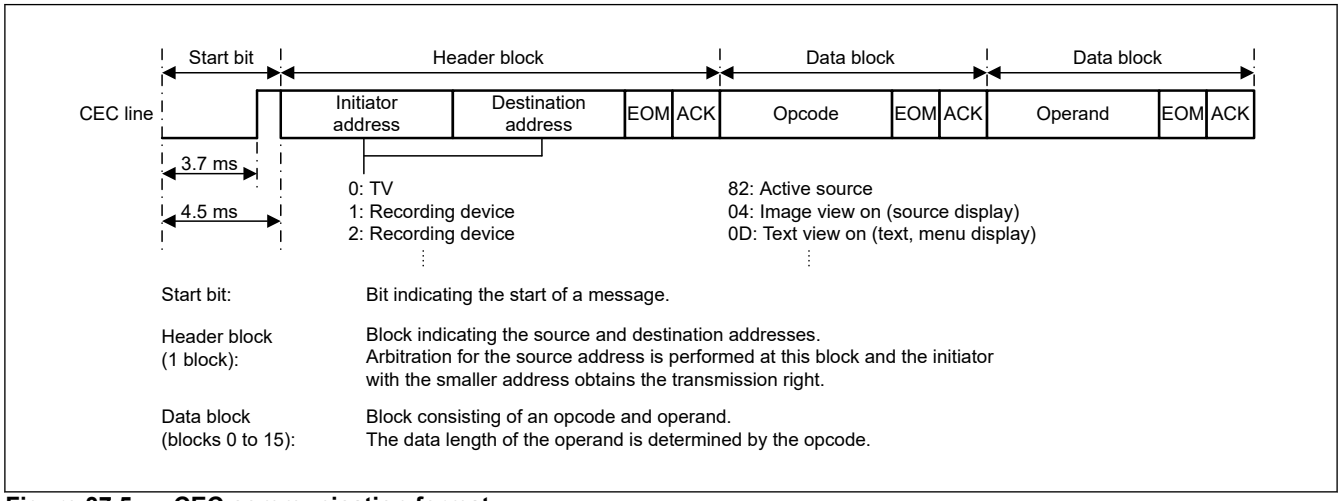

Figure 37.5 CEC communication format

37.3.1.2 Communication Types

CEC transmission/reception takes place in the state of a direct address message or broadcast message. In a CEC communication, the transmitting side transmits a start bit and message (data) and the receiving side receives the message and returns a desired acknowledge signal to the transmitting side. CEC transmission/reception consist of a start bit and data and performs all transmissions/receptions of CEC.

37.3.1.3 Bit Timing

Figure 37.6 shows an example of the pulse format of a start bit. Whether the start bit is valid is determined at the low-level period (a) and bit period (b).

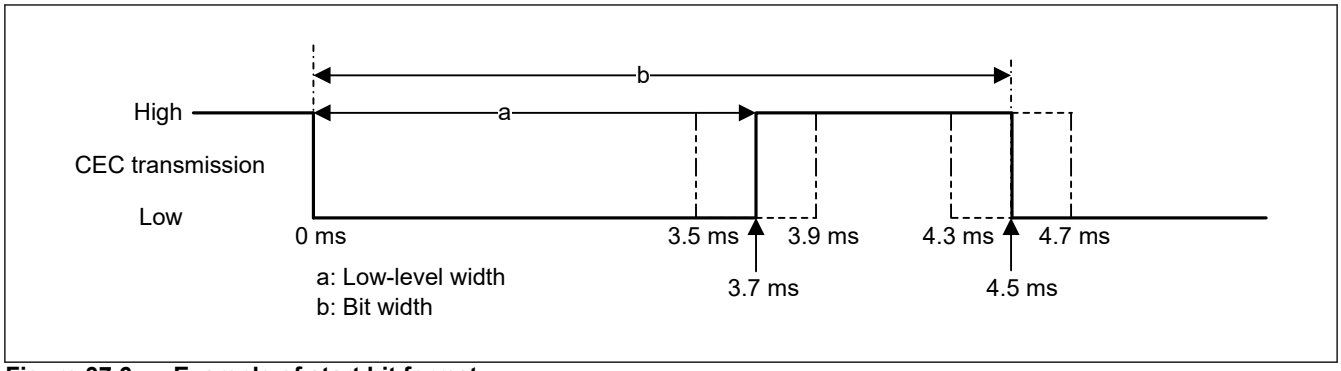

Figure 37.6 Example of start bit format

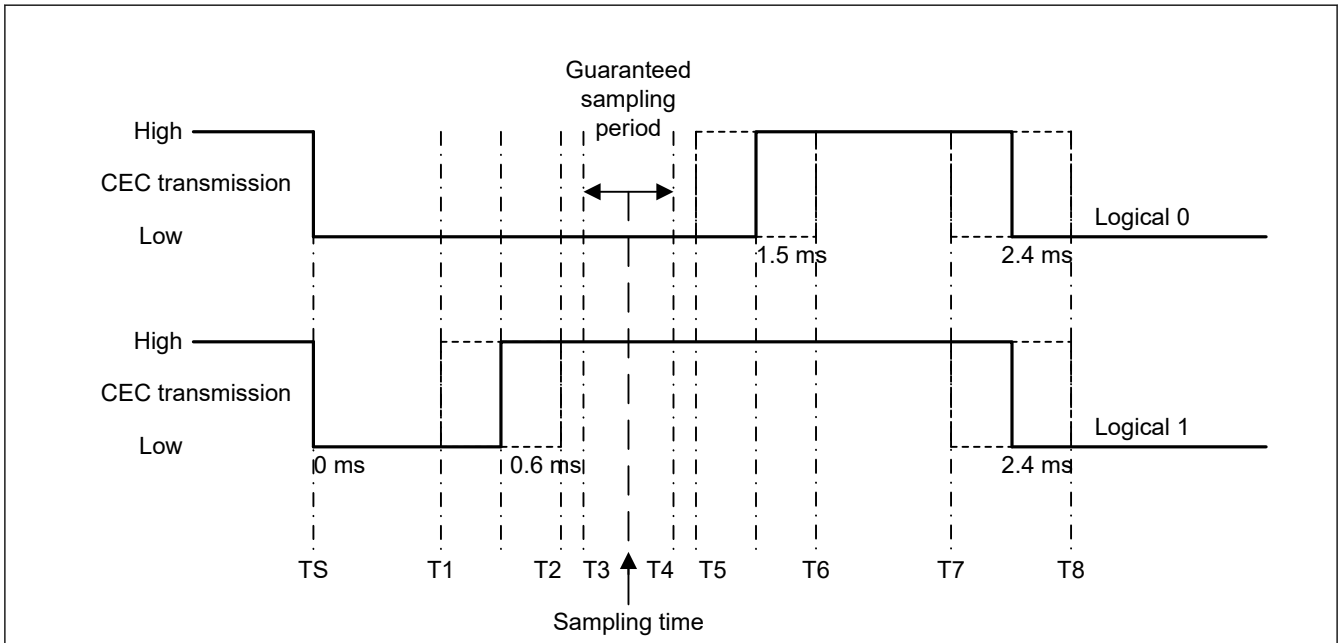
Figure 37.7 shows an example of the pulse format of a data bit timing. A data bit is sampled at a sampling timing set with the CEC reception data sampling time setting register (NOMT). If the result of sampling is low, the pulse format is logical 0. If the result of sampling is high, the pulse format is logical 1. The last change from high to low of a data bit is the start of the next data bit. Consequently, the last data bit remains high.



Ts	0 ms	The bit start event
T1	0.4 ms	The earliest time for a low/high transition when indicated by a logical 1
T2	0.8 ms	The latest time for a low/high transition when indicated by a logical 1
T3	0.85 ms	The earliest time for safely sampling the signal line to determine its state
T4	1.25 ms	The latest time for safely sampling the signal line to determine its state
T5	1.3 ms	The earliest time at which a device is permitted to return to a high impedance state (logical 0)
T6	1.7 ms	The latest time at which a device is permitted to return to a high impedance state (logical 0)
T7	2.05 ms	The earliest time for the start of a following bit
	2.4 ms	The nominal data bit period
T8	2.75 ms	The latest time for the start of a following bit

Figure 37.7 Example of data bit format

37.3.1.4 Header Block and Data Block

All data blocks consists of 10 bits and have the same structure. Figure 37.8 shows the format of header and data blocks. An information bit has different meaning for a header block and data block, and indicates the data, opcode, and address. EOM (End of Message) and ACK (Acknowledge) are control bits and have the same meanings for header block and data block.

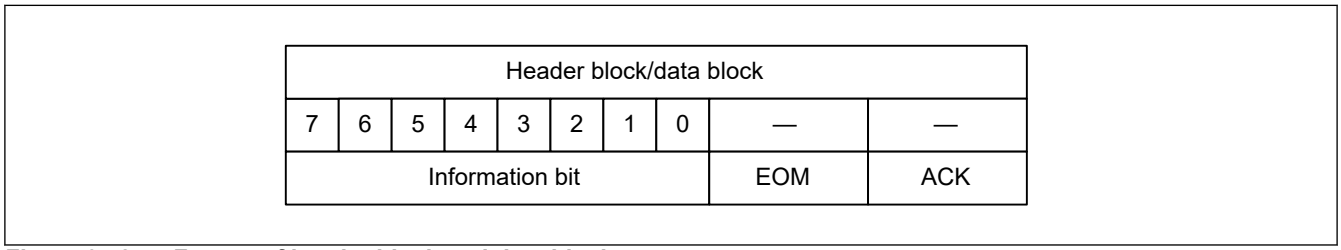


Figure 37.8 Format of header block and data block

A header block consists of an initiator logical address, destination logical address, EOM (End of Message), and ACK (Acknowledge). Information bits 7 to 4 indicate initiator logical addresses and bits 3 to 0 indicate destination logical addresses. The EOM of a header block is used for “ping” with another device (checking whether the power of another device is turned on). “ping” can be checked by setting EOM = 1 and transmitting only the header block (transmitting a message without data blocks). For direct address transmission, the power of the device to which the header block is transmitted is turned on if an ACK is returned.

37.3.1.5 EOM (End of Message)

An EOM indicates whether the transmitted block is the last block of a message. It is added to an information bit and output.

EOM bit = 0: When more blocks follow.

EOM bit = 1: When the transmitted block is the last block.

37.3.1.6 ACK (Acknowledge)

The meaning of an ACK depends on whether the receiving party of a transmission is a direct address message or broadcast message. The result of comparing the received data and CEC line data is transmitted to the transmitting side as an ACK or NACK.

The initiator outputs logical 1 at the ACK bit timing. Consequently, a follower determines the logic level of the ACK bit.

- An ACK (ACK = logical 0) is the normal value for a direct address message:
  1. If no error exists in the header block and the local address is used, the ACK bit is logical 0.
  2. If no error exists in the data blocks, the ACK bit is logical 0.
  3. If an error exists in the header block or another address is used, the ACK bit is logical 1.
  4. If an error exists in the data blocks, the ACK bit is logical 1.
- An NACK (ACK = logical 1) is the normal value for a broadcast message:
  1. If one or more followers have abandoned the message, the ACK bit is logical 0.
  2. If no followers have abandoned the message, the ACK bit is logical 1.

37.3.2 Operating Clocks

The CEC can use one of the following clocks as its operating clock: the divided clock of the peripheral module clock (PCLKB), or the directly clock of the CECCLK supplied from the main clock or sub clock oscillator. When using the CECCLOCK as the CEC operating clock, take note of the respective procedures for supplying these clocks. The following describes how to supply these clocks.

CEC clock can be selected from PCLKB/2^5, PCLKB/2^6, PCLKB/2^7, PCLKB/2^8, PCLKB/2^9, PCLKB/2^{10}, CECCLK (When using SOSC), and CECCLK/2^8 (When using MOSC).

37.3.3 CEC Communication Functions

37.3.3.1 Communication Bit Width Adjustment Function

This function can be used to set the low-level width and bit width of the start bit and data bit during a transmission. The values of some registers must be set according to the specified relationships. Set the following registers to ensure the relationships are kept:

- STATL < STATB
- LGC1L < LGC0L < DATB

The relationships between the various width setting registers (see section 37.2.9. STATL : CEC Transmission Start Bit Low Width Setting Register to section 37.2.13. DATB : CEC Transmission Data Bit Width Setting Register) and the bit timing are shown in (1) to (3).

(1) Start bit

The STATL register is used to set the low-level width and the STATB register is used to set the bit width of the start bit. Figure 37.9 shows the output waveform of the start bit.

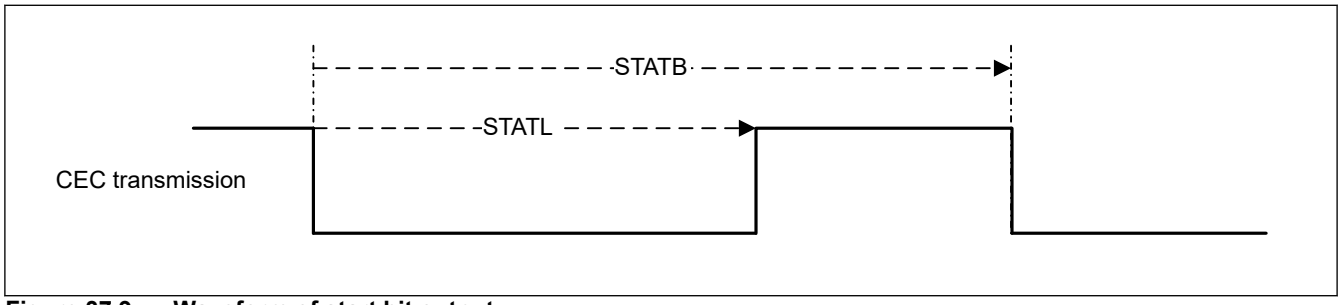

Figure 37.9 Waveform of start bit output

(2) Data bit (logical 0)

The LGC0L register is used to set the low-level width and the DATB register is used to set the bit width of the data bit of logical 0. Figure 37.10 shows the output waveform of the data bit (logical 0).

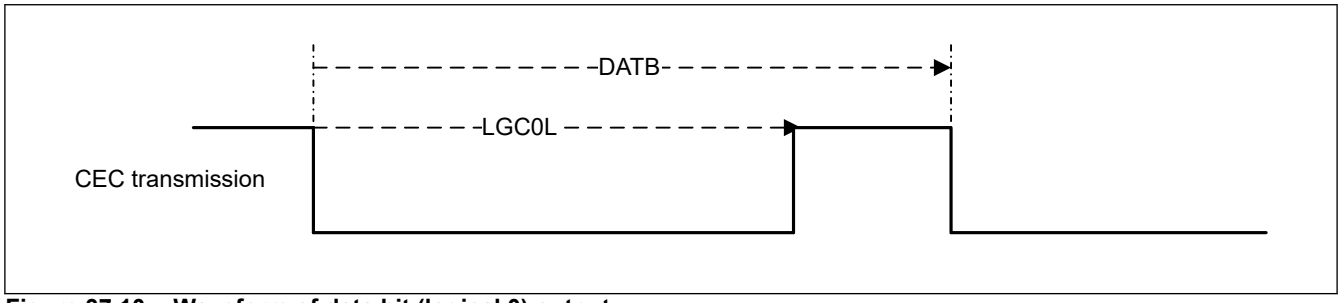

Figure 37.10 Waveform of data bit (logical 0) output

(3) Data bit (logical 1)

The LGC1L register is used to set the low-level width and the DATB register is used to set the bit width of the data bit of logical 1. Figure 37.11 shows the output waveform of the data bit (logical 1).

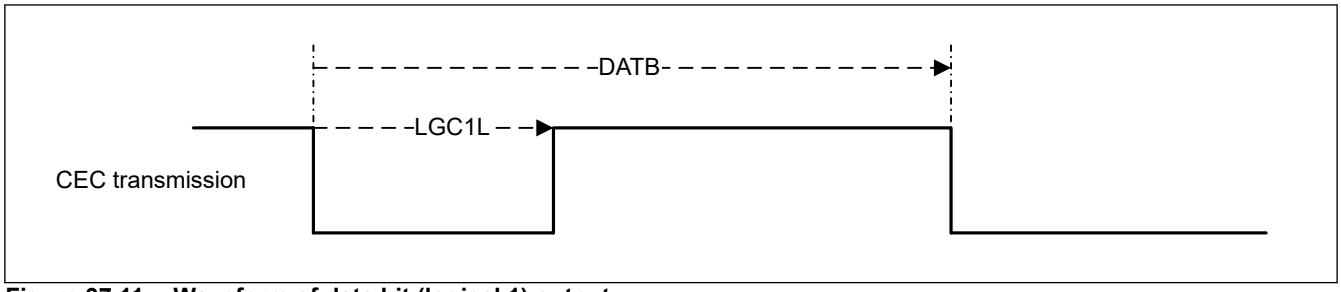

Figure 37.11 Waveform of data bit (logical 1) output

37.3.3.2 Receive Bit Timing Check Function

The CEC transmission/reception circuit has a timing check function that determines whether the low-level width and bit width of the start bit and data bit during reception are within the set range. The timing check period can be set using the various timing determination registers (see section 37.2.14. STATLL : CEC Reception Start Bit Minimum Low Width Setting Register to section section 37.2.23. DATBH : CEC Reception Data Bit Maximum Bit Width Setting Register).

The values of some registers must be set according to the specified relationships. Set the following registers to ensure the relationships are kept:

- STATLL < STATLH
- STATBL < STATBH
- LGC0LL < LGC0LH
- LGC1LL < LGC1LH
- DATBL < DATBH

The relationships between the timing determination registers and bit timing are shown in (1) to (3).

(1) Start bit

The STATLL register is used to set the minimum low-level width and the STATLH register is used to set the maximum low-level width of the start bit. The STATBL register is used to set the minimum value of the start bit and the STATBH register is used to set the maximum value of the start bit width. Figure 37.12 shows the timing at which the start bit is received.

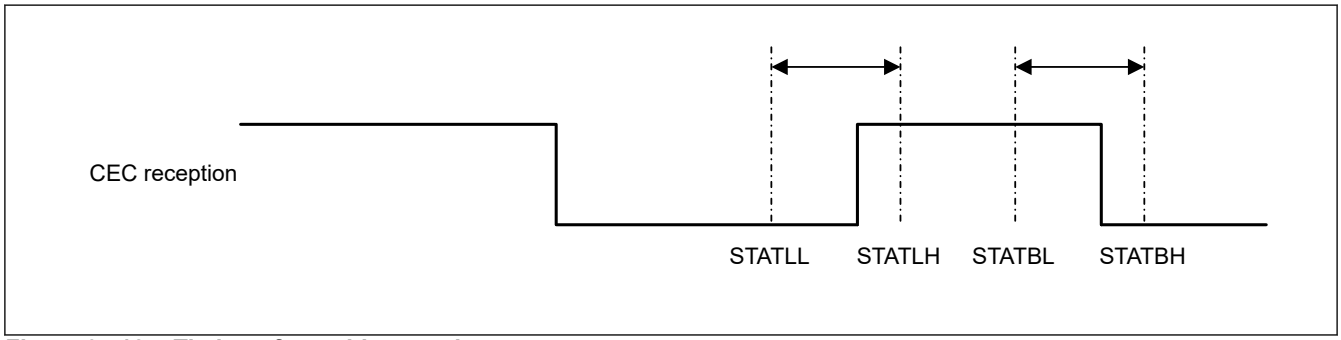

Figure 37.12 Timing of start bit reception

(2) Data bit (logical 0)

The LGC0LL register is used to set the minimum low-level width and the LGC0LH register is used to set the maximum low-level width of the data bit (logical 0). The DATBL register is used to set the minimum value the data bit and the DATBH register is used to set the maximum value of the data bit width. Figure 37.13 shows the timing at which the data bit (logical 0) is received.

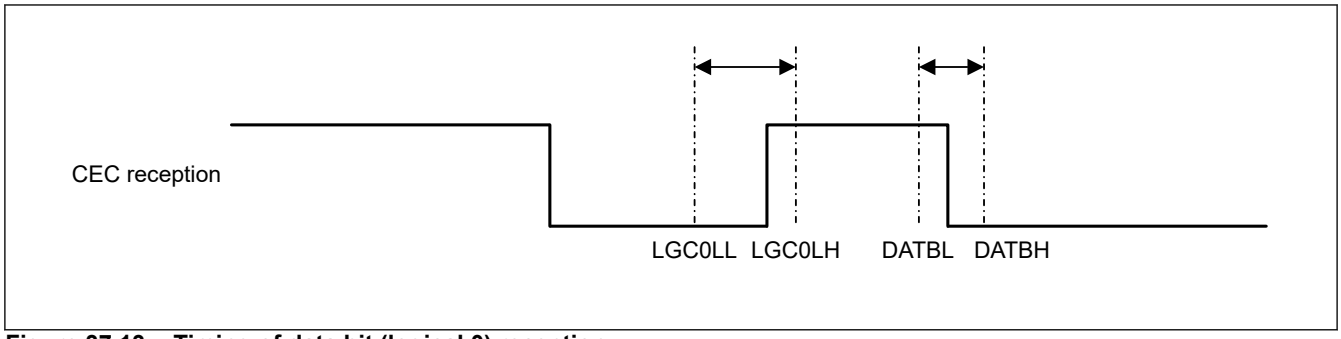

Figure 37.13 Timing of data bit (logical 0) reception

(3) Data bit (logical 1)

The LGC1LL register is used to set the minimum low-level width and the LGC1LH register is used to set the maximum low-level width of the data bit (logical 1). The DATBL register is used to set the minimum value data bit width and the DATBH register is used to set the maximum value of the data bit width. Figure 37.14 shows the timing at which the data bit (logical 1) is received.

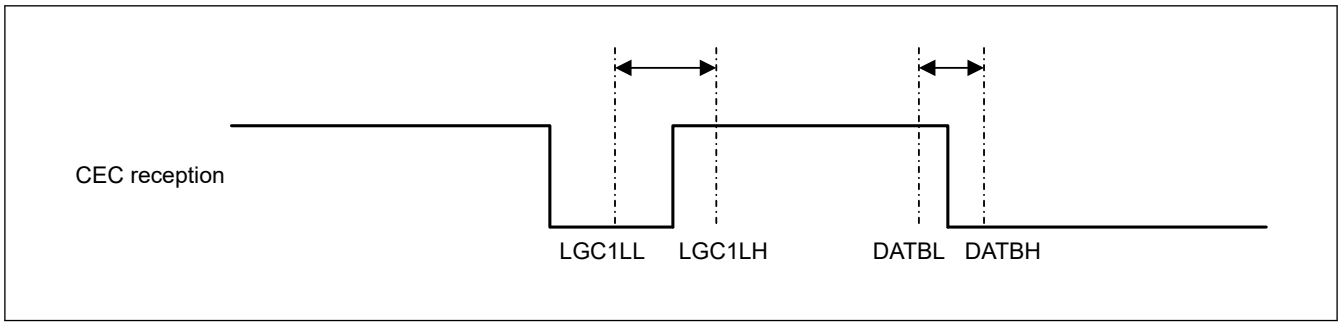

Figure 37.14 Timing of data bit (logical 1) reception

37.3.3.3 Initial CEC Communication Settings

The initial CEC communication setting flow is explained below. The logical address acquisition flow is executed by setting the various control registers and using direct address transmission after a reset. In a logical address acquisition transmission, EOM = 1 is set because the same address is set for the source and destination addresses and only the header block is transmitted. Additionally, to prevent a false address match from occurring before the local address is determined, CECRXEN = 0 must be set before the CADR register setting. Figure 37.15 shows the logical allocation timing diagram and Table 37.6 lists the operation procedure and an explanation of the operation.

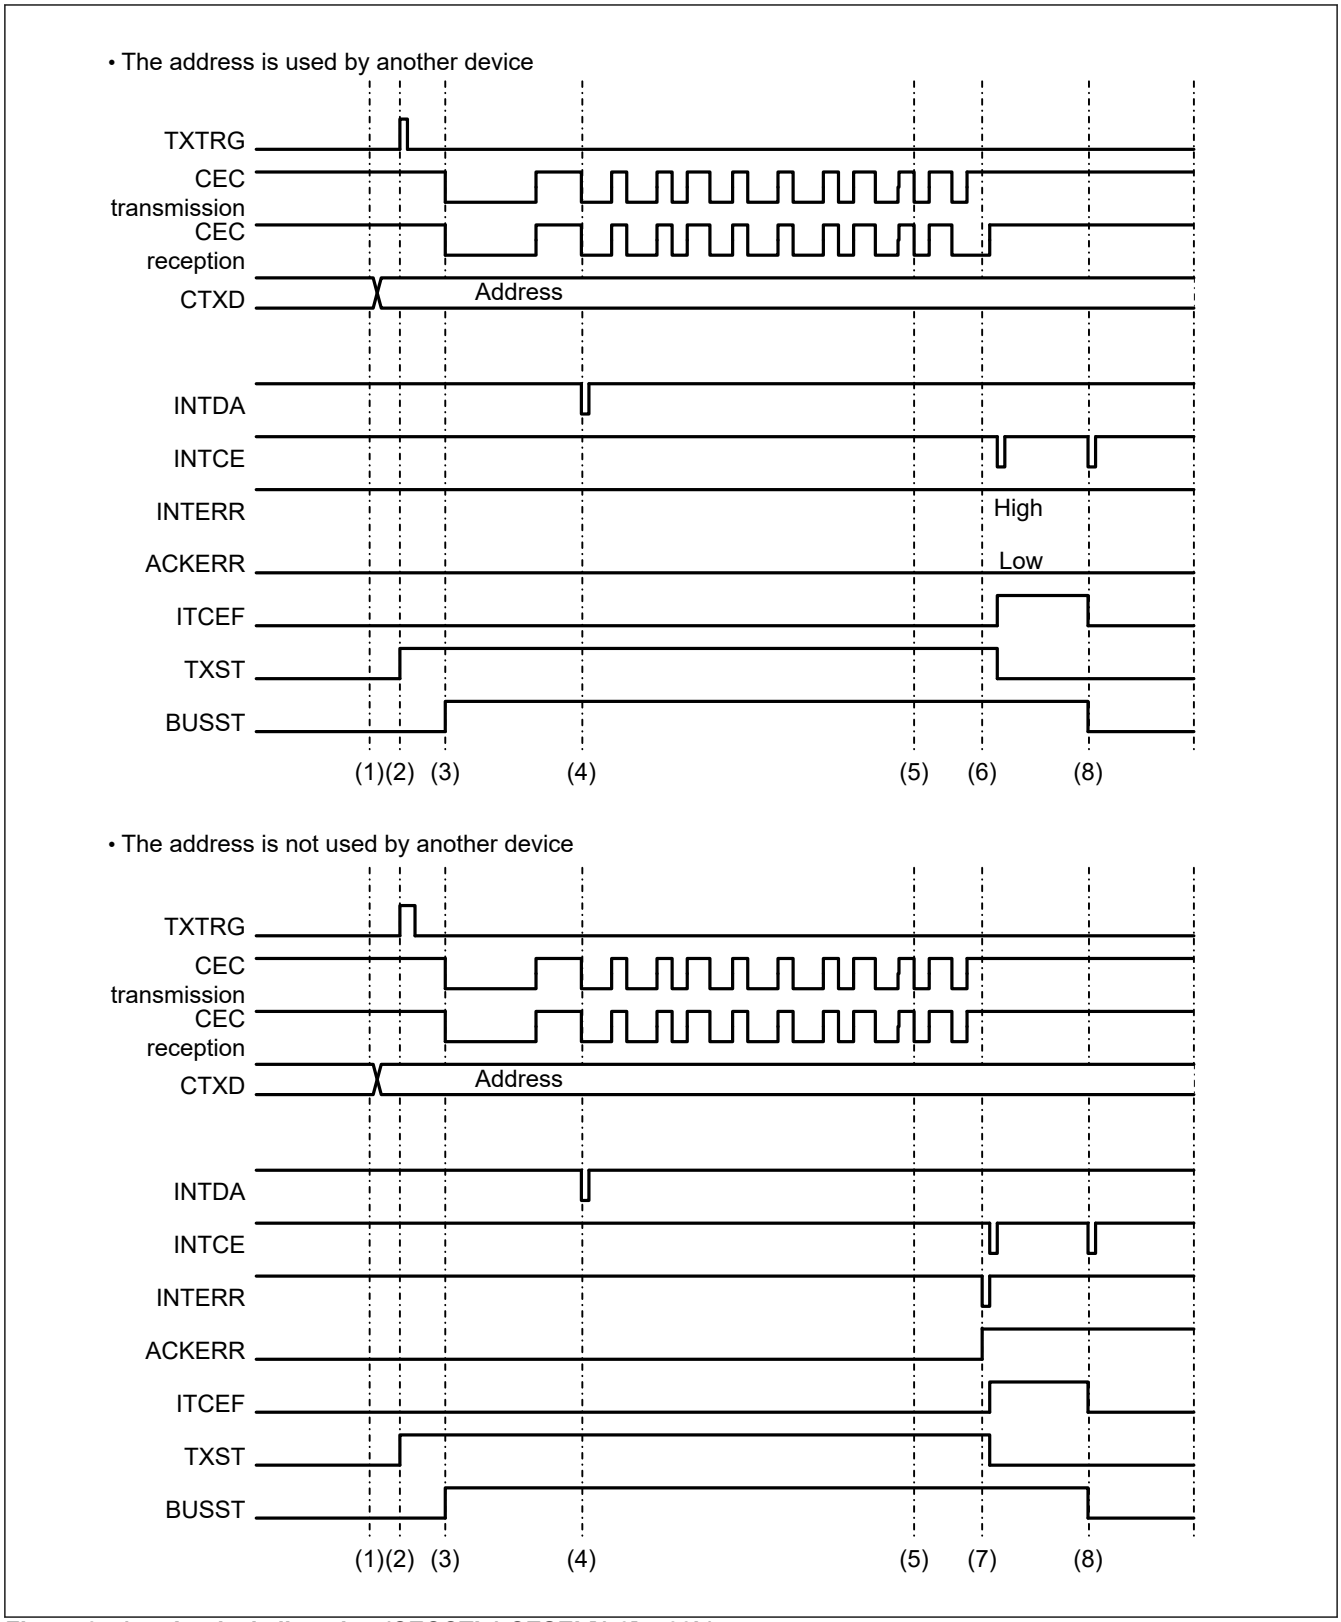

Figure 37.15 Logical allocation (CECCTL1.CESEL[1:0] = 00b)

Table 37.6 Initial CEC communication setting procedure (1 of 2)

Stage	Step	Software manipulation	CEC state
Initial CEC setting	1	[IO initial setting] Select CECIO function for P206 or P706 Set to NMOS open drain output [CEC clock setting] Set the CCL[2:0] bits. [Reception rejection control setting] Set CECRXEN to 0. [Setting for reporting address mismatch] Set CINTMK. [Noise elimination selection] Set CDFC (Specify whether to use the noise filter). [Start bit low-level/bit width setting] Set the low/bit width to STATL/STATB. [Logical 0/1 low-level/bit width setting] Set the low/bit width to LGC0L/LGC1L/DATB. [Sampling time setting] Specify the time to sample the received data for NOMT. [Bit width setting] Specify the bit width for NOMP. [Register settings for timing check] Set the low-level width timing check period of the start bit to STATLL/STATLH. Set the bit width timing check period of the start bit to STATBL/STATBH. Set the low-level width timing check period of the data bit (logical 0) to LGC0LL/LGC0LH. Set the low-level width timing check period of the data bit (logical 1) to LGC1LL/LGC1LH. Set the bit width timing check period of the data bit to DATBL/DATBH. [Bus lock detection setting] Set up BLERRD (select whether to detect bus locking). [Start bit timing error detection setting] Set STERRD (select whether to detect timing errors of the start bit). [Communication complete interrupt setting] Set the CESEL[1:0]. [Signal-free time setting] Set the SFT[1:0] bits (set the signal-free time detection time). [CEC clock supply] Set CECE to 1.	The CEC clock is stopped.
	2	—	The CEC clock is supplied. Transmission can be performed. The signal-free time is started. BUSST becomes 1. BUSST becomes 0 and the communication standby state is entered after counting up to the set values of the SFT[1:0] bits.

Table 37.6 Initial CEC communication setting procedure (2 of 2)

Stage	Step	Software manipulation	CEC state
Logical address allocation	3	[EOM setting] Set EOM to 1. [Transmit data setting] (1) Set the transmit data (logical address) to CTXD. [Bus-free state check] Check that BUSST is 0. [Starting transmit operation] (2) Set TXTRG to 1.	—
	4	—	Transmission is started. The start bit is output (3).
	5	—	The values set in the CTXD register are sequentially output at the same time as INTDA is output when the header block output is started (4).
	6	Do not write the next data, because only the header block is transmitted.	—
	7	—	1 is output from the EOM bit (5).
	8	[Local address setting]	The ACK bit is received.
	8-1	ACK: Change the transmitted address and then retransmit the address, because it is used by another station.	When logical 0 is received, INTERR is not output and the ACKERR flag is not set (6).
	8-2	NACK: Use the transmitted address as the local address, because the transmitted address is not used by another station (CADR setting).	When logical 1 is received, INTERR is output and the ACKERR flag is set (7).
	9	—	INTCE is output according to the CESEL[1:0] and SFT[1:0] bit settings (8).
Reception rejection	10	[Reception rejection control setting] Set CECRXEN to 1.	—
	11	—	The communication standby state is entered.

37.3.3.4 CEC Transmission

A CEC transmission performs a receive operation even during transmission and performs an arbitration check, a data check, and a timing check.

The value of the reception buffer register (CRXD) during a transmit operation, however, is not guaranteed.

A new start bit detected during transmission (the time from when a start bit is detected until the EOM of the last frame is received) is ignored and detected as a timing error. Communication is not restarted. Figure 37.16 shows the basic timing of transmission, and Table 37.7 shows the procedure for manipulating CEC transmission.

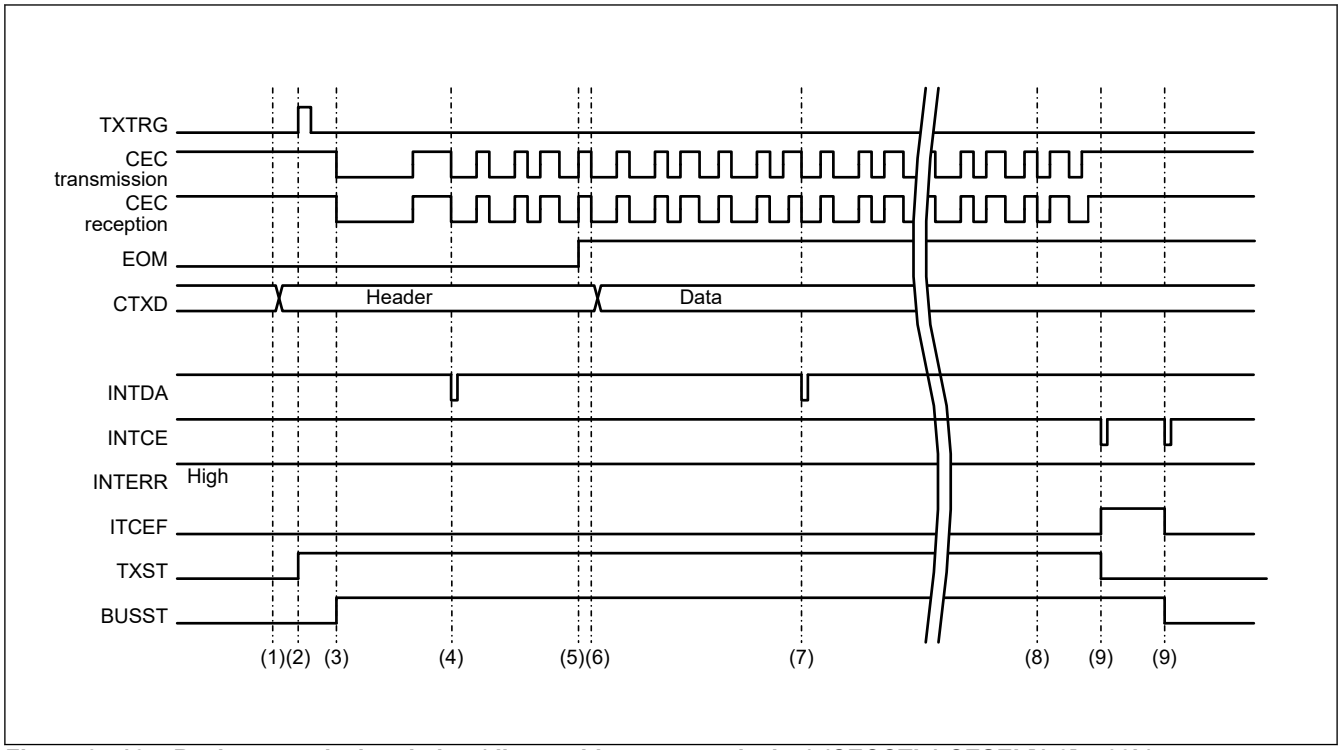

Figure 37.16 Basic transmission timing (direct address transmission) (CECCTL1.CESEL[1:0] = 00b)

(1) CEC transmission manipulation procedure

Table 37.7 CEC transmission manipulation procedure

Stage	Step	Software manipulation	CEC state
Initial CEC setting	1	See Table 37.6.	—
CEC transmit operation	2	[Signal-free time setting] Set the SFT[1:0] bits. (set the signal-free time detection time.) [EOM setting] (1) Set EOM (EOM = 0). [Transmit data setting] (1) Set the transmit data to CTXD. [Bus-free state check] Check that BUSST is 0. [Starting transmit operation] (2) Set TXTRG to 1.	—
	3	—	Transmission is started. The start bit is output (3).
	4	—	The values set in the CTXD register are sequentially output at the same time as INTDA is output when the header block output is started (4).
	5	[EOM setting] (5) Set the EOM of the next frame (EOM = 1) before the next frame starts (7). [Transmit data setting] (6) Set the transmit data to CTXD.	—
	6	—	Outputting the data of the second frame is started (7). 1 is output at the EOM bit position because the last frame is reached (8). INTCE is output according to the CESEL[1:0] and SFT[1:0] bit settings (9). The communication standby state is entered.

(2) Broadcast transmission

When 0xF is set to the destination address of the header block transmit data (CTXD), the CEC recognizes the current transmission as a broadcast transmission and operates. Normally, the communication is determined as a successful operation when logical 0 is received at the ACK bit timing. However, in broadcast communication, the communication is a successful operation when logical 1 is received at the ACK bit timing.

The CEC determines whether the communication is a direct communication or broadcast communication by looking at the transmit data of the header block, and automatically determines whether the reception of logical 0 or logical 1 has been successfully performed.

(3) CEC transmission interrupt

The CEC has three interrupt functions, namely a data interrupt (INTDA), a communication complete interrupt (INTCE), and an error interrupt (INTERR). Figure 37.17 shows the timing for generating interrupts during transmission.

A data interrupt (INTDA) occurs at the start of each block.

A communication complete interrupt (INTCE) can be generated if ACK reception for a data block for which EOM is set to 1 ends, if the signal-free time specified using the CECCTL1.SFT[1:0] bits elapses, or if both conditions occur, depending on the settings of the CECCTL1.CESEL[1:0] bits.

An error interrupt (INTERR) is generated if any of the following errors is detected during any period of communication:

- Timing
- ACK
- Underrun
- Transmission.

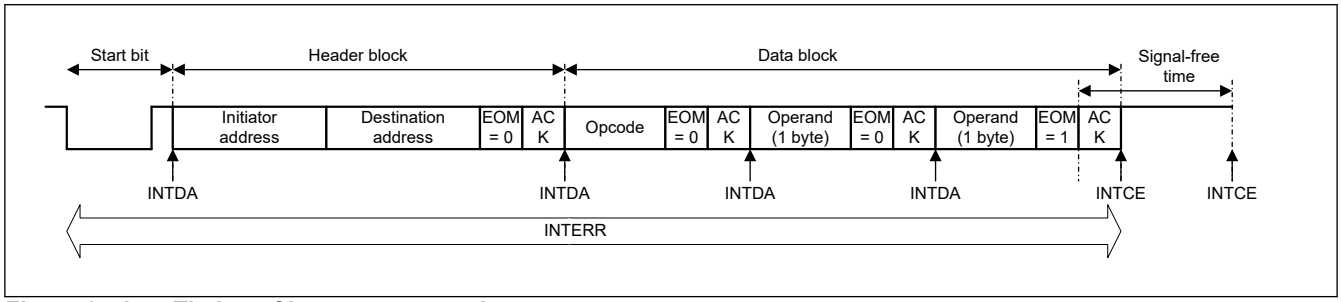

Figure 37.17 Timing of interrupt generation

If the falling edge of the CEC line is detected when receiving the ACK bit by setting EOM to 1 (before receiving the ACK bit ends), an irregular operation is performed as shown in Table 37.8 according to that timing.

Table 37.8 Operation if falling edge of CEC line is detected before receiving ACK bit ends

CEC line falling timing	CECCTL1.CESEL[1:0] bit setting	INTCE generation	Handling of ACK bit	Operation after CEC line falls
After the minimum data bit value (DATBL ≤ counter)	CESEL[1:0] = 00b or CESEL[1:0] = 01b	INTCE is generated once when the CEC line falls	Handling the ACK bit is enabled because it has the correct width. (ACK or NACK is correctly determined.)	The start of the next communication is recognized and then determines whether to receive the start bit starts.
	CESEL[1:0] = 10b	INTCE is not generated		
Before the minimum data bit value (counter < DATBL)	CESEL[1:0] = 00b or CESEL[1:0] = 01b	INTCE is generated once when the CEC line falls	ACK cannot be correctly determined because it has the incorrect width. (if ACKTEN is set to 1, a timing error occurs.)	
	CESEL[1:0] = 10b	INTCE is not generated		

(4) Receiving error handling pulse

During initiator operation, if the received data is at low level when the maximum low-level width of logical 0 is reached, an error handling pulse is received, a timing error occurs, transmission stops, and communication standby state is entered as shown in Figure 37.18.

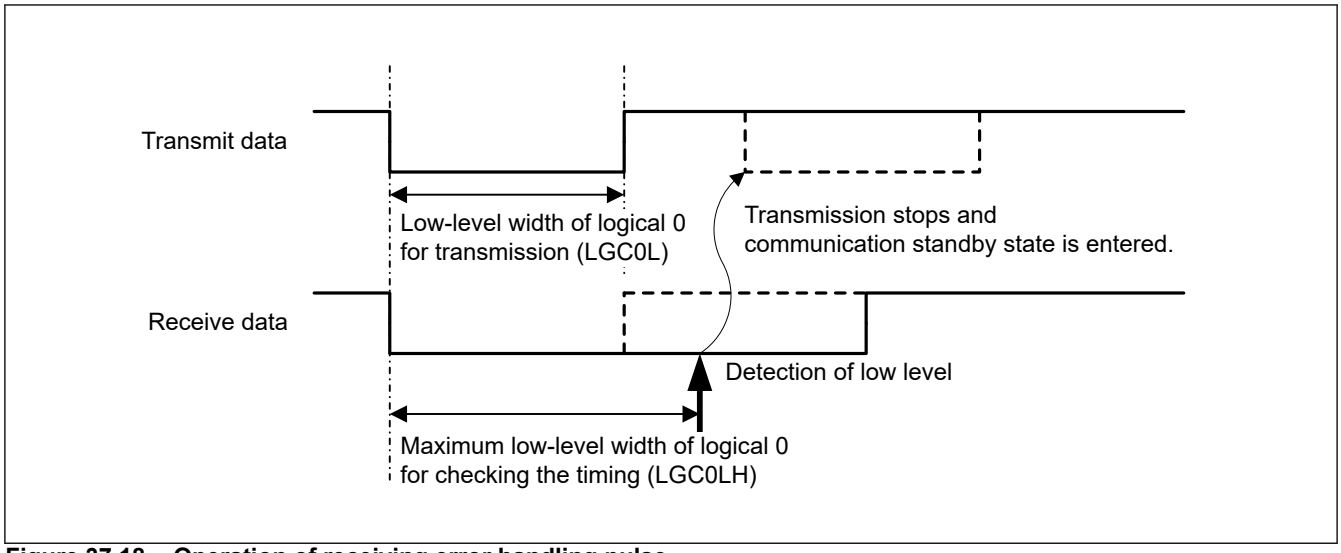

Figure 37.18 Operation of receiving error handling pulse

37.3.3.5 CEC Reception

During reception, the data is received at the sampling timing set by the CEC reception data sampling time setting register (NOMT) and stored in the reception buffer register (CRXD).

The receive operation differs depending on the CECCTL0.CECRXEN bit setting value, CECCTL1.CINTMK bit setting value, communication type (direct address communication or broadcast communication), and whether the reception address and local address match.

The correspondences between various conditions and the operations are shown in Table 37.9.

A new start bit detected during transmission (the time from when a start bit is detected until the EOM of the last frame is received) is ignored and detected as a timing error. However, when the restart reception function is used (CECEXMOD.RERCVEN = 1), a timing error is detected and determined as the start of new reception, so reception operation is performed again.

Table 37.9 Operation during CEC reception (1 of 2)

CEC RXEN	**0**	**1**							
Communication type	**—**	**Start bit**	**Header**			**Direct data**			**Broadcast data**
Address match/ mismatch	**—**	**—**	**Mismatch**		**Match**	**Mismatch**		**Match**	**—**
CINTMK bit	**—**	**—**	**0**	**1**	**—**	**0**	**1**	**—**	**—**

Error flag operation	Not supported	Not supported	Supported	Supported	Supported	Not supported	Supported	Supported	Supported
Error detection (other than short bit width detection)	Not supported	Supported*4	Supported	Supported	Supported	Not supported	Supported	Supported	Supported

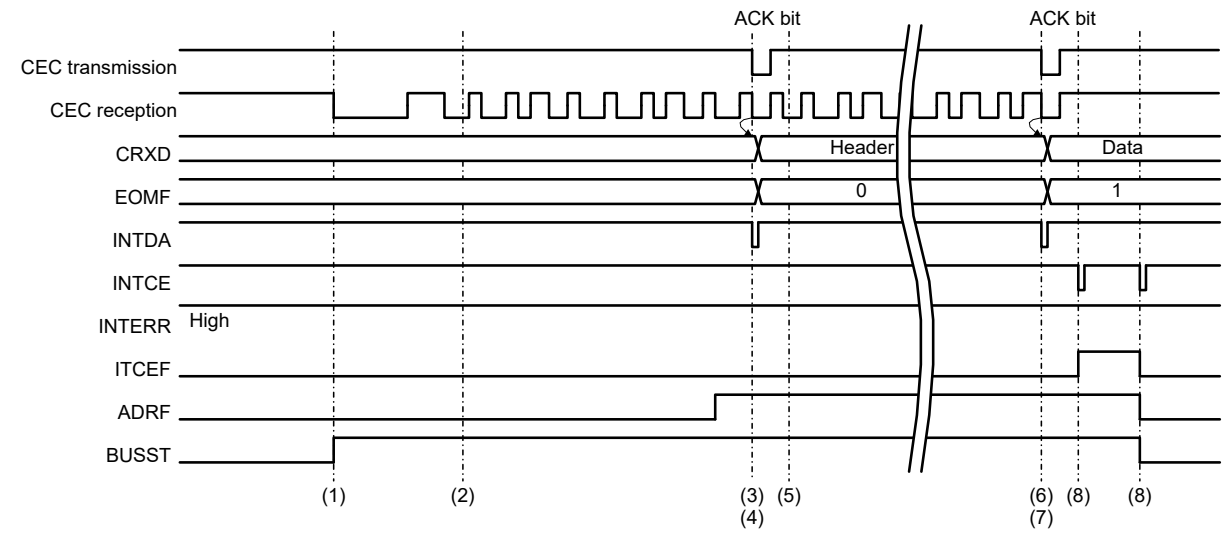
Table 37.9 Operation during CEC reception (2 of 2)

CEC RXEN	0	1							
Communication type	—	Start bit	Header			Direct data			Broadcast data
Address match/ mismatch	—	—	Mismatch		Match	Mismatch		Match	—
CINTMK bit	—	—	0	1	—	0	1	—	—
Error detection (short bit width detection)	Not supported	Supported*4	Supported	Supported	Supported	Supported	Supported	Supported	Supported
Error handling output	Not supported	Not supported	Supported	Supported	Supported	Supported	Supported	Supported	Supported
Bus lock detection*1	Supported*2	Supported	Supported	Supported	Supported	Supported	Supported	Supported	Supported
ACK/NACK output	Not supported	Not supported	Supported	Supported	Supported	Not supported	Not supported	Supported	Supported
Signal-free time count	Not supported	Supported	Supported	Supported	Supported	Supported	Supported	Supported	Supported

Note 1. Bus lock errors are detected by setting CECCTL1.BLERRD.
Note 2. A bus lock error is detected but a flag is not set.
Note 3. Only if an error is detected.
Note 4. This is supported only if detecting timing errors for the start bit (CECCTL1.STERRD = 1). An error is detected but a flag is not set.

(1) CEC reception manipulation procedure

For the receiving operation of a direct address message, Figure 37.19 and Table 37.10 show operation when the addresses match, and Figure 37.20 and Table 37.11 show operation when the addresses do not match.

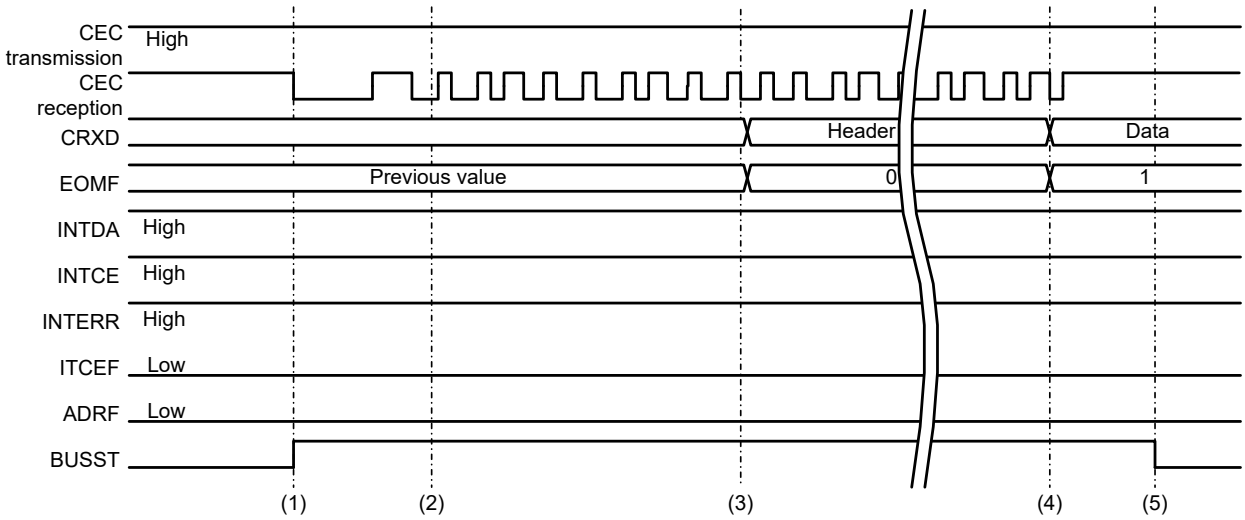


Note: (1) to (8) in Figure 37.19 correspond to (1) to (8) in Table 37.10.

Figure 37.19 Basic reception timing (1) (direct address reception, CECCTL1.CESEL[1:0] = 00b)

Table 37.10 CEC reception manipulation procedure (1)

Stage	Step	Software manipulation	CEC state
Initial CEC setting	1	See Table 37.6.	—
CEC receive operation	2	—	[Start bit detection] The falling edge of the CEC reception signal is detected and a receive operation is started (1). [Sampling] The data is sampled at the NOMT setting time and sequentially stored in the shift register (2). [Address match interrupt] INTDA is generated because the address received at the header block matched with the local address (3).
	3	Prepare for receiving data by returning from low power consumption mode or the like in response to INTDA generation. Use EOMF to check whether to continue transmission or whether it is the last frame.	—
	4	—	[ACK bit transmission] Logical 0 is transmitted at the ACK bit timing because the reception was successful (4).
	5	—	[Continuing reception] The data of the second frame is continuously received (5). [Receive data interrupt] When receiving 8-bit data is complete, the data is transferred to CRXD and INTDA is generated (6).
	6	Read the receive data from CRXD in response to INTDA generation. Use EOMF to check whether to continue transmission or whether it is the last frame.	
	7	—	[ACK bit transmission] Logical 0 is transmitted at the ACK bit timing because the reception was successful (7). [Reception completion] The reception is judged to be completed because EOM = 1 is received and INTCE is output according to the CECCTL1.CESEL[1:0] and CECCTL1.SFT[1:0] bit settings (8).



Note: (1) to (5) in Figure 37.20 correspond to (1) to (5) in Table 37.11.

Figure 37.20 Basic reception timing (2) (CECCTL0.CECRXEN = 1, direct address, address mismatch, CECCTL1.CINTMK = 0)

Table 37.11 CEC reception manipulation procedure (2)

Stage	Step	Software manipulation	CEC state
CEC receive operation	1	—	[Start bit detection] The falling edge of the CEC reception signal is detected and a receive operation is started. Set BUSST flag (1). [Sampling] The data is sampled at the NOMT setting time and sequentially stored in the shift register (2). [Address match interrupt] INTDA is not generated and neither ACK nor NACK is returned because the address received at the header block does not match the local address and CINTMK is 0 (3). However, monitoring of the CEC line continues in order to check the bit length and detect completion of communication. [ACK bit transmission] Neither ACK nor NACK is returned because communication is performed between other stations (4). [Reception completion] Communication between other stations is complete because EOM = 1 is received, the signal-free time is counted according to the SFT[1:0] bit settings, and BUSST is cleared to 0 (5).

(2) Broadcast reception

The reception flow and timing check period are the same as those of direct address reception. If the destination address transmitted by the initiator is 0xF, the communication operates as a broadcast reception.

The differences from direct address reception are as follows:

- Logical 1 is transmitted at the ACK bit timing in a normal operation.
- If reception failed or CECRXEN = 0 is set, logical 0 is transmitted at the ACK bit timing.

(3) CEC reception interrupt

Three interrupt functions, namely a data interrupt (INTDA), communication complete interrupt (INTCE), and error interrupt (INTERR) are provided. Figure 37.21 shows the timing for generating interrupts during CEC reception.

A data interrupt (INTDA) is output at the following timings during reception (follower):

- When the address received at the header block of a direct address communication matched the local address

- When address reception is complete at the header block of a direct address communication when CECCTL1.CINTMK = 1 is set
- When address reception of a broadcast communication is complete at the header block
- When data reception is complete at the data block and the receive data is stored in the CRXD register

Communication complete interrupt INTCE is output at the following timings during reception (follower):

- CECCTL1.CESEL[1:0] = 00b
  INTCE is output if receiving the ACK bit of the last frame (EOM = 1) ends, if the signal-free time is counted, if the falling edge of the CEC line is detected in the high-level period of the ACK bit of the last frame, or while the signal-free time is counted.
- CECCTL1.CESEL[1:0] = 01b
  INTCE is output if receiving the ACK bit of the last frame (EOM = 1) ends, if the falling edge of the CEC line is detected in the high-level period of the ACK bit of the last frame, or while the signal-free time is counted.
- CECCTL1.CESEL[1:0] = 10b
  INTCE is output if the signal-free time is counted.

An error interrupt (INTERR) is output at the following timings during reception (follower):

- When a timing error is detected
- When an overrun error is detected
- When a bus lock error is detected while CECCTL1.BLERRD = 1 is set

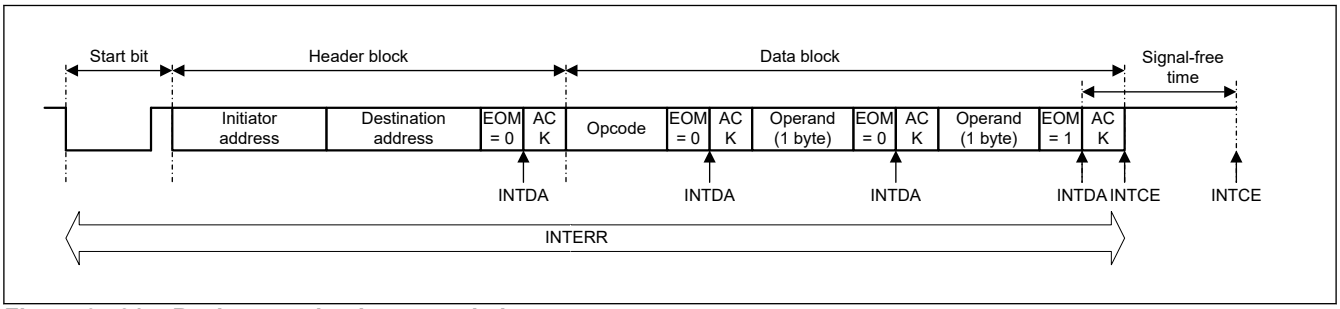


Figure 37.21 Basic reception interrupt timing

37.3.3.6 Status Flag Functions

Table 37.12 lists status flags.

Table 37.12 Status flags

No.	Status flag	Register.Bit symbol
1	Address match detection flag	CECS.ADRF
2	Bus busy detection flag	CECS.BUSST
3	Transmission status flag	CECS.TXST
4	EOM flag	CECS.EOMF
5	INTCE generation source flag	CECS.ITCEF
6	Signal-free time rewrite disable report flag	CECS.SFTST
7	CEC line monitor	CECEXMON.CECLNMON
8	ACK flag	CECEXMON.ACKF

(1) Address match detection flag

As shown in Figure 37.22, during follower operation, if the destination address of the header block received during direct address communication matches the address set by the CEC local address setting register (CADR) or during broadcast communication, the address match flag (CECS.ADRF) is set to 1 at the same time when a data interrupt (INTDA) of the header block is generated.

The address match flag is cleared at the timing of the communication completion interrupt (INTCE) that is generated on completion of the signal-free time counting after the last frame (EOM = 1) is received.

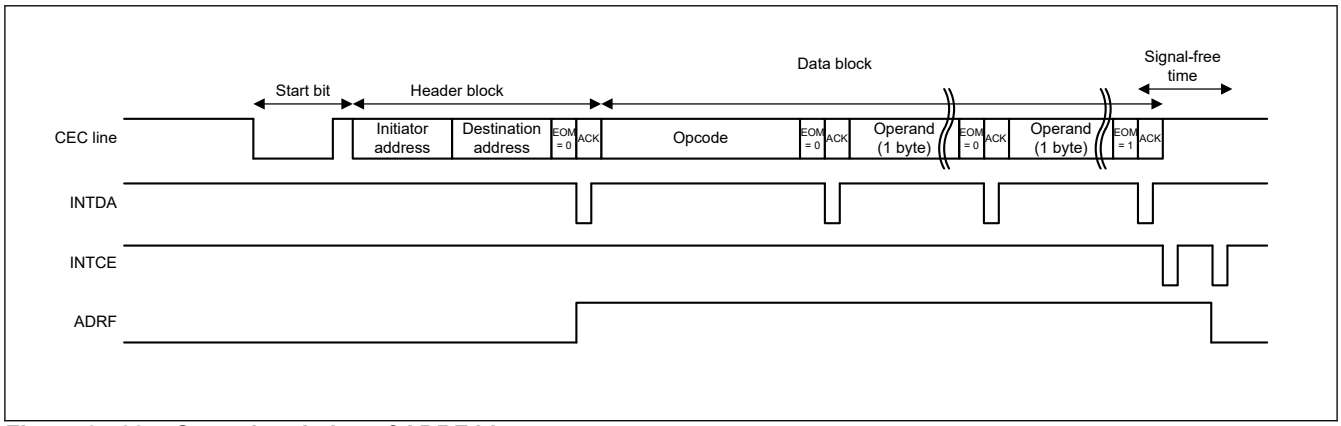

Figure 37.22 Operation timing of ADRF bit

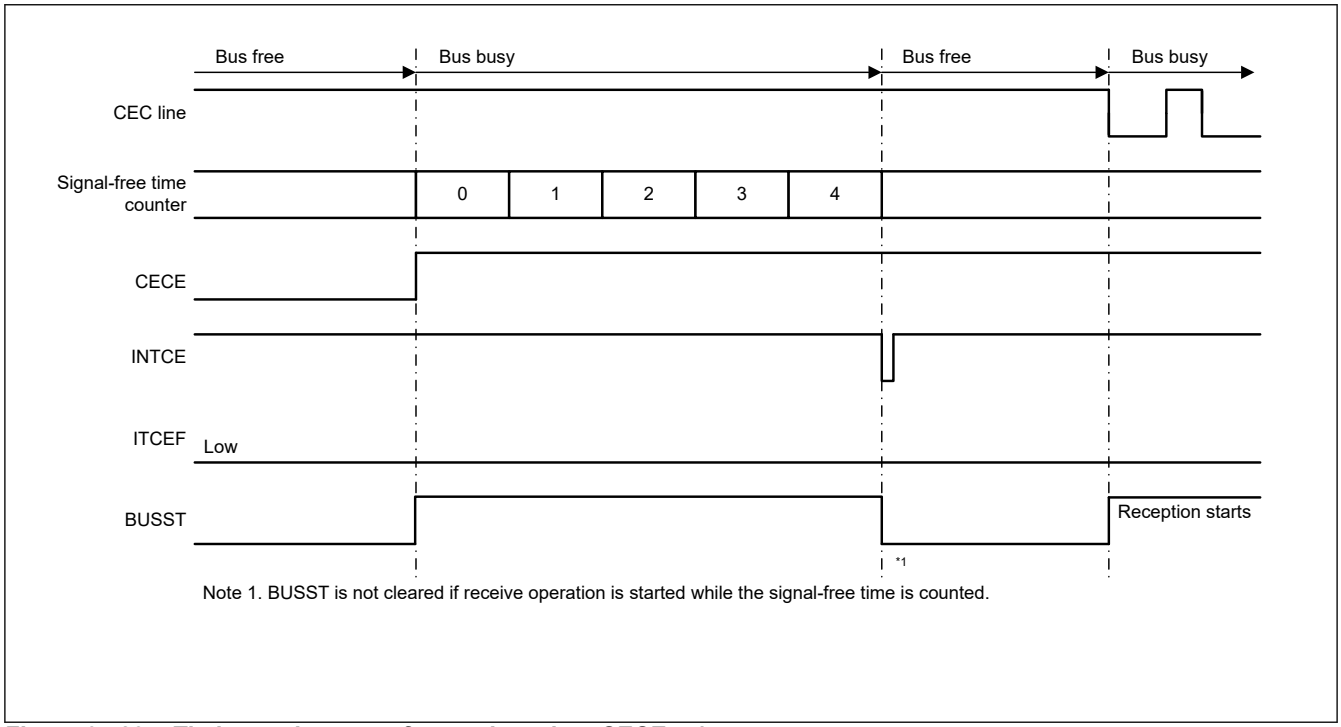
(2) Bus busy detection flag

Figure 37.23 to Figure 37.25 show the timing operation of the Bus Busy Flag (CECS.BUSST). When CEC operation is enabled (CECCTL0.CECE = 0→1) or operation of the CEC line is detected, the Bus Busy Flag (CECS.BUSST) is set. After communication completes and the signal-free time has elapsed, the Bus Busy Flag is then cleared.



Note 1. BUSST is not cleared if receive operation is started while the signal-free time is counted.

Figure 37.23 Timing at the start of reception when CECE = 1

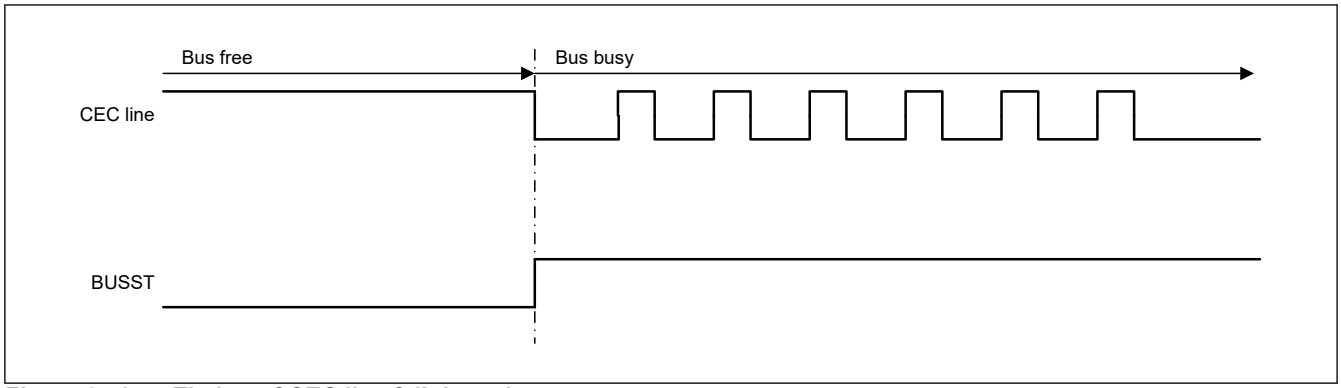


Figure 37.24 Timing of CEC line fall detection

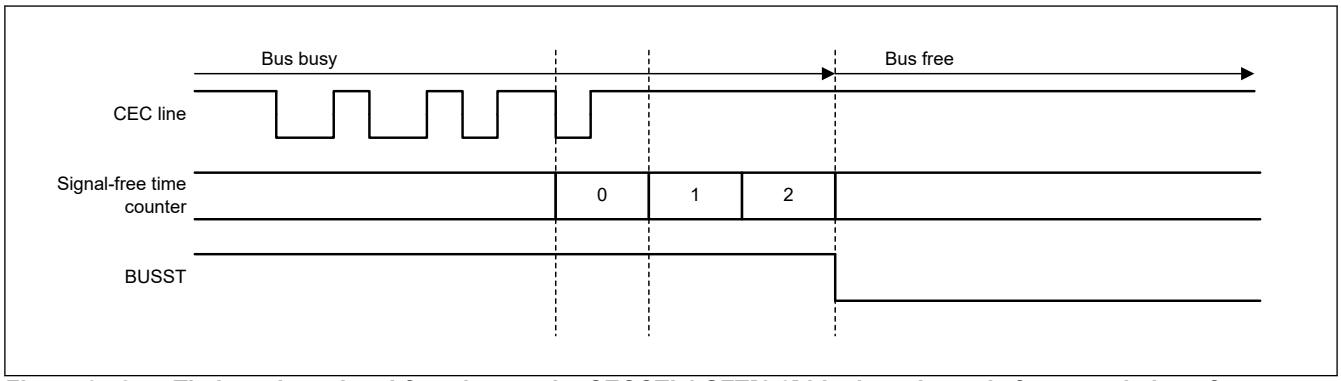

Figure 37.25 Timing when signal-free time set by CECCTL1.SFT[1:0] bits has elapsed after completion of communication

(3) Transmission status flag

As shown in Figure 37.26, when 1 is written to the Transmission Start Trigger Bit (CECCTL0.TXTRG) during initiator operation, the transmission status flag (CECS.TXST) is set.

The transmission status flag is cleared when the communication complete interrupt (INTCE) that is generated on completion of ACK reception for the data block with EOM = 1. However, as shown in Figure 37.27, if arbitration is lost, the transmission status flag is cleared at the same time when an error interrupt (INTERR) is generated and the Arbitration Loss Detection Flag (CECES.AERR) is set.

Likewise, if an underrun error occurs, the Transmission Status Flag is cleared as the same time when an error interrupt is generated.

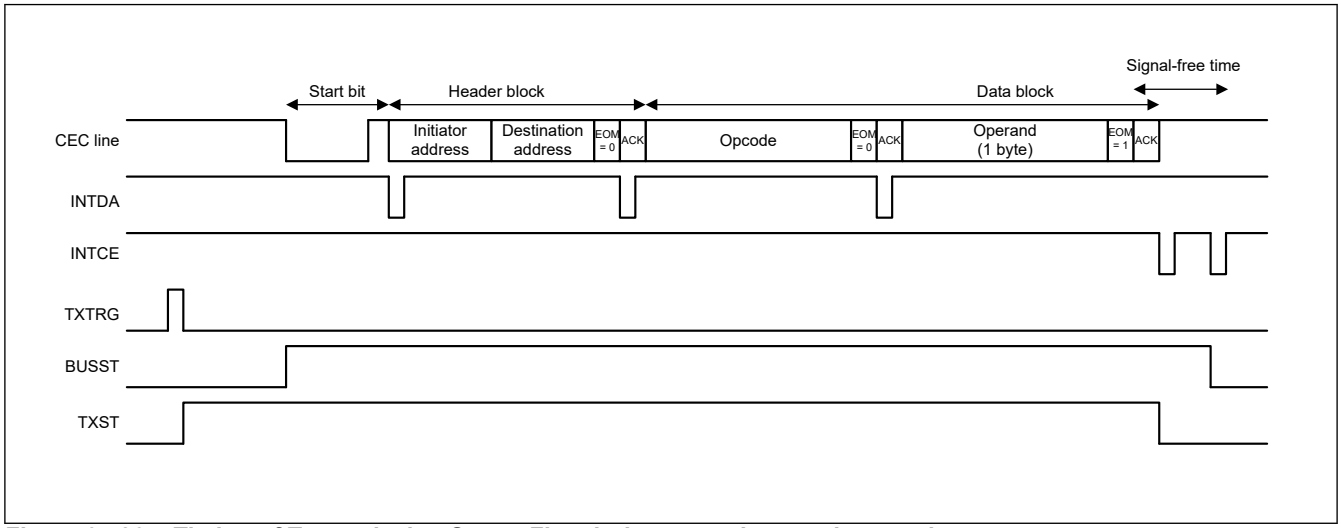

Figure 37.26 Timing of Transmission Status Flag during normal transmit operation

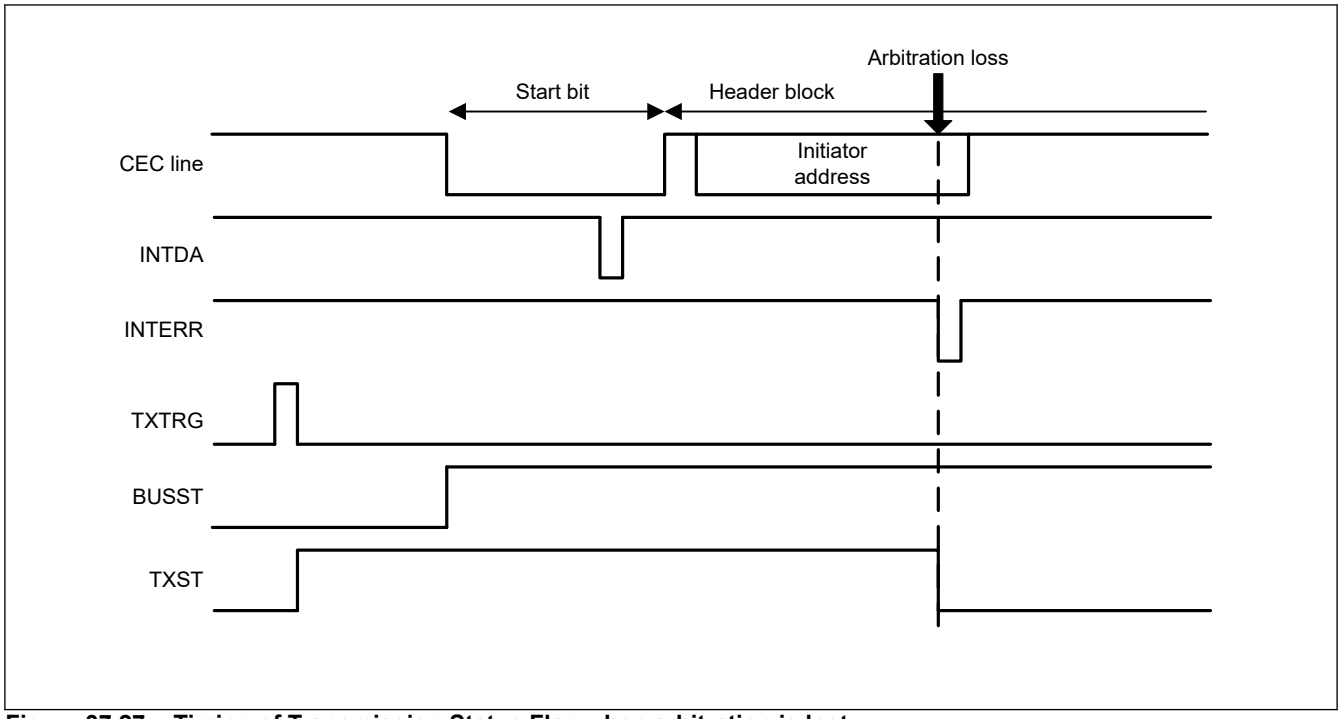

Figure 37.27 Timing of Transmission Status Flag when arbitration is lost

(4) EOM flag

As shown in Figure 37.28, during follower operation, the EOM flag (CECS.EOMF) is updated at the same time when a data interrupt (INTDA) is generated.

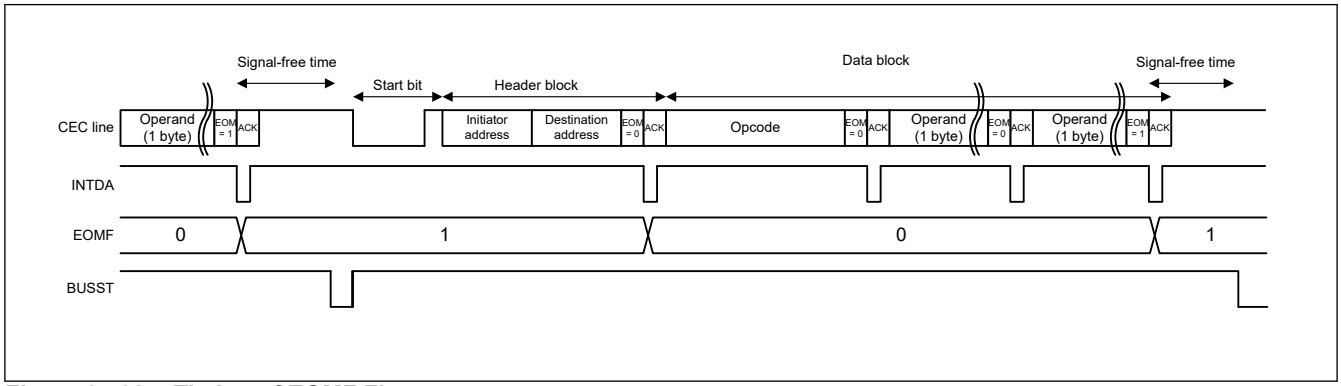

Figure 37.28 Timing of EOMF Flag

(5) INTCE generation source flag

This flag indicates which source was the generation source when a communication complete interrupt (INTCE) is generated. The INTCE Generation Source Flag (CECS.ITCEF) is set at the same time as the communication complete interrupt (INTCE) at the timing of ACK reception of the last block or when an error occurs.

After communication is complete, the INTCE Generation Source Flag is cleared when the signal-free time has elapsed. However, if receive operation is started during the signal-free time, the INTCE Generation Source Flag is not cleared and remains 1. Figure 37.29 shows an example of using the INTCE Generation Source Flag (CECS.ITCEF) to check the INTCE generation source.

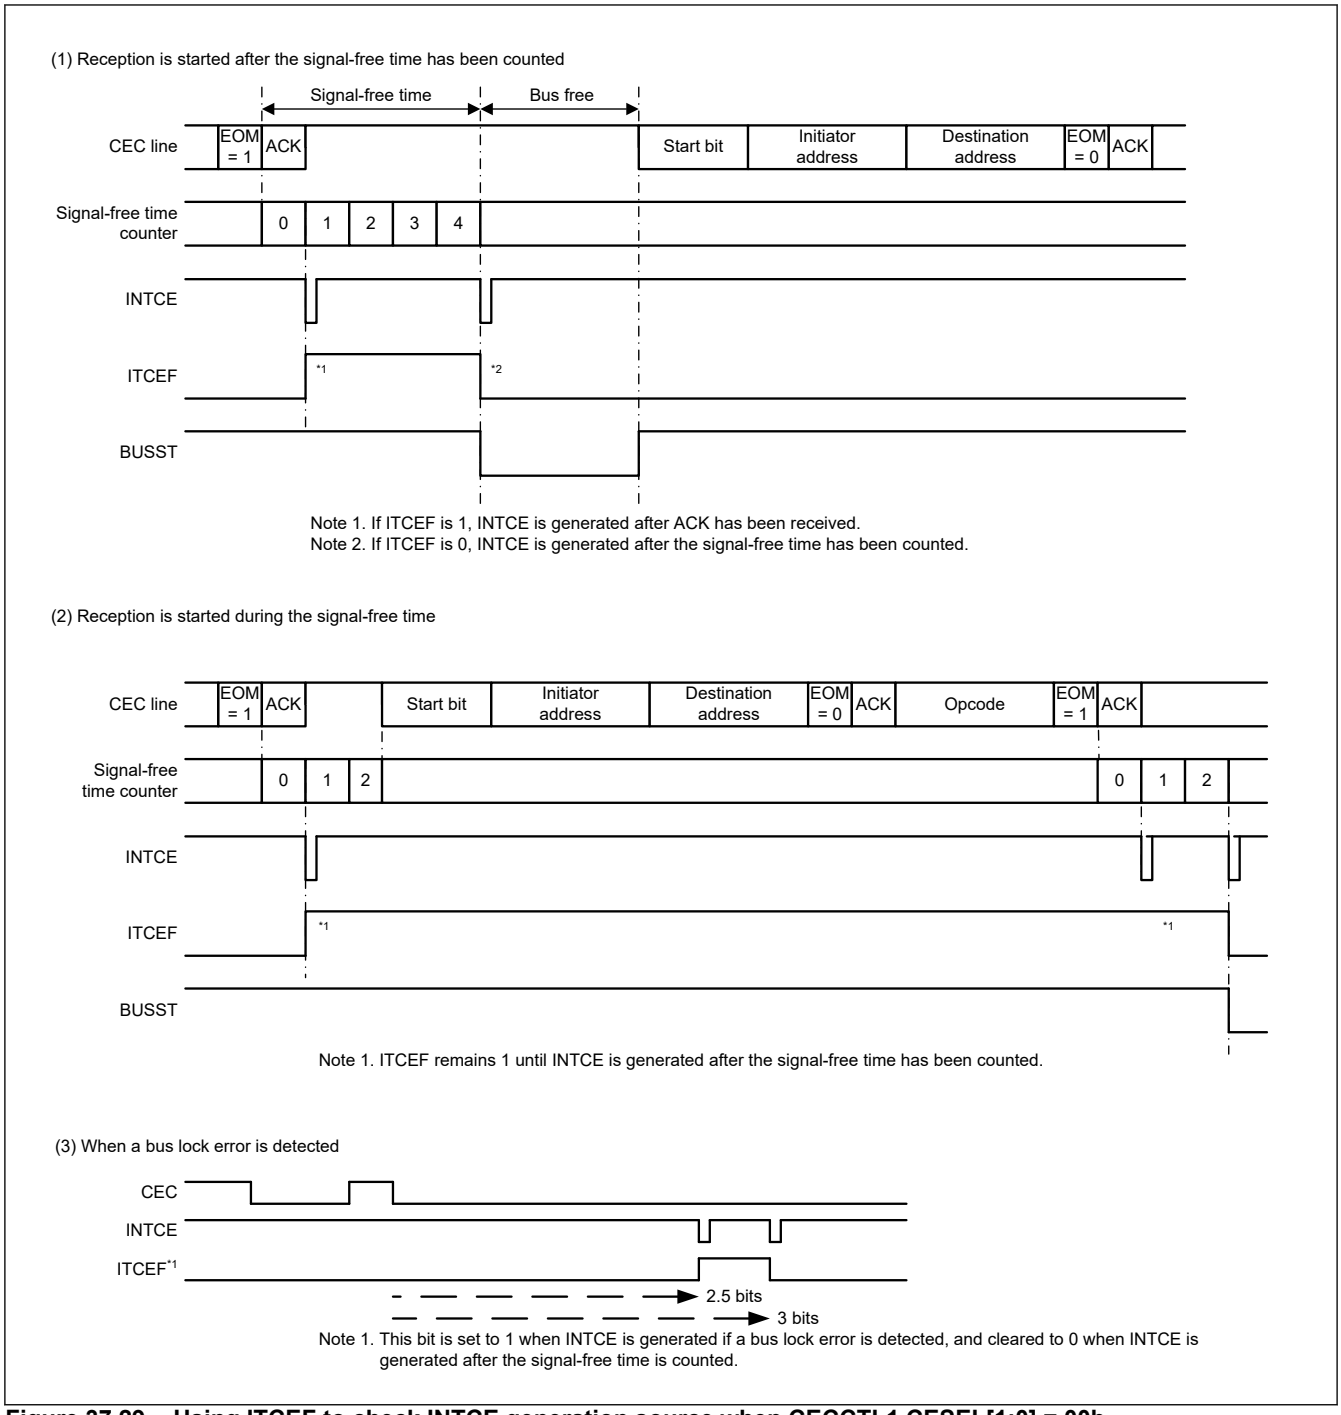

Figure 37.29 Using ITCEF to check INTCE generation source when CECCTL1.CESEL[1:0] = 00b

(6) Signal-free time rewrite disable report flag

This flag indicates the rewrite disable period of the signal-free time data width select bits (CECCTL1.SFT[1:0]). As shown in Figure 37.30, when the CECCTL1.SFT[1:0] bits are accessed, the Signal-free Time Rewrite Disable Report Flag (CECS.SFTST) is set.

This flag is cleared after the CECCTL1.SFT[1:0] bit setting is applied to the CEC internal control circuit.

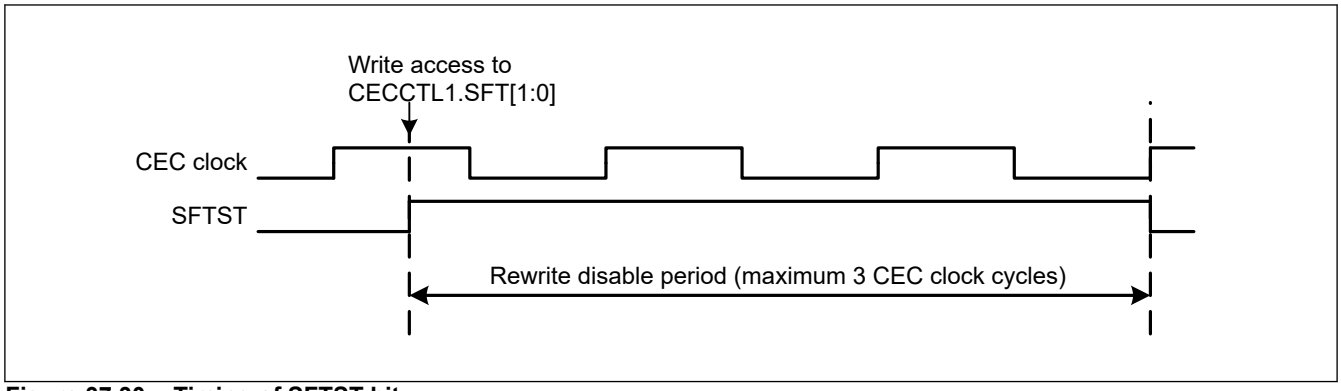

Figure 37.30 Timing of SFTST bit

(7) CEC line monitor

Figure 37.31 shows the timing operation of the CECEXMON.CECLNMON bit.

The state of the CEC pin can be read by reading the CECEXMON.CECLNMON bit.

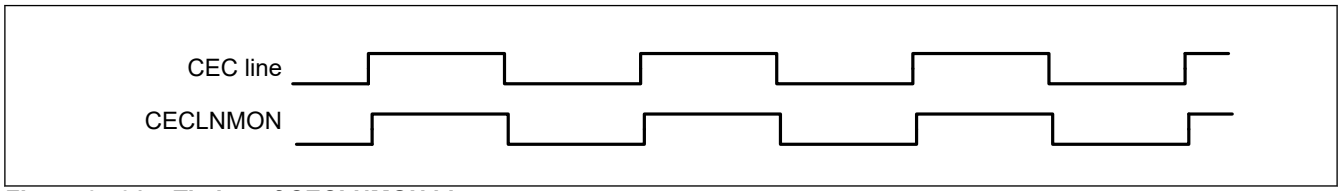

Figure 37.31 Timing of CECLNMON bit

(8) ACK flag

During follower operation, the ACK flag (CECEXMON.ACKF) is updated at the timing of ACK bit reception.

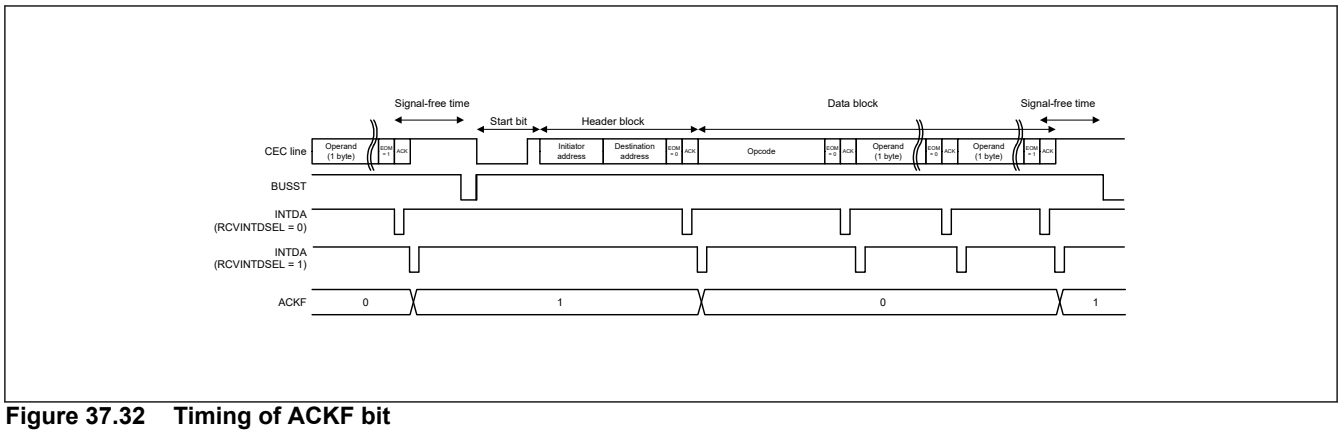

Figure 37.32 Timing of ACKF bit

As shown in Figure 37.32, when reading the ACKF bit while CECEXMD.RCVINTDSEL = 0, the received ACK state can be read by reading this bit when a 1-bit wait time has elapsed after a data interrupt (INTDA) is generated. (if this bit is read after a data interrupt is generated, the ACK of the previously received data is read).

When reading the ACKF bit while CECEXMD.RCVINTDSEL = 1, read this bit after a data interrupt (INTDA) is generated. The ACK of the newest received data can be read.

37.3.3.7 CEC Interrupts

The CEC transmission/reception circuit generates three interrupt requests.

- Data interrupt (INTDA)
  During transmission, this interrupt is generated at the timing when transmission of each block is started. During reception, this interrupt is generated at the timing of each completion of EOM bit reception if CECEXMD.RCVINTDSEL is 0, and each completion of ACK bit transmission if CECEXMD.RCVINTDSEL = 1, depending on the value of the Reception Interrupt Timing Change bit.

- Communication complete interrupt (INTCE)
  During both transmission and reception, this interrupt is generated on completion of the message or signal-free time is complete. It is also possible to select only one of the two (completion of the message or signal-free time) by setting the communication complete Interrupt Generation Timing Change Bits (CECCTL1.CESEL[1:0]).
- Error interrupt (INTERR)
  This interrupt is generated when an error is generated.

Figure 37.33 shows the timing for generating each interrupt.

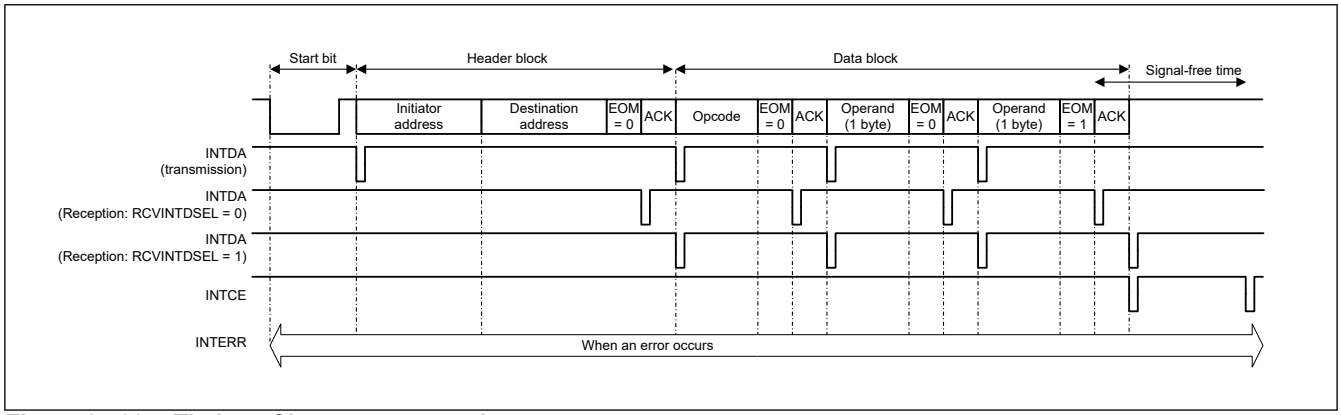

Figure 37.33 Timing of interrupt generation

Each of three interrupt requests can be used to output two types of interrupt requests. Use the two types exclusively depending on the application of the interrupt request. See Table 37.13 for details on the application corresponding to each CEC interrupt request.

Table 37.13 CEC interrupt sources

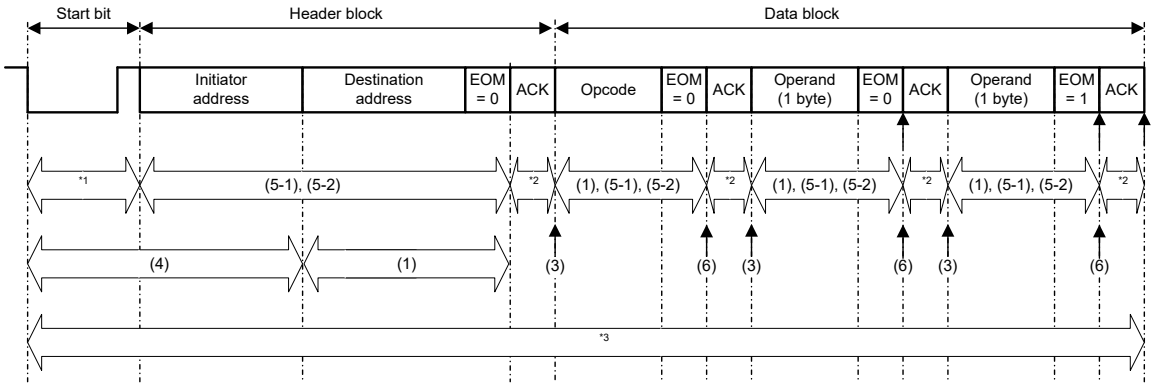
Name	Corresponding source				
	CPU interrupt	DTC activation	DMAC activation	Return from Software Standby mode	Return from All-Module Clock Stop mode
INTDA	Possible	Possible	Possible	Not possible	Not possible
INTCE	Possible	Possible	Possible	Not possible	Not possible
INTERR	Possible	Not possible	Not possible	Not possible	Not possible

37.3.3.7.1 Error Interrupt Sources

Table 37.14 lists the seven errors that CEC can detect for the initiator and follower, and Figure 37.34 shows the error detection period.

Table 37.14 Errors that can be detected for the initiator and follower

Error	Initiator	Follower
(1) Transmission error	Detected	Not detected
(2) ACK error	Detected	Not detected
(3) Underrun error	Detected	Not detected
(4) Arbitration error	Detected	Not detected
(5-1) Timing error (low-level width)	Detected	Detected
(5-2) Timing error (bit width)	Detected	Detected
(6) Overrun error	Not detected	Detected
(7) Bus lock error	Not detected	Detected



Note 1. (5-1) and (5-2) if detecting timing errors for the start bit (CECCTL1.STERRD = 1).
Note 2. (5-2) if detecting timing errors for the ACK bit (CECCTL0.ACKTEN = 1), in addition to (2) and (5-1).
Note 3. (7) if detecting bus lock errors (CECCTL1.BLERRD = 1).

Figure 37.34 Error detection period

The details of each error are explained in the sections that follow.

(1) Transmission error

As shown in Figure 37.35, during initiator operation, the logic of the data the initiator transmitted is compared with that of the CEC line receive data and a transmission error occurs when they differ. Errors are determined at the timing specified by the value set to the CEC Reception Data Sampling Time Setting Register (NOMT). Errors are determined during the data bit period of the frame that includes the EOM bit. An error interrupt (INTERR) is generated after error detection, the Transmission Error Detection Flag (CECES.TXERR) is set, and transmission is stopped according to the value of the flag.

A communication complete interrupt INTCE is generated at the end of the bit at which transmission stopped and after the signal-free time is counted, according to the values specified for CECCTL1.CESEL[1:0].

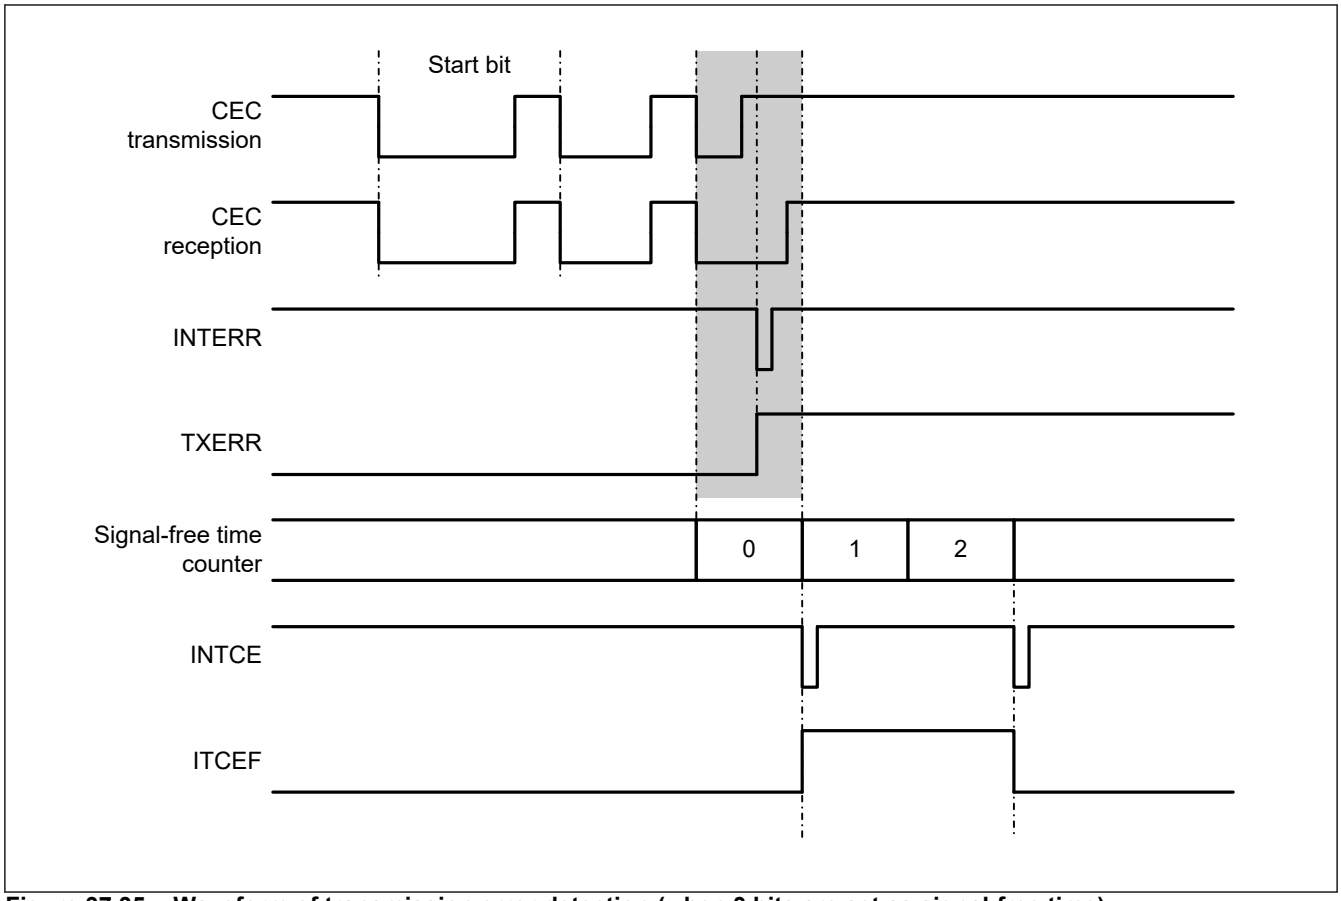


Figure 37.35 Waveform of transmission error detection (when 3 bits are set as signal-free time)

When a transmission error is detected, the transmit operation is stopped at the bit where the error was detected, regardless of the set value of the CECCTL0.EOM bit.

When EOM = 0 is received even though the initiator is transmitting EOM = 1, the transmission is a transmission error and therefore, stopped. Because EOM = 0, the follower determines that transmission should continue and so it waits for data reception. If CECCTL1.BLERRD is set to 1, whether the received data is at a high or low level can be detected.

(2) ACK error

During direct address transmission, an ACK error occurs when the initiator receives logical 1 at the ACK bit timing. During broadcast transmission, an ACK error occurs when the initiator receives logical 0 at the ACK bit timing. Figure 37.36 shows the timing of ACK error detection.

Errors are determined at the timing of the value set in the CEC Reception Data Sampling Time Setting Register (NOMT). After an error is detected, an error interrupt (INTERR) is generated and the ACK Error Detection Flag (CECES.ACKERR) is set. At the end of the ACK bit, communication standby state is entered and the signal-free time is counted. A communication complete interrupt (INTCE) occurs once or twice depending on the set values of the CECCTL1.CESEL[1:0] bits.

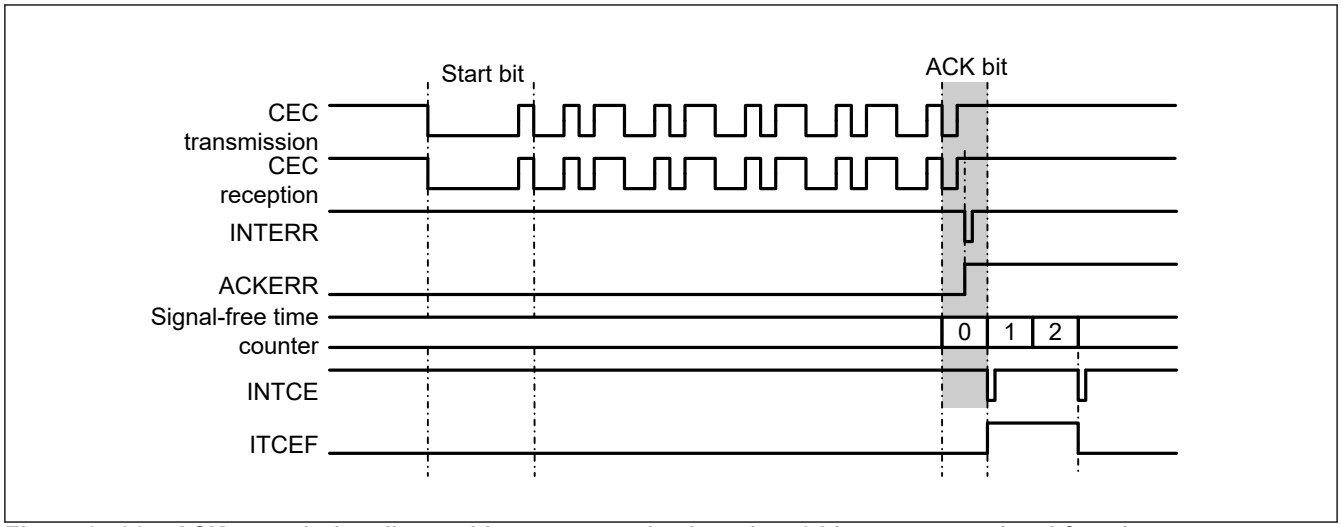

Figure 37.36 ACK error during direct address communication when 3 bits are set as signal-free time

(3) Underrun error

An underrun error occurs when no data is set to the transmission buffer when transmitting the next data is started. When an underrun is detected as shown in Figure 37.37, an error interrupt (INTERR) is generated, the Underrun Error Detection Flag (CECES.UERR) is set, the transmission is aborted, and communication standby state is entered. A communication complete interrupt (INTCE) occurs once or twice depending on the set values of the CECCTL1.CESEL[1:0] bits.

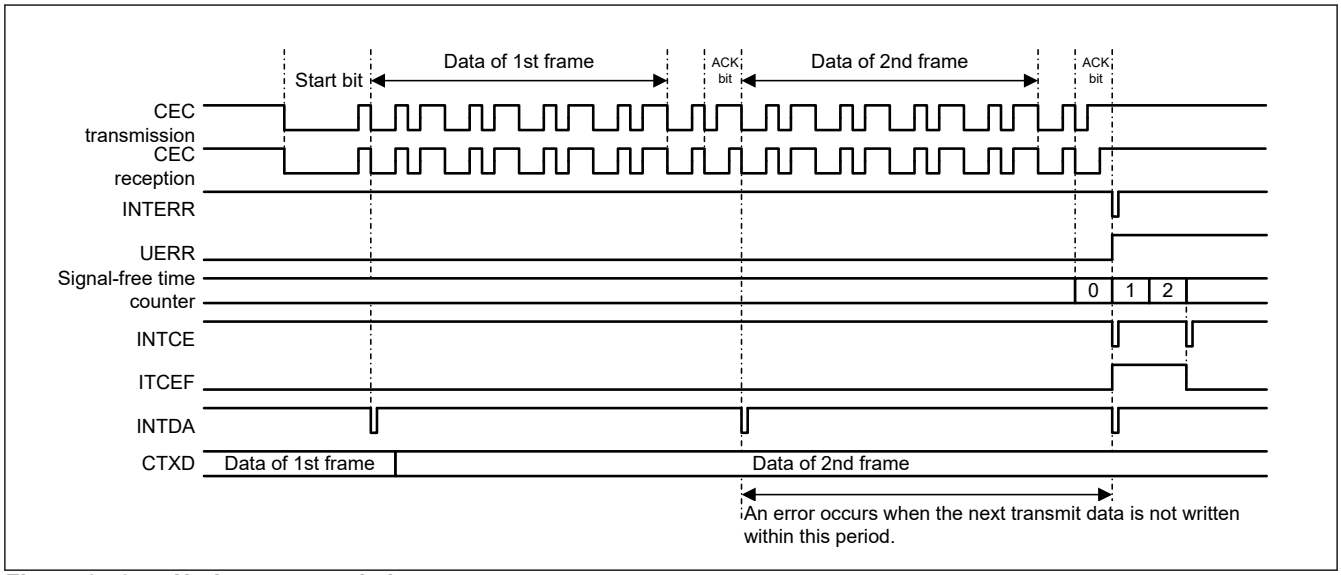

Figure 37.37 Underrun error timing

(4) Arbitration error

As shown in Figure 37.38, if logical 0 is received in response to logical 1 transmission during the period from the transmission start trigger (CECCTL0.TXTRG) being set to the source address being transmitted, an arbitration error occurs. Errors between setting the transmission start trigger and outputting the start bit are determined when low level is output to the CEC transmission signal. While the source address is being transmitted, errors are determined at the timing of the value set to the CEC Reception Data Sampling Time Setting Register (NOMT). After an error is detected, an error interrupt (INTERR) is generated and the Arbitration Loss Detection Flag (CECES.AERR) is set. At this time, the transmission is aborted, but the receive operation continues. Multiple error flags may be detected, as shown in Figure 37.39, until the source address detection period is entered.

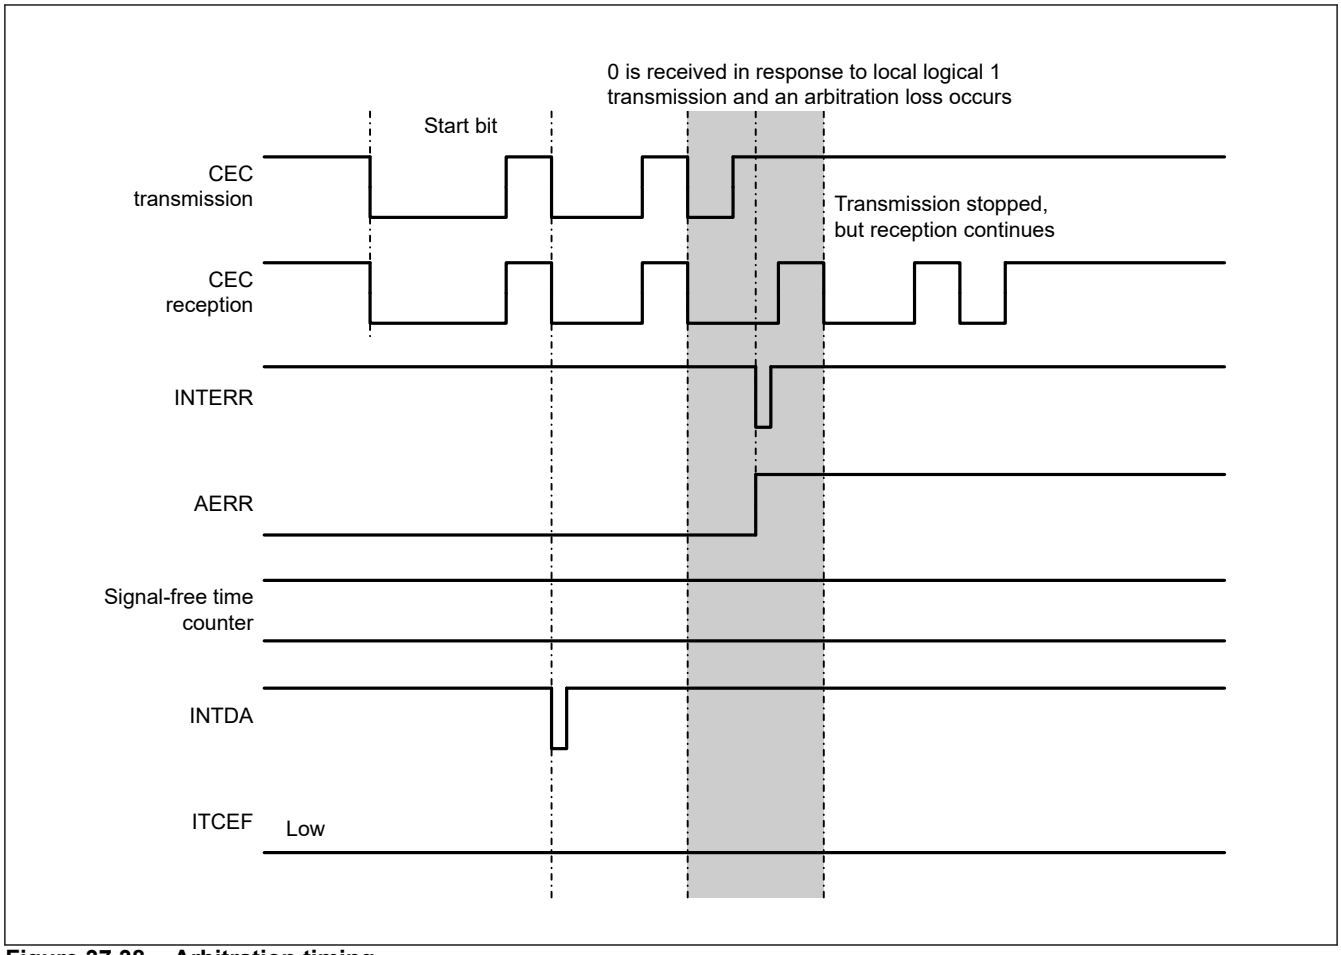

Figure 37.38 Arbitration timing

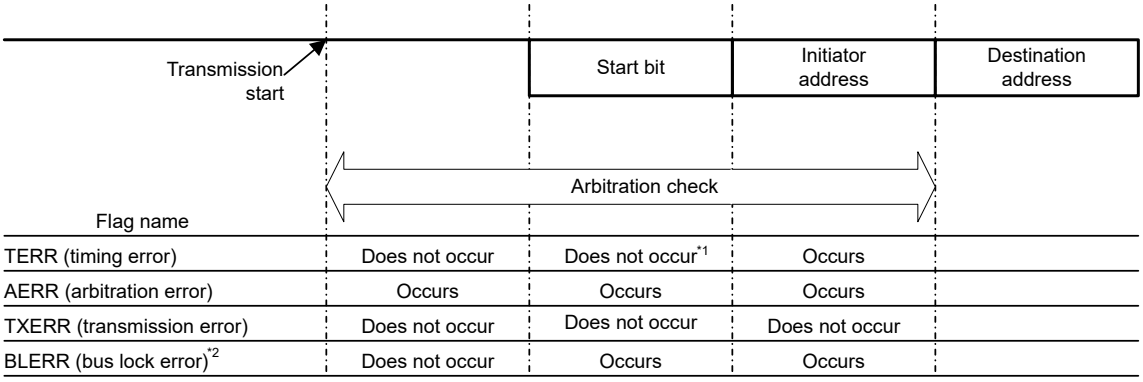

Flag name			
TERR (timing error)	Does not occur	Does not occur*1	Occurs
AERR (arbitration error)	Occurs	Occurs	Occurs
TXERR (transmission error)	Does not occur	Does not occur	Does not occur
BLERR (bus lock error)*2	Does not occur	Occurs	Occurs

Note 1. If CECCTL1.STERRD is 1, the start bit timing is checked, but no error interrupt is generated.
Note 2. If CECCTL1.BLERRD is 1, a bus lock error is detected.

Figure 37.39 Arbitration error and other errors

Detailed description of arbitration error

Details about the arbitration check performed from the time when the transmission start trigger (CECCTL0.TXTRG) is set until the initiator address output period are provided in the sections that follow.

Arbitration check by setting transmission start trigger (CECCTL0.TXTRG)

The arbitration check is performed when two CEC clock cycles have elapsed after the transmission start trigger (CECCTL0.TXTRG) is set. If an arbitration loss is determined, an error interrupt (INTERR) is generated, the Arbitration Loss Detection Flag (CECES.AERR) is set, and the mode is switched to reception mode.

Start bit output period

If low level is detected at the reception line when the transmission start trigger (CECCTL0.TXTRG) is set and the start bit is actually output, the Arbitration Loss Detection Flag (CECES.AERR) is set and the mode is switched to reception mode. If the rising edge of the reception line is detected beyond the maximum low-level width of the start bit set by STATLH, the Arbitration Loss Detection Flag (CECES.AERR) is set and the mode is switched to reception mode.

Initiator address output period

After transmission of the start bit is complete, a logic check is performed at the same time as the transmission start of the initiator address. If an address earlier than the local address is detected, an error interrupt (INTERR) is generated, the Arbitration Loss Detection Flag (CECES.AERR) is set, and the mode is switched to reception mode.

(5) Timing error

Timing errors of the CEC reception signal are checked during initiator or follower operation. A timing error occurs if the CEC reception signal is outside the range of the compare register set. As shown in Figure 37.40, low-level width timing errors are detected when the rising edge is detected. Timing errors for the minimum bit width are detected when the falling edge is detected, and timing errors for the maximum bit width are detected if there is no falling edge even though the maximum bit width has exceeded. Whether to check the ACK bit timing can be selected using the CECCTL0.ACKTEN bit. However, even if CECCTL0.ACKTEN is set to 1, the maximum bit width is not checked only for the ACK bit of the last data block (when CECCTL0.EOM = 1). The minimum bit width is checked. As shown in Figure 37.41, if a timing error with a short bit width is detected during follower operation, a low-level pulse (error handling pulse) that has a bit width 1.5 times the bit width specified using the NOMP register is transmitted.

An error handling pulse is not transmitted if a start bit timing error is detected.

If a timing error other than one that has a short bit width is detected during initiator operation, transmission immediately stops. During follower operation, reception continues as shown in Figure 37.42, and logical 1 is transmitted during direct address communication and logical 0 is transmitted during broadcast communication at the ACK bit timing. The generation of a communication complete interrupt (INTCE) depends on the set values of CECCTL1.CESEL[1:0]. If a timing error for the minimum bit width of the last ACK bit is detected, a communication complete interrupt (INTCE) is output at the same time as an error interrupt (INTERR).

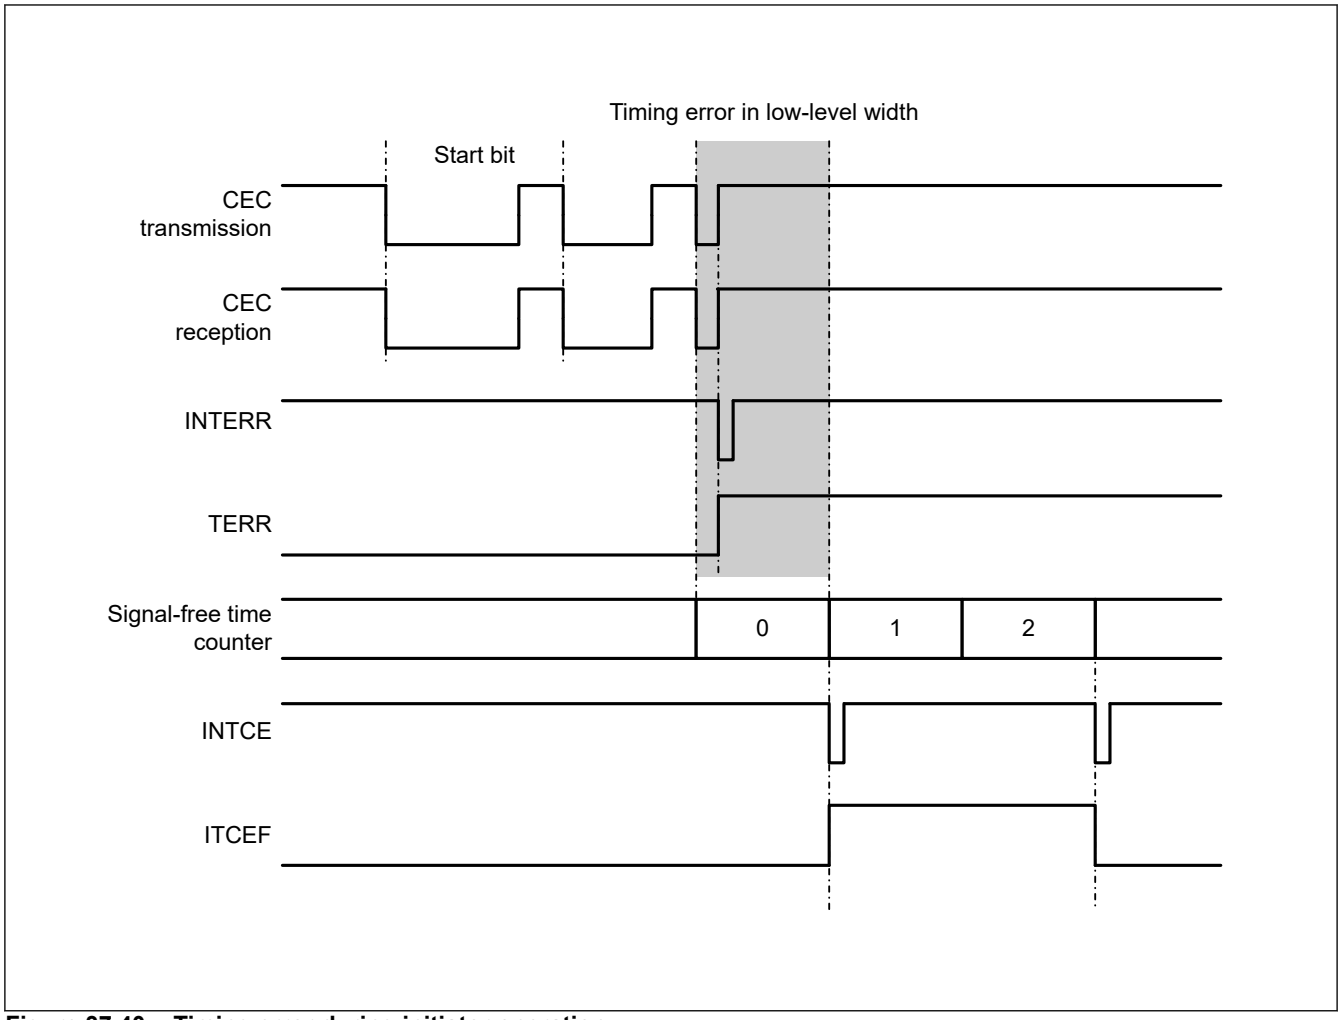

Figure 37.40 Timing error during initiator operation

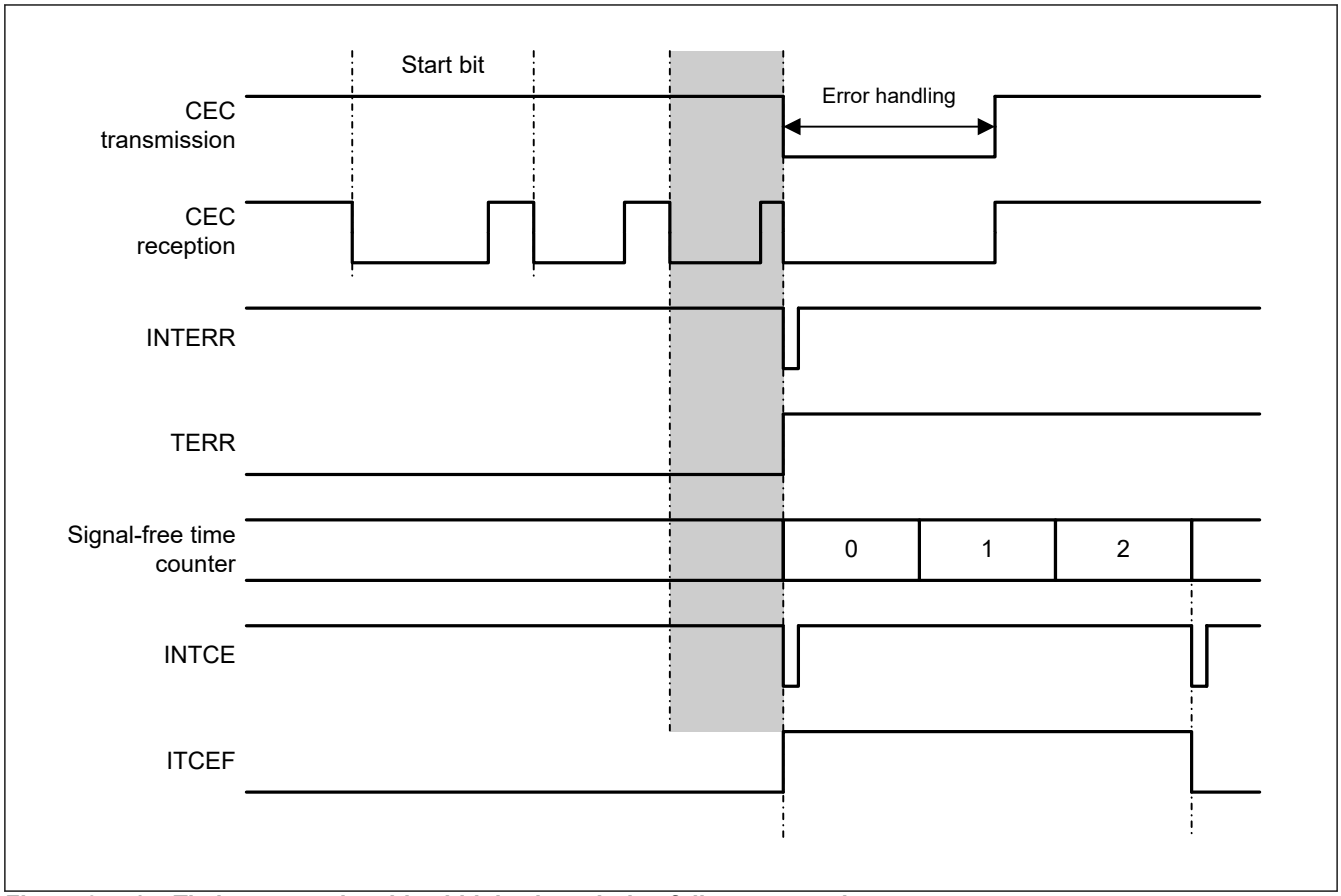

Figure 37.41 Timing error when bit width is short during follower operation

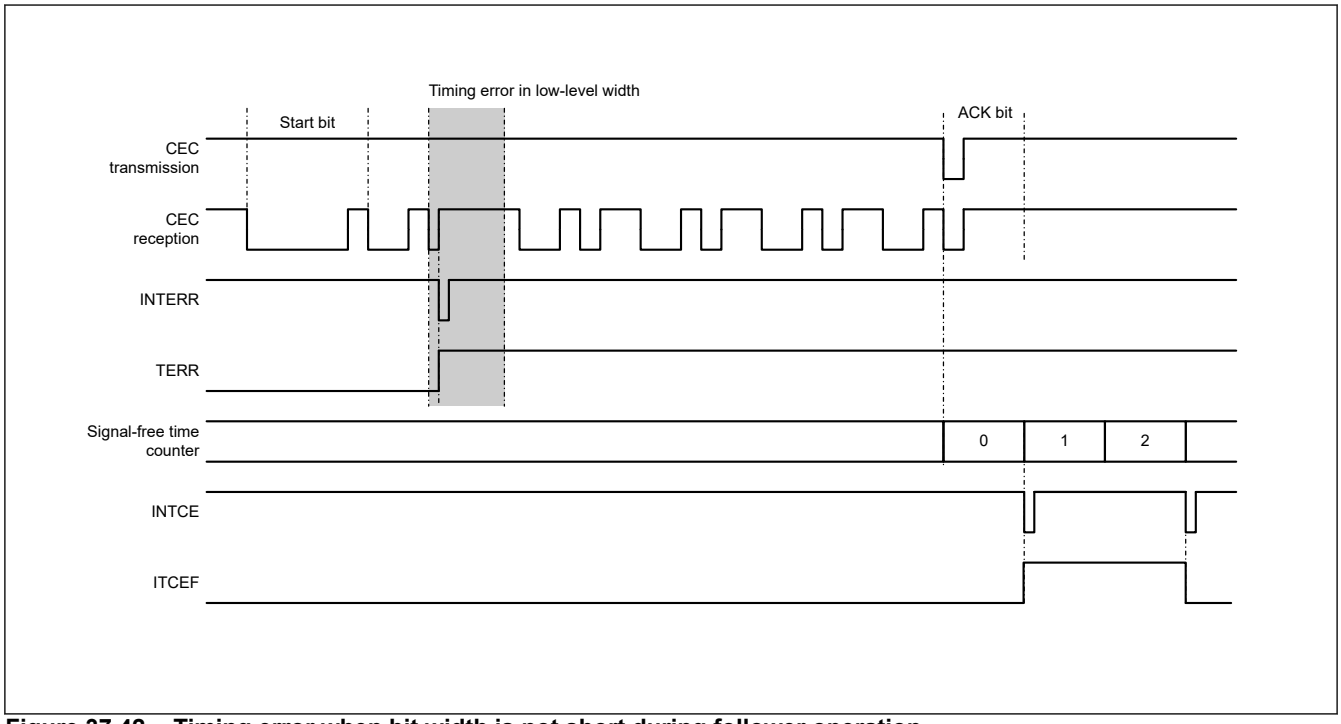

Figure 37.42 Timing error when bit width is not short during follower operation

(6) Overrun error

If receiving the next data is complete before reading data from the Reception Buffer Register (CRXD) during follower operation, an overrun error occurs. As shown in Figure 37.43, an error interrupt (INTERR) is generated, and the Overrun

Error Detection Flag (CECES.OERR) is set. Afterward, logical 1 is returned during direct address communication and logical 0 is returned during broadcast communication at the ACK transmission timing of the block in which an overrun error occurred. The failure of reception is reported to the initiator, and reception standby state is entered. A communication complete interrupt (INTCE) operates according to the setting of the CECCTL1.CESEL[1:0] bits.

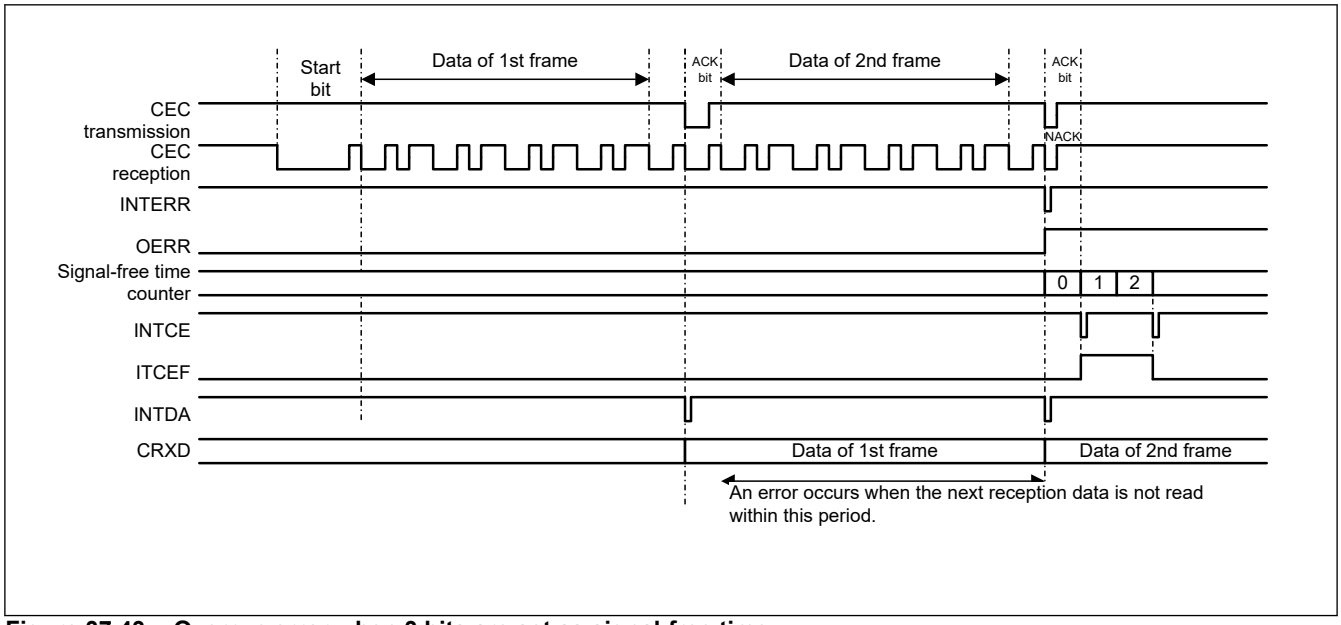

Figure 37.43 Overrun error when 3 bits are set as signal-free time

(7) Bus lock error

When bus lock errors are set to be detected (CECCTL1.BLERRD = 1), a bus lock error occurs if the bus is in the communication status (CECS.BUSST = 1) and the CEC reception signal stays high or low for a period corresponding to 2.5 times the data bit width specified by using the NOMP register. Figure 37.44 shows the timing of bus lock error detection.

If an error is detected, an error interrupt (INTERR) is generated, the Bus Lock Error Detection Flag (CECES.BLERR) is set, communication standby state is entered, and the signal-free time is counted. A communication complete interrupt (INTCE) operates according to the setting of the CECCTL1.CESEL[1:0] bits. Bus lock errors are detected only for the follower.

When bus lock errors are not set to be detected (CECCTL1.BLERRD = 0), no bus lock error is detected. To determine whether the bus is locked, monitor the CECEXMON.CECLNMON bit, and use software to determine and handle bus locking.

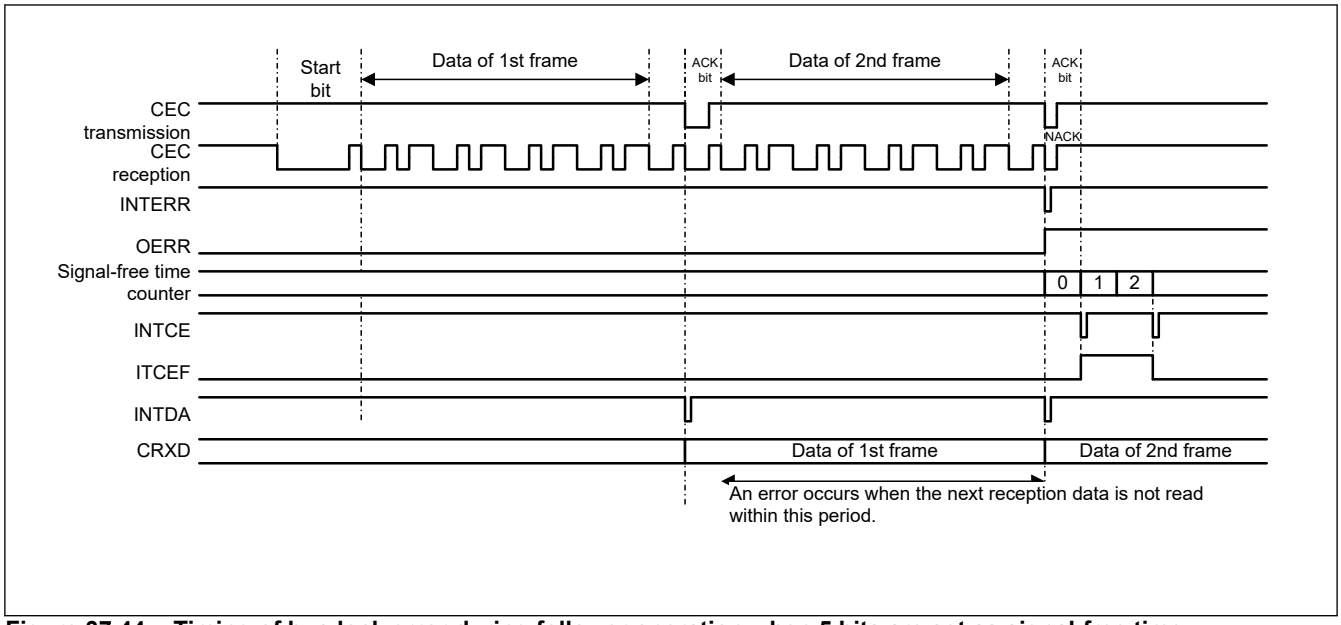

Figure 37.44 Timing of bus lock error during follower operation when 5 bits are set as signal-free time

37.3.3.7.2 Clearing Error Flag

An error flag set to the CEC Communication Error Status Register (CECES) can be cleared by setting 1 to the corresponding bit in the CEC Communication Error Flag Clear Trigger Register (CECFC). Figure 37.45 shows an example when an arbitration error occurs. An Arbitration Loss Detection Flag can be cleared by setting 0x20 to the CECFC register.

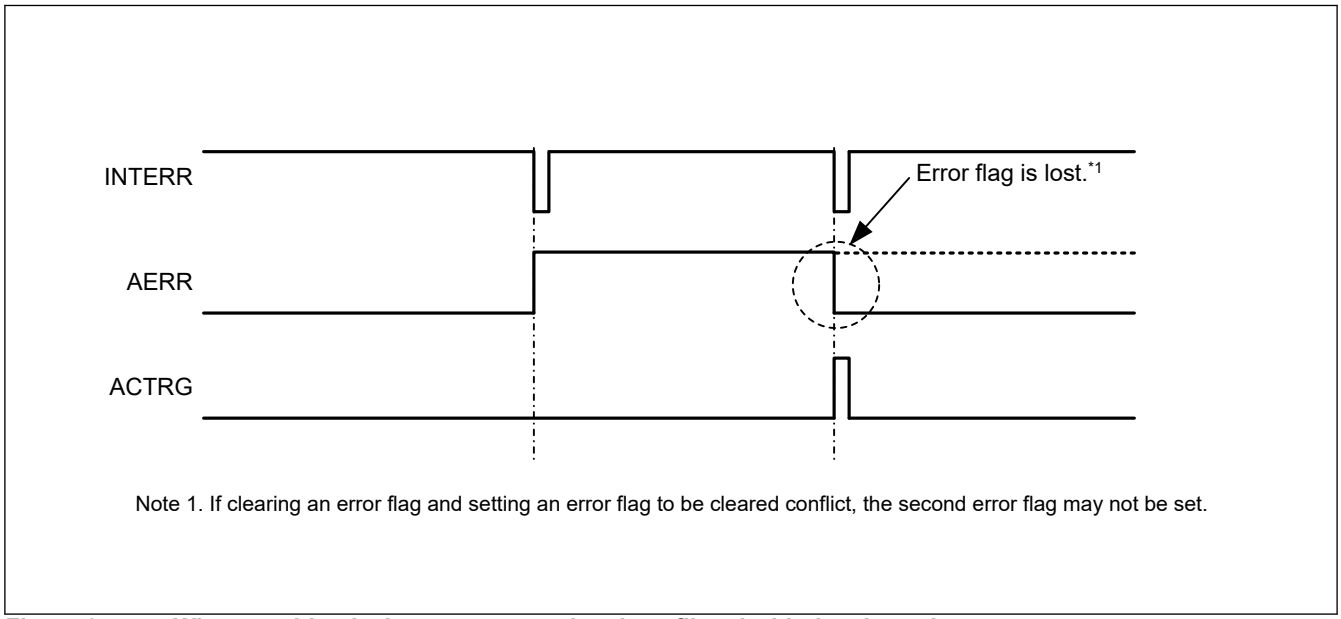

Figure 37.45 When two identical errors occurred and conflicted with the clear trigger

37.3.3.8 Signal-Free Time

The end of the signal-free time is reported by generating a communication complete interrupt by detecting a match with the specified time (3, 5, or 7 bits of the bit width specified using the NOMP register). The number of bits of the signal-free time is specified using the CECCTL1.SFT[1:0] bits. A communication complete interrupt is generated by setting up the CECCTL1.CESEL[1:0] bits. Counting the signal-free time always starts when the falling edge of the received data is detected. During normal communication, counting the signal-free time starts after the falling edge of the ACK bit is detected, if CECCTL0.EOM = 1.

Even if an error occurs, counting the signal-free time is started after communication is stopped.

If an error handling pulse (a low-level pulse that has a bit width of 1.5 times the bit width) is acknowledged, the signal-free time is counted starting at the falling edge of the error handling pulse signal. Figure 37.46 shows an operation example in which the detection of a 7-data bit width signal-free time when CECCTL1.CESEL[1:0] = 00b and CECCTL1.SFT[1:0] = 10b.

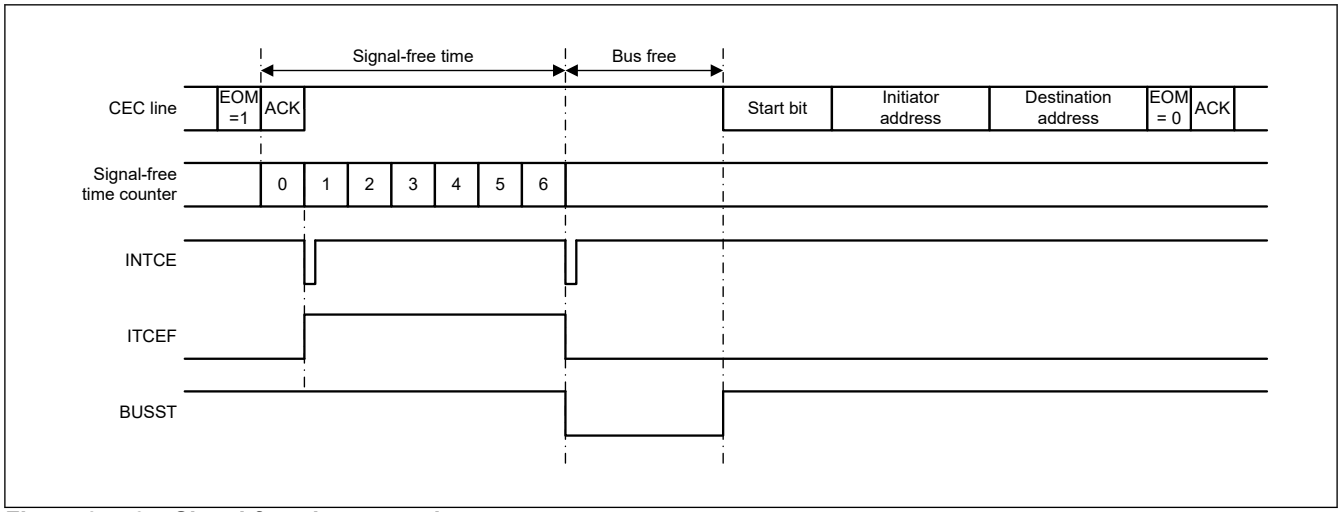

Figure 37.46 Signal-free time operation

Rewriting the values of the CECCTL1.SFT[1:0] bits to the number of bits smaller than the current number of bits while counting the signal-free time must be completed until the rewritten bit count values match. If rewriting is not performed in time, the counter overflows and the signal-free time period continues until the number of bits match again. Figure 37.47 shows an example when the data bit width is changed from 5 to 3 bits.

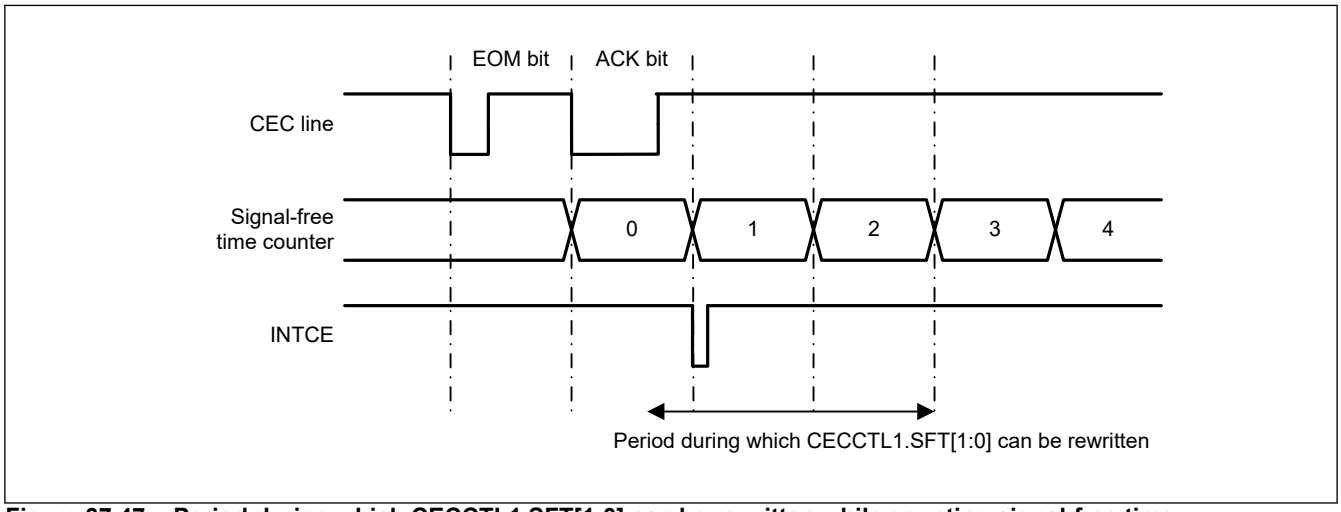

Figure 37.47 Period during which CECCTL1.SFT[1:0] can be rewritten while counting signal-free time

Starting receive operation during signal-free time

If a falling edge of the CEC reception signal is detected while counting the signal-free time, a receive operation is started as shown in Figure 37.48. A communication complete interrupt (INTCE) is not output even if the output of INTCE after counting the signal-free time is set, because the count operation of the signal-free time counter is stopped at this time.

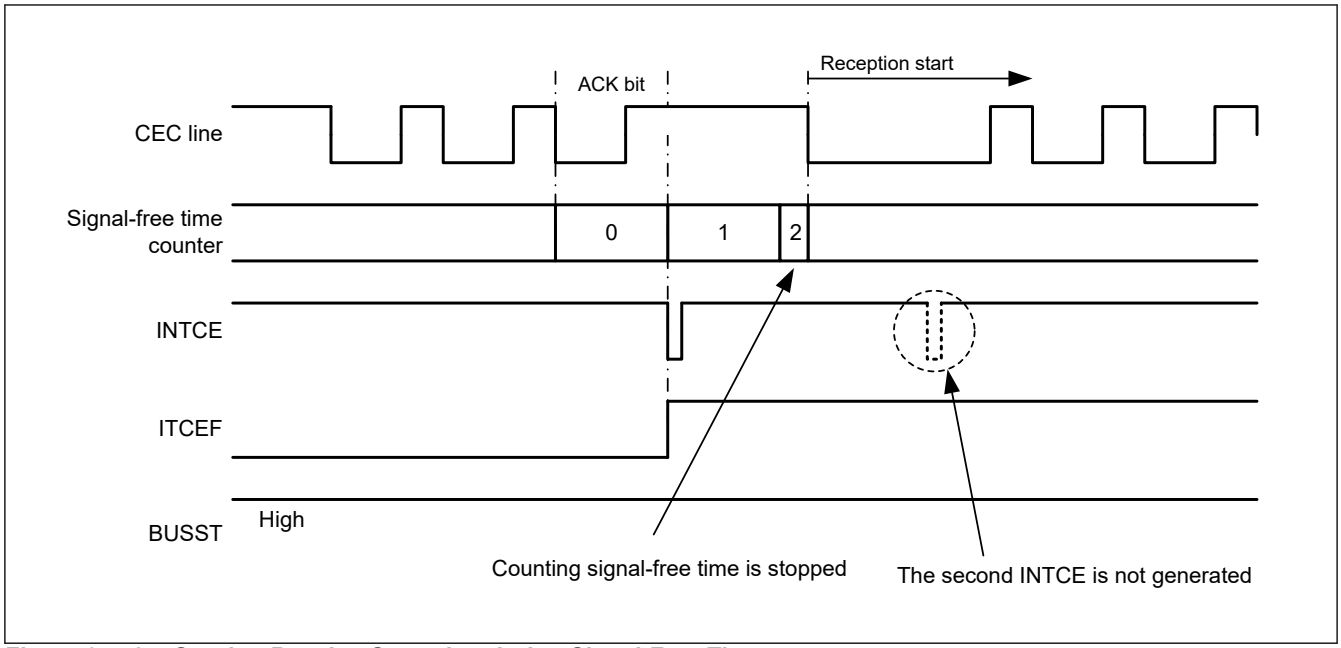

Figure 37.48 Starting Receive Operation during Signal-Free Time

37.3.3.9 Function that Restarts Reception by Detecting Start Bit during Reception

This function is used to restart reception starting from the detected start bit if a new start bit is detected during receive operation (follower operation), as shown in Figure 37.49. This function is enabled by enabling the Start Detection Restart Reception Enable Bit (CECEXMD.RERCVEN = 1).

A start bit is determined when received data matches the set value of the registers (STATLL, STATLH, STATBL, or STATBH) of the received start bit width, and reception is restarted.

Since the start bit is received during reception, a timing error occurs. An error occurs on the falling edge at the beginning of the start bit or at the header block.

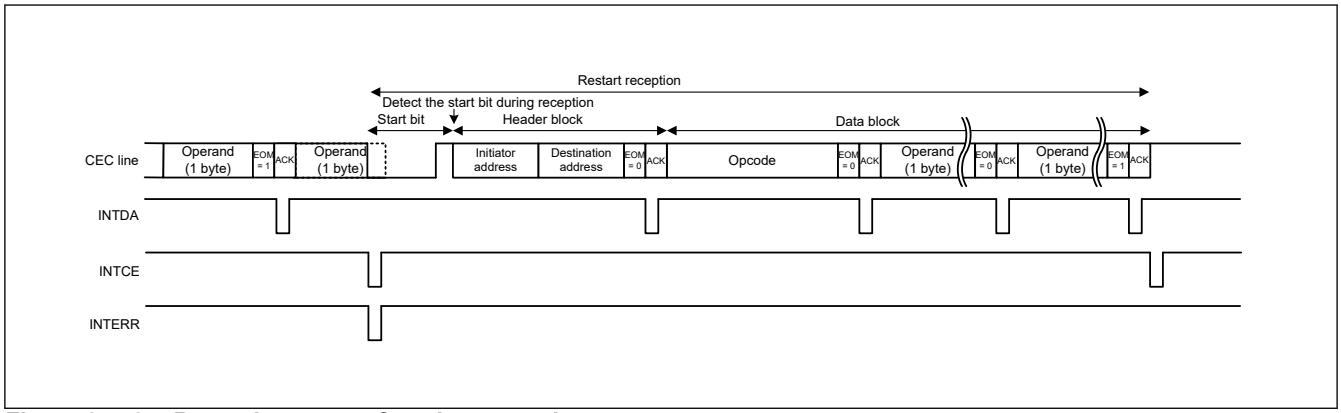

Figure 37.49 Reception restart function operation

37.4 Usage Notes

37.4.1 Recovery from low power consumption state

The CECIO terminal can be used as an IRQ input terminal. For the corresponding IRQ interrupt, if the interrupt request is enabled and the ICU IRQCRi.IRQMD[1:0] bits are set to 01b (falling edge) and the power consumption is changed to the low power consumption state, it recovers from the low power consumption state at the falling edge. Since the CEC operating clock is stopped in software standby mode, disable the start bit timing check. If MOSC is selected as the CEC operating clock, adjust the setting value of the MOSCWTCR.MSTS bit so that the MOSC supply is restarted during the start bit L period.

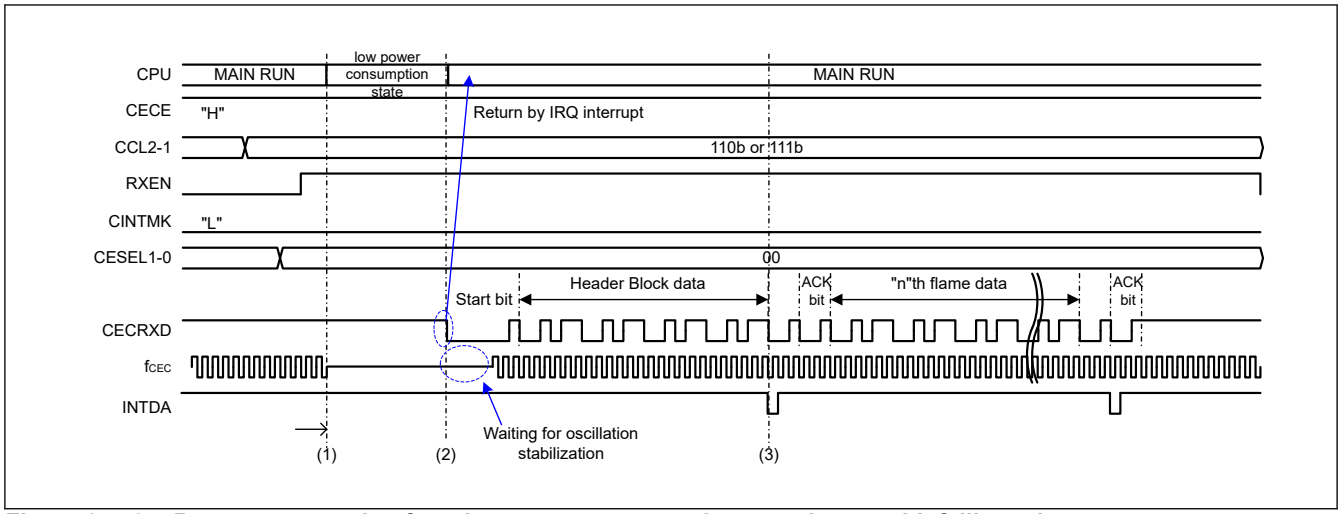

Figure 37.50 Recovery operation from low power consumption state by start bit falling edge

In the recovery operation from the low power consumption state by the start bit falling edge, even if data other than the own station address is received by direct address reception, it recovers from the low power consumption state.

When the CINTMK bit of CECCTL1 is set to 1, a CEC interrupt can be generated even when data other than the own station address is received. By checking the ADRF bit of CECS during data reception interrupt processing, it is possible to check whether the data was received to the local station address.

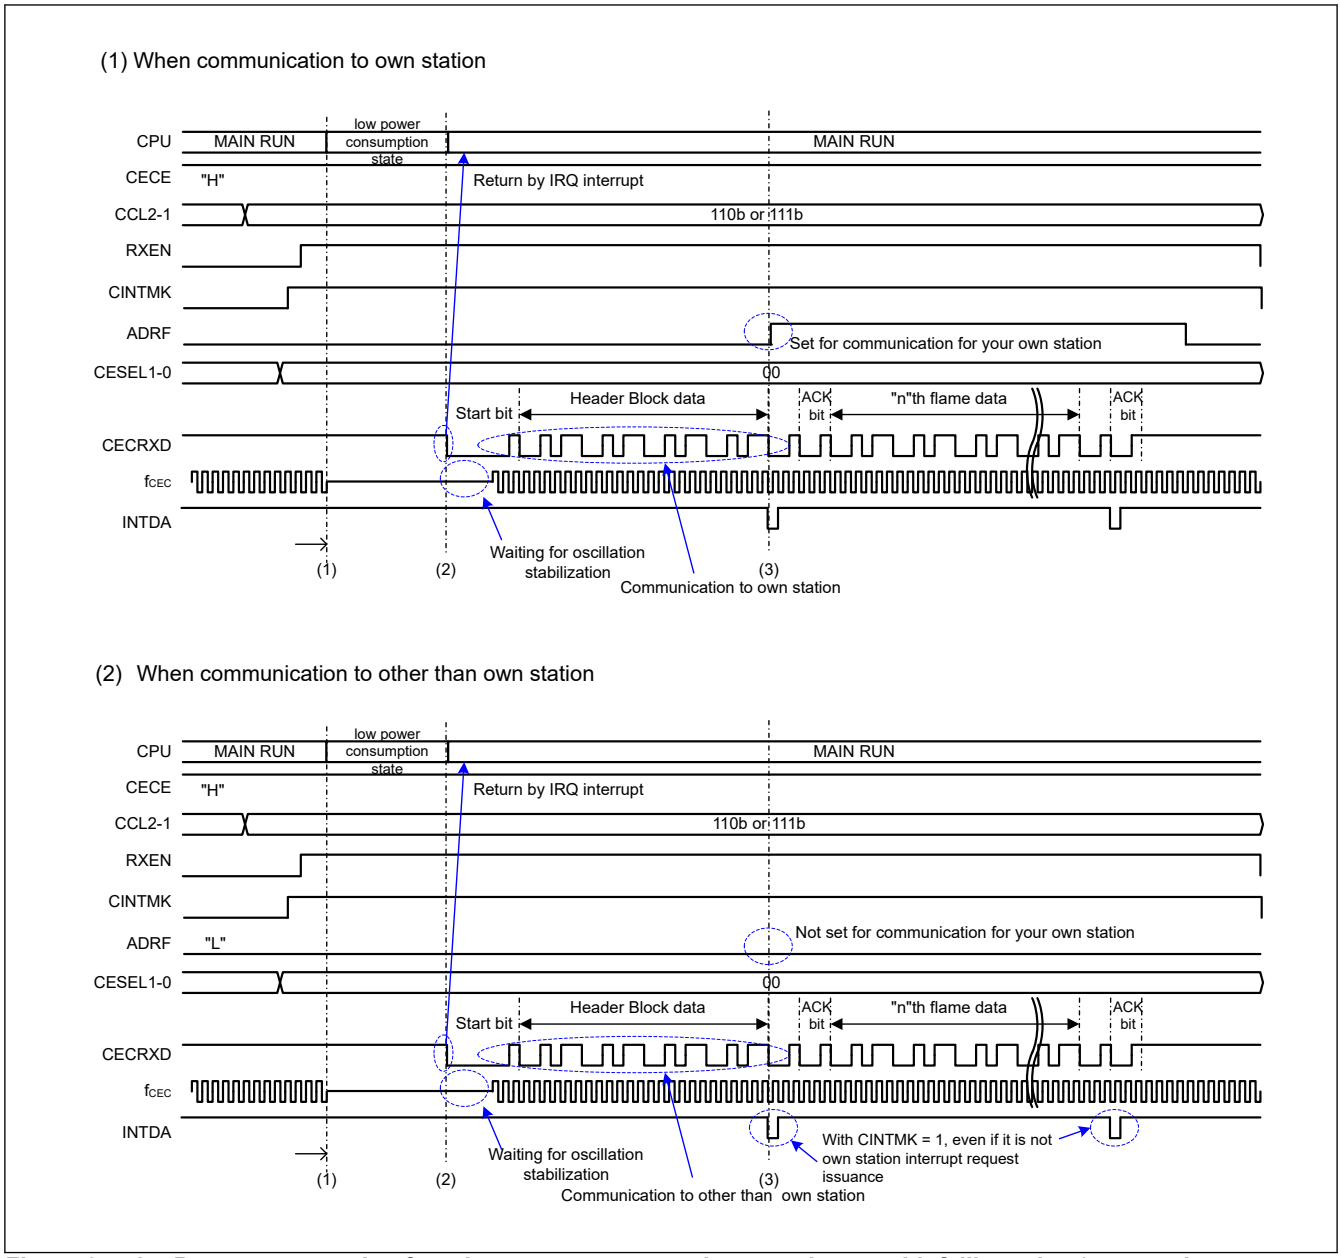

Figure 37.51 Recovery operation from low power consumption state by start bit falling edge (own station judgment)

37.4.2 Settings for Module-Stop Function

The Module Stop Control Register (MSTPCR) can enable or disable CEC operation. The CEC module is initially stopped after reset.

Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

37.4.3 Settings for Clock Division Ratio

Set the peripheral module clock (PCLKB) frequency to higher than the CEC operating clock frequency.

37.4.4 Notes on re-reception function by detection of start bit during reception

37.4.4.1 Precautions for re-receive function by detecting start bit during reception

If a new start bit is detected during reception operation (follower operation), the CEC line may be fixed at Low, so please note the following notes.

- To detect the high or low fixed (bus lock) state of the CEC line, set CECCTL1.BLERRD to 1 and enable the bus lock detection function.
- If the cause of the INTERR interrupt is a bus lock error (CECES.BLERR = 1), clear CECCTL0.CECE to 0 once in the INTERR interrupt processing, and initialize the internal sequencer of the CEC transmission/reception circuit. After that, set CECCTL0.CECE to 1 again. Even if CECCTL0.CECE is cleared to 0, the CEC register will not be reset. See Figure 37.52 for an example of the INTERR interrupt processing flow when a bus lock error occurs.

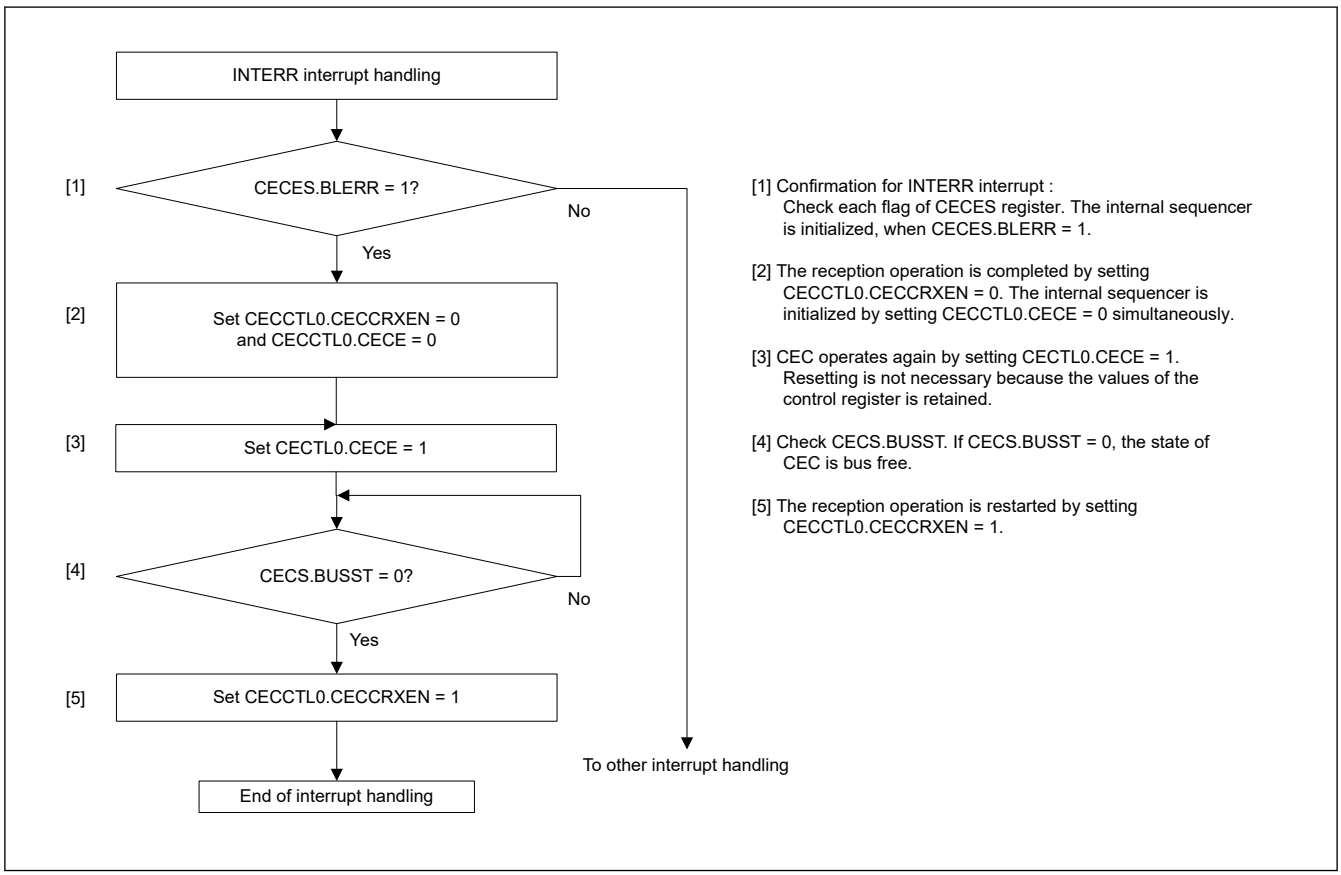

Figure 37.52 Example of INTERR interrupt processing flow when a bus lock error occurs

38. Serial Sound Interface Enhanced (SSIE)

38.1 Overview

The Serial Sound Interface Enhanced (SSIE) can transmit and receive audio data to and from various devices that support any of audio data formats, such as I^2S, monaural, and TDM.

38.2 Features

Table 38.1 Features of SSIE

Item		Description
Number of channels		One channel, SSIE0
Communication mode		• Master/slave • Transmission/reception (SSIE0 full duplex communication or half-duplex communication)
Communication format		• I^2S format • Monaural format • TDM format
Serial data		• MSB first • Data can be left-justified or right-justified. • Data delay (1 clock cycle) or no delay selectable for the period from SSILRCK/SSIFS to SSITXD0/SSIRXD0/SSIDATA0 • System word length: 8, 16, 24, 32, 48, 64, 128, or 256 bits • Data word length: 8, 16, 18, 20, 22, 24, or 32 bits • Padding polarity: Low or high
Bit clock (SSIBCK)	In master mode	• Two clock sources available (AUDIO_CLK/GPT output (GTIOC2A)) • Clock source division ratio: 1/1, 1/2, 1/4, 1/6, 1/8, 1/12, 1/16, 1/24, 1/32, 1/48, 1/64, 1/96, and 1/128. • Supply/stop is selectable while communication is halted.
	In master/slave mode	• Polarity (rising edge or falling edge) selectable
LR clock/frame synchronization (SSILRCK/ SSIFS)	In master mode	• Polarity (low level or high level) selectable • Supply/stop is selectable while communication is halted.
Transmit data (SSITXD0/ SSIDATA0) and receive data (SSIRXD0/ SSIDATA0)	Transmission	• Muting method (transmission of transmit FIFO data or transmission of data fixed to 0) selectable
FIFO	Capacity	• Transmit FIFO/receive FIFO: 4 bytes × 32 stages
	Data alignment	• Data alignment method (left-justification or right-justification) selectable for the data transfer between FIFO and shift register
Interrupt	Interrupt output	• Communication error/idle mode • Receive data full • Transmit data empty
Low power consumption function		• Whether to supply the audio clock selectable in master mode
Module stop function	• Module stop state can be set to reduce power consumption.	
TrustZone Filter	• Security attribution can be set.	

The following table lists and defines the terms used for the communication formats SSIE can use:

Table 38.2 Definition of terms (1 of 2)

Term	Definition
Start trigger	First edge of the signal on the SSILRCK/SSIFS pin when the signal is set to the value specified in LRCKP to enable communication

Table 38.2 Definition of terms (2 of 2)

Term	Definition
Frame boundary	Point where SSIE starts transferring the first data of a frame or the point where SSIE ends transferring the last data of the frame
Frame word number	Number of sound channels per frame
System word length	Number of bits per channel
Data word length	Number of significant bits per channel
Control bits for communication formats	• SSICR register: FRM, DWL, SWL, LRCKP, SPDP, SDTA, PDTA, and DEL bits • SSIFCR register: BSW bit • SSIOFR register: OMOD bit • SSISCR register: TDES[4:0] and RDFS[4:0] bits

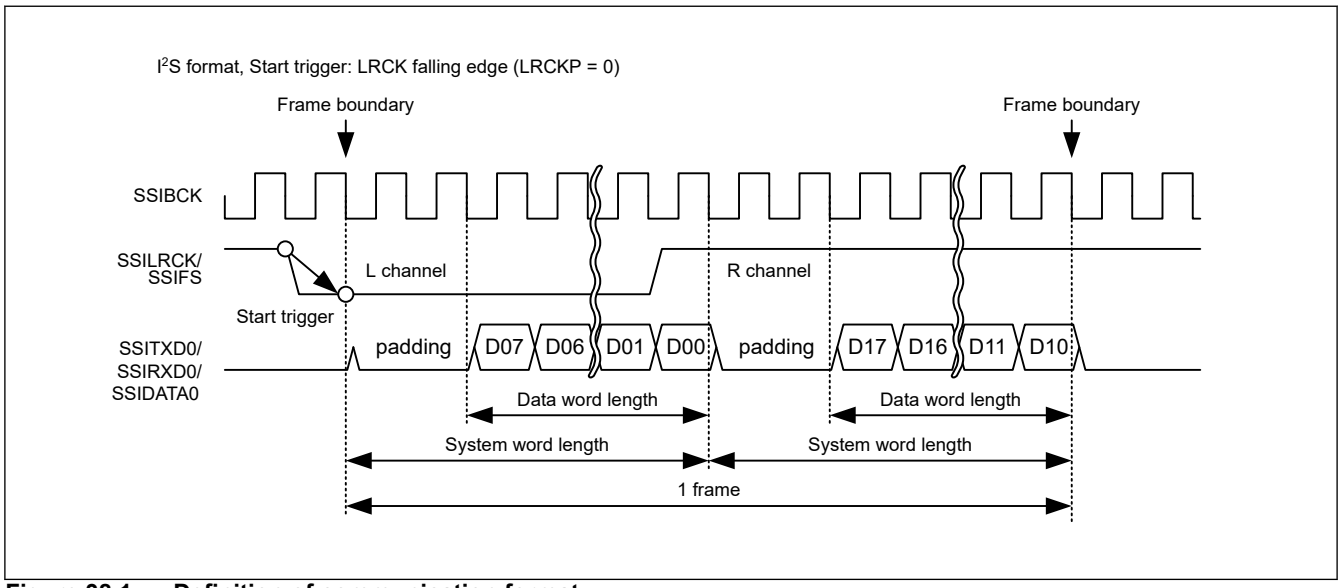

Figure 38.1 Definition of communication format

</table>

Note 1. Writing to these bits while SSIE is in a communication state (SSISR.IIRQ = 0) is prohibited. If the value of these bits is changed by rewriting, subsequent operation is unpredictable.

Note 2. If the TEN bit or REN bit is rewritten, make sure that the SSISR.IIRQ bit is in the desired status. If the value of the TEN or REN bit is changed by rewriting, subsequent operation is unpredictable. For example, when transmission or reception is enabled, check that SSISR.IIRQ is 0; when transmission or reception is disabled, check that SSISR.IIRQ is 1.

With this register, select an audio clock, control interrupt requests, select data formats, and set an operation mode.

TEN and REN bits (Transmission and Reception Enable)

The TEN and REN bits enable/disable transmission and reception. When 1 is written to one of these bits, the corresponding communication operation starts in synchronization with a start trigger by the SSILRCK/SSIFS signal. For details, see section 38.8.2. Transmission to section 38.8.4. Transmission and Reception. When 0 is written to this bit, the current communication operation stops at the next frame boundary. To use SSIE for both transmission and reception, always write 1 to these bits together. When stopping the communication using SSIE, always disable both transmission and reception (write 0 to the TEN and REN bits).

If you want to stop SSIE before a frame boundary is reached, perform a software reset procedure.

MUEN bit (Mute Enable)

The MUEN bit sets/clears the mute function for the data output from the SSITXD0/SSIDATA0 pin. When this bit is set to 1 in the middle of a frame, the SSITXD0/SSIDATA0 output changes to 0 at the next frame boundary. When this bit is set to 0 in the middle of a frame, the SSITXD0/SSIDATA0 output changes to the data of transmit FIFO data register at the next frame boundary. Note that this bit controls data only. Status flags and interrupt signals are normally generated.

Changing the value of this bit must be performed only after setting the communication format to be used.

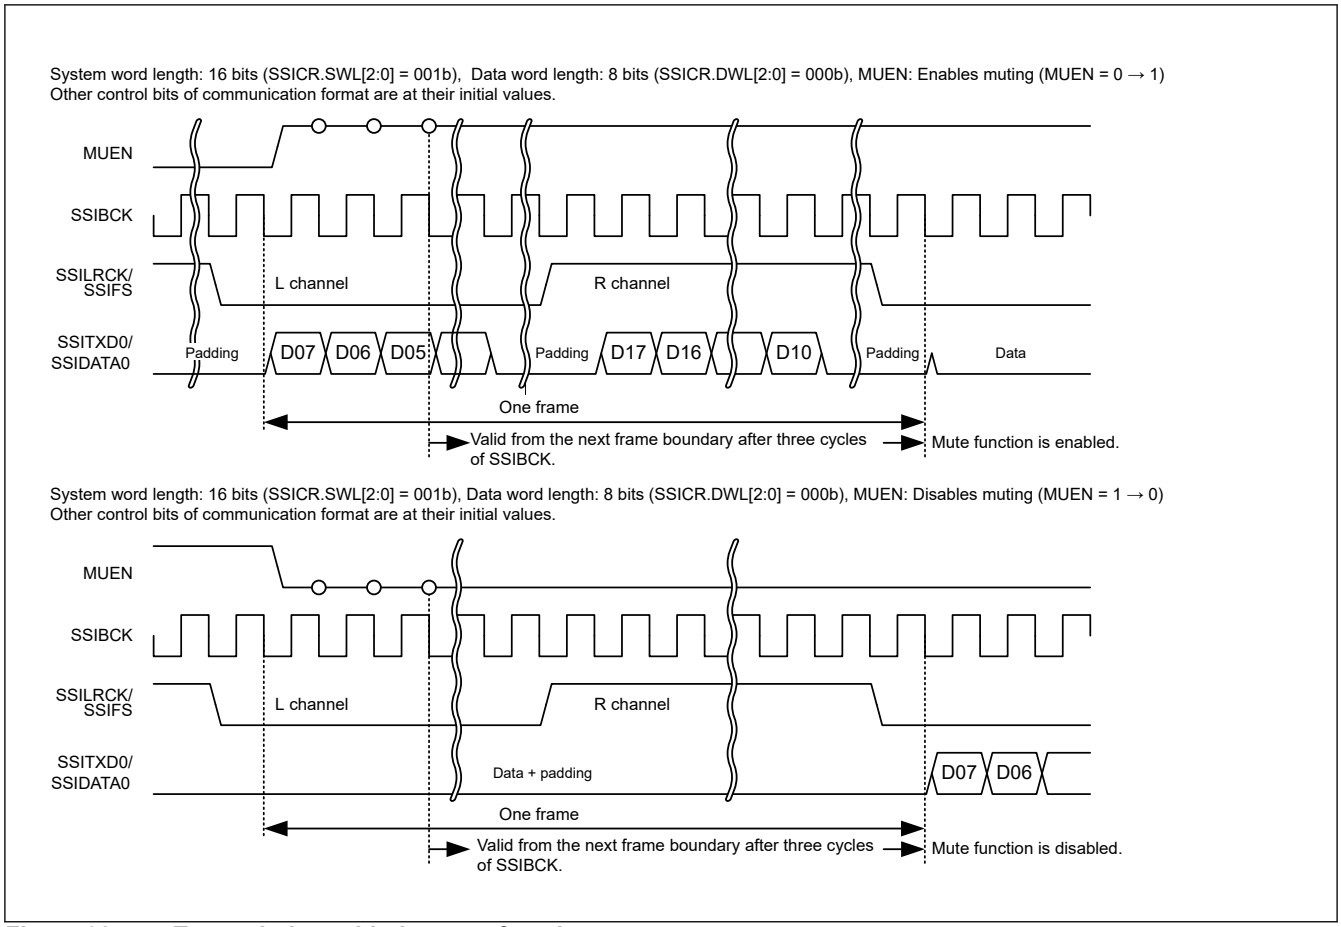

Figure 38.5 Transmit data with the mute function set

CKDV[3:0] bits (Selects Bit Clock Division Ratio)

The CKDV[3:0] bits set the division ratio of the bit clock based on AUDIO_MCK in master-mode communication (MST= 1). In slave-mode communication (MST = 0), setting of these bits are invalid.

Writing to this bit must be performed when the supply of AUDIO_MCK is stopped. For details about the timing, see the detailed description of the AUCKE bit in section 38.4.3. SSIFCR : FIFO Control Register.

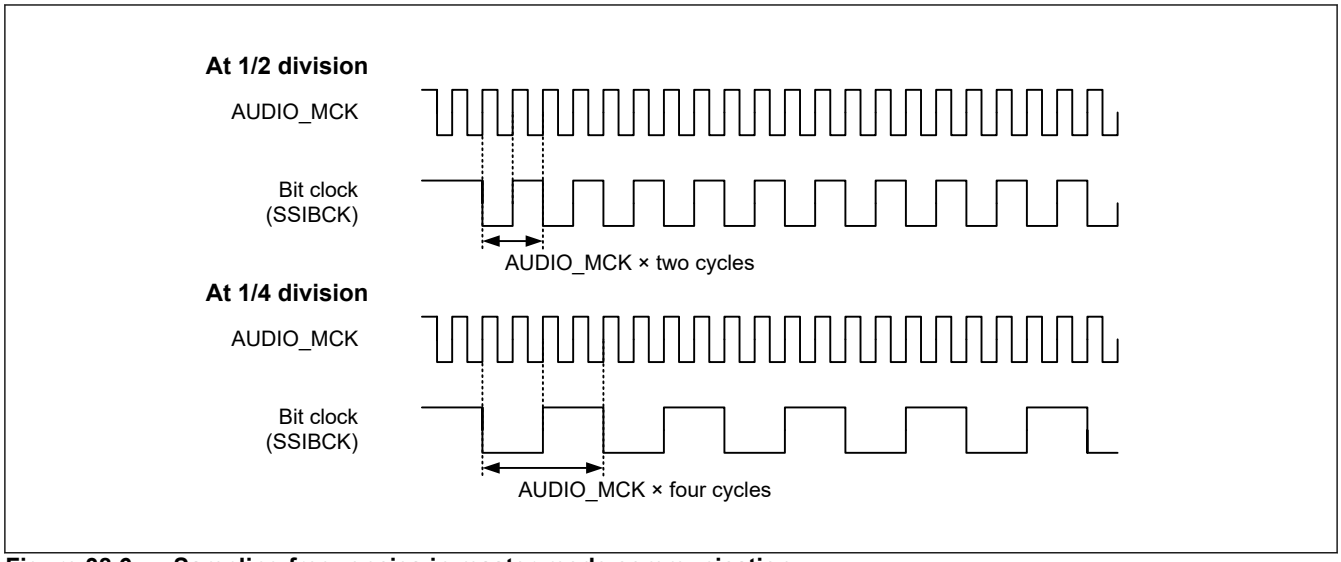

Figure 38.6 Sampling frequencies in master-mode communication

DEL bit (Selects Serial Data Delay)

The DEL bit sets whether or not there will be a delay between SSILRCK/SSIFS and SSITXD0/SSIRXD0/SSIDATA0.

For the I^2S or TDM format, set the DEL bit to 0. When the monaural format is used, setting of this bit changes the high period width of SSILRCK/SSIFS. For details, see section 38.5.2. Monaural Format. When using a compatible communication format, specify a setting of this bit that enables communication.

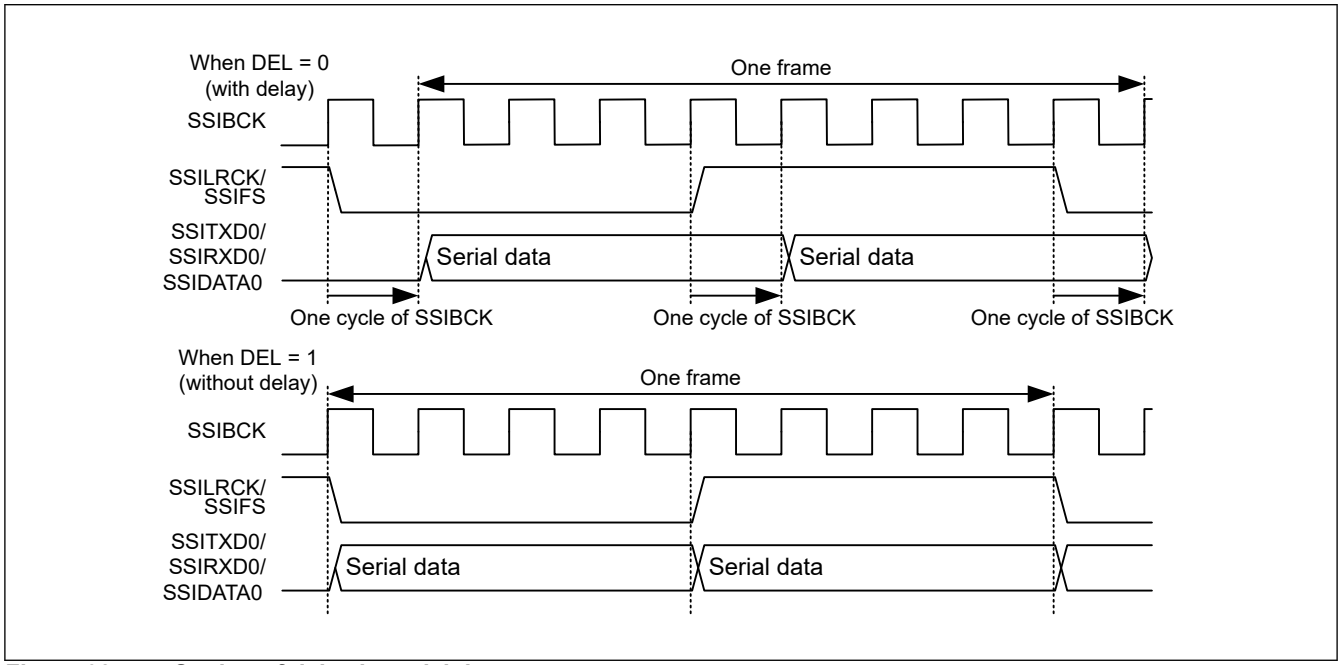

Figure 38.7 Setting of delay in serial data

PDTA bit (Selects Placement Data Alignment)

The PDTA bit sets how to align placement data. With the setting of data word length as 32 bits (SSICR.DWL[2:0] = 110b), this bit is invalid.

At transmission, see Figure 38.8.

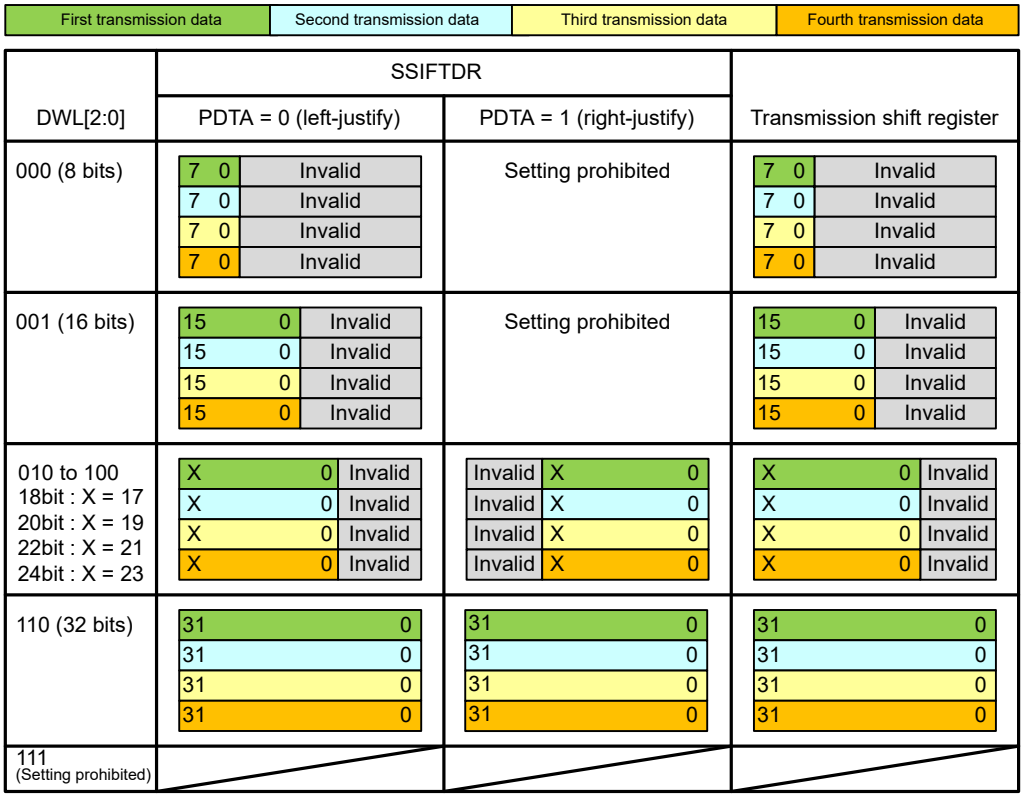

Figure 38.8 Alignment of placement data at transmission

At reception, see Figure 38.9.

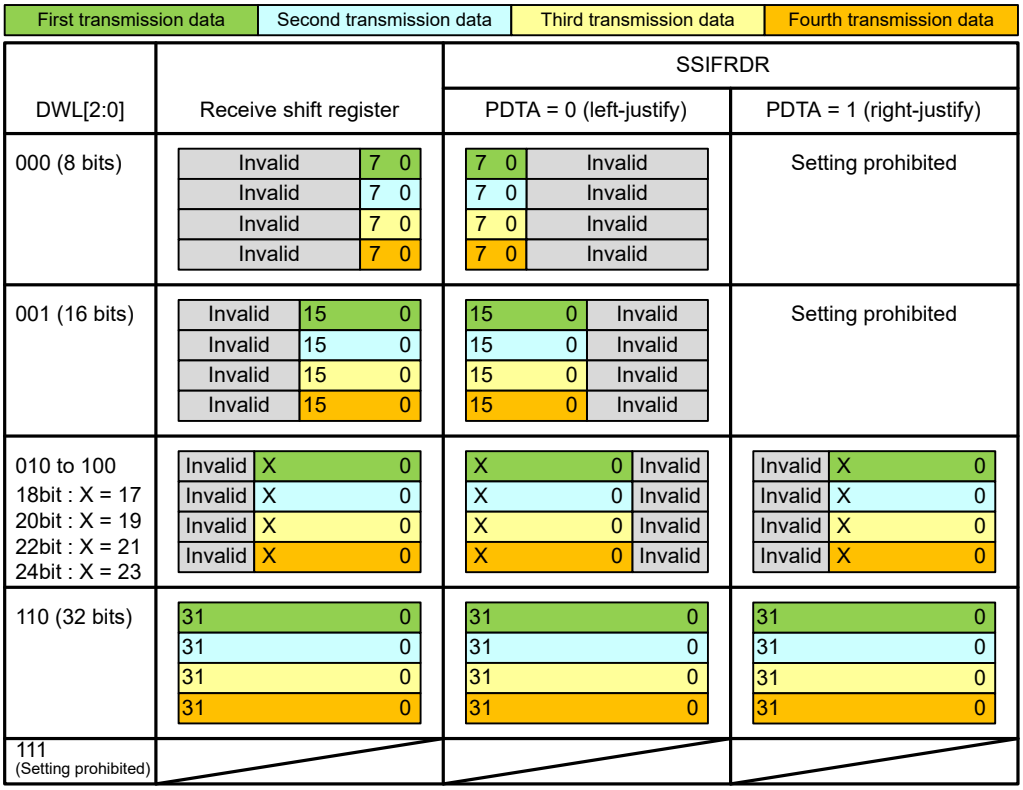

Figure 38.9 Alignment of placement data at reception

SDTA bit (Selects Serial Data Delay)

The SDTA bit sets how to align serial data and padding bits. For communication without padding bits, this bit is invalid.

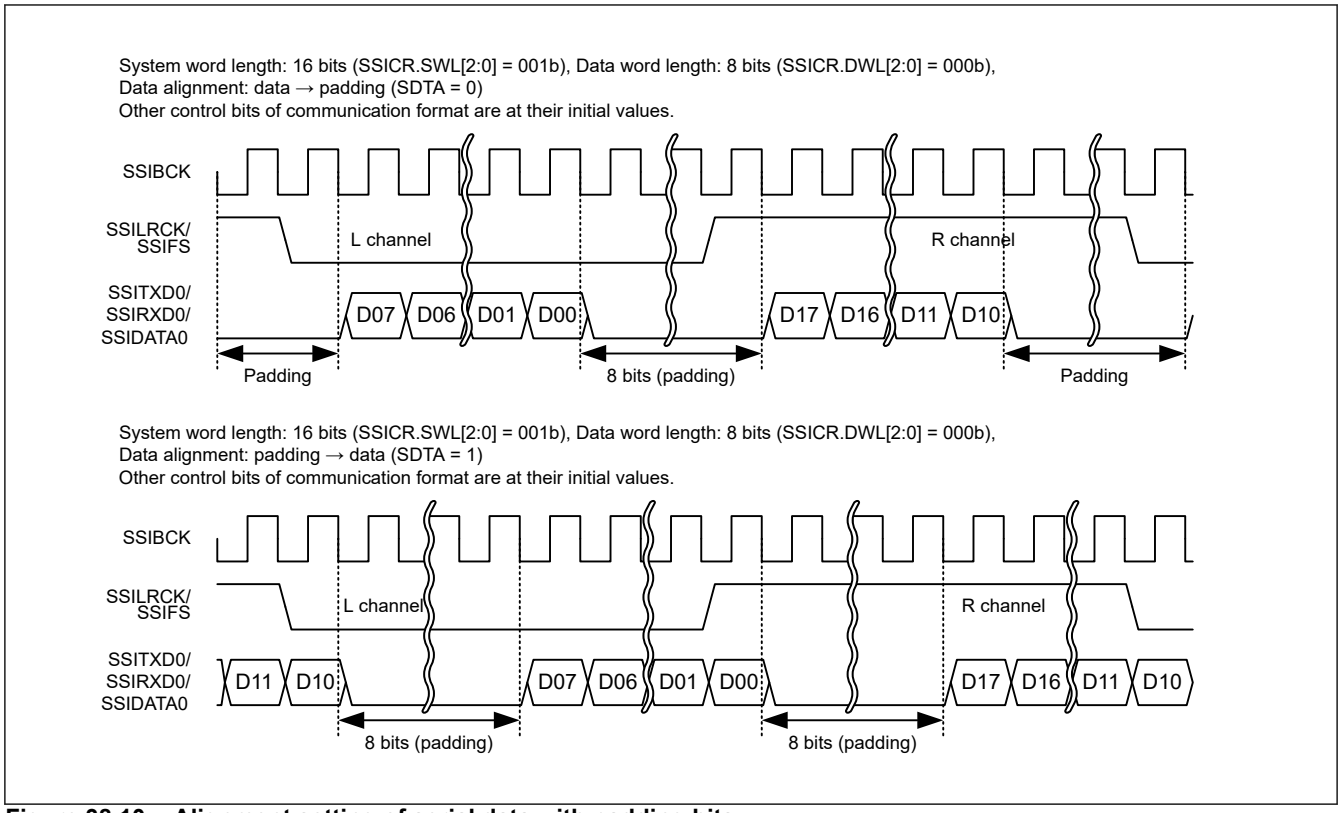

Figure 38.10 Alignment setting of serial data with padding bits

SPDP bit (Selects Serial Padding Polarity)

The SPDP bit sets polarity of padding bits.

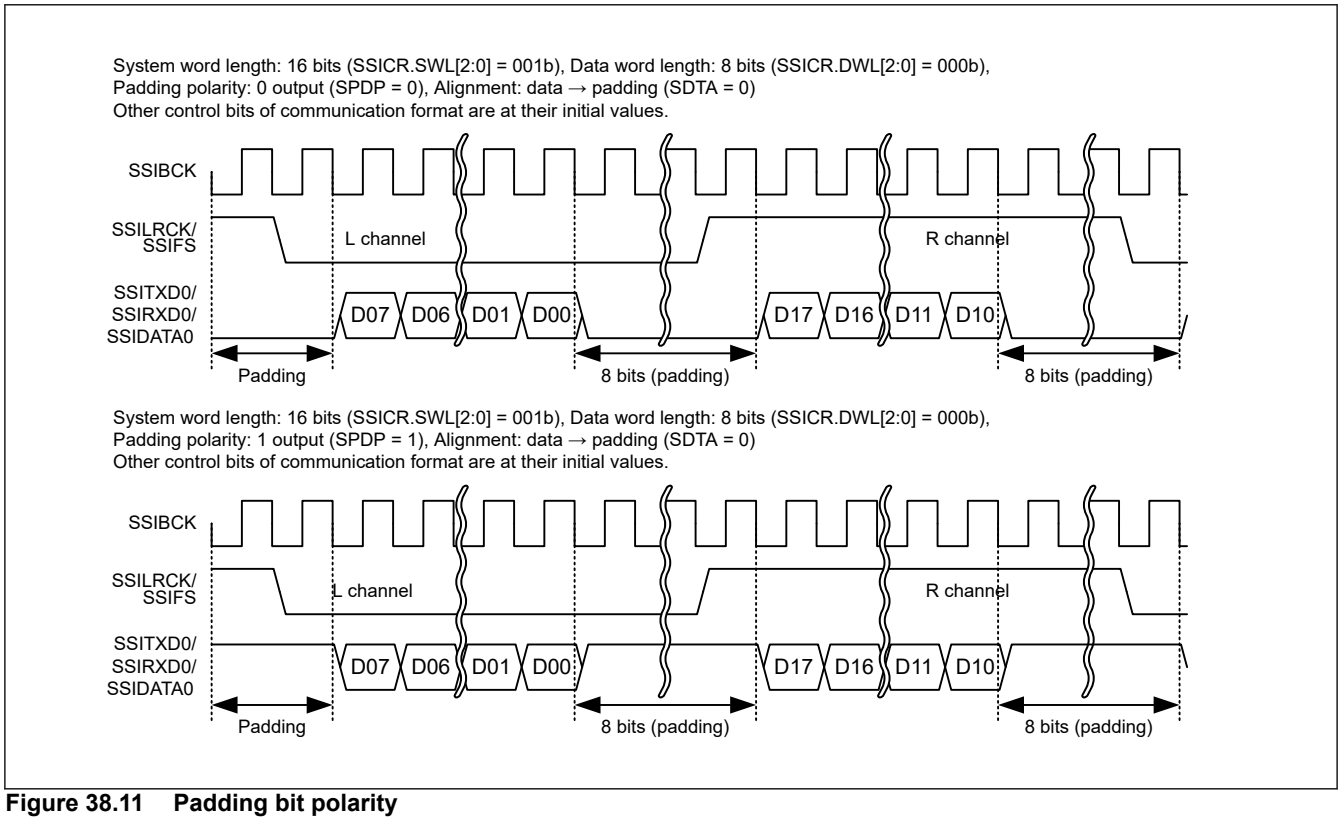

Figure 38.11 Padding bit polarity

LRCKP bit (Selects the Initial Value and Polarity of LR Clock/Frame Synchronization Signal)

The LRCKP bit sets the initial value and polarity of SSILRCK/SSIFS. Set this bit according to the communication format to be used in SSIE. See Table 38.3 Initial output value and polarity of SSILRCK/SSIFS pin. For the slave-mode communication (MST = 0), only the start trigger is used.

Writing to these bits must be performed when the LR clock supply to the SSILRCK/SSIFS pin is stopped. For details about the output of LR clock, see the detailed description of the LRCONT bit in section 38.4.7. SSIOFR : Audio Format Register.

Table 38.3 Initial output value and polarity of SSILRCK/SSIFS pin

Communication Format	Expected Initial State	Setting Value of LRCKP
I^2S	High	0
Monaural	Low	1
TDM	Low	1

Note: When the format to be used is compatible with the I^2S, monaural, or TDM format, specify settings to enable communication with the respective formats.

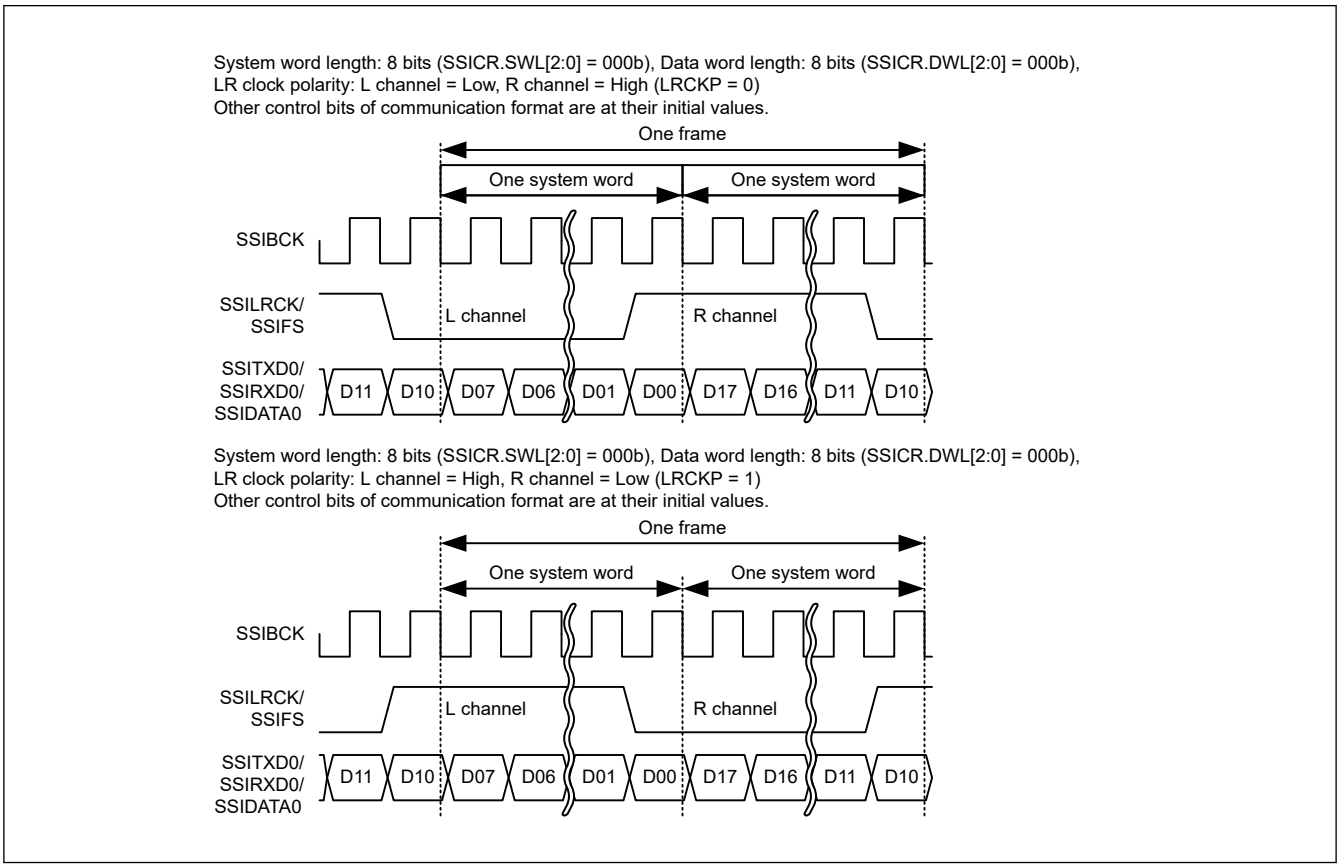

Figure 38.12 LR clock/frame synchronization polarity setting

BCKP bit (Selects Bit Clock Polarity)

The BCKP bit sets the bit clock polarity.

Writing to this bit must be performed when the supply of AUDIO_MCK is stopped. For details about the timing, see the detailed description of the AUCKE bit in section 38.4.3. SSIFCR : FIFO Control Register.

Table 38.4 Bit clock polarity (1 of 2)

Communication	Master/Slave	Timing	BCKP = 0	BCKP = 1
Reception	Slave	At SSILRCK/SSIFS sampling	SSIBCK rising edge	SSIBCK falling edge
	Master/slave	At SSIRXD0/SSIDATA0 sampling	SSIBCK rising edge	SSIBCK falling edge

Table 38.4 Bit clock polarity (2 of 2)

Communication	Master/Slave	Timing	BCKP = 0	BCKP = 1
Transmission	Master	At change of SSILRCK/SSIFS output	SSIBCK falling edge	SSIBCK rising edge
	Master/slave	At change of SSITXD0/SSIDATA0 output	SSIBCK falling edge	SSIBCK rising edge

MST bit (Master Enable)

The MST bit sets master-/slave-mode communication.

Writing to this bit must be performed when the supply of AUDIO_MCK is stopped. For details about the timing, see the detailed description of the AUCKE bit in section 38.4.3. SSIFCR : FIFO Control Register.

SWL[2:0] bits (Selects System Word Length)

The SWL[2:0] bits set the number of bits in one system word. Padding bits are sent and received in relation with one data word set with DWL[2:0]. See Table 38.11 for details.

Writing to these bits must be performed when the LR clock supply to the SSILRCK/SSIFS pin is stopped. For details about the output of LR clock, see the detailed description of the LRCONT bit in section 38.4.7. SSIOFR : Audio Format Register.

DWL[2:0] bits (Selects Data Word Length)

The DWL[2:0] bits set the number of bits in one data word. The data word length (number of bits per data word) must not exceed the system word length (number of bits per system word). For details, see Table 38.11.

FRM[1:0] bits (Selects Frame Word Number)

The FRM[1:0] bits set the frame word number in individual communication formats.

Writing to these bits must be performed when the LR clock supply to the SSILRCK/SSIFS pin is stopped. For details about the output of LR clock, see the detailed description of the LRCONT bit in section 38.4.7. SSIOFR : Audio Format Register.

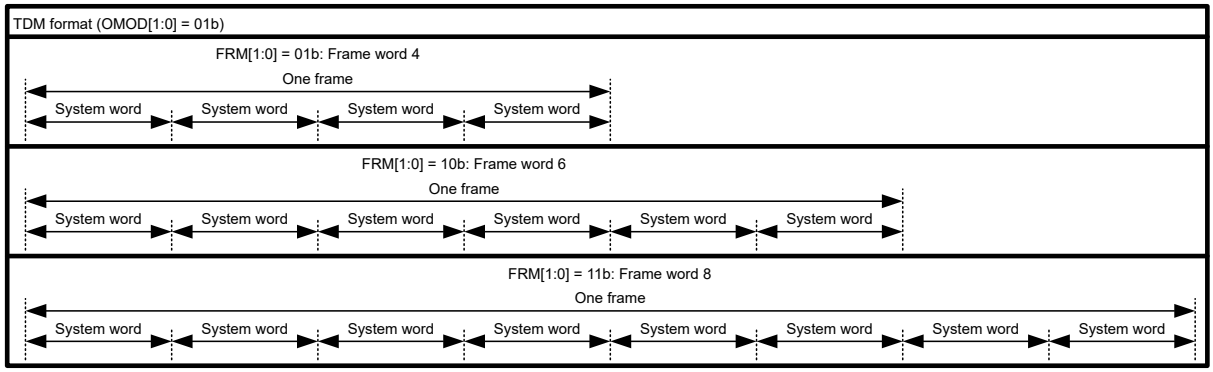

Figure 38.13 Frame word number

IIEN bit (Idle Mode Interrupt Output Enable)

The IIEN bit enables/disables output of idle mode interrupts. By enabling this bit (set it to 1), an interrupt is output at a rising edge of SSISR.IIRQ = 1. An interrupt is also output when this bit is changed from 0 to 1 while SSISR.IIRQ = 1.

ROIEN bit (Receive Overflow Interrupt Output Enable)

The ROIEN bit enables/disables output of receive overflow interrupts. By enabling this bit (set it to 1), an interrupt is output at a rising edge of SSISR.ROIRQ = 1. An interrupt is also output when this bit is changed from 0 to 1 while SSISR.ROIRQ = 1.

RUIEN bit (Receive Underflow Interrupt Output Enable)

The RUIEN bit enables/disables output of receive underflow interrupts. By enabling this bit (set it to 1), an interrupt is output at a rising edge of SSISR.RUIRQ = 1. An interrupt is also output when this bit is changed from 0 to 1 while SSISR.RUIRQ = 1.

TOIEN bit (Transmit Overflow Interrupt Output Enable)

The TOIEN bit enables/disables output of transmit overflow interrupts. By enabling this bit (set it to 1), an interrupt is output at a rising edge of SSISR.TOIRQ = 1. An interrupt is also output when this bit is changed from 0 to 1 while SSISR.TOIRQ = 1.

TUIEN bit (Transmit Underflow Interrupt Output Enable)

The TUIEN bit enables/disables output of transmit underflow interrupts. By enabling this bit (set it to 1), an interrupt is output at a rising edge of SSISR.TUIRQ = 1. An interrupt is also output when this bit is changed from 0 to 1 while SSISR.TUIRQ = 1.

CKS bit (Selects an Audio Clock for Master-mode Communication)

The CKS bit sets the audio clock in master-mode communication (MST = 1). In slave-mode communication (MST = 0), setting of this bit is invalid.

Writing to this bit must be performed when the supply of AUDIO_MCK is stopped. For details about the timing, see the detailed description of the AUCKE bit in section 38.4.3. SSIFCR : FIFO Control Register.

38.4.2 SSISR : Status Register

Base address: SSIE0 = 0x4009_D000

Offset address: 0x04

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	TUIRQ	TOIRQ	RUIRQ	ROIRQ	IIRQ	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
24:0	—	These bits are read as 0. The write value should be 0.	R/W
25	IIRQ	Idle Mode Status Flag 0: In the communication state 1: In the idle state	R
26	ROIRQ	Receive Overflow Error Status Flag 0: No receive overflow error is generated. 1: A receive overflow error is generated.	R/W
27	RUIRQ	Receive Underflow Error Status Flag 0: No receive underflow error is generated. 1: A receive underflow error is generated.	R/W
28	TOIRQ	Transmit Overflow Error Status Flag 0: No transmit overflow error is generated. 1: A transmit overflow error is generated.	R/W
29	TUIRQ	Transmit Underflow Error Status flag 0: No transmit underflow error is generated. 1: A transmit underflow error is generated.	R/W
31:30	—	These bits are read as 0. The write value should be 0.	R/W

This register is configured with status flags that indicate SSIE operational state.

IIRQ flag (Idle Mode Status Flag)

The IIRQ flag is a status flag that indicates the idle state. It indicates whether SSIE is in the idle state or communication state.

For details, see Figure 38.14 and Figure 38.15.

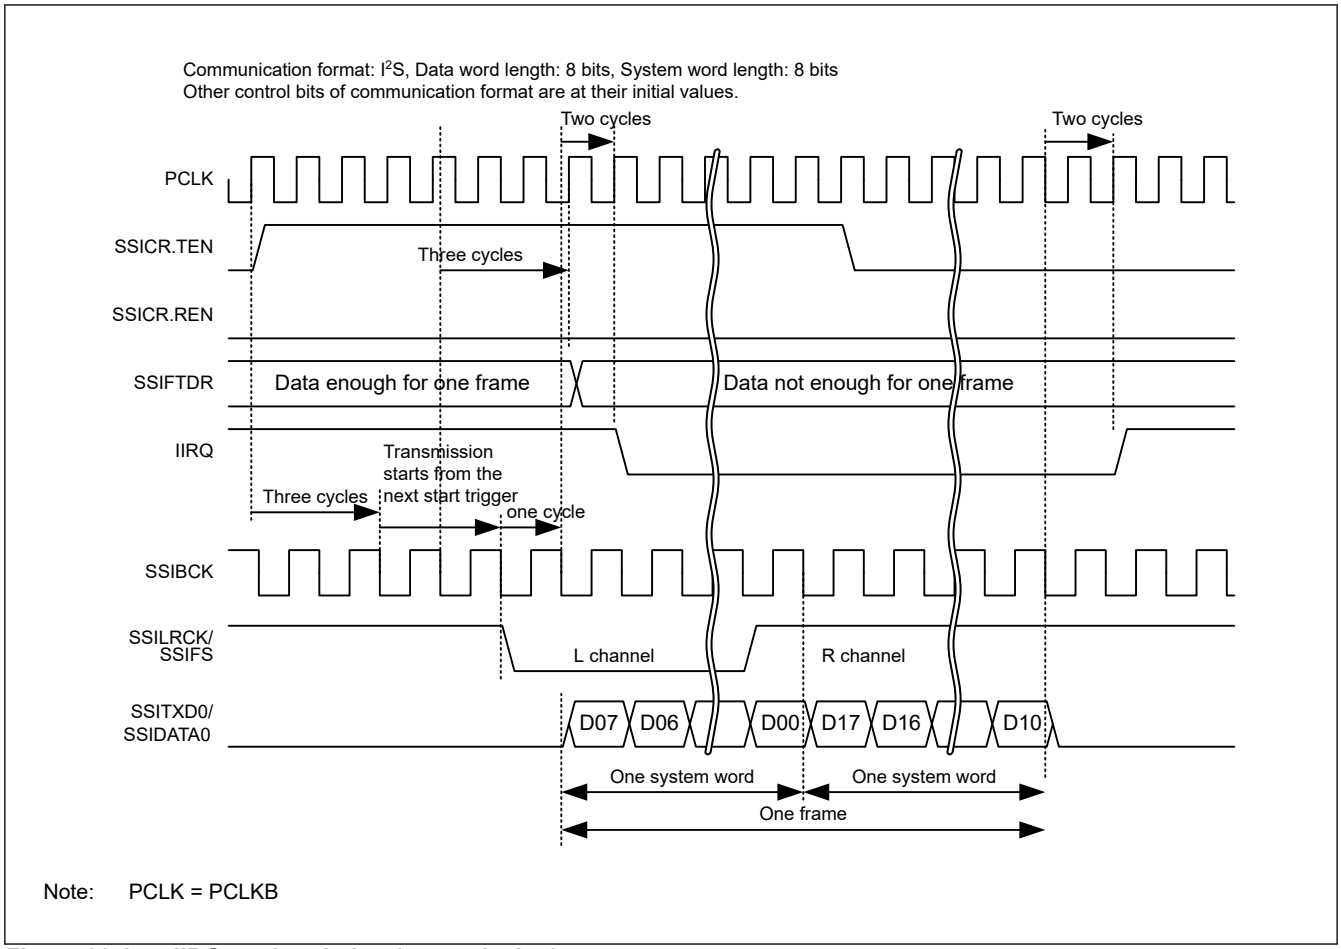

Figure 38.14 IIRQ setting timing (transmission)

- Transmitter (dedicated to transmission)

[Clearing condition]

While transmission was enabled (SSICR.TEN = 1 and SSICR.REN = 0), the transmit data for a transmission frame was written to the SSIFTDR register, and a start trigger was generated by the SSILRCK/SSIFS signal.

[Clearing timing]

1 SSIBCK cycle + 2 PCLKB cycles after generation of the start trigger that is the clearing condition.

[Setting condition]

While transmission and reception were disabled (SSICR.TEN = 0 and SSICR.REN = 0), transmission of one frame was complete.

[Setting timing]

2 PCLKB cycles after the end of transmission (at a frame boundary) that is the setting condition.

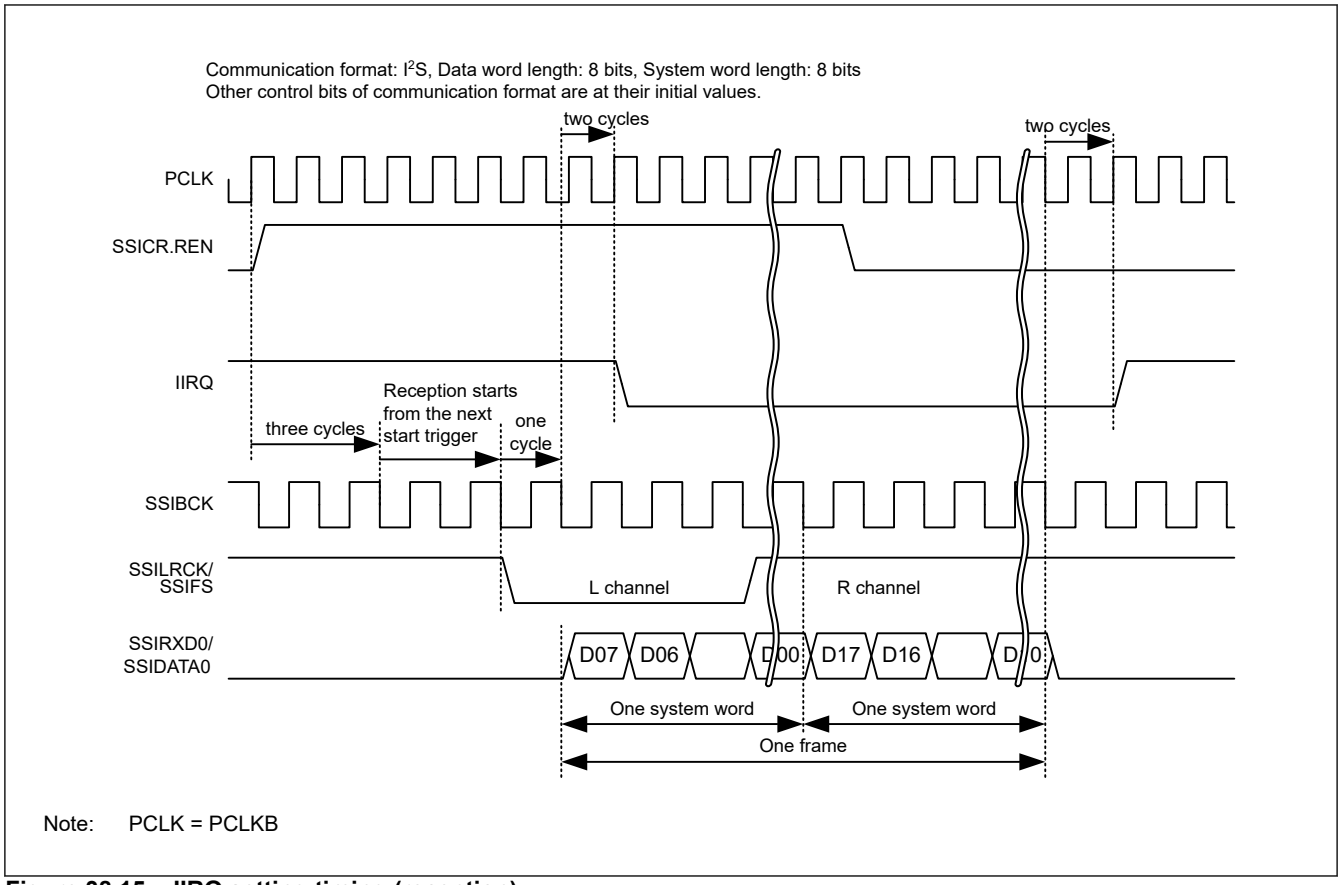

Figure 38.15 IIRQ setting timing (reception)

- Receiver (dedicated to reception)

[Clearing condition]

While reception was enabled (SSICR.TEN = 0 and SSICR.REN = 01, a start trigger was generated by the SSILRCK/SSIFS signal.

[Clearing timing]

1 SSIBCK cycle + 2 PCLKB cycles after generation of the start trigger that is the clearing condition.

[Setting condition]

While transmission and reception were disabled (SSICR.TEN = 0 and SSICR.REN = 0), reception of one frame was complete.

[Setting timing]

2 PCLKB cycles after the end of reception (at a frame boundary) that is the setting condition.

- Transceiver (transmission and reception)

[Clearing condition]

While transmission and reception were enabled (SSICR.TEN = 1 and SSICR.REN = 1), the transmit data for a transmission frame was written to the SSIFTDR register, and a start trigger is generated by the SSILRCK/SSIFS signal.

[Clearing timing]

1 SSIBCK cycle + 2 PCLKB cycles after generation of the start trigger that is the clearing condition.

[Setting condition]

While transmission and reception were disabled (SSICR.TEN = 0 and SSICR.REN = 0), transmission of one frame was complete.

[Setting timing]

2 PCLKB cycles after the end of transmission (at a frame boundary) that is the setting condition.

ROIRQ flag (Receive Overflow Error Status Flag)

The ROIRQ flag is a status flag that indicates a receive overflow error. This flags is set by automatic determination but it must be cleared by register access. This flag indicates that received data is supplied at a higher rate than requested. Data is not transferred from the receive shift register to SSIFRDR where a receive overflow error is generated. For the procedure to recover from the overflow error, see section 38.8.6. Error Handling. This flag is not cleared by a receive FIFO data register reset (SSIFCR.RFRST).

[Priority order for setting and clearing]

Setting is prioritized.*1

[Clearing condition]

When either of the following operations is done:

1. Writing 0 to this bit after reading 1 from this bit*2
2. Enabling communication (changing SSICR.REN from 0 to 1).

[Clearing timing]

Clearing timing corresponding to the above clearing condition:

1. When 0 is written to this bit after reading 1 from this bit (same as the timing in Figure 38.19)
2. 1 PCLKB cycle after writing 1 to SSICR.REN.*3

[Setting condition]
At completion of receiving new data while SSIFRDR is full.

[Setting timing]
3 cycles of PCLKB after reception is completed.

Note 1. This bit is cleared by a software reset (SSIFCR.SSIRST = 1). The software reset has priority over all the clearing conditions described above.
Note 2. After reading 1 from this bit, this bit is cleared when one of the following three conditions is met:
- A software reset (SSIFCR.SSIRST = 1) is done.
- After 1 has been read, writing of 0 is complete.
- 1 PCLKB cycle passes after 1 has been written to SSICR.REN.

Note 3. After communication is enabled (by changing the value of SSICR.REN bit from 0 to 1), the reception error flags (RUIRQ and ROIRQ in the SSISR register) are cleared. If, however, the SSISR register is read continuously, the cleared status of the reception error flags might be unable to be read.

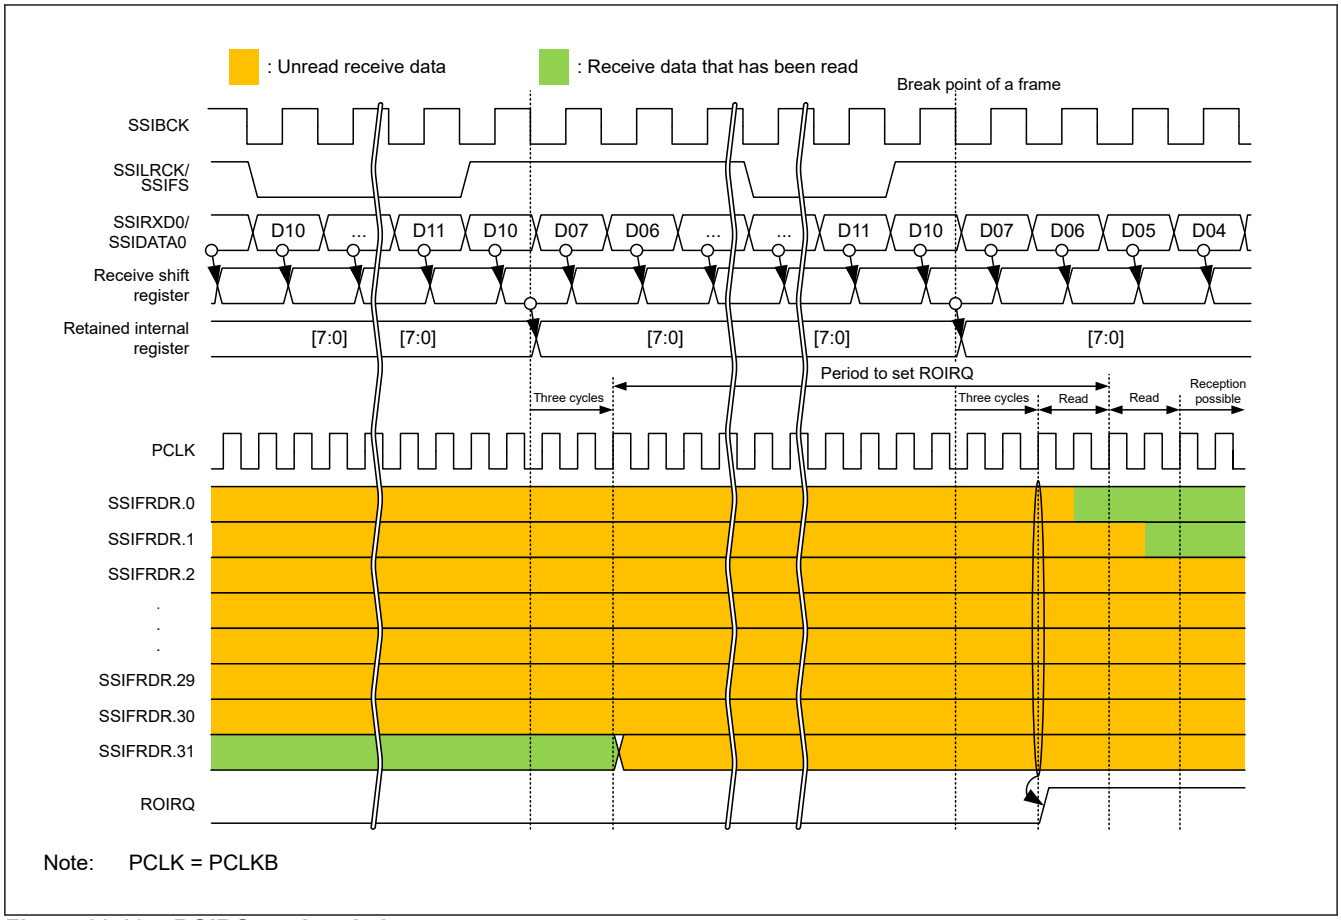

Figure 38.16 ROIRQ setting timing

RUIRQ flag (Receive Underflow Error Status Flag)

The RUIRQ flag is a status flag that indicates a receive underflow error. This flags is set by automatic determination but it must be cleared by register access. This flag indicates that SSIFRDR is read while it is empty. Data read from SSIFRDR where a receive underflow error is generated is invalid. See section 38.8.6. Error Handling for the error recovery procedure. This flag is not cleared by a receive FIFO data register reset (SSIFCR.RFRST). Note, however, that this flag is not set even if the SSIFRDR register is read while the receive FIFO data register is reset (by setting SSIFCR.RFRST to 1).

[Priority order for setting and clearing]

Setting is prioritized.*1

[Clearing condition]

When either of the following operations is done:

1. Writing 0 to this bit after reading 1 from this bit*2
2. Enabling communication (changing SSICR.REN from 0 to 1).

[Clearing timing]
Clearing timing corresponding to the above clearing condition

1. When 0 is written to this bit after reading 1 from this bit (same as the timing in Figure 38.19)
2. 1 PCLKB cycle after writing 1 to SSICR.REN.*3

[Setting condition]

Reading from SSIFRDR while it is empty.

[Setting timing]

At completion of reading from SSIFRDR. See Figure 38.17.

Note 1. This bit is cleared by a software reset (SSIFCR.SSIRST = 1). The software reset has priority over all the clearing conditions described above.

Note 2. After reading 1 from this bit, this bit is cleared when one of the following three conditions is met:

- A software reset (SSIFCR.SSIRST = 1) is done.
- After 1 has been read, writing of 0 is complete.
- 1 PCLKB cycle passes after 1 has been written to SSICR.REN.

Note 3. After communication is enabled (by changing the value of SSICR.REN bit from 0 to 1), the reception error flags (RUIRQ and ROIRQ in the SSISR register) are cleared. If, however, the SSISR register is read continuously, the cleared status of the reception error flags might be unable to be read.

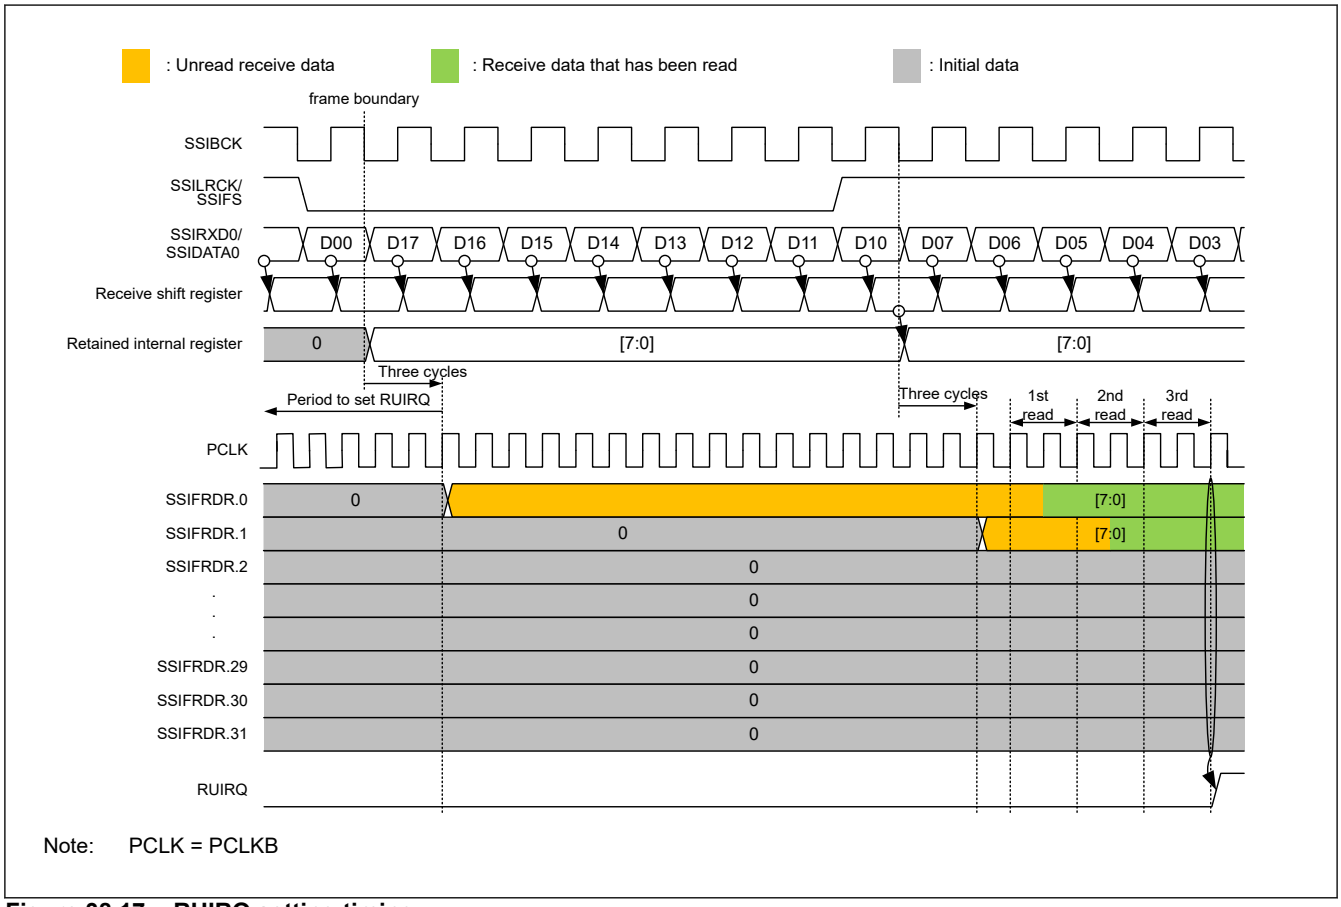

Figure 38.17 RUIRQ setting timing

TOIRQ flag (Transmit Overflow Error Status Flag)

The TOIRQ flag is a status flag that indicates a transmit overflow error. This flag is set by automatic determination but it must be cleared by register access. This flag indicates that an attempt has been made to write data to the SSIFTDR register when the register is full of data. The data writing that causes a transmit overflow is ignored. For the procedure to recover from the overflow error, see section 38.8.6. Error Handling. This flag is not cleared by a transmit FIFO data register reset (SSIFCR.TFRST).

[Priority order for setting and clearing]

Setting is prioritized.*1

[Clearing condition]

When either of the following operations is done:

1. Writing 0 to this bit after reading 1 from this bit*2
2. Enabling communication (changing SSICR.TEN from 0 to 1).

[Clearing timing]

Clearing timing corresponding to the above clearing condition

1. When 0 is written to this bit after reading 1 from this bit (same as the timing in Figure 38.19)
2. 1 PCLKB cycle after writing 1 to SSICR.TEN.*3

[Setting condition]

An attempt was made to write data to the SSIFTDR register when the register is full of data.

[Setting timing]

At completion of writing to SSIFTDR. For details, see Figure 38.18.

Note 1. This bit is cleared by a software reset (SSIFCR.SSIRST = 1). The software reset has priority over all the clearing conditions described above.

Note 2. After reading 1 from this bit, this bit is cleared when one of the following three conditions is met:
- A software reset (SSIFCR.SSIRST = 1) is done.
- After 1 has been read, writing of 0 is complete.
- 1 PCLKB cycle passes after 1 has been written to SSICR.TEN.

Note 3. After communication is enabled (by changing the value of SSICR.TEN bit from 0 to 1), the transmission error flags (TOIRQ and TUIRQ in the SSISR register) are cleared. If, however, the SSISR register is read continuously, the cleared status of the transmission error flags might be unable to be read.

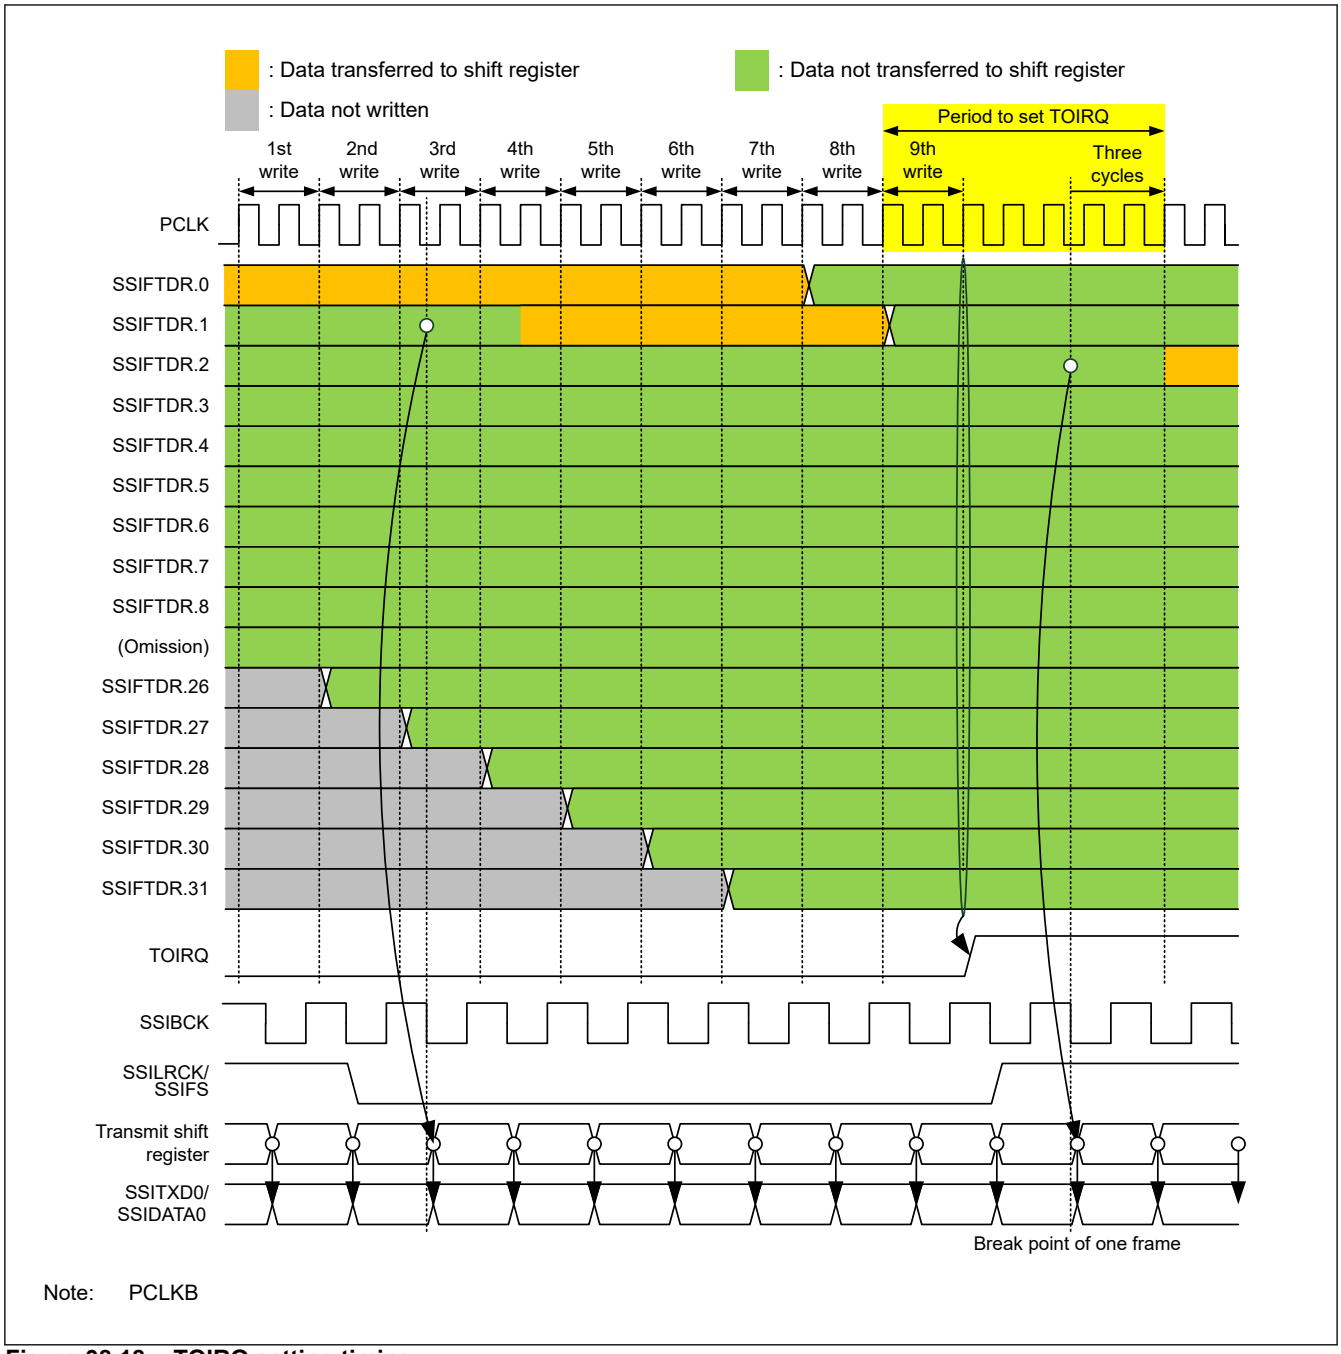

Figure 38.18 TOIRQ setting timing

TUIRQ flag (Transmit Underflow Error Status flag)

The TUIRQ flag is a status flag that indicates a transmit underflow error. This flag is set by automatic determination but it must be cleared by register access. This flag indicates that writing the serial data required for a frame to SSIFTDR did not catch up with transmission of the frame. Even if this flag is cleared after it has been set, the SSITXD0/SSIDATA0 output remains to be 0. To output the data written to the transmit FIFO data register (SSIFTDR) to the SSITXD0/SSIDATA0 pin, follow the communication stop procedure in Figure 38.56 and error-handling procedure in Figure 38.57. For the procedure to recover from an error, see section 38.8.6. Error Handling. This flag is not cleared by a reset of transmit FIFO data register (by the SSIFCR.TFRST signal).

[Priority order for setting and clearing]

Setting is prioritized.*1

[Clearing condition]

When either of the following operations is done:

1. Writing 0 to this bit after reading 1 from this bit*2
2. Enabling communication (changing SSICR.TEN from 0 to 1).

[Clearing timing]

Clearing timing corresponding to the above clearing condition

1. When 0 is written to this bit after reading 1 from this bit
2. 1 PCLKB cycle after writing 1 to SSICR.TEN.*3

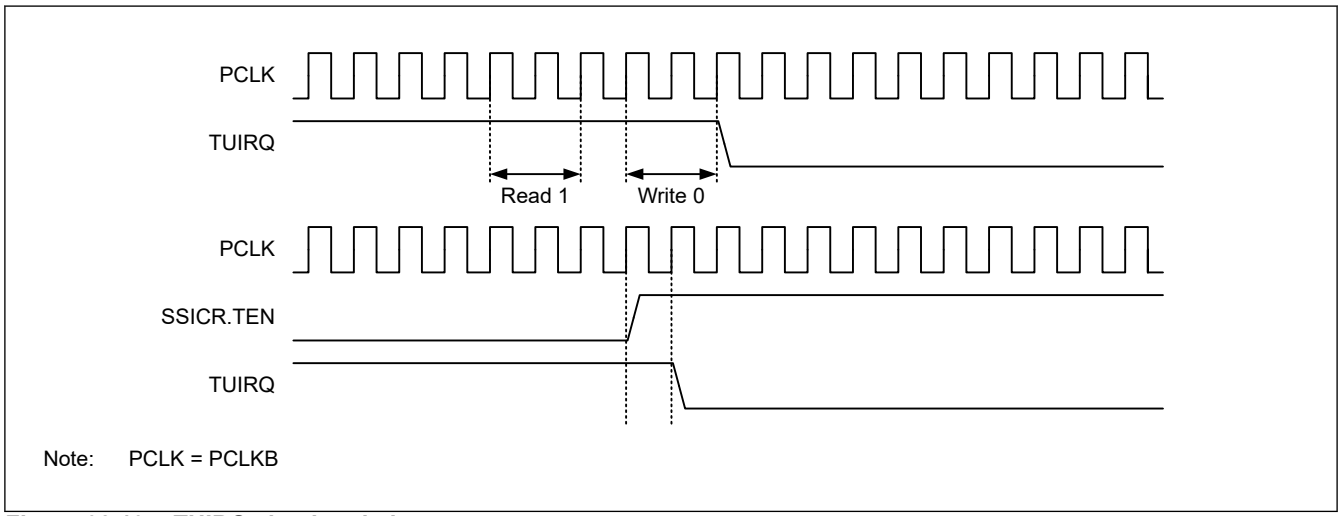

Figure 38.19 TUIRQ clearing timing

Note 1. This bit is cleared by a software reset (SSIFCR.SSIRST = 1). The software reset has priority over all the clearing conditions described above.

Note 2. After reading 1 from this bit, this bit is cleared when one of the following three conditions is met:
- A software reset (SSIFCR.SSIRST = 1) is done.
- After 1 has been read, writing of 0 is complete.
- 1 PCLKB cycle passes after 1 has been written to SSICR.TEN.

Note 3. After communication is enabled (by changing the value of SSICR.TEN bit from 0 to 1), the transmission error flags (TOIRQ and TUIRQ in the SSISR register) are cleared. If, however, the SSISR register is read continuously, the cleared status of the transmission error flags might be unable to be read.

[Setting condition]

When communication continues over a frame boundary, the transmit data required for the next frame has not been written to SSIFTDR. For details, see Figure 38.20 and Figure 38.21.

[Setting timing]

3 PCLKB cycles after the frame boundary. For details, see Figure 38.20.

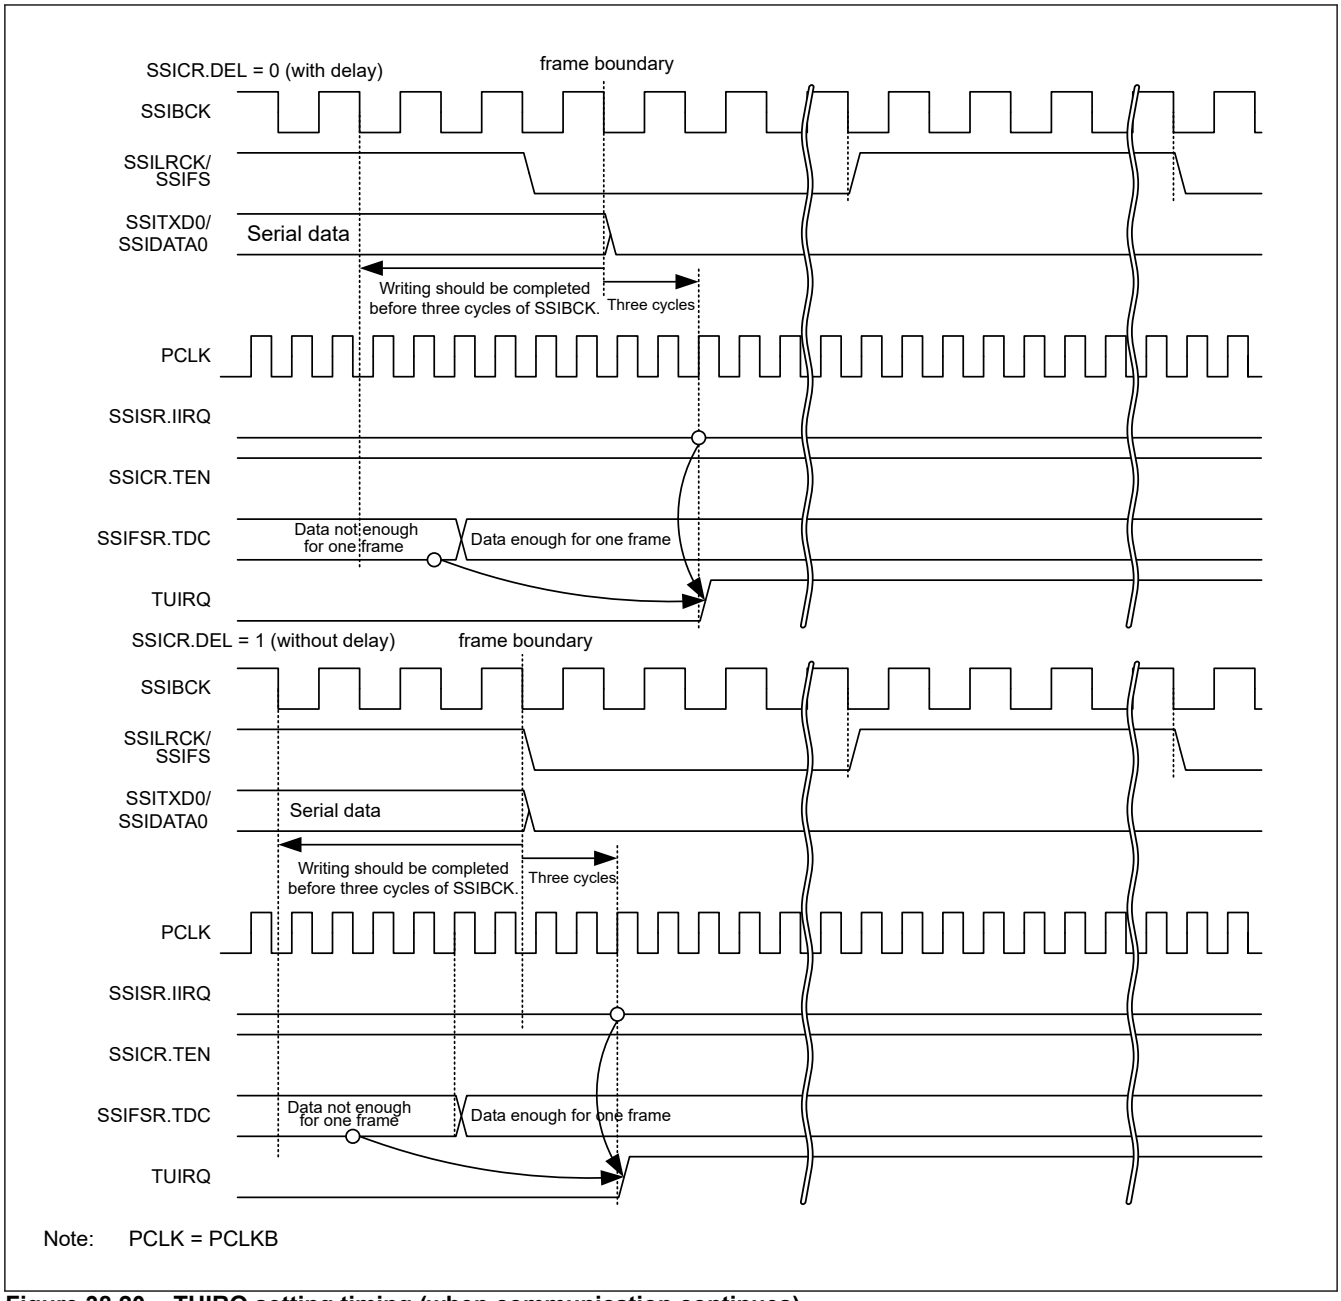

Figure 38.20 TUIRQ setting timing (when communication continues)

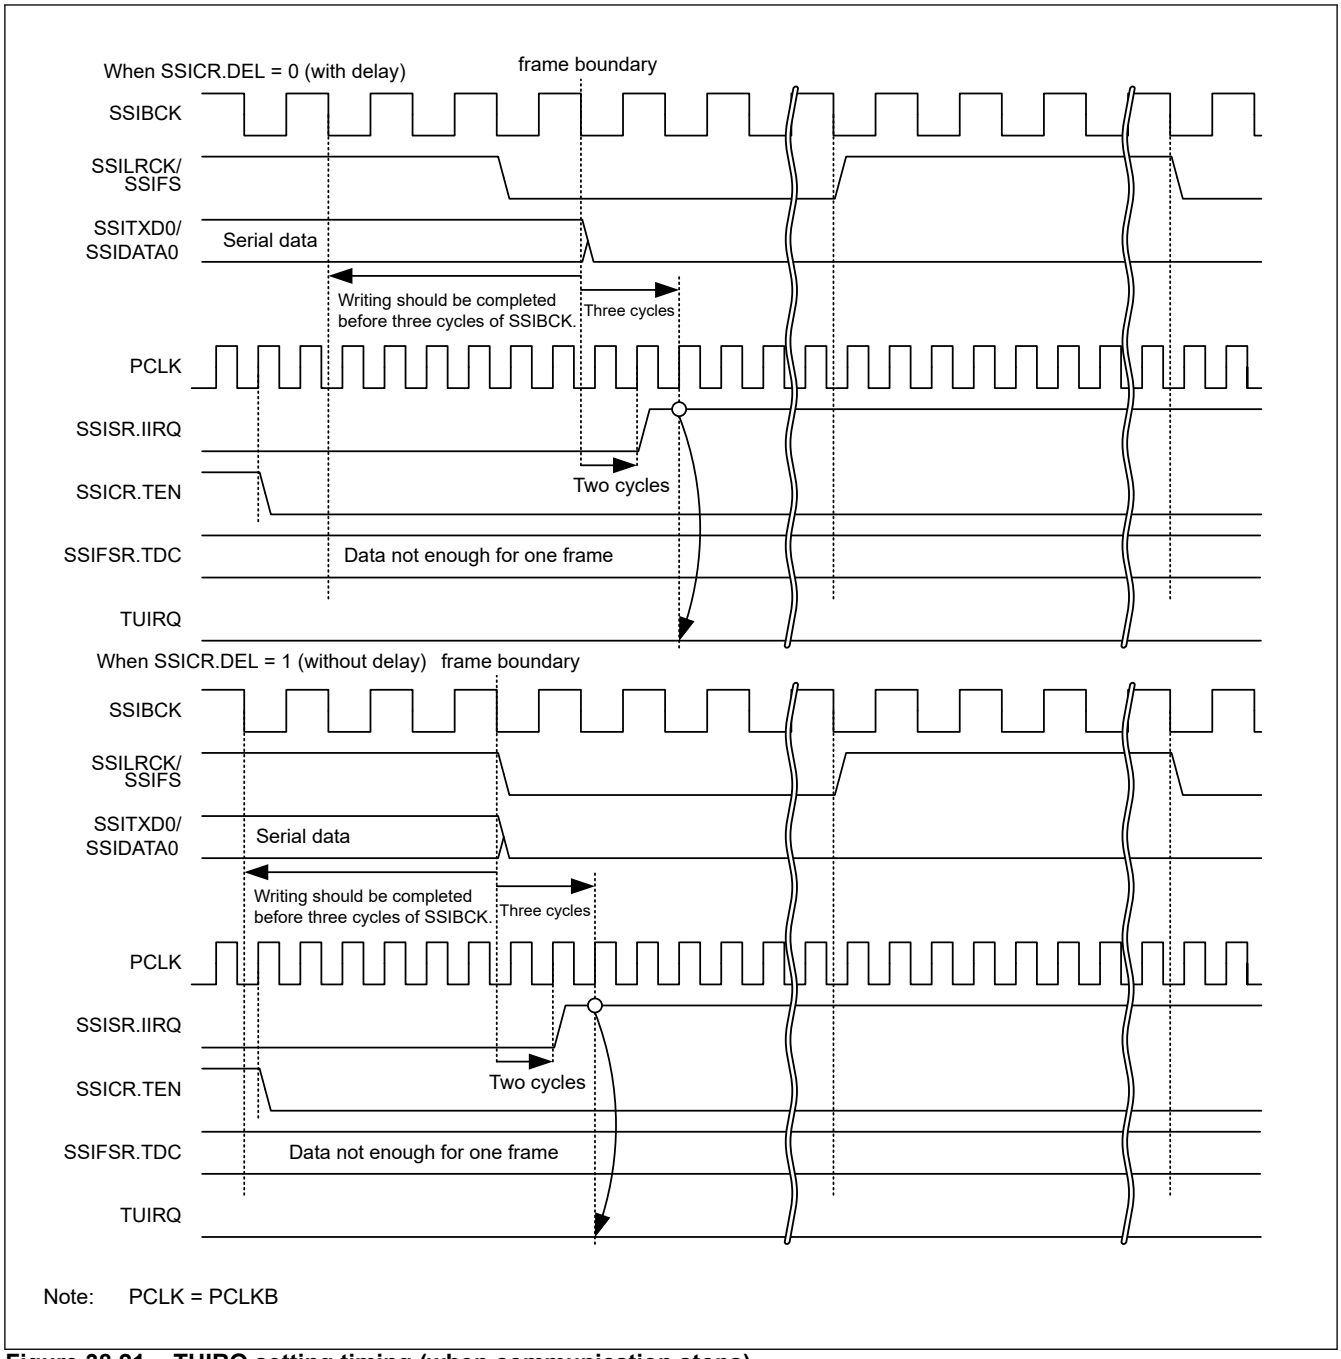

Figure 38.21 TUIRQ setting timing (when communication stops)

38.4.3 SSIFCR : FIFO Control Register

Base address: SSIE0 = 0x4009_D000

Offset address: 0x10

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	AUCKE	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SSIRST
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	BSW	—	—	—	—	—	—	—	TIE	RIE	TFRST	RFRST
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	RFRST	Receive FIFO Data Register Reset*1 0: Clears a receive data FIFO reset condition 1: Sets a receive data FIFO reset condition	R/W
1	TFRST	Transmit FIFO Data Register Reset*1 0: Clears a transmit data FIFO reset condition 1: Sets a transmit data FIFO reset condition	R/W
2	RIE	Receive Data Full Interrupt Output Enable 0: Disables receive data full interrupts 1: Enables receive data full interrupts	R/W
3	TIE	Transmit Data Empty Interrupt Output Enable 0: Disables transmit data empty interrupts 1: Enables transmit data empty interrupts	R/W
10:4	—	These bits are read as 0. The write value should be 0.	R/W
11	BSW	Byte Swap Enable*1 0: Disables byte swap 1: Enables byte swap	R/W
15:12	—	These bits are read as 0. The write value should be 0.	R/W
16	SSIRST	Software Reset 0: Clears a software reset condition 1: Sets a software reset condition	R/W
30:17	—	These bits are read as 0. The write value should be 0.	R/W
31	AUCKE	AUDIO_MCK Enable in Mastermode Communication*1 0: Disables supply of AUDIO_MCK 1: Enables supply of AUDIO_MCK	R/W

Note 1. Writing to these bits while SSIE is in a communication state (SSISR.IIRQ = 0) is prohibited. If the value of these bits is changed by rewriting, subsequent operation is unpredictable.

This register sets a software reset, byte swap, and enable/disable of interrupt requests.

RFRST bit (Receive FIFO Data Register Reset)

The RFRST bit sets a software reset of the receive FIFO data register (SSIFRDR). Writing 1 to this bit initializes the internal state related to SSIFRDR. The register bits subject to the software reset triggered by this bit are indicated by shading in Table 38.5. Because this bit is not automatically cleared after it has been set, write 0 to this bit to release the register bits from the software reset. After writing 0 to this bit, be sure to check that this bit is 0 before starting the next procedural step.

This bit is subject to the software reset by the SSIRST bit. Because the software reset by the SSIRST bit has priority over the reset by this bit, setting this bit is ignored when the SSIRST bit is set.

Table 38.5 Bits subject to software reset by the RFRST bit

TFRST bit (Transmit FIFO Data Register Reset)

The TFRST bit sets a software reset of the transmit FIFO data register (SSIFTDR). Writing 1 to this bit initializes the internal state related to SSIFTDR. The register bits subject to the software reset triggered by this bit are indicated by shading in Table 38.6. Because this bit is not automatically cleared after it has been set, write 0 to this bit to release the register bits from the software reset. After writing 0 to this bit, be sure to check that this bit is 0 before starting the next procedural step.

This bit is subject to the software reset by the SSIRST bit. Because the software reset by the SSIRST bit has priority over the reset by this bit, setting this bit is ignored when the SSIRST bit is set.

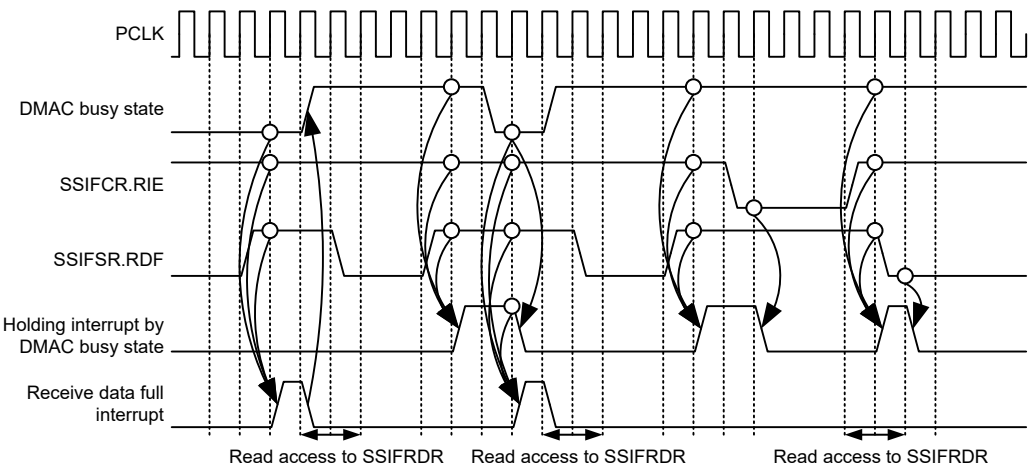
RIE bit (Receive Data Full Interrupt Output Enable)

The RIE bit enables/disables output of receive data full interrupts. Use a receive data full interrupt as an interrupt to trigger data reading from the receive FIFO data register. Write 1 to this bit after specifying the setting condition for receive data full interrupt (by using the SSISCR.RDFS bit). Figure 38.22 shows the timing of generating the receive data full interrupt.

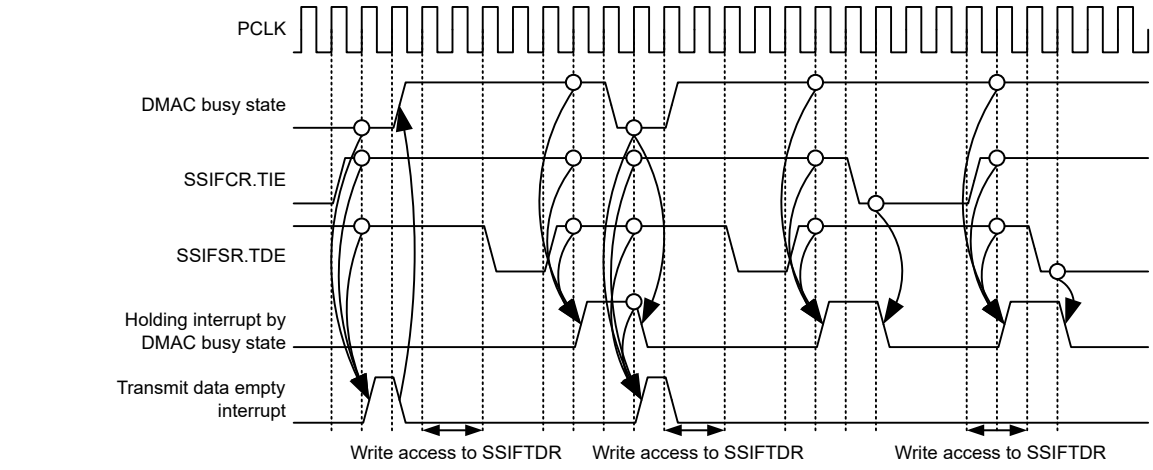


Note: PCLK = PCLKB

Figure 38.22 Timing of receive data full interrupt

TIE bit (Transmit Data Empty Interrupt Output Enable)

The TIE bit enables/disables output of transmit data empty interrupts. Use a transmit data empty interrupt as an interrupt to trigger data writing to the transmit FIFO data register. Write 1 to this bit after specifying the setting condition for transmit data empty interrupt (by using the SSISCR.TDES bit). Figure 38.23 shows the timing of generating the transmit data empty interrupt.



Note: PCLK = PCLKB

Figure 38.23 Timing of transmit data empty interrupt

BSW bit (Byte Swap Enable)

The BSW bit enables/disables byte swap of register access for the transmit FIFO data register (SSIFTDR) and the receive FIFO data register (SSIFRDR). This bit is valid only with 16-bit access or 32-bit access to SSIFTDR and SSIFRDR. For details, see Figure 38.24.

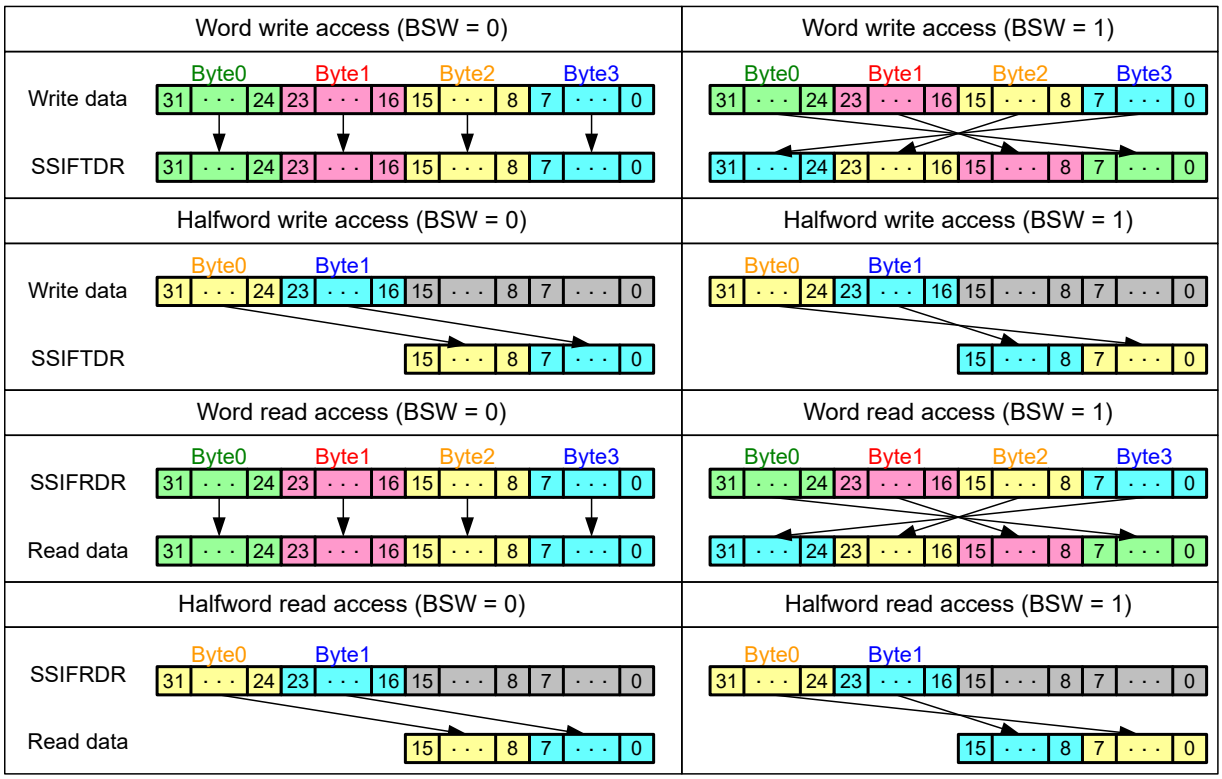


Figure 38.24 Operation example of byte swap

SSIRST bit (Software Reset)

The SSIRST bit sets a software reset of SSIE. Writing 1 to this bit initializes the internal state of SSIE. The register bits subject to the software reset triggered by this bit are indicated by shading in Table 38.7. Because this bit is not automatically

cleared after it has been set, write 0 to this bit to release the register bits from the software reset. After writing 0 to this bit, be sure to check that this bit is 0 before starting the next procedural step.

To stop communication of SSIE immediately, after turning off the peripheral functions, write 1 to this bit. Initialization by a software reset is performed without any relation with the bit clock.

Table 38.7 Bits subject to software reset by the SSIRST bit

Symbol	Address (BASE+)		+0								+1

AUCKE bit (AUDIO_MCK Enable in Mastermode Communication)

The AUCKE bit enables/disables supply to AUDIO_MCK while in master-mode communication (MST = 1).

Changing the value of this bit must be performed only after specifying the settings related to AUDIO_MCK (by using the CKS, MST, BCKP, and CKDV bits in the SSICR register).

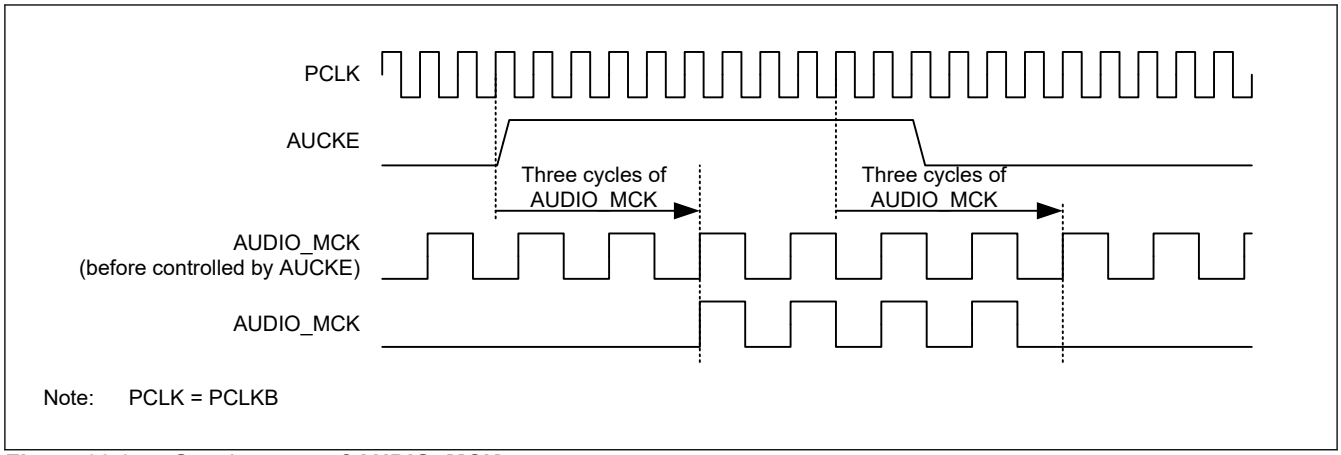

Figure 38.25 Stop/resume of AUDIO_MCK

Note: In slave-mode communication (SSICR.MST = 0), SSIE needs supply of SSIBCK. To stop BCK on the master side, make sure that SSIE is in the idle state (SSISR.IIRQ = 1). If BCK is stopped before SSIE becomes idle, take the procedure to start communication in Figure 38.52 or wait for an idle state by taking the procedure to resume communication in Figure 38.58.

In master-mode communication (SSICR.MST = 1), SSIE operates with the audio clock (AUDIO_MCK). To stop SSIE completely, make sure that SSIE is in the idle state (SSISR.IIRQ = 1) and then write 0 to SSIFCR.AUCKE. If 0 is written to SSIFCR.AUCKE before SSIE becomes idle, take the procedure to start communication in Figure 38.52.

Figure 38.26 and Figure 38.27 show the timings of signal operation in the period from setting this bit to 1 to the output to the SSIBCK pin.

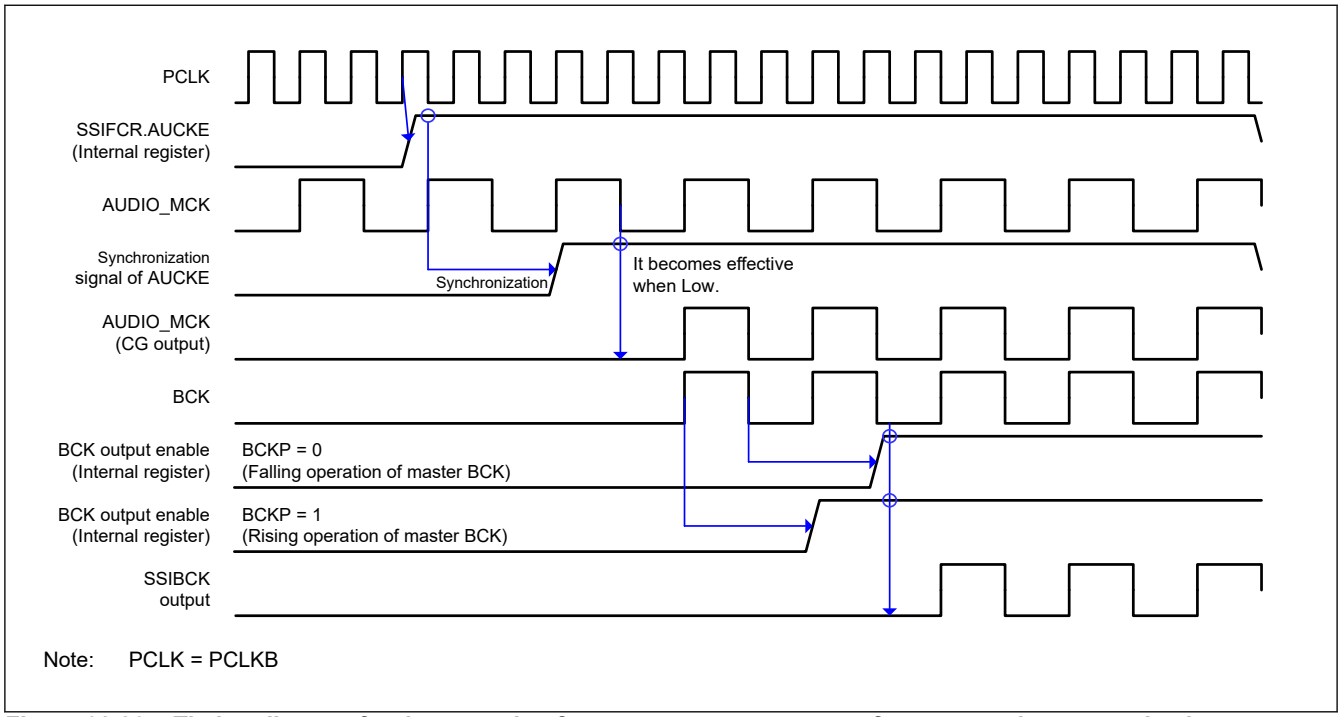

Figure 38.26 Timing diagram for the operation from system reset to start of master-mode communication

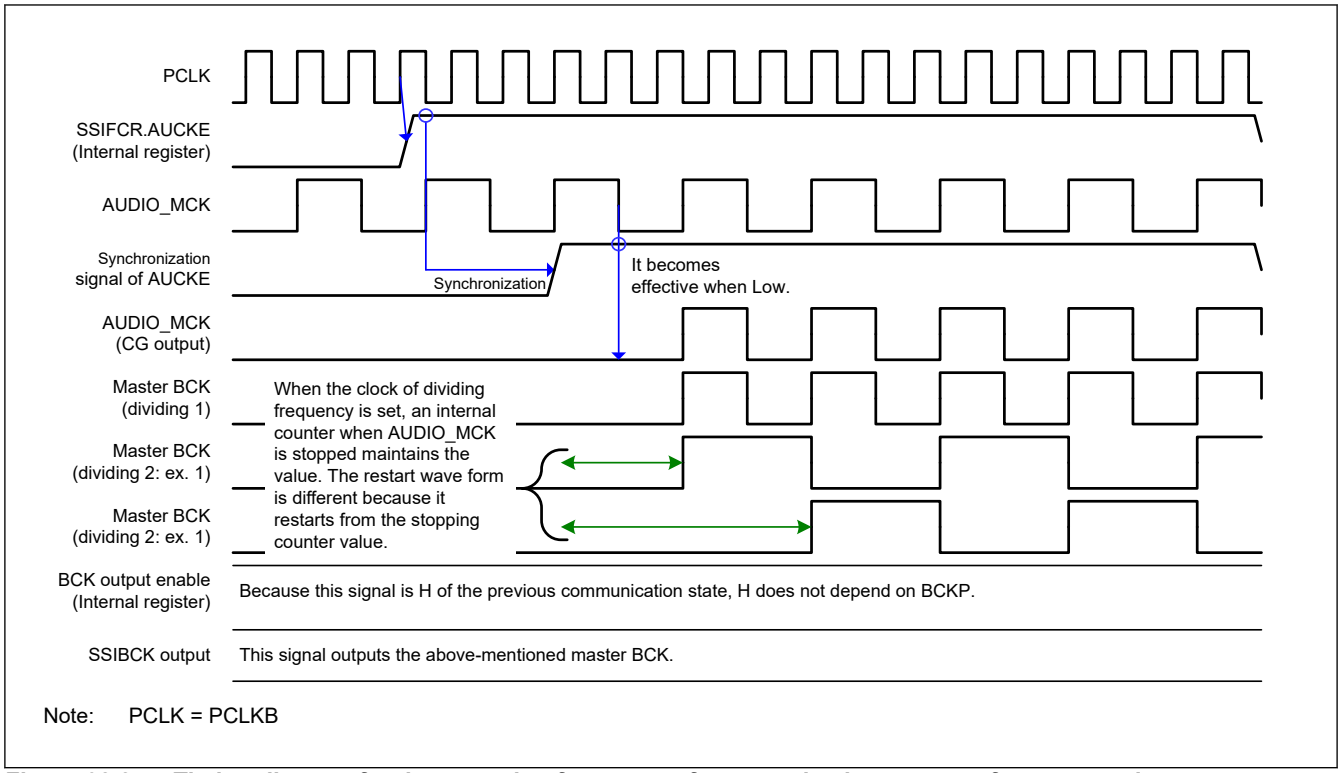

Figure 38.27 Timing diagram for the operation from stop of communication to start of master-mode communication

Note: If the supply of AUDIO_MCK stops, the value of the SSIBCK pin is held. Therefore, the SSIBCK signal might stop in the H (high level) state.

38.4.4 SSIFSR : FIFO Status Register

Base address: SSIE0 = 0x4009_D000

Offset address: 0x14

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	TDC[5:0]						—	—	—	—	—	—	—	TDE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	RDC[5:0]						—	—	—	—	—	—	—	RDF
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	RDF	Receive Data Full Flag 0: The size of received data in SSIFRDR is not more than the value of SSISCR.RDFS. 1: The size of received data in SSIFRDR is not less than the value of SSISCR.RDFS plus one.	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W
13:8	RDC[5:0]	Number of Receive FIFO Data Indication Flag Number of receive FIFO data indication flag	R
15:14	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
16	TDE	Transmit Data Empty Flag 0: The free space of SSIFTDR is not more than the value of SSISCR.TDES. 1: The free space of SSIFTDR is not less than the value of SSISCR.TDES plus one.	R/W
23:17	—	These bits are read as 0. The write value should be 0.	R/W
29:24	TDC[5:0]	Number of Transmit FIFO Data Indication Flag Number of transmit FIFO data indication flag	R
31:30	—	These bits are read as 0. The write value should be 0.	R/W

This register is configured with status flags that indicate the status of the transmit FIFO data register and the receive FIFO data register.

RDF flag (Receive Data Full Flag)

The RDF flag indicates that the receive FIFO data register (SSIFRDR) has unread received data not less than the amount set with the SSISCR.RDFS bit plus one. This flag is set by automatic determination but it must be cleared by register access.

[Priority order for setting and clearing]

Clearing is prioritized.

[Clearing condition]

Either of the following two:*1

1. Writing 0 to this bit after reading 1 from this bit (CPU operation)*2
2. Last access (DTC/DMAC operation) to read data from SSIFRDR by an interrupt routine using the DTC and DMAC.

[Clearing timing]

Clearing timing corresponding to the above clearing condition

1. When 0 is written to this bit after reading 1 from this bit (same as the timing in Figure 38.19)
2. After the PCLKB cycle in which the last access instruction is issued to read data from SSIFRDR by an interrupt routine using the DTC and DMAC.

[Setting condition]

SSIFTDR has free space not less than the amount set with the SSIFCR.TTRG bit plus one.

[Setting timing]

At completion of transfer from the shift register that results in SSIFRDR having data not less than the amount set with the SSISCR.RDFS bit plus one.

Note 1. These bits are cleared by a software reset (SSIFCR.SSIRST = 1) and receive FIFO data register reset (SSIFCR.RFRST = 1). Reset conditions available for these bits are the software reset and receive FIFO data register reset as well as the clearing conditions described above.

Note 2. After reading 1 from this bit, this bit is cleared when one of the following four conditions is met:
- A software reset is done (SSIFCR.SSIRST = 1).
- A receive FIFO data register reset is done (SSIFCR.RFRST = 1).
- After 1 has been read, writing of 0 is complete.
- Last access is performed to read data from SSIFRDR by an interrupt routine using the DTC and DMAC.

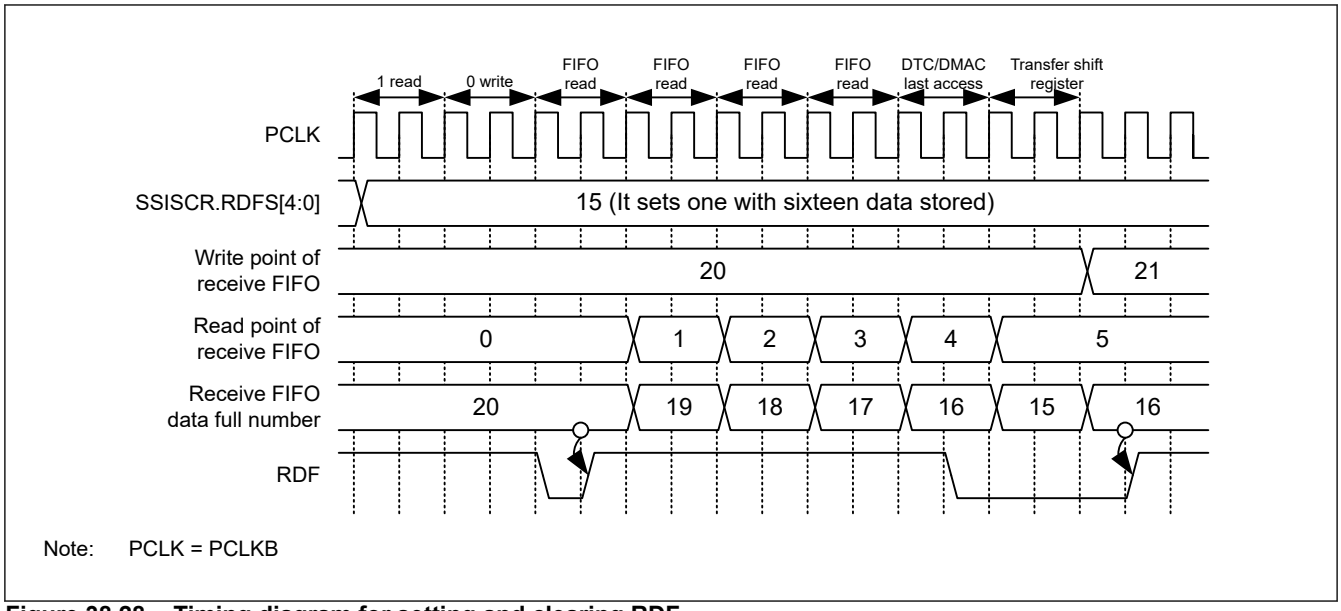

Figure 38.28 Timing diagram for setting and clearing RDF

RDC[5:0] flags (Number of Receive FIFO Data Indication Flag)

The RDC[5:0] flags indicate the number of valid data that are stored in the receive FIFO data register (SSIFRDR). With this flag as 0x00, there is no received data. With 0x20, the register is filled with received data and there is no free space.

TDE flag (Transmit Data Empty Flag)

The TDE flag indicates that the transmit FIFO data register (SSIFTDR) has free space not less than the amount set with the SSIFCR.TTRG bit plus one. This flag is set by automatic determination but it must be cleared by register access.

[Priority order for setting and clearing]

Clearing is prioritized.*1

[Clearing condition]

Either of the following two:

1. Writing 0 to this bit after reading 1 from this bit (CPU operation)*2
2. Last access (DTC/DMAC operation) to write data to SSIFTDR by an interrupt routine using the DTC and DMAC.

[Clearing timing]

Clearing timing corresponding to the above clearing condition

1. When 0 is written to this bit after reading 1 from this bit (same as the timing in Figure 38.19)
2. Last access (DTC/DMAC operation) to write data to SSIFTDR by an interrupt routine using the DTC and DMAC.

[Setting condition]

SSIFTDR has free space not less than the amount set with the SSIFCR.TTRG bit plus one.

[Setting timing]

While operating on PCLKB, SSIFTDR is found to have free space not less than “size set in the SSISCR.TDES bits + 1.”

Note 1. This bit is cleared by a software reset (SSIFCR.SSIRST = 1) and transmit FIFO data register reset (SSIFCR.TFRST = 1). The software reset and transmit FIFO data register reset have priority over all the clearing conditions described above.

Note 2. After reading 1 from this bit, this bit is cleared when one of the following four conditions is met:
- A software reset is done (SSIFCR.SSIRST = 1).
- A transmit FIFO data register reset is done (SSIFCR.TFRST = 1).
- After 1 has been read, writing of 0 is complete.
- Last access is performed to write data to SSIFTDR by an interrupt routine using the DTC and DMAC.

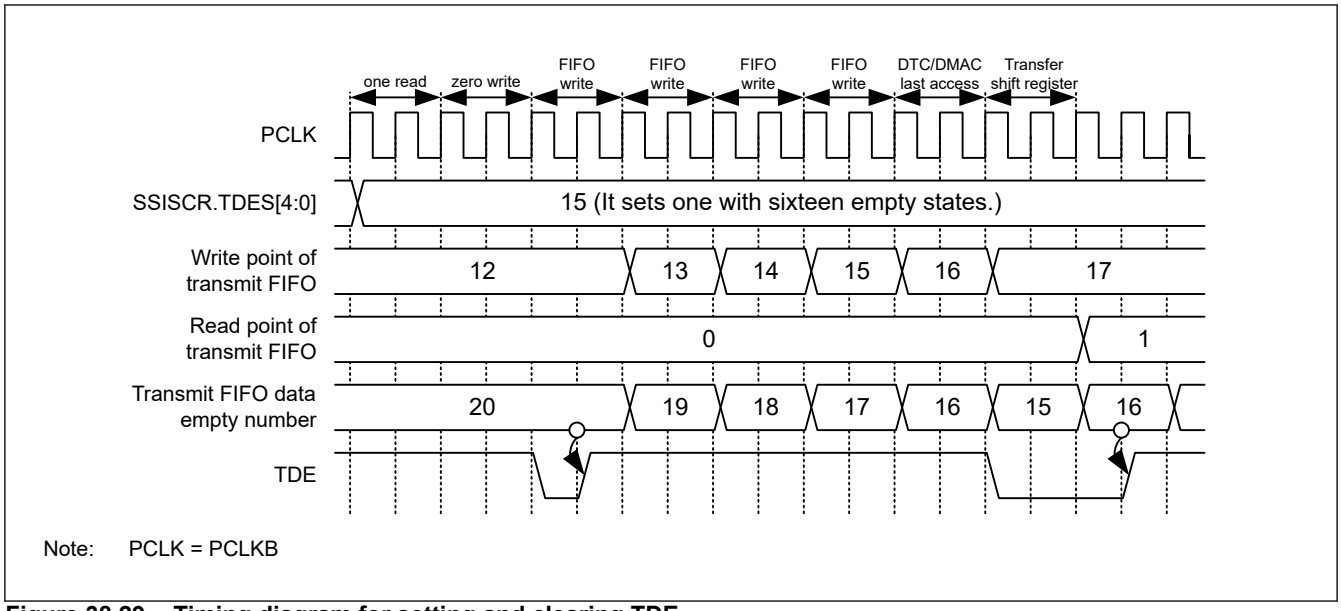

Figure 38.29 Timing diagram for setting and clearing TDE

TDC[5:0] flags (Number of Transmit FIFO Data Indication Flag)

The TDC[5:0] flags indicate the number of valid data that are stored in the transmit FIFO data register (SSIFTDR). With this flag as 0x00, there is no data to be transmitted. With 0x20, there is no space to write data.

38.4.5 SSIFTDR : Transmit FIFO Data Register

Base address: SSIE0 = 0x4009_D000

Offset address: 0x18

Bit position:	31																													0
Bit field:	SSIFTDR[31:0]																													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	SSIFTDR[31:0]	Transmit FIFO Data	W

This register stores data to be serially transmitted. 0 is returned when this register is read.

When you use this register for transmission, specify data writing to this register as the DTC/DMAC operation that is triggered by a transmit data empty interrupt. Determine the access size to this register according to the data word length to be communicated in Table 38.8.

Table 38.8 Register access restriction to FIFOs (1 of 2)

Access Size				
SSICR.DWL[2:0]	Data Word Length	Byte	Halfword	Word
000b	8	✓	—	—
001b	16	—	✓	—
010b	18	—	—	✓
011b	20	—	—	✓
100b	22	—	—	✓
101b	24	—	—	✓
110b	32	—	—	✓

Table 38.8 Register access restriction to FIFOs (2 of 2)

Access Size				
SSICR.DWL[2:0]	Data Word Length	Byte	Halfword	Word
111b	Setting prohibited	—	—	—

Figure 38.30 shows register access to the transmit FIFO data register.

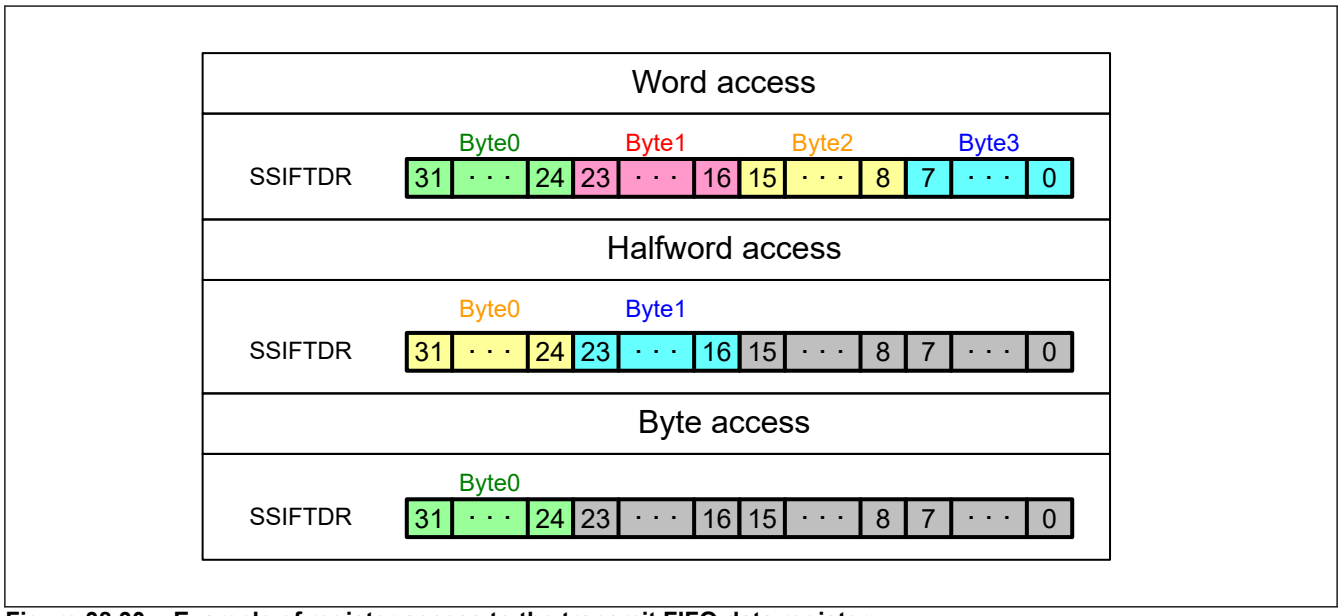

Figure 38.30 Example of register access to the transmit FIFO data register

Figure 38.31 shows the configurations and operation examples of the transmit FIFO data register and transmit shift register. The configurations are for storing data to FIFO and not related with communication.

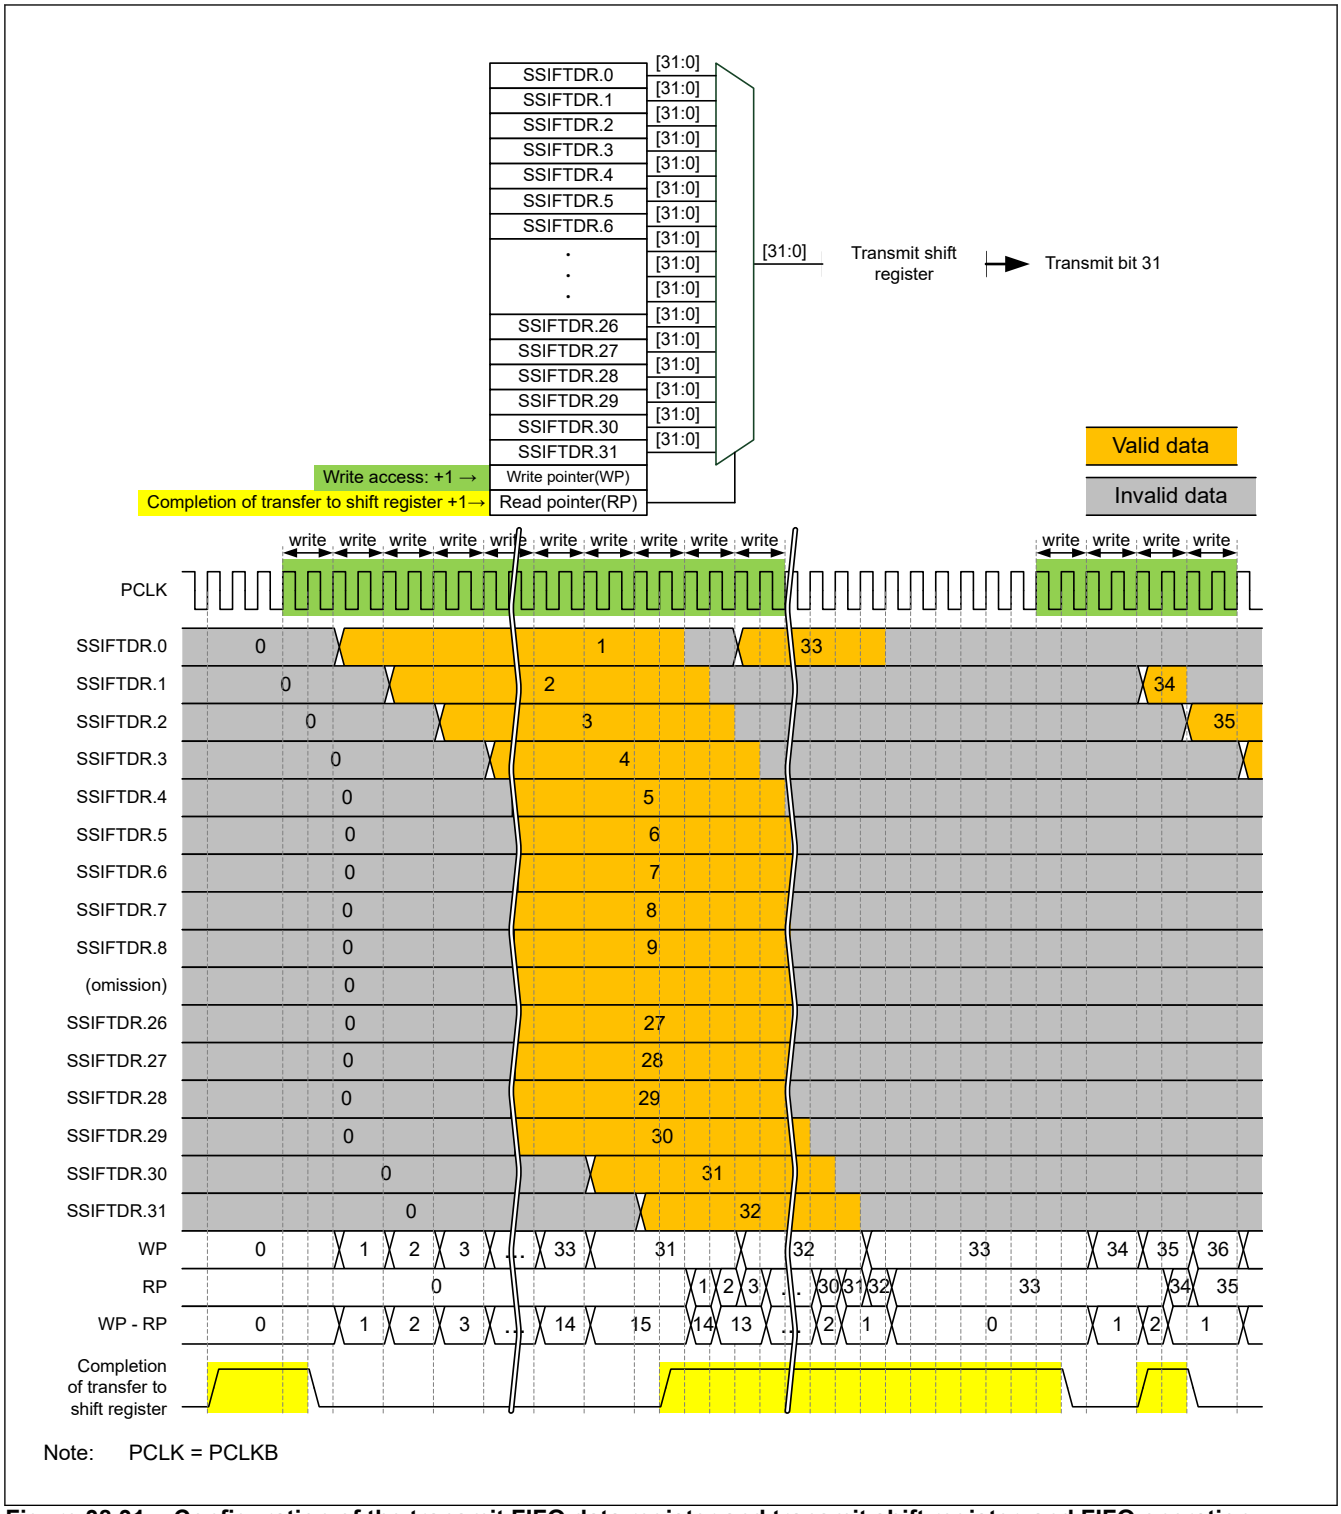

Figure 38.31 Configuration of the transmit FIFO data register and transmit shift register, and FIFO operation example

38.4.6 SSIFRDR : Receive FIFO Data Register

Base address: SSIE0 = 0x4009_D000

Offset address: 0x1C

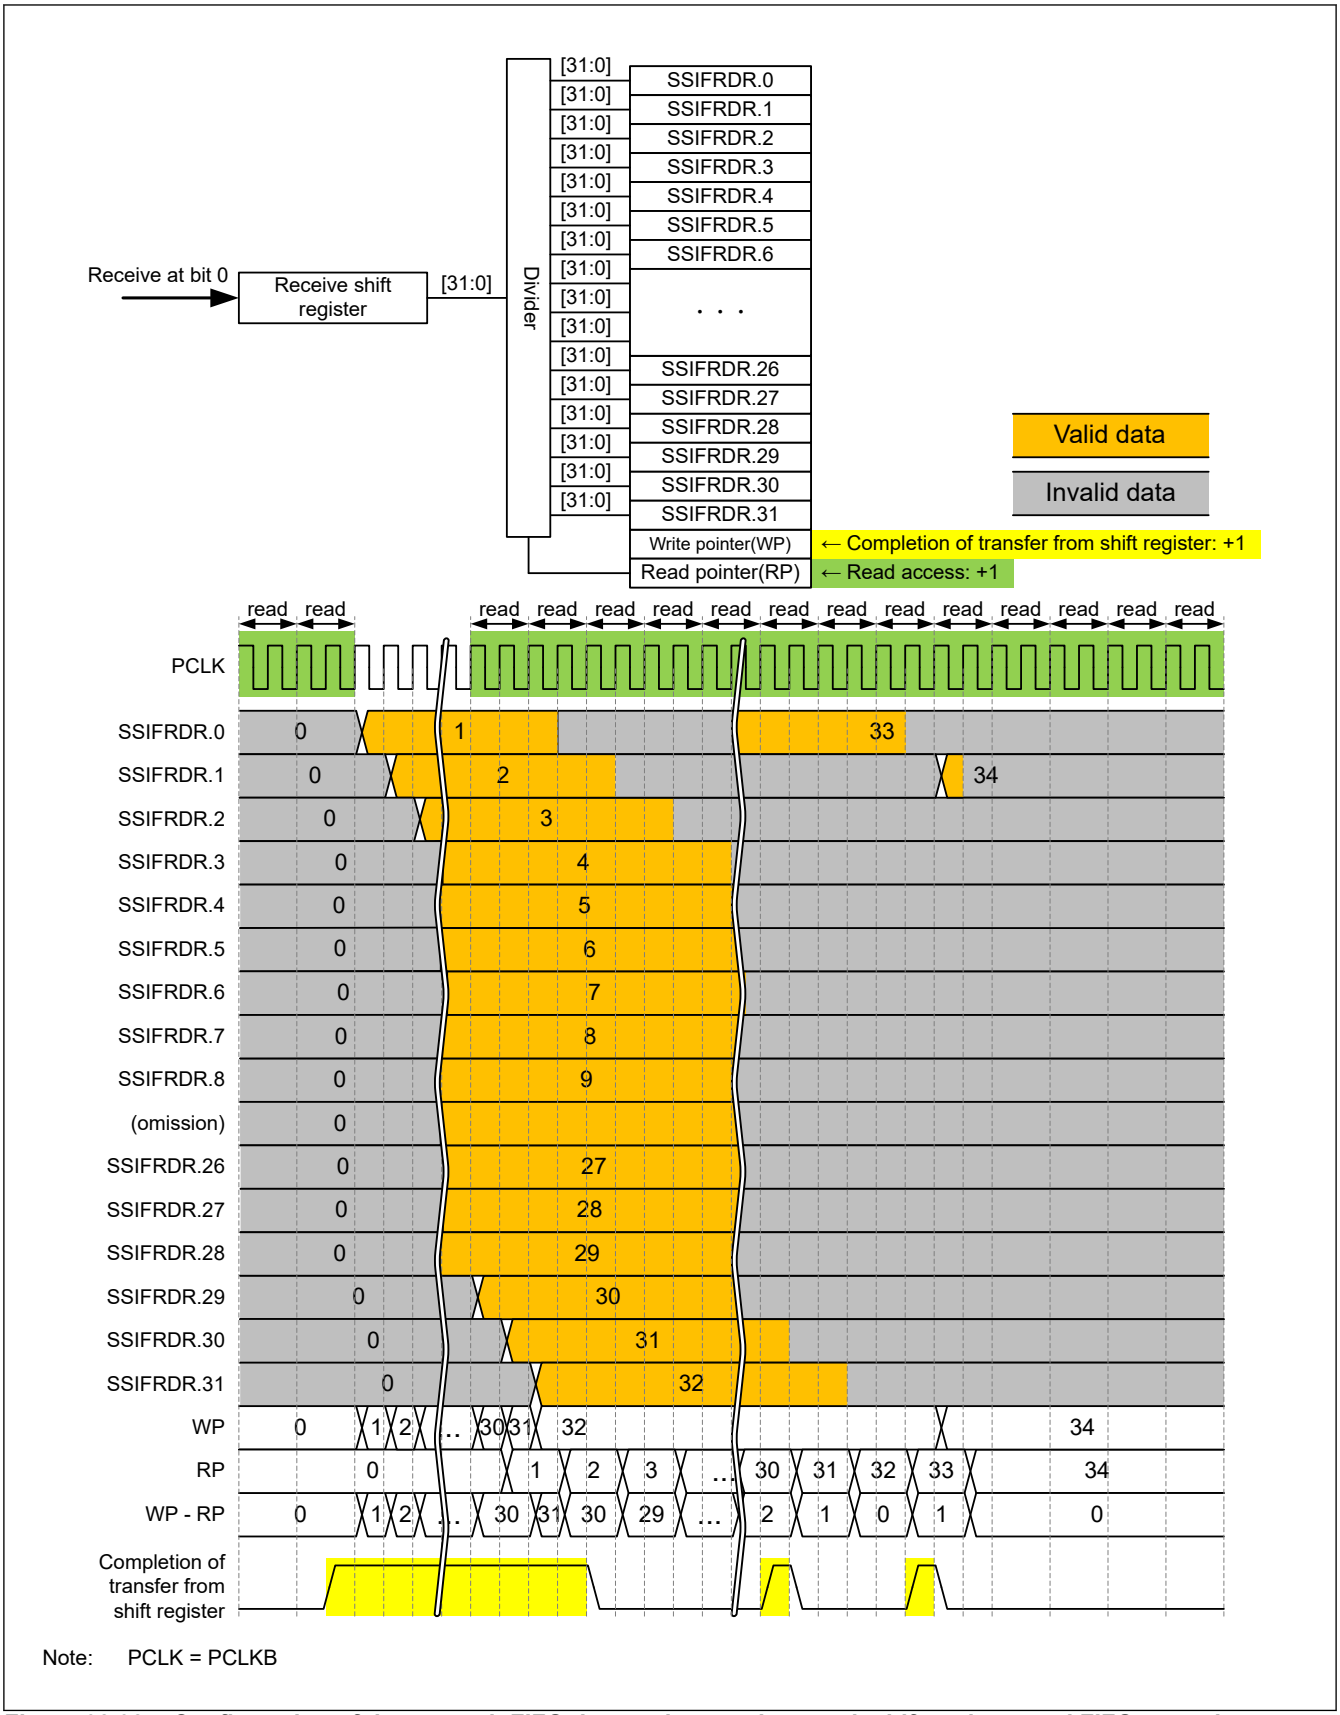
Bit position:	31																												0
Bit field:	SSIFRDR[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	SSIFRDR[31:0]	Receive FIFO Data	R

When you use this register for reception, specify data reading from this register as the DTC/DMAC operation that is triggered by a transmit data empty interrupt. Determine the access size to this register according to the data word length to be communicated in Table 38.8.

Register access to the receive FIFO data register is same as for the transmit FIFO data register.

Figure 38.31 shows the configurations and operation examples of the receive FIFO data register and receive shift register.



Note: PCLK = PCLKB

Figure 38.32 Configuration of the transmit FIFO data register and transmit shift register, and FIFO operation example

38.4.7 SSIOFR : Audio Format Register

Base address: SSIE0 = 0x4009_D000

Offset address: 0x20

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	BCKASTP	LRCONT	—	—	—	—	—	—	OMOD[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	OMOD[1:0]	Audio Format Select*3 *4 0 0: I^2S format 0 1: TDM format 1 0: Monaural format 1 1: Setting prohibited	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W
8	LRCONT	Whether to Enable LRCK/FS Continuation*1 *2 0: Disables LRCK/FS continuation 1: Enables LRCK/FS continuation	R/W
9	BCKASTP	Whether to Enable Stopping BCK Output When SSIE is in Idle Status*1 *2 0: Always outputs BCK to the SSIBCK pin 1: Automatically controls output of BCK to the SSIBCK pin	R/W
31:10	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. This bit is valid only in master-mode communication (SSICR.MST = 1). The setting is invalid in slave-mode communication (SSICR.MST = 0).

Note 2. The BCKASTP and LRCONT bits must not be set to 1 together.

Note 3. While SSIE is communicating (SSISR.IIRQ = 0), writing to these bits is prohibited. If the value of these bits is changed by writing, subsequent operation is unpredictable.

Note 4. If the communication format of other-party device is compatible with a communication format of SSIE, specify and use the communication format that enables communication with the other-party device.

This register is used to set an audio format (which involves the settings of communication format, LR clock/frame synchronization continuation mode, and BCK output stop).

OMOD[1:0] bits (Audio Format Select)

The OMOD[1:0] bits set an audio format. Writing to these bits must be performed when the LR clock supply to the SSILRCK/SSIFS pin is stopped. For details about the output of LR clock, see the detailed description of the LRCONT bit in section 38.4.7. SSIOFR : Audio Format Register.

LRCONT bit (Whether to Enable LRCK/FS Continuation)

The LRCONT bit enables or disables the output from SSILRCK/SSIFS pin when the communication mode is master-mode communication (SSICR.MST = 1) and SSIE is in the idle state (SSISR.IIRQ = 1).

Even in the idle state, a signal can output from the SSILRCK/SSIFS pin when this bit is set to 1 (to enable LR clock/frame synchronization continuation) in master mode (SSICR.MST = 1).

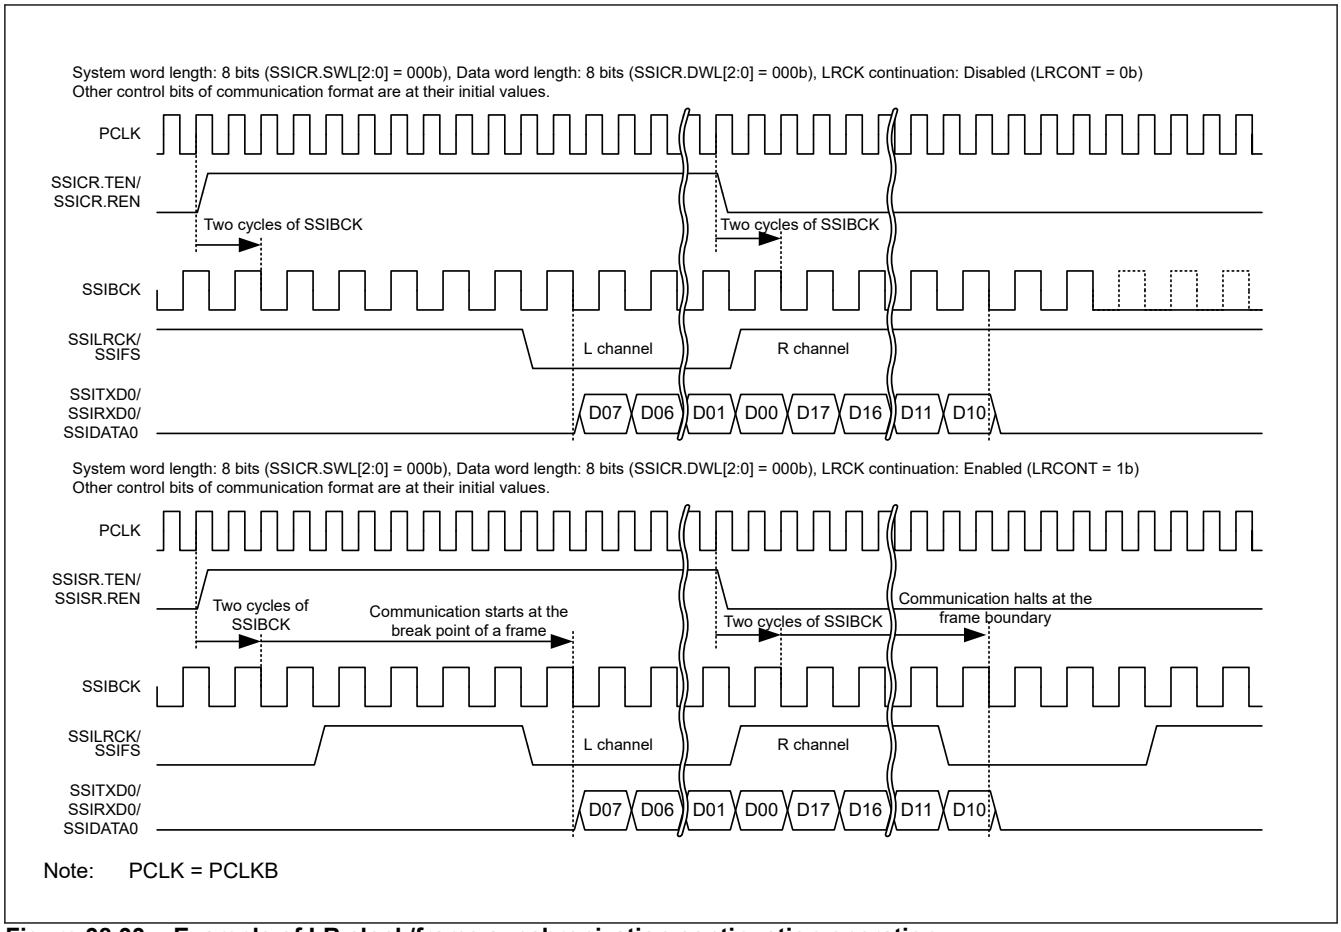


Figure 38.33 Example of LR clock/frame synchronization continuation operation

BCKASTP bit (Whether to Enable Stopping BCK Output When SSIE is in Idle Status)

The BCKASTP bit turns on or off the function to output BCK to the SSIBCK pin according to the communication shown in Figure 38.34 and Figure 38.35 in master-mode communication (SSICR.MST = 1).

Changing the value of this bit must be performed only after setting the communication format to be used.

This bit must be used in the following way:

Write 0 to the BCKASTP bit, and then start communication. During the communication, write 1 to the BCKASTP bit. By this operation, the bit clock output to the SSIBCK pin stops automatically when the communication stops. To resume the communication, set SSIE to the idle state (SSICR.IIRQ = 1), enable the supply of AUDIO_MCK (SSIFCR.AUCKE = 1), and then write 0 to the BCKASTP bit.

When the communication mode is master-mode communication (SSICR.MST = 1) and SSIE is in the idle state (SSICR.IIRQ = 1):

Table 38.9 BCKASTP bit status and SSIBCK pin output

BCKASTP Bit	SSIBCK Pin Output Status
0	Output
1	Stopped

Note: The BCKASTP bit cannot be used when the other-party device (which is a slave) requires the clock output from the SSIBCK pin before and during communication. In such a case, use the BCKASTP bit to stop the clock only after communication. For the timing of enabling the clock stop function, see Figure 38.34.

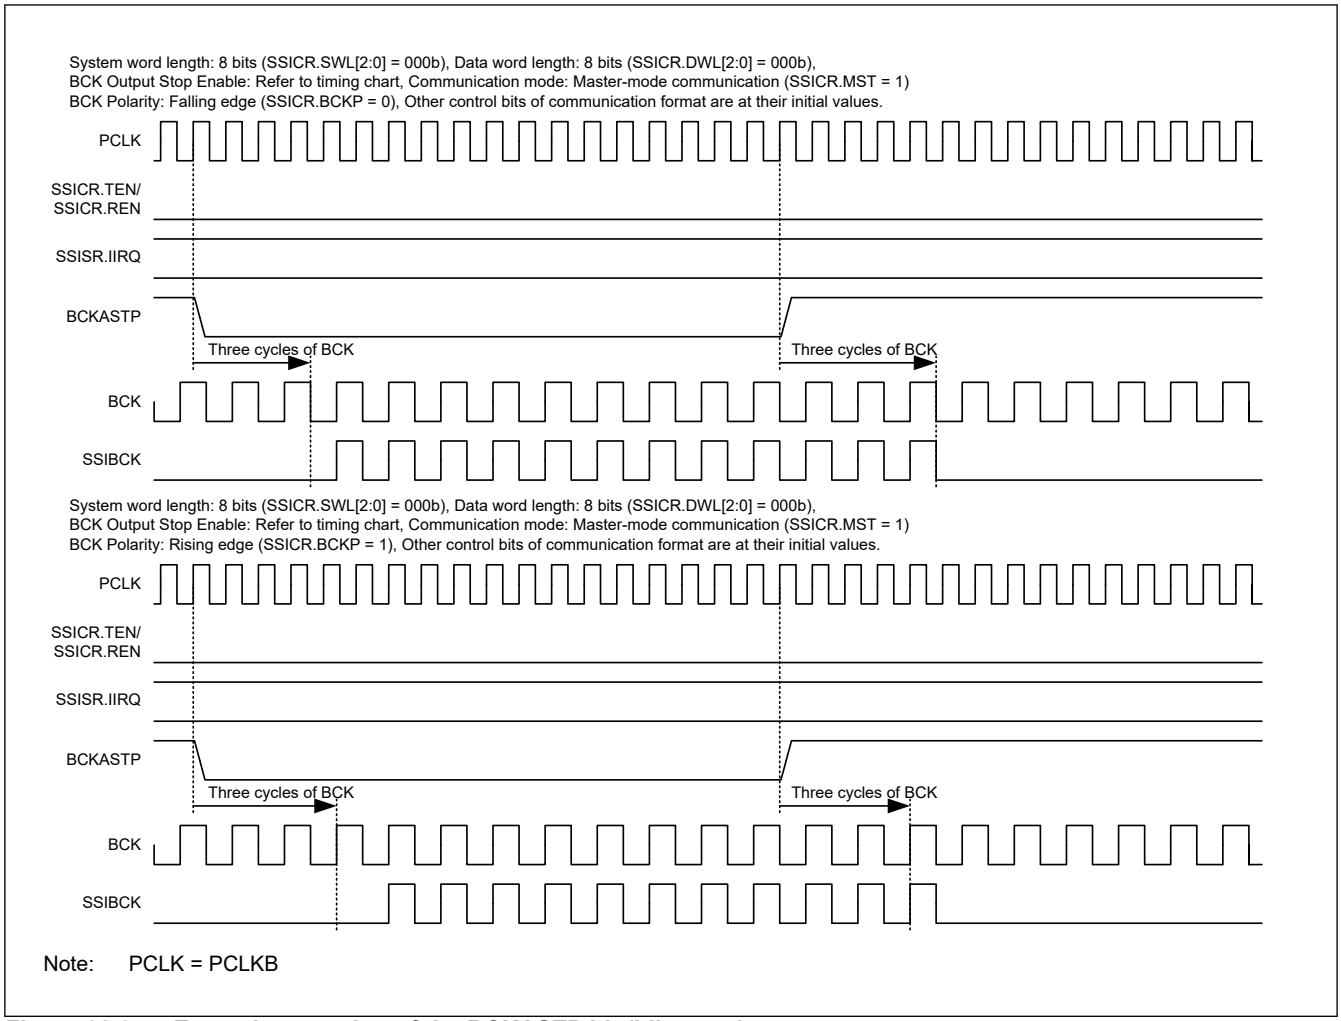

Figure 38.34 Example operation of the BCKASTP bit (idle state)

When the communication mode is master-mode communication (SSICR.MST = 1) and the BCK output stop function is enabled (BCKASTP = 1):

Details of the BCK output to the SSIBCK pin are as follows:

Output start timing: BCK is output in appropriate timing so that a valid edge is generated when the LR clock/frame synchronization signal shifts to a valid value.

Output stop timing: 1 to 1.5 clock cycles after a frame boundary.

For details about the timings, see the timing diagram in Figure 38.35.

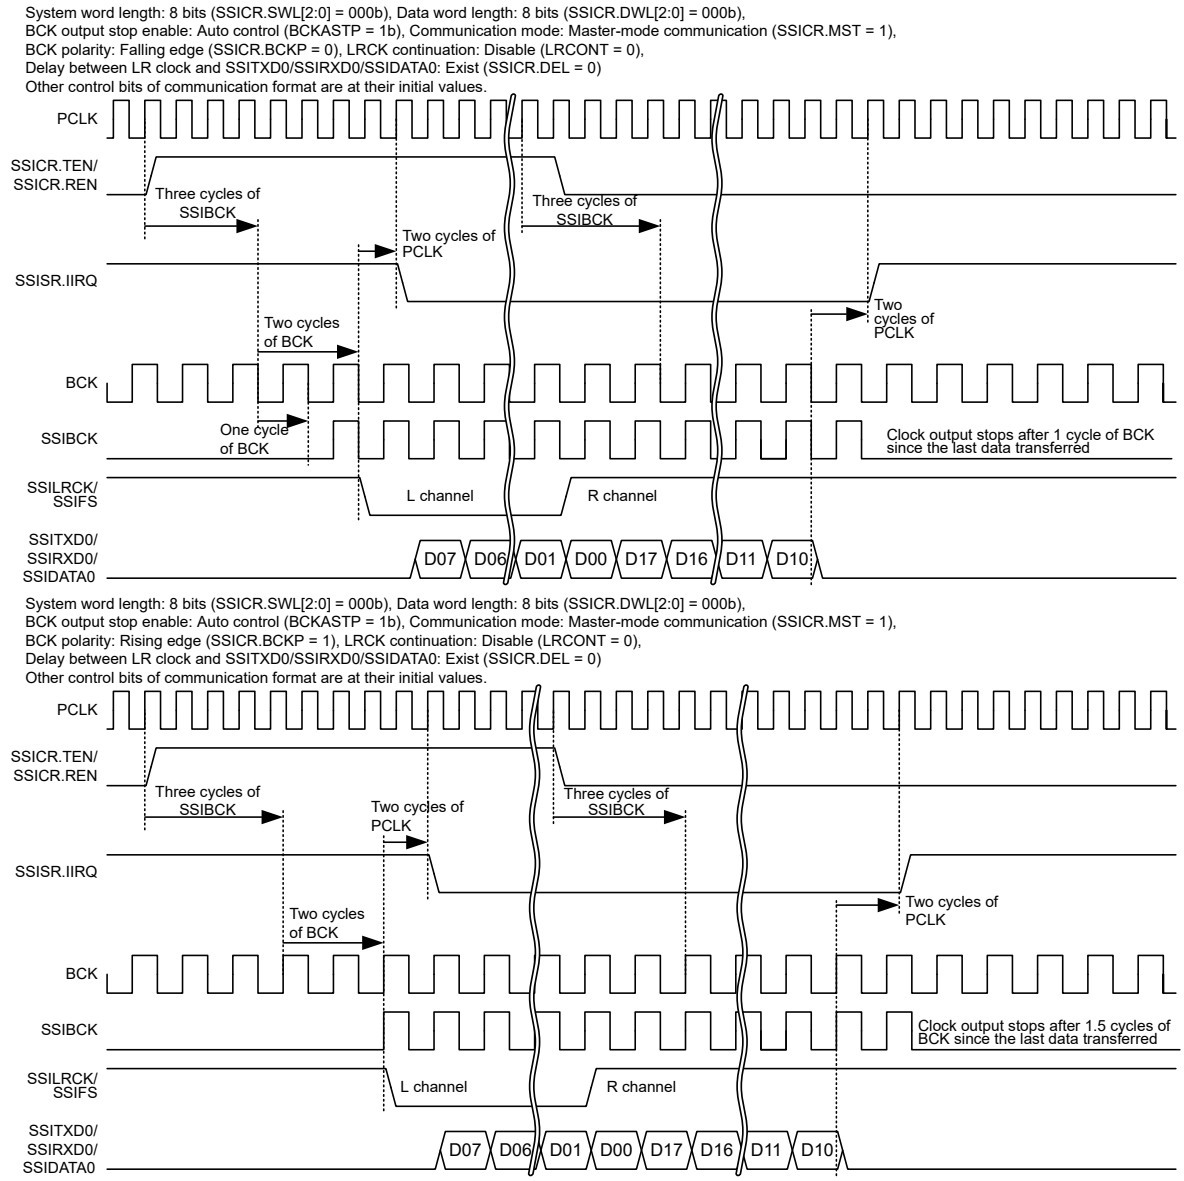

Figure 38.35 Example operation of the BCKASTP bit (communication operation with BCKASTP = 1)

38.4.8 SSISCR : Status Control Register

Base address: SSIE0 = 0x4009_D000

Offset address: 0x24

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	TDES[4:0]					—	—	—	RDFS[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
4:0	RDFS[4:0]	RDF Setting Condition Select*1 0x00: SSIFRDR has one stage or more data size. 0x01: SSIFRDR has two stages or more data size. ⋮ 0x1E: SSIFRDR has thirty-one stages or more data size. 0x1F: SSIFRDR has thirty-two stages or more data size.	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W
12:8	TDES[4:0]	TDE Setting Condition Select*1 0x00: SSIFTDR has one stage or more free space. 0x01: SSIFTDR has two stages or more free space. ⋮ 0x1E: SSIFTDR has thirty-one stages or more free space. 0x1F: SSIFTDR has thirty-two stages or more free space.	R/W
31:13	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Writing to these bits while SSIE is in a communication state (SSISR.IIRQ = 0) is prohibited. If written, the operation performed immediately after writing is not guaranteed.

RDFS[4:0] bits (RDF Setting Condition Select)

The RDFS[4:0] bits set the setting condition of the receive data full flag (RDF).

TDES[4:0] bits (TDE Setting Condition Select)

The TDES[4:0] bits set the setting condition of the transmit data empty flag (TDE).

38.5 Communication Formats

SSIE supports three communication formats. Table 38.10 shows supported communication formats.

Table 38.10 Supported communication formats

Communication Format	SSIOFR.OMOD[1:0]
I²S format	00
TDM format	01
Monaural format	10

The following describes the serial data structure shared by communication formats. A serial data structure is defined by the system word length (set in SSICR.SWL[2:0]) and the data word length (set in SSICR.DWL[2:0]). If the data word length is shorter than the system word length, padding bits are transferred in the serial data. For details, see Figure 38.36.

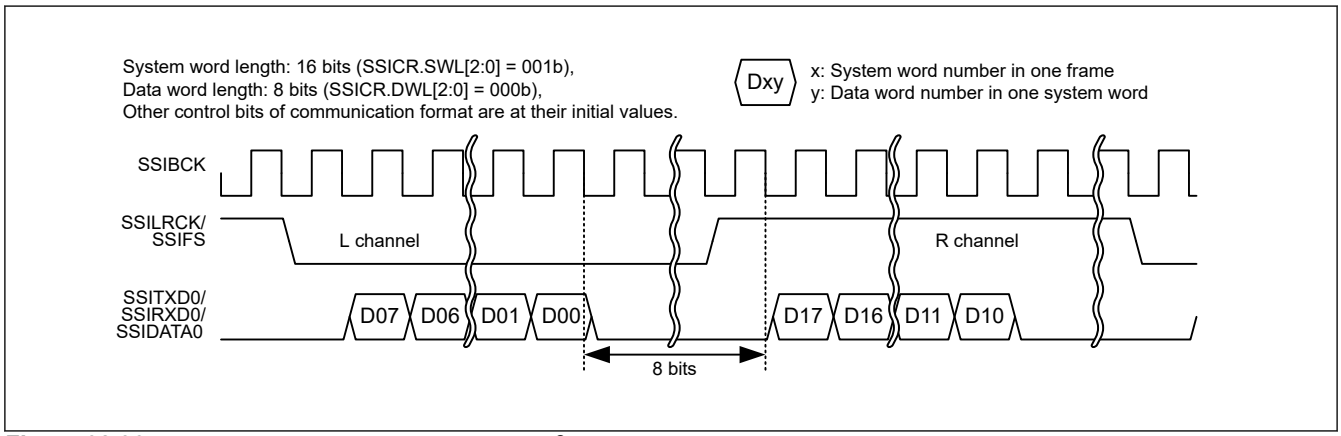

Figure 38.36 Example of padding bit transfer (I²S format: system word length > data word length)

Table 38.11 lists the number of padding bits to be transferred with each combination of system word length (SSICR.SWL[2:0]) and data word length (SSICR.DWL[2:0]). "-" indicates that the setting is prohibited.

Table 38.11 Number of padding bits

	SSICR.DWL[2:0]	000b	001b	010b	011b	100b	101b	110b	111b
SSICR.SWL[2:0]	System Word Length	8	16	18	20	22	24	32	Setting prohibited
000b	8	0	—	—	—	—	—	—	—
001b	16	8	0	—	—	—	—	—	—
010b	24	16	8	6	4	2	0	—	—
011b	32	24	16	14	12	10	8	0	—
100b	48	40	32	30	28	26	24	16	—
101b	64	56	48	46	44	42	40	32	—
110b	128	120	112	110	108	106	104	96	—
111b	256	248	240	238	236	234	232	224	—

38.5.1 I²S Format

The I²S format is a communication format used for connection with I²S-compatible serial devices. With this format setting (SSIOFR.OMOD[1:0] = 00b), one frame is configured with two system words, one for the channel L and the other for channel R. The SSILRCK/SSIFS signals are at a low level for the channel L and at a high level for the channel R. Set the polarity of the signals with the SSICR.LRCKP bit. Figure 38.37 shows the I²S format without padding. See Figure 38.36 for the format with padding.

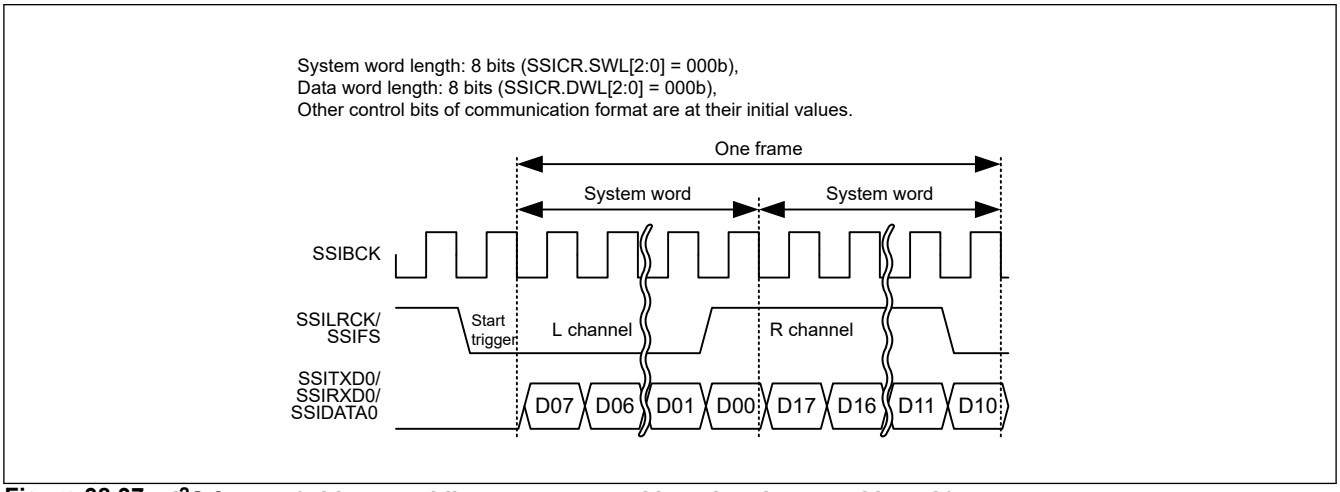

Figure 38.37 I²S format (without padding: system word length = data word length)

For the state of external pins when SSIE is in the idle state, see section 38.7.1. Idle State.

Note: SSIE has the SSILRCK/SSIFS pin, which indicates the synchronization of communication. When SSIE is in slave mode (SSICR.MST = 0), the communication format SSIE uses must match that of the other-party device to communicate. SSIE uses the signal input by the SSILRCK/SSIFS pin only as a trigger to start communication.

38.5.2 Monaural Format

The monaural format is a communication format used for connection with monaural-compatible serial devices. When the monaural format is specified (SSIOFR.OMOD[1:0] = 10b) for use, one frame consists of one system word. Also, a rising edge of the SSILRCK/SSIFS signal indicates a communication start trigger. Figure 38.38 and Figure 38.39 respectively show the monaural formats without and with padding.

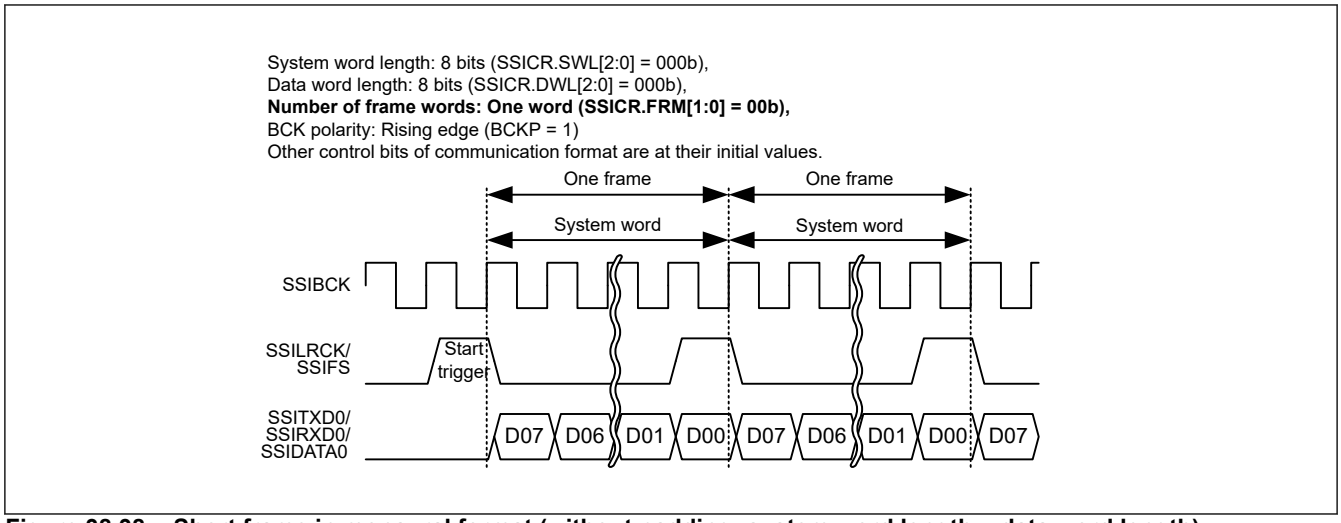

Figure 38.38 Short frame in monaural format (without padding: system word length = data word length)

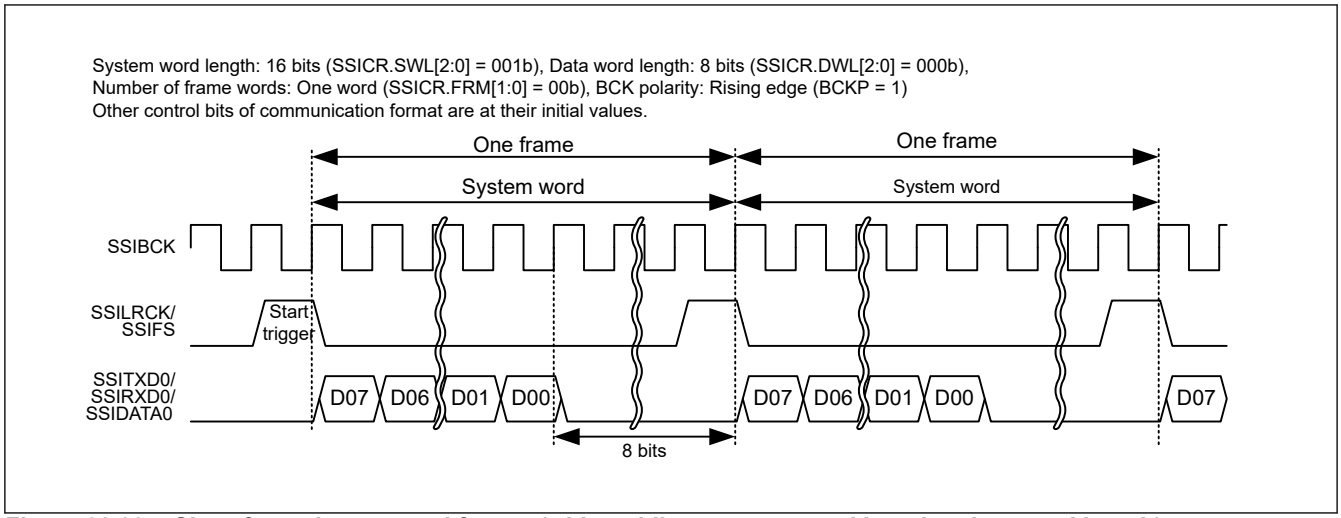

Figure 38.39 Short frame in monaural format (with padding: system word length > data word length)

The monaural formats supported by SSIE consist of short frames and long frames. See section 38.5.2.1. Short frame and section 38.5.2.2. Long frame for the difference between these two frames.

For the state of external pins state when SSIE is in the idle state, see section 38.7.1. Idle State.

Note: SSIE has the SSILRCK/SSIFS pin, which indicates the synchronization of communication. When SSIE is in slave mode (SSICR.MST = 0), the communication format SSIE uses must match that of the other-party device to communicate. SSIE uses the signal input by the SSILRCK/SSIFS pin only as a trigger to start communication.

38.5.2.1 Short frame

When a short frame is used (SSICR.DEL = 0), the SSILRCK/SSIFS signal indicating the start of serial data is set to high level only for 1 cycle of SSIBCK. Data transfer starts at the falling edge of the signal.

38.5.2.2 Long frame

When a long frame is used (SSICR.DEL = 1), the SSILRCK/SSIFS signal indicating the start of serial data is set to high level only for 2 cycles of SSIBCK. See Figure 38.40. Data transfer starts at the rising edge of the signal.

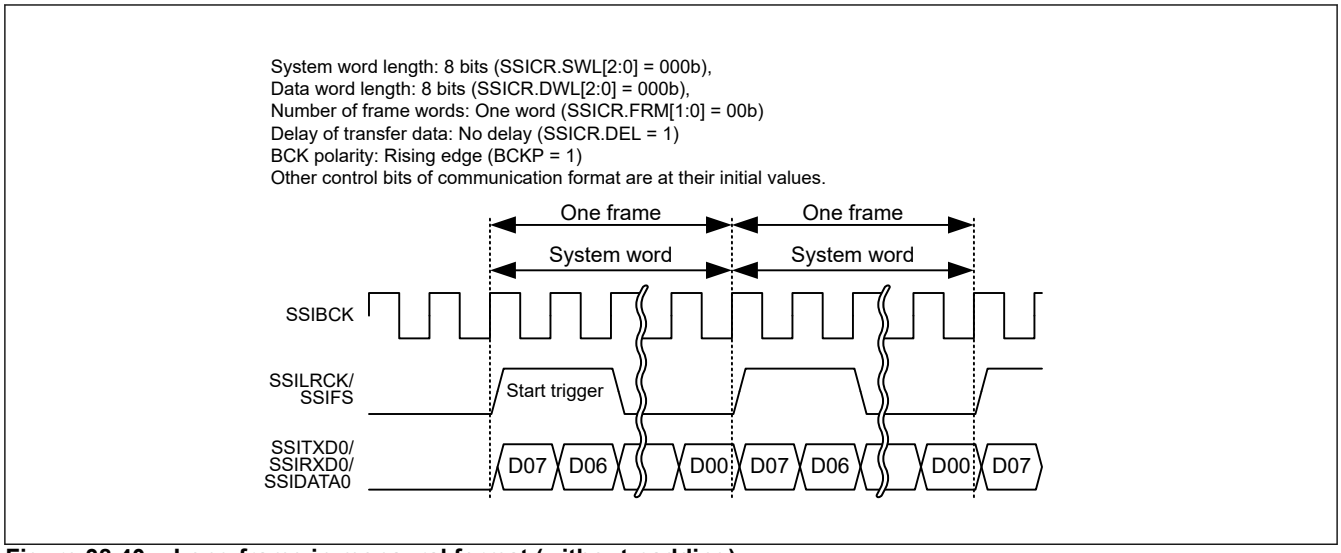

Figure 38.40 Long frame in monaural format (without padding)

38.5.3 TDM Format

The TDM format is a communication format used for connection with TDM-compatible multi-channel devices. With this format setting (SSIOFR.OMOD[1:0] = 01b), one frame is configured with four to eight system words set with the SSICR.FRM[1:0] bits. With this format, the SSILRCK/SSIFS signal is at a high level for the first one system word and at a low level for the rest. The pulse generated on the SSILRCK/SSIFS signal is defined as the SYNC pulse and its rising edge means a start of one frame. Figure 38.41 and Figure 38.42 respectively show the TDM formats without and with padding.

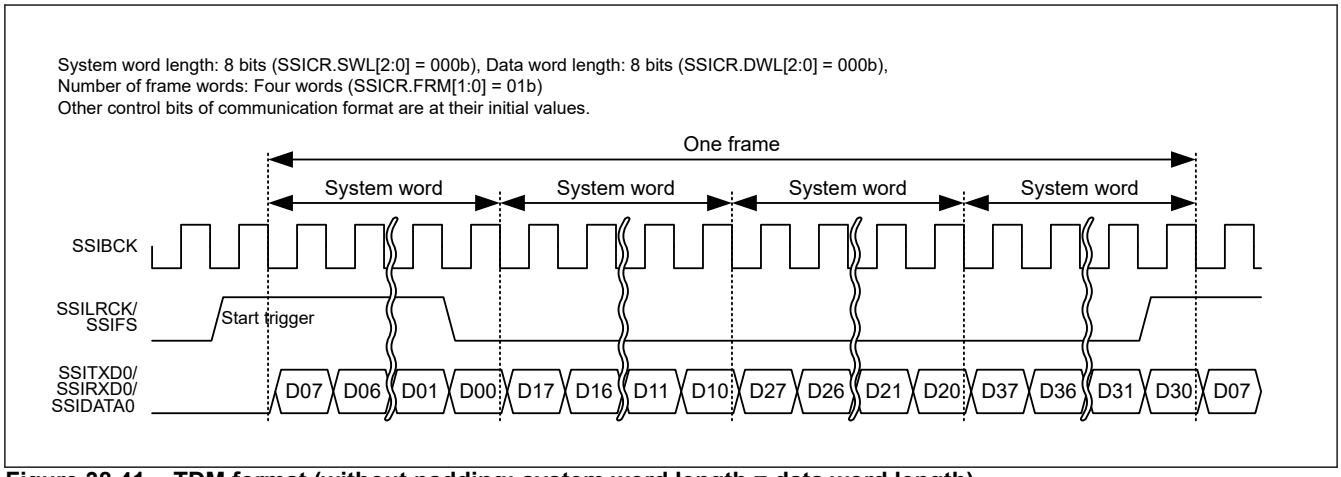

Figure 38.41 TDM format (without padding: system word length = data word length)

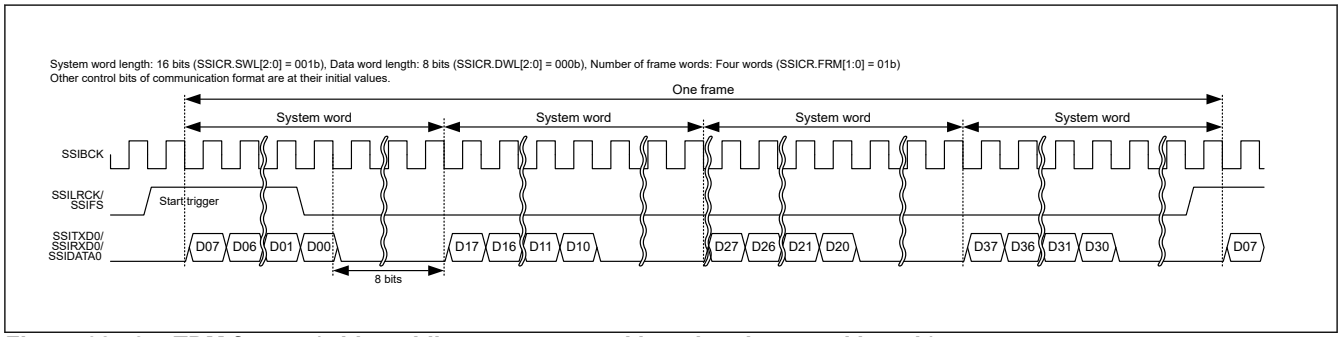

Figure 38.42 TDM format (with padding: system word length > data word length)

For the state of external pins when SSIE is in the idle state, see section 38.7.1. Idle State.

Note: SSIE has the SSILRCK/SSIFS pin, which indicates the synchronization of communication. When SSIE is in slave mode (SSICR.MST = 0), the communication format SSIE uses must match that of the other-party device to communicate. SSIE uses the signal input by the SSILRCK/SSIFS pin only as a trigger to start communication.

38.6 Communication Modes

SSIE supports the following communication modes. Table 38.13 lists the control bits that are not available with each communication mode. See section 38.6.1. Slave-mode Communication to section 38.6.5. Transmission and Reception for details of these communication modes.

Table 38.12 Communication modes

Communication Mode	SSICR.MST Bit	SSICR.REN Bit	SSICR.TEN Bit
Slave-mode transmission	0	0	1
Slave-mode reception	0	1	0
Slave-mode transmission and reception	0	1	1
Master-mode transmission	1	0	1
Master-mode reception	1	1	0
Master-mode transmission and reception	1	1	1

Table 38.13 Control bits that cannot be used in each communication mode

Control Bit	Slave-mode Reception	Slave-mode Transmission	Slave-mode Transmission and Reception	Master-mode Reception	Master-mode Transmission	Master-mode Transmission and Reception
SSICR.CKS	Invalid	Invalid	Invalid	Available	Available	Available

SSIFCR.TIE	Invalid	Available	Available	Invalid	Available	Available
SSIFCR.RIE	Available	Invalid	Available	Available	Invalid	Available
SSIFCR.TFRST	Invalid	Available	Available	Invalid	Available	Available
SSIFCR.RFRST	Available	Invalid	Available	Available	Invalid	Available
SSIOFR.BCKASTP	Invalid	Invalid	Invalid	Available	Available	Available
SSIOFR.LRCONT	Invalid	Invalid	Invalid	Available	Available	Available
SSIOFR.OMOD	Available	Available	Available	Available	Available	Available
SSISCR.TDES	Invalid	Available	Available	Invalid	Available	Available
SSISCR.RDFS	Available	Invalid	Available	Available	Invalid	Available

“Invalid” means it has no effect on operation. Writing is possible.

38.6.1 Slave-mode Communication

SSIE operates in slave mode with SSICR.MST = 0. The SSIBCK and SSILRCK/SSIFS signals to be used for serial-data communication must be supplied from an external device. If these signals do not match the communication format set for SSIE, operation is not guaranteed.

38.6.2 Master-mode Communication

SSIE operates in master mode with SSICR.MST = 1. The SSIBCK and SSILRCK/SSIFS signals to be used for serialdata communication must be internally generated from the audio clock. These signals use the format according to the setting of

SSIE. If the communication format the slave device uses does not match the communication format set for SSIE, the operation is unpredictable.

38.6.3 Transmission

SSIE transmits serial data to the other-party device when the SSICR.TEN bit is 1 and the SSICR.REN bit is 0. If the communication format the other-party device uses does not match the communication format set for SSIE, the operation is unpredictable.

38.6.4 Reception

SSIE receives serial data from the other-party device when the SSICR.TEN bit is 0 and the SSICR.REN bit is 1. If the communication format the other-party device uses does not match the communication format set for SSIE, the operation is unpredictable.

38.6.5 Transmission and Reception

SSIE transmits and receives serial data to and from the other-party device when the SSICR.TEN bit is 1 and the SSICR.REN bit is 1. If the communication format the other-party device uses does not match the communication format set for SSIE, the operation is unpredictable.

38.7 Operation

SSIE has the following two main operation states Figure 38.43 shows SSIE state transition.

- Idle state (SSISR.IIRQ = 1)
- Communication state (SSISR.IIRQ = 0).

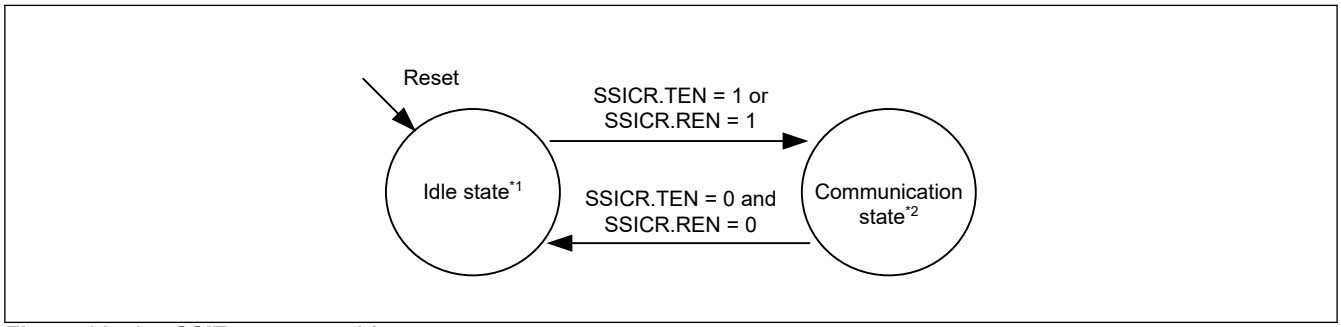

Figure 38.43 SSIE state transition

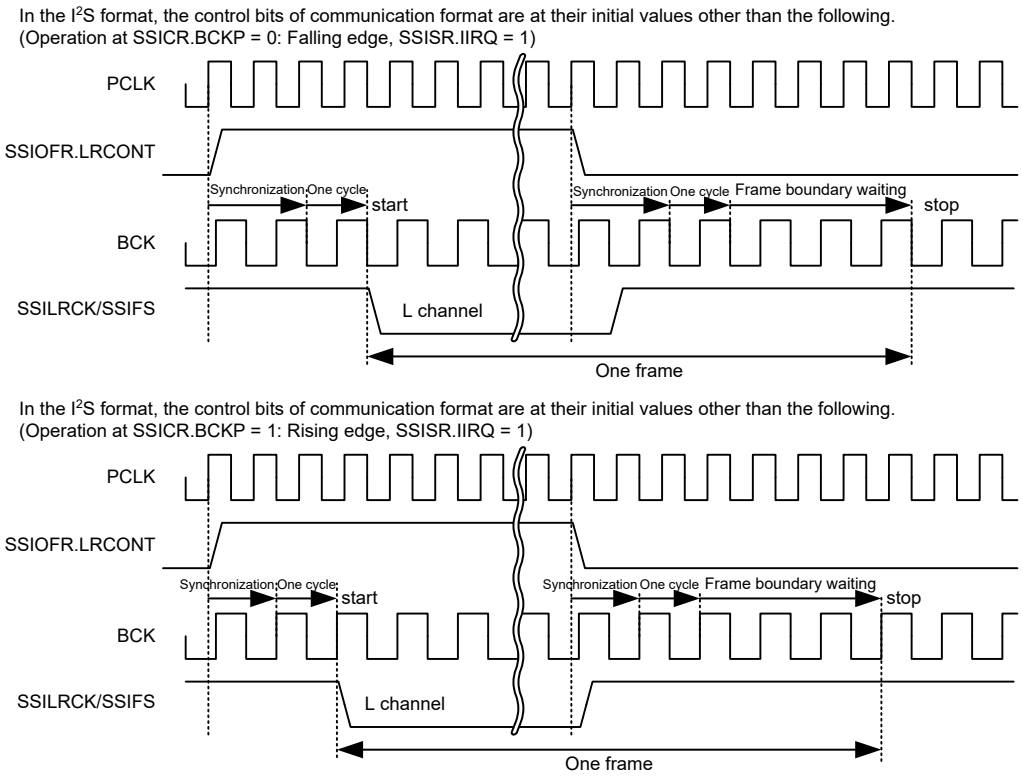
Note: See section 38.8.1. Start Communication for details of the idle state.
See section 38.8.2. Transmission for details of the communication state.

38.7.1 Idle State

In this state, communication of SSIE is halted. If, however, the SSICR.MST bit is 1, output of the BCK and LR clock/frame synchronization signals to external pins can be controlled according to the settings of SSIOFR.BCKASTP and SSIOFR.LRCONT bits. This function is common to all formats. For details, see Table 38.14.

Table 38.14 Output from external pins in the idle state

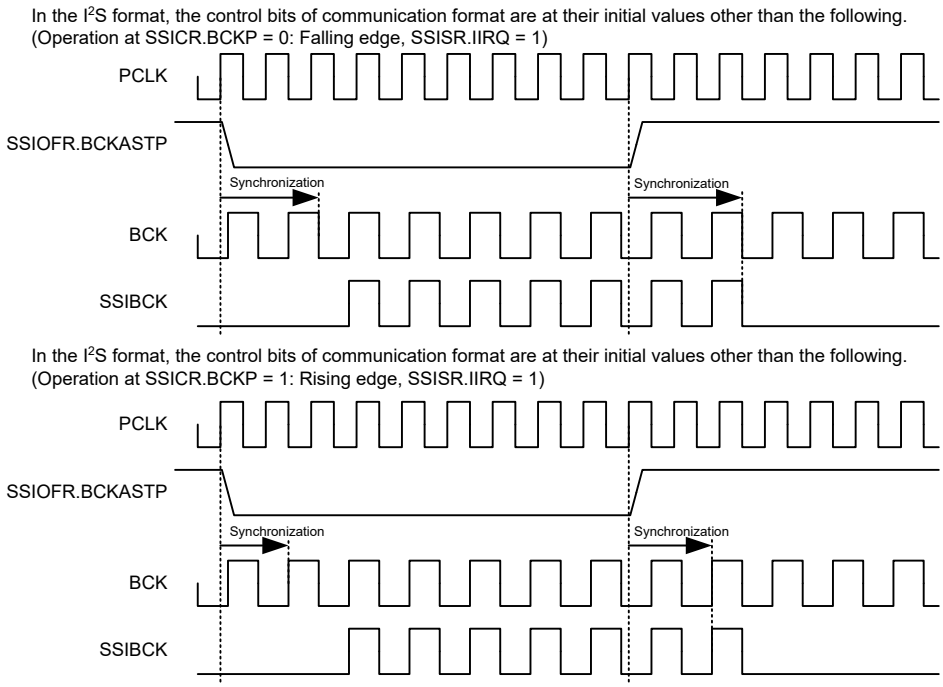
SSICR.MST	SSIOFR.BCKASTP	SSIOFR.LRCONT	Output from Pins		
			SSIBCK	SSILRCK/SSIFS	SSITXD0/SSIDATA0
0	—	—	Stop	Stop	Stop
1	0	0	Supply	Stop	Stop
1	0	1	Supply	Supply	Stop
1	1	0	Stop	Stop	Stop
1	1	1	Stop	Supply	Stop



Note: PCLK = PCLKB

Figure 38.44 Example of disabling LR clock/frame synchronization continuation by SSIOFR.LRCONT

Note: To stop the output to the SSILRCK/SSIFS pin with SSIOFR.LRCONT when SSIE is in the idle state in mastermode communication (SSICR.MST = 1), note the following: The output stops when the value of the SSIOFR.LRCONT bit is changed from 1 to 0. Make sure that the other-party device is not affected.



Note: PCLK = PCLKB

Figure 38.45 Example of stopping SSIBCK with SSIOFR.BCKASTP

Note: To stop the output to the SSIBCK pin with SSIOFR.BCKASTP in master-mode communication (SSICR.MST = 1) and while SSIE is in the idle state, note the following: The output stops when the value of the SSIOFR.BCKASTP bit is changed from 0 to 1. So, make sure that the other-party device is not affected.

38.7.2 Communication States

In this state, SSIE is during communication. Figure 38.46 shows transitions of communication states and Table 38.15 lists the conditions for transition. If the transition condition is not satisfied, the state does not transit.

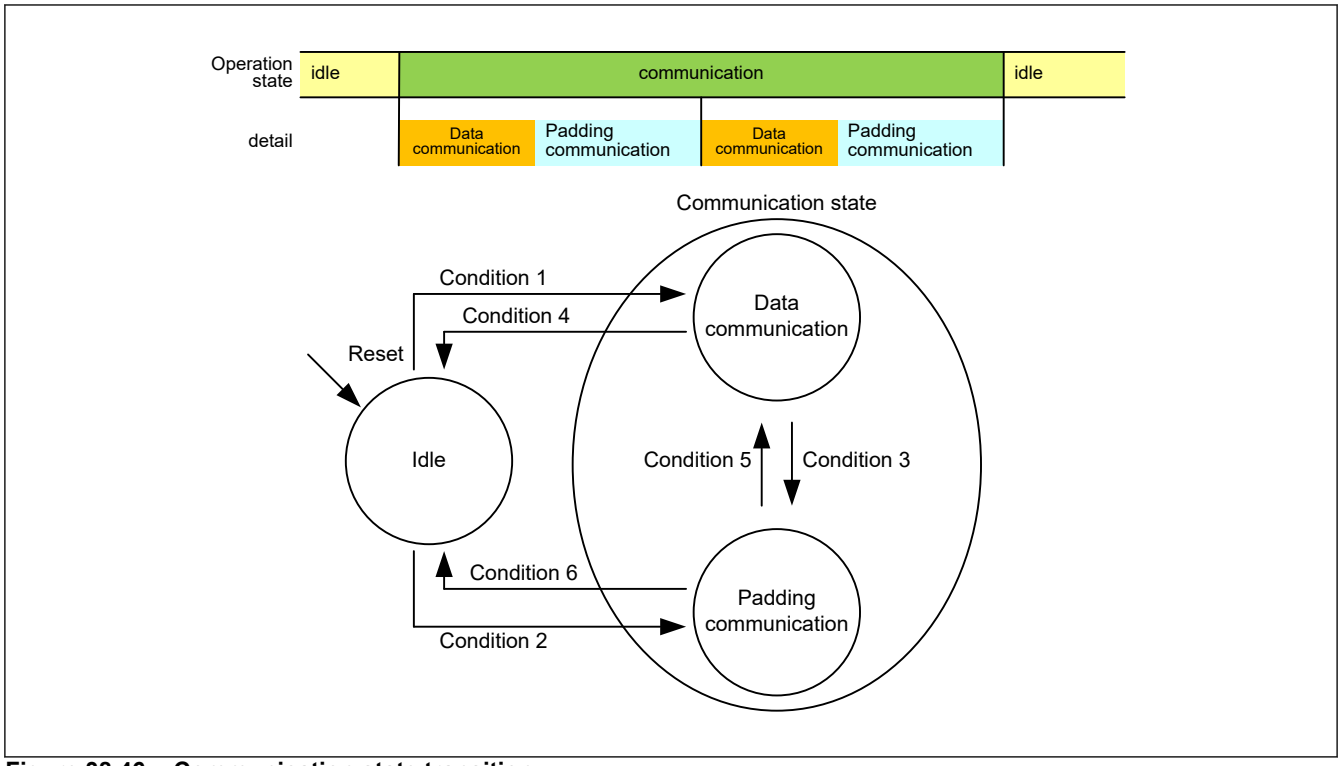


Figure 38.46 Communication state transition

Table 38.15 Condition for communication state transition

Condition Number	Condition for Transition
1	Writing SSICR.TEN = 1 or SSICR.REN = 1 while SSICR.SDTA = 0 or in the setting without padding bits.
2	Writing SSICR.TEN = 1 or SSICR.REN = 1 while SSICR.SDTA = 1 and in the setting with padding bits.
3	The following three conditions are all met: ● SSICR.TEN = 1 or SSICR.REN = 1 ● In the setting with padding bits ● The last bit of the data words has been transferred.
4	Both the following two conditions are met: ● SSICR.SDTA = 1 or without padding bits ● While SSICR.TEN = 0 and SSICR.REN = 0, the last bit of the data words in a frame has been transferred.
5	Transfer of the last padding bit is completed while SSICR.TEN = 1 or SSICR.REN = 1
6	Both the following two conditions are met: ● SSICR.SDTA = 0 and with padding bits ● While SSICR.TEN = 0 and SSICR.REN = 0, the last padding bit has been transferred.

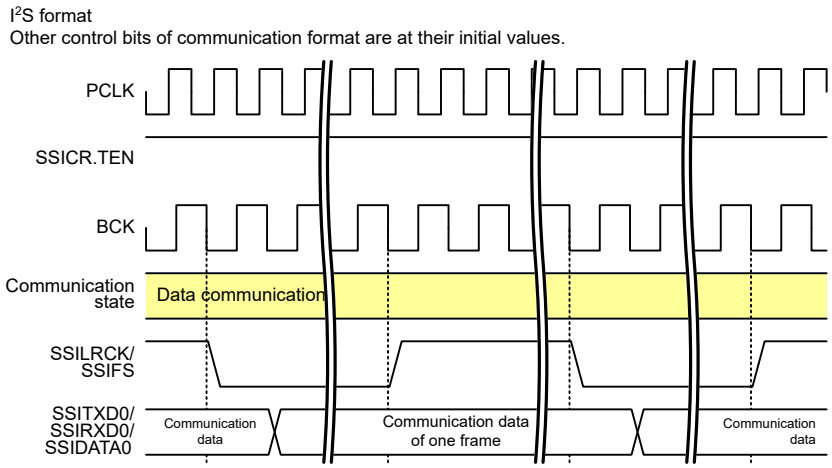
See Table 38.11 for the setting with/without padding bits.

38.7.2.1 Data communication state

In this state, SSIE is during communication. Data of the data word length set with the SSICR.DWL[2:0] bits is transmitted, received, or transmitted and received.

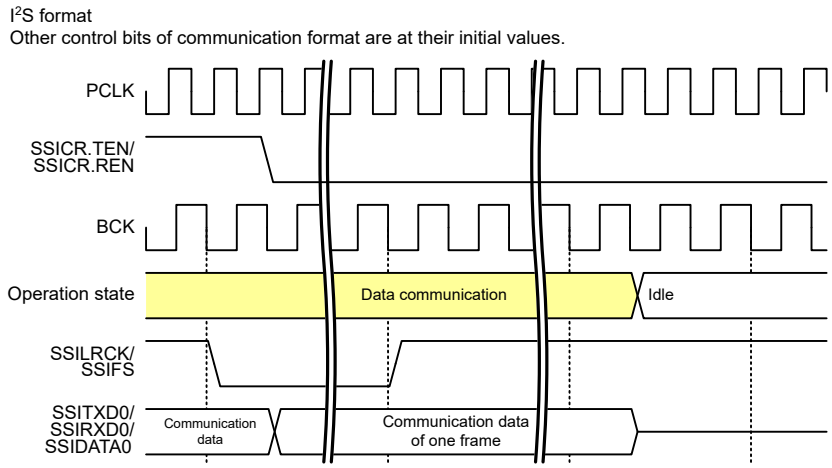
- State Transition in the Setting without Padding Bits

During communication (SSISR.IIRQ = 0), SSIE is during data communication for all the time. By disabling transmission and reception (SSICR.TEN = 0, SSICR.REN = 0), SSIE transits to the idle state. For details, see Figure 38.47 and Figure 38.48.



Note: PCLK = PCLKB

Figure 38.47 Continuation of the data communication



Note: PCLK = PCLKB

Figure 38.48 Halt from the data communication (without padding bits)

- State Transition in the Setting with Padding Bits

When SSIE ends transfer of the last bit of a data word during communication (SSISR.IIRQ = 0), SSIE transitions from the data communication state to the padding communication state in Figure 38.49. Except in the status with SSICR.SDTA = 1 and transmission and reception disabled (SSICR.TEN = 0 and SSICR.REN = 0), SSIE transitions from the data communication state to the idle state when it stops communication in Figure 38.51.

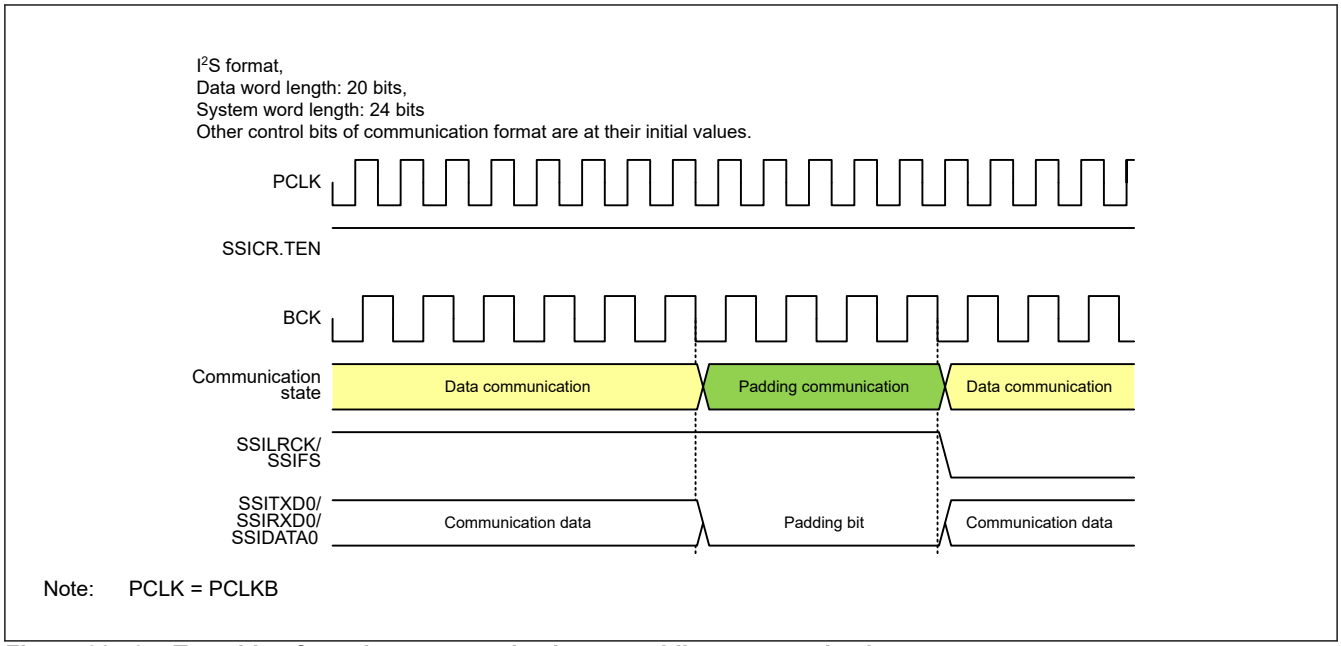


Figure 38.49 Transition from data communication to padding communication

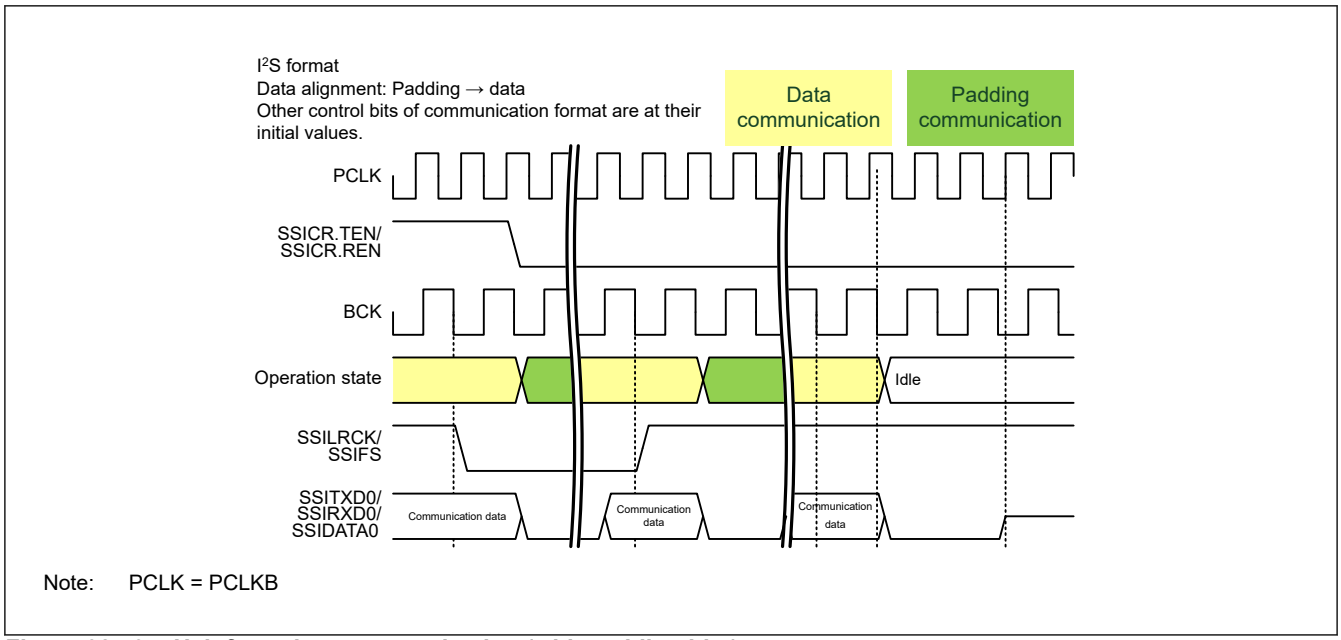

Figure 38.50 Halt from data communication (with padding bits)

38.7.2.2 Padding communication

In this state, SSIE is during communication. The padding bits set with the SSICR.SWL[2:0] bits and SSICR.DWL[2:0] bits are transmitted, received, or transmitted and received.

- State Transition in the Setting with Padding Bits

When SSIE ends transfer of the last padding bit during communication (SSISR.IIRQ = 0), SSIE transitions to the data communication state in Figure 38.49. If SSIE is in the status with SSICR.SDTA = 0 and transmission and reception disabled (SSICR.TEN = 0 and SSICR.REN = 0), SSIE transitions from the padding communication state to the idle state when it stops communication in Figure 38.51.

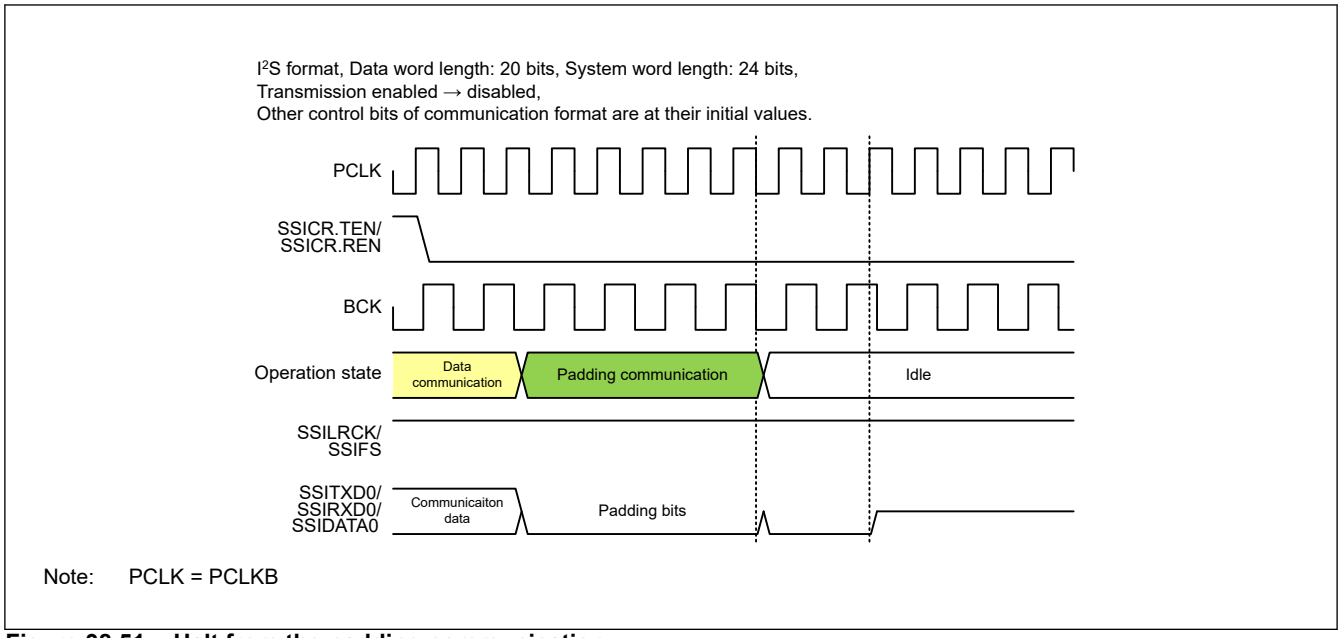

Figure 38.51 Halt from the padding communication

38.8 Communication Operation

Figure 38.52 shows the communication flow of SSIE.

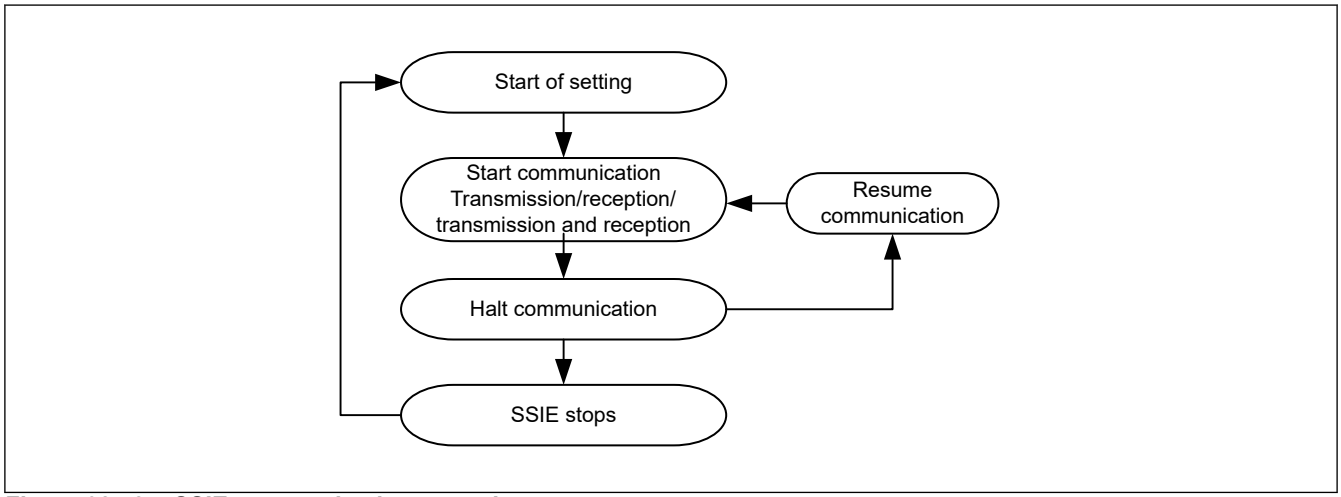

Figure 38.52 SSIE communication operation

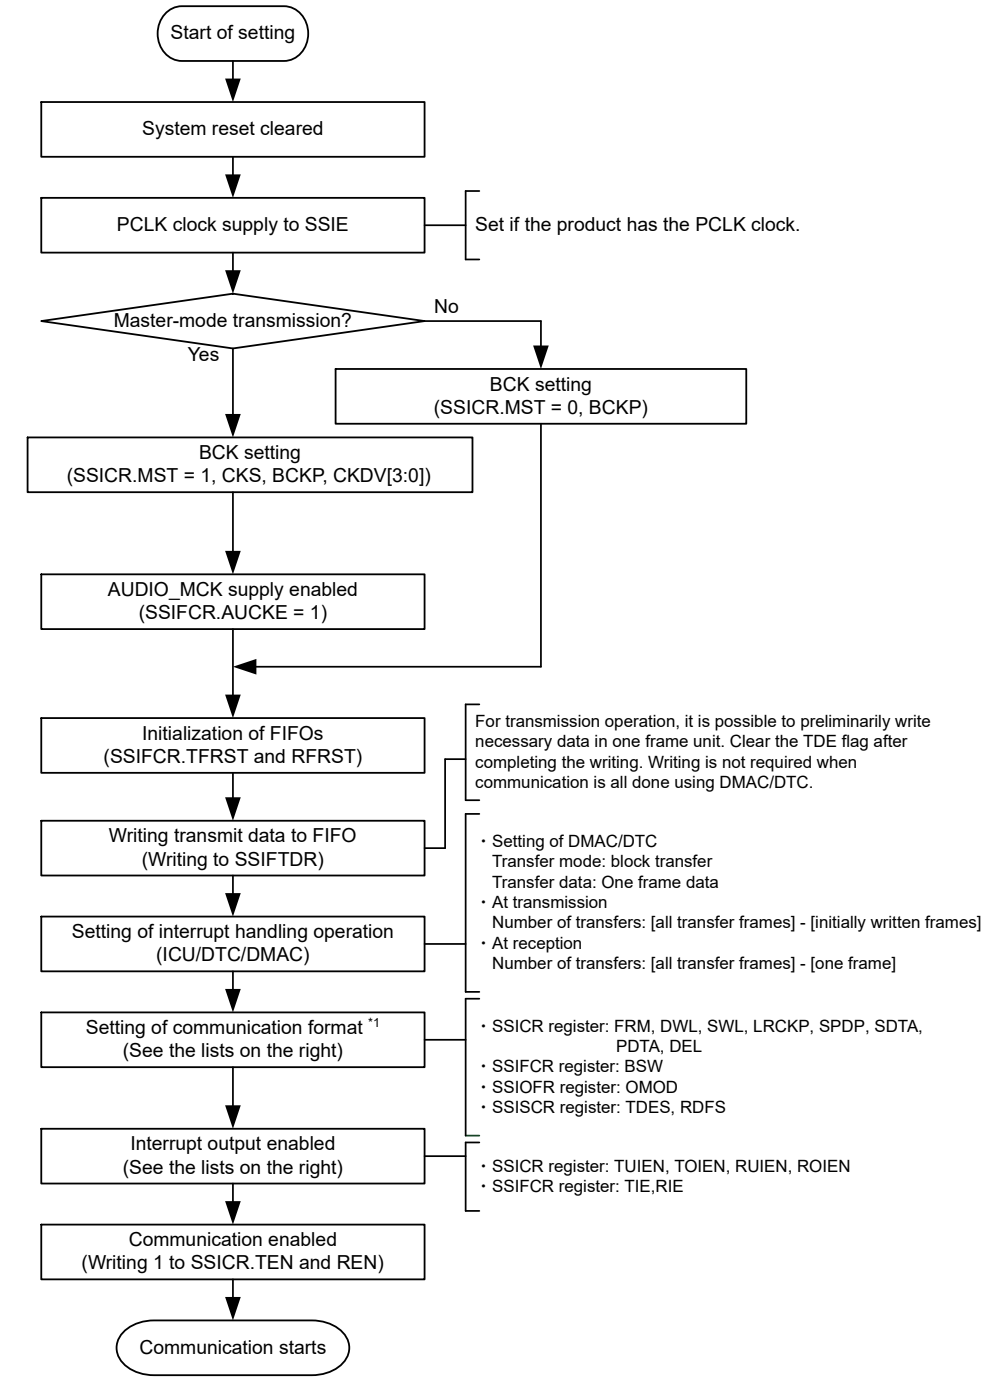
The procedure of each operation is described from section 38.8.1. Start Communication to section 38.8.7. Resume Communication.

38.8.1 Start Communication

This section describes how to start communication of SSIE. Figure 38.53 shows the procedure to start communication. Be sure to follow the procedure. See section 38.8.2. Transmission for transmission operation and section 38.8.3. Reception for reception operation.



Note: PCLK = PCLKB
Note 1. Set SSICR.MUEN, SSIOFR.BCKASTP, and SSIOFR.LRCONT after completing the setting of the communication format.

Figure 38.53 Procedure to start communication (CPU operation procedure)

SSIE can perform continuous communication based on interrupts by the DTC/DMAC. For transmission, write 1 to SSIFCR.TIE, SSICR.TUIEN, and SSICR.TOIEN. For reception, write 1 to SSIFCR.RIE, SSICR.RUIEN, and SSICR.ROIEN.

38.8.2 Transmission

The transmission procedure in Figure 38.54 must be followed throughout a transmission operation.

After transmission is enabled (SSICR.TEN = 1 and SSICR.REN = 0), SSIE starts transmission when a start trigger is generated by SSILRCK/SSIFS with the serial data for at least a frame contained in the transmit FIFO data register

(SSIFTDR). SSIE outputs a transmit data empty interrupt to the DTC/DMAC according to the TDE setting condition (SSISCR.TDES) and the status of transmit data empty interrupt enable (SSIFCR.TIE) bit specified in the communication start procedure. This interrupt requests writing to the transmit FIFO data register (SSIFTDR). In the communication start procedure, specify writing to the transmit FIFO data register (SSIFTDR) as the DTC/DMAC operation in response to the transmit data empty interrupt. With this setting, SSIE can continuously transmit data not through the CPU. The transmit data empty interrupt is generated when the free space size of transmit FIFO data register reaches the value set in SSISCR.TDES. The number of times of writing must be specified in accordance with the free space size of the transmit FIFO data register indicated by the transmit data empty interrupt. If an error occurs, perform the error-handling procedure as instructed in the communication stop procedure.

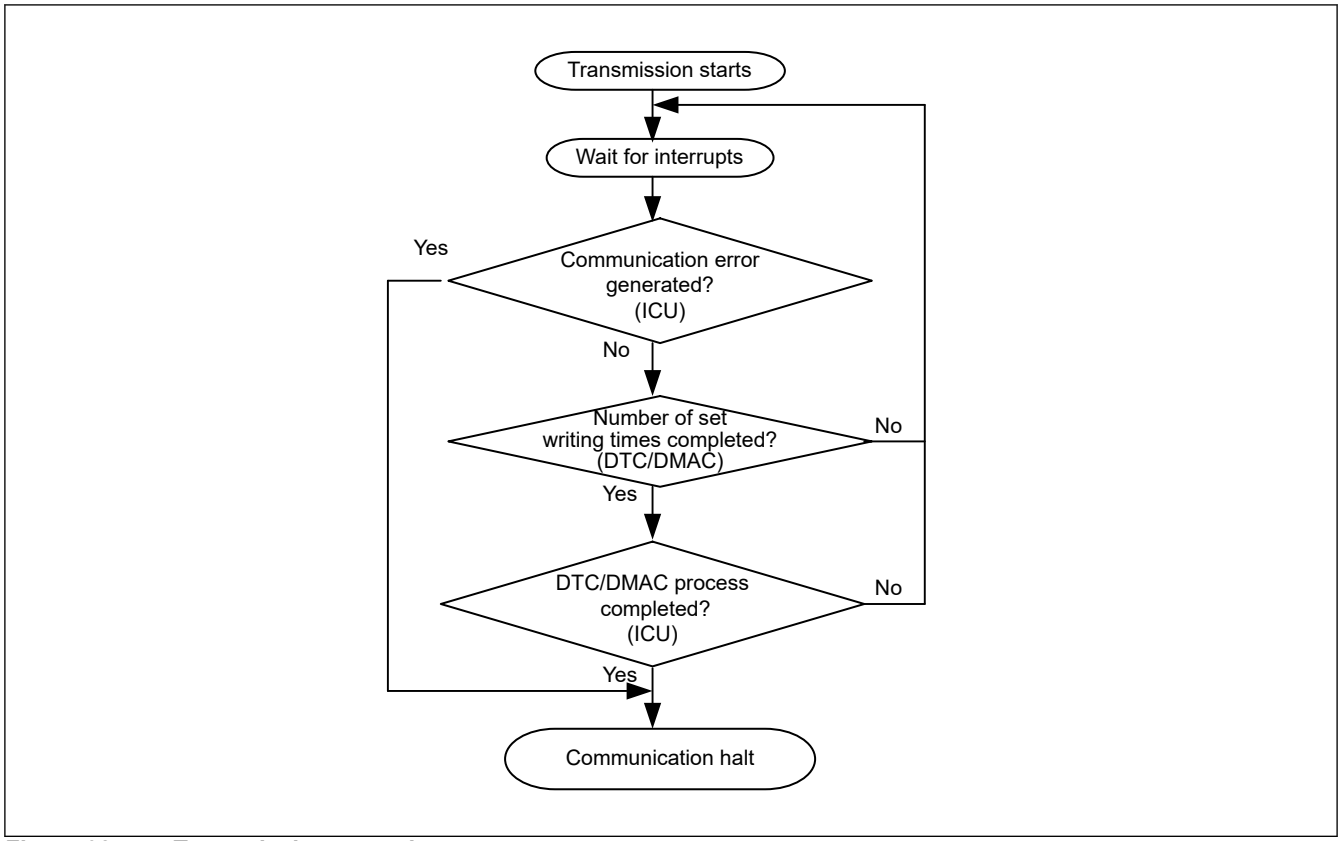


Figure 38.54 Transmission procedure

Note: The communication flow defined in SSIE uses the DTC/DMAC. If you do not use the DTC/DMAC, perform polling of the value 1 of SSIFSR.TDE to write data to SSIFTDR. The number of times of writing data to SSIFTDR by detecting the value 1 of SSIFSR.TDE must be in accordance with the free space size of the transmit FIFO data register specified by SSISCR.TDES. After as much transmit data as the free space size is written to SSIFTDR, the SSIFSR.TDE flag must be cleared. Continuous transmission is enabled by repeating data writing. If the SSIFSR.TDE flag is not cleared, the flag is not cleared automatically.

38.8.3 Reception

The reception procedure in Figure 38.55 must be followed throughout a reception operation.

After reception is enabled (SSICR.TEN = 0 and SSICR.REN = 1), SSIE starts reception when a start trigger is generated by SSILRCK/SSIFS. SSIE outputs a receive data full interrupt to the DTC/DMAC according to the RDF setting condition (SSISCR.RDFS) and the status of receive data full interrupt enable (SSIFCR.RIE) bit specified in the communication start procedure. This interrupt requests data reading from the receive FIFO data register (SSIFRDR). In the communication start procedure, specify reading from the receive FIFO data register (SSIFRDR) as the DTC/DMAC operation in response to the receive data full interrupt. With this setting, SSIE can continuously read data not through the CPU. The receive data full interrupt is generated when data as much as the capacity of receive FIFO data register has been stored. The number of times of reading must be specified in accordance with the data size of the receive FIFO data register indicated by the receive data full interrupt. If an error occurs, perform the error-handling procedure as instructed in the communication stop procedure.

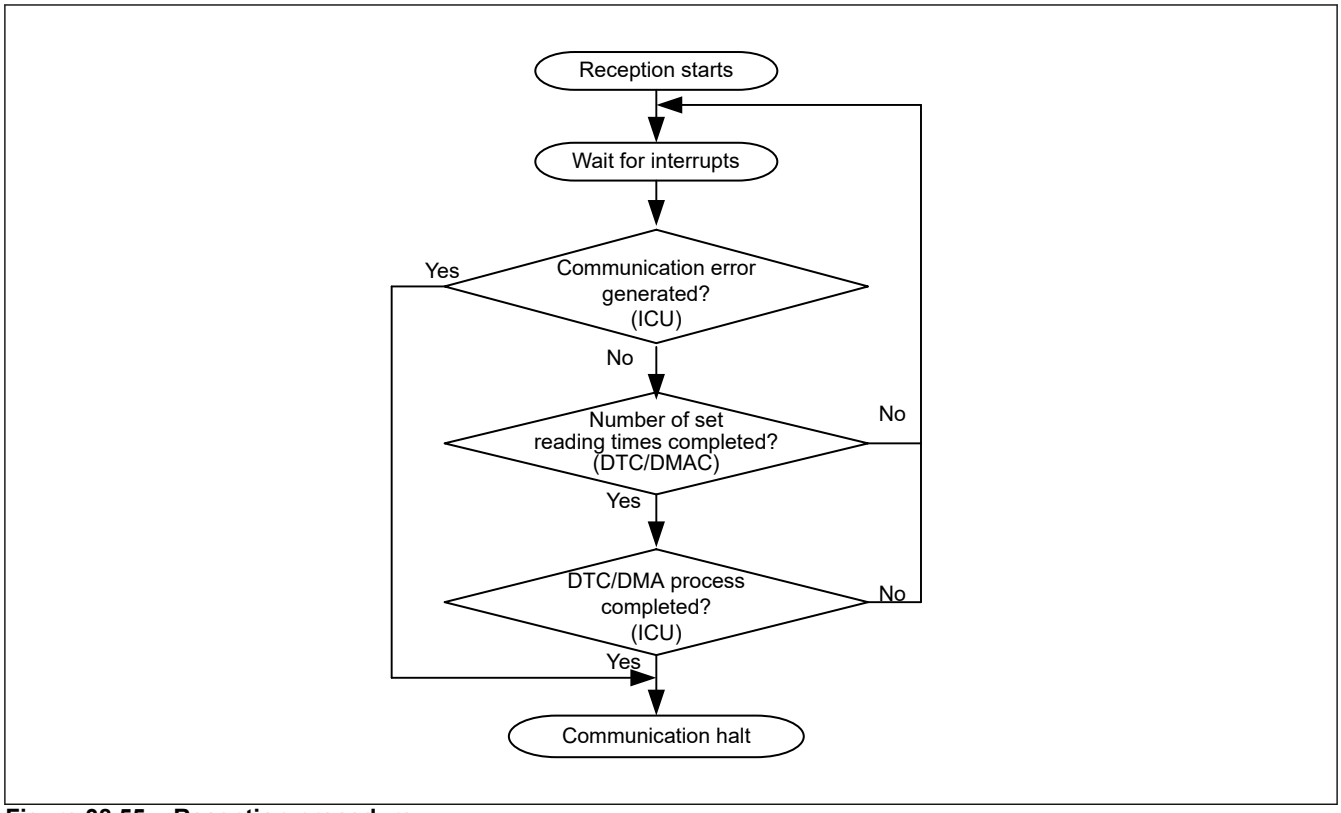

Figure 38.55 Reception procedure

Note: The communication flow defined in SSIE uses the DTC/DMAC. If you do not use the DTC/DMAC, perform polling of the value 1 of SSIFSR.RDF to read data from SSIFRDR. The number of times of reading data from SSIFRDR by detecting the value 1 of SSIFSR.RDF must be in accordance with the receive data storage capacity of the receive FIFO data register specified by SSISCR.RDFS. After received data is read from SSIFRDR, the SSIFSR.RDF flag must be cleared. Continuous reception is enabled by repeating data reading. If the SSIFSR.RDF flag is not cleared, the flag is not cleared automatically.

38.8.4 Transmission and Reception

After transmission and reception are enabled (SSICR.TEN = 1 and SSICR.REN = 1), SSIE starts transmission and reception when a start trigger is generated by SSILRCK/SSIFS with the serial data for at least a frame contained in the transmit FIFO data register (SSIFTDR). SSIE can continuously transmit and receive data by performing the procedures described in section 38.8.2. Transmission and section 38.8.3. Reception, respectively. For how to stop transmission and reception, see section 38.8.5. Halt Communication.

38.8.5 Halt Communication

This section describes how to halt communication of SSIE. Figure 38.56 shows the procedure to halt communication. Be sure to follow the procedure.

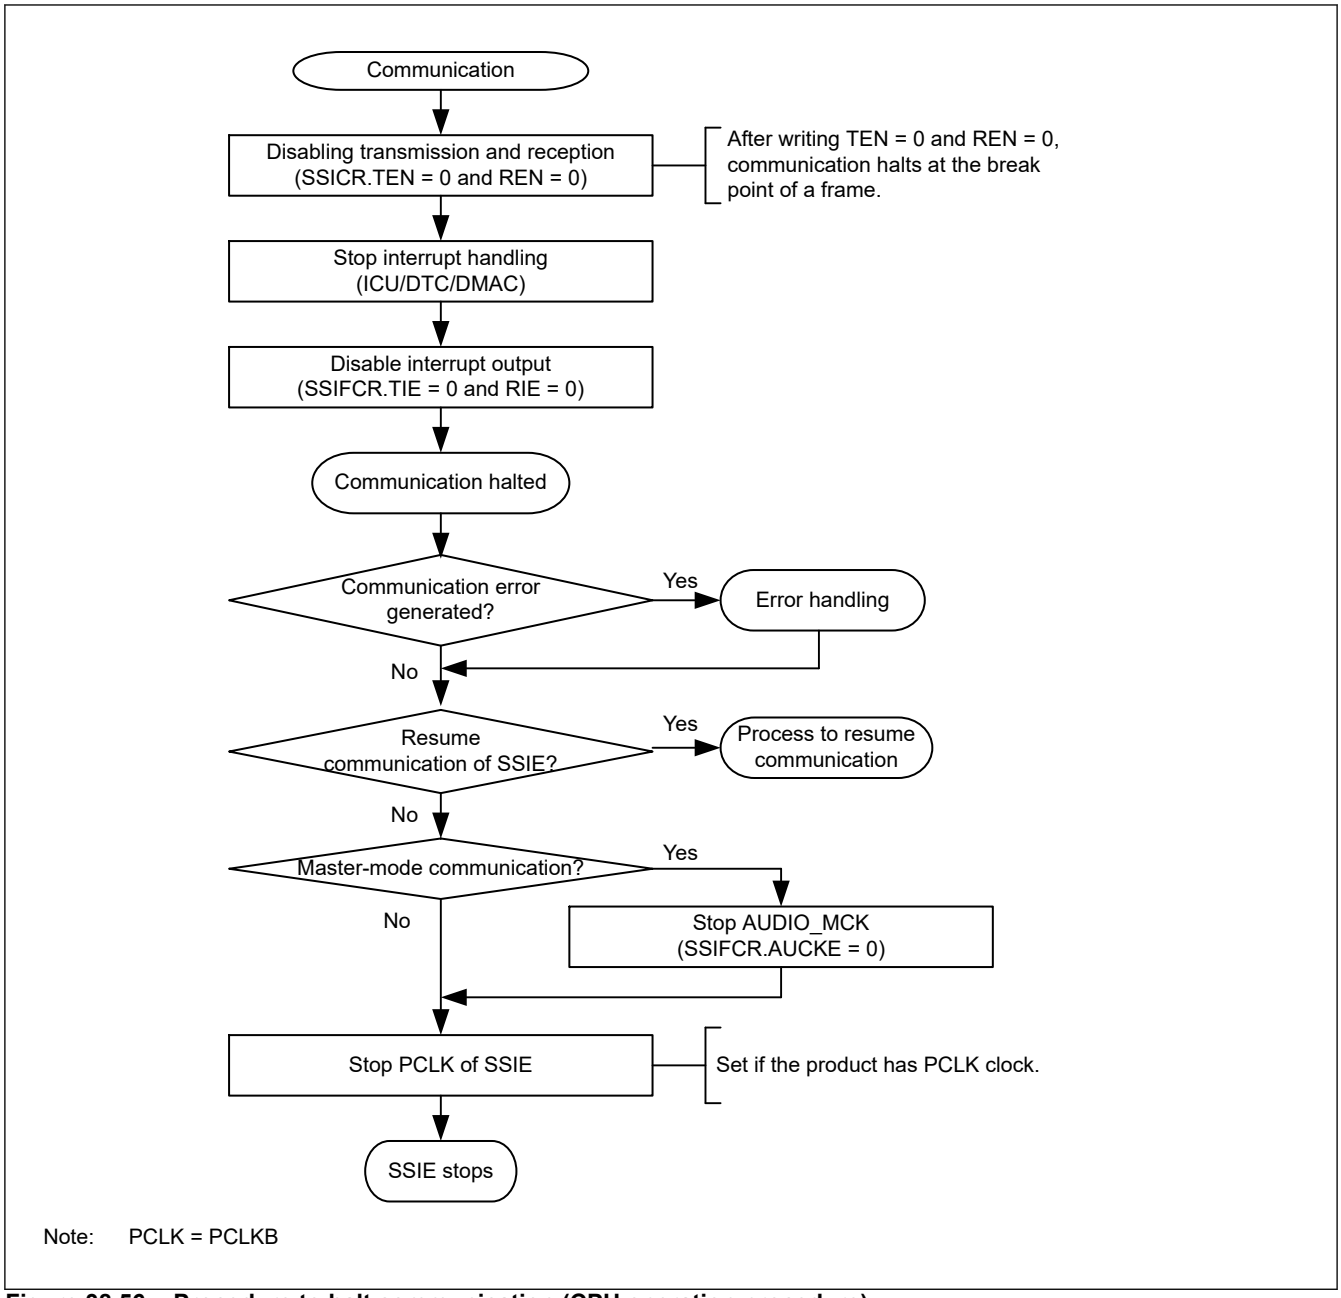

Figure 38.56 Procedure to halt communication (CPU operation procedure)

To halt the communication of SSIE, supply of the following clocks are required until the SSISR.IIRQ bit indicates an idle state.

- Input clock from the SSIBCK pin when SSICR.MST = 0
- AUDIO_MCK when SSICR.MST = 1
  To resume communication of SSIE in the previous setting, see section 38.8.7. Resume Communication.

Note: When communication of SSIE is halted according to the procedure to halt communication in Figure 38.56, resume communication according to the procedure to resume communication in Figure 38.58.

38.8.6 Error Handling

SSIE has the following four errors.

- Transmit underflow error
- Transmit overflow error
- Receive underflow error

- Receive overflow error.

When an underflow error or overflow error is generated, SSIE need to be restarted. Follow the procedure to halt communication in Figure 38.56 and error-handling procedure in Figure 38.57.

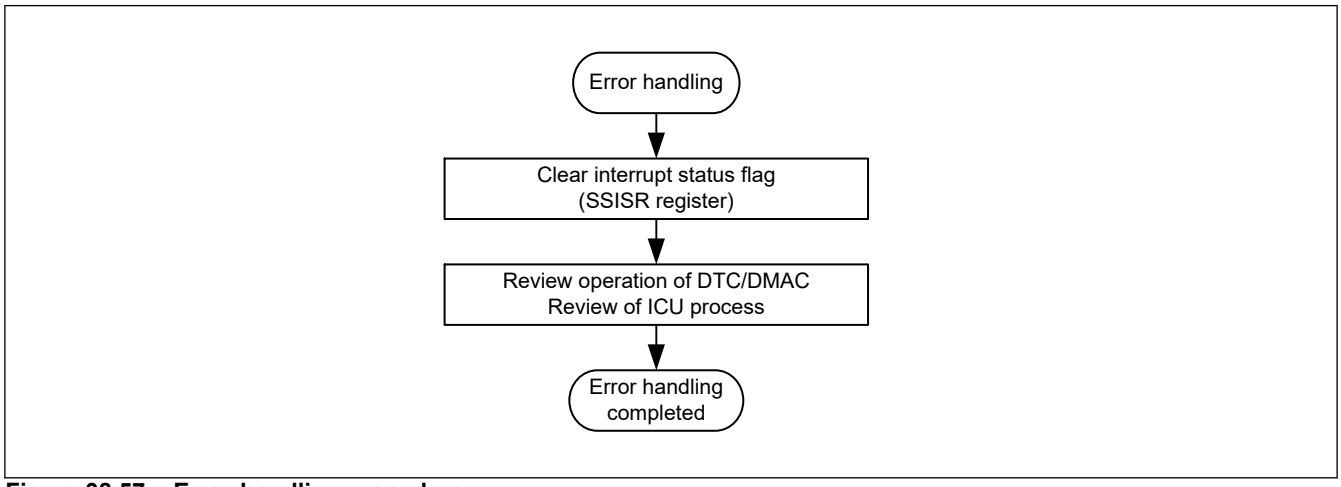

Figure 38.57 Error-handling procedure

Four error operations are described as follows. When the interrupt output enable bit of the SSICR register is enabled and error flags are set, an error interrupt is generated. See section 38.4.2. SSISR : Status Register for the setting conditions of error flags.

(1) Transmit Underflow Error

If a transmit underflow error occurs, review the number of times of writing data to the transmit FIFO data register (SSIFTDR) in response to a transmit data empty interrupt. After a transmit underflow error occurs, SSIE outputs 0s as data. To normally output the serial data written to the transmit FIFO data register (SSIFTDR) to the SSITXD0/SSIDATA0 pin, follow the procedure to halt communication in Figure 38.56 and error-handling procedure in Figure 38.57. After this error occurs, serial data is consumed as usual. If you resume communication, write the serial data from the beginning.

(2) Transmit Overflow Error

If a transmit overflow error occurs, review the number of times of writing data to the transmit FIFO data register (SSIFTDR) in response to transmit data empty interrupts. The serial data written to the transmit FIFO data register (SSIFTDR) that caused the transmit overflow error becomes invalid. This error can occur regardless of whether a transmission operation is being done. To recover from the error, follow the procedure to halt communication in Figure 38.56 and error-handling procedure in Figure 38.57. When you resume communication, deal with the invalid serial data appropriately.

(3) Receive Underflow Error

If a receive underflow error occurs, review the number of times of reading data from the receive FIFO data register (SSIFRDR) in response to receive data full interrupts. The values read from the receive FIFO data register (SSIFRDR) that caused the receive underflow error are undefined. This error can occur regardless of whether a reception operation is being done. To recover from the error, follow the procedure to halt communication in Figure 38.56 and error-handling procedure in Figure 38.57.

(4) Receive Overflow Error

If a receive overflow error occurs, review the number of times of reading data from the receive FIFO data register (SSIFRDR) in response to receive data full interrupts. The receive data that caused the receive overflow error cannot be stored in the receive FIFO data register (SSIFRDR). To recover from the error, follow the procedure to halt communication in Figure 38.56 and error-handling procedure in Figure 38.57.

38.8.7 Resume Communication

When you resume the communication using SSIE, follow the communication resume procedure in Figure 38.58. The communication resume procedure is designed on the assumption that you resume the communication stopped by the

communication stop procedure without changing any settings. If you want to change clock and slave/master settings, use and follow the communication start procedure in Figure 38.53. For details about the transmission operation and reception operation after starting communication, see section 38.8.2. Transmission and section 38.8.3. Reception, respectively.

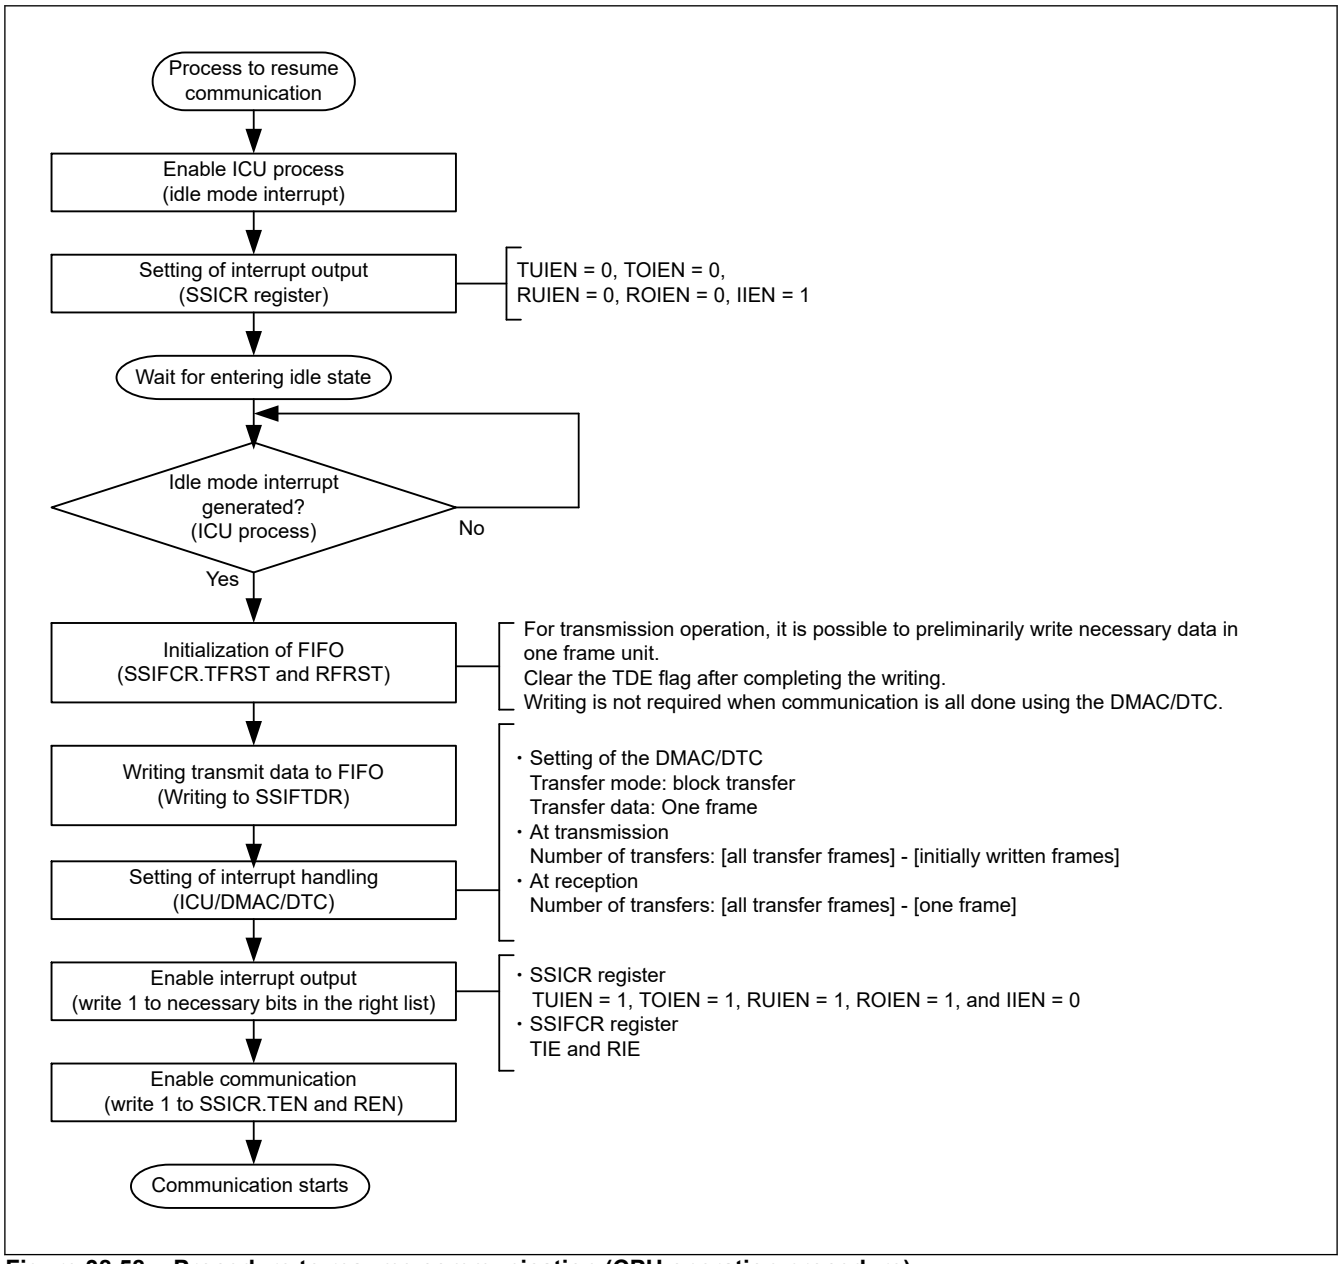

Figure 38.58 Procedure to resume communication (CPU operation procedure)

38.9 Interrupts

Table 38.16 lists the interrupt sources. Set enable/disable of interrupt output of each source with the TUIEN, TOIEN, RUIEN, ROIEN, and IIEN bits in the SSICR register and the TIE and RIE bits in the SSIFCR register.

Table 38.16 SSIE interrupt sources

Channel	Interrupt source	Description	Interrupt flag	DMAC/DTC activation
SSIE0	SSIE0_SSIF	• Transmit underflow interrupt • Transmit overflow interrupt • Receive underflow interrupt • Receive overflow interrupt • Idle interrupt	SSISR.TUIRQ SSISR.TOIRQ SSISR.RUIRQ SSISR.ROIRQ SSISR.IIRQ	Not possible
	SSIE0_SSIRXI	Receive data full interrupt	SSIFSR.RDF	Possible
	SSIE0_SSITXI	Transmit data empty interrupt	SSIFSR.TDE	Possible

38.9.1 SSIE0_SSIF Interrupt

This interrupt source combines five interrupts. Enable output of necessary interrupts before using SSIE. The five interrupts are operated by using the flags assigned to individual interrupts and interrupt output enable bits. To clear an interrupt, set the interrupt enable to 0 or clear the interrupt flag to 0.

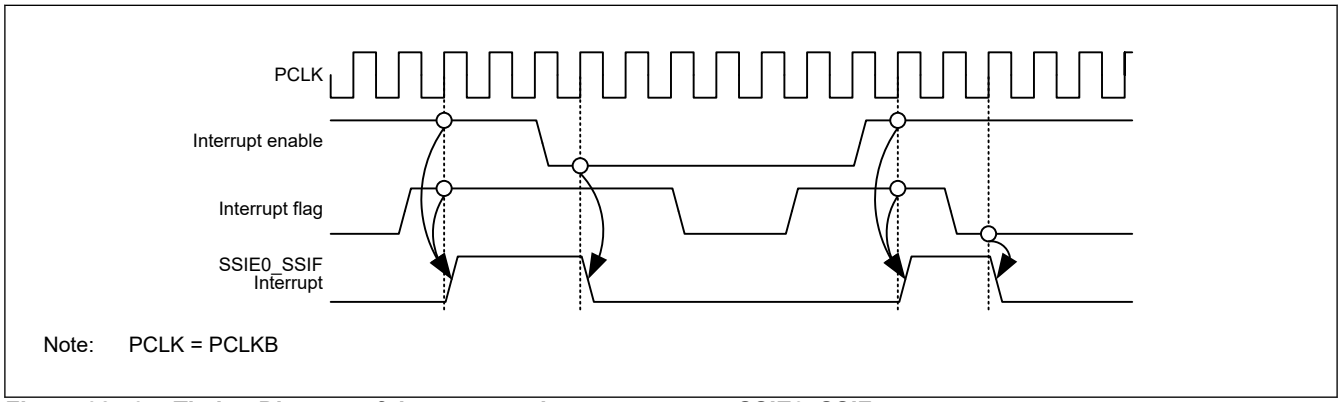

Figure 38.59 Timing Diagram of the common interrupt source, SSIE0_SSIF

- Transmit underflow interrupt

As the transmit underflow interrupt, SSISR.TUIRQ is output while SSICR.TUIEN = 1. When you use SSIE for transmission, enable the output of this interrupt (SSICR.TUIRQ = 1). If this interrupt occurs, follow instructions in the procedure to halt communication in Figure 38.56 and error-handling procedure in Figure 38.57.

- Transmit overflow interrupt

As the transmit overflow interrupt, SSISR.TOIRQ is output while SSICR.TOIRQ = 1. When you use SSIE for transmission, enable the output of this interrupt (SSICR.TOIRQ = 1). If this interrupt occurs, follow instructions in the procedure to halt communication in Figure 38.56 and error-handling procedure in Figure 38.57.

- Receive underflow interrupt

As the receive underflow interrupt, SSISR.RUIRQ is output while SSICR.RUIRQ = 1. When you use SSIE for reception, enable the output of this interrupt (SSICR.RUIRQ = 1). If this interrupt occurs, follow instructions in the procedure to halt communication in Figure 38.56 and error-handling procedure in Figure 38.57.

- Receive overflow interrupt

As the receive overflow interrupt, SSISR.ROIRQ is output while SSICR.ROIRQ = 1. When you use SSIE for reception, enable the output of this interrupt (SSICR.ROIRQ = 1). If this interrupt occurs, follow instructions in the procedure to halt communication in Figure 38.56 and error-handling procedure in Figure 38.57.

- Idle mode interrupt

As the idle mode interrupt, SSISR.IIRQ is output while SSICR.IIEN = 1. This interrupt is used to make sure that communication has stopped fully.

38.9.2 SSIE0_SSITXI Interrupt

The transmit data empty interrupt is a pulse interrupt that is output when the following condition is met:

- SSIFCR.TIE = 1 and SSIFSR.TDE = 1
  SSIE operation: When the value of SSIFSR.TDE changes from 0 to 1 while the value of SSIFCR.TIE is 1
  CPU instruction: When the value of SSIFCR.TIE changes from 0 to 1 while the value of SSIFSR.TDE is 1

This interrupt is subject to the interrupt suppression function. If an interrupt condition for this interrupt occurs when the DTC/DMAC is busy (when the DTC/DMAC cannot accept interrupts), the interrupt suppression function holds the output of this interrupt. The held interrupt will be output after the DTC/DMAC is enabled to accept interrupts. For details, see Figure 38.60.

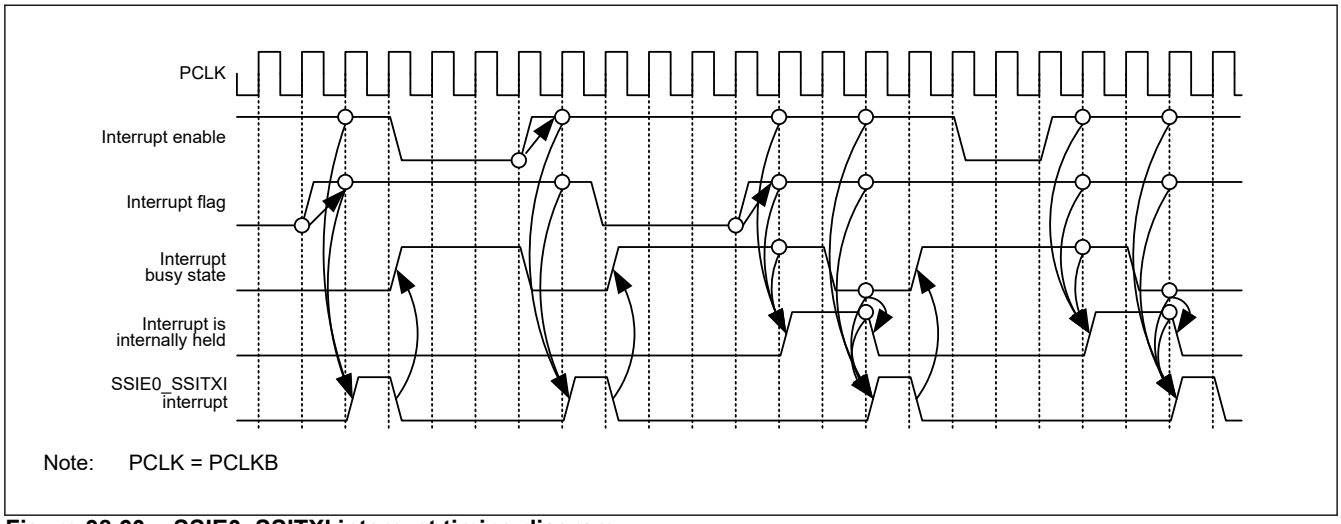

Figure 38.60 SSIE0_SSITXI interrupt timing diagram

38.9.3 SSIE0_SSIRXI Interrupt

The receive data full interrupt is a pulse interrupt that is output when the following condition is met:

- SSIFCR.RIE = 1 and SSIFSR.RDF = 1.
  SSIE operation: When the value of SSIFSR.RDF changes from 0 to 1 while the value of SSIFCR.RIE is 1
  CPU instruction: When the value of SSIFCR.RIE changes from 0 to 1 while the value of SSIFSR.RDE is 1

This interrupt is subject to the interrupt suppression function. If an interrupt condition for this interrupt occurs when the DTC/DMAC is busy (when the DTC/DMAC cannot accept interrupts), the interrupt suppression function holds the output of this interrupt. The held interrupt will be output after the DTC/DMAC is enabled to accept interrupts. The behavior of this interrupt is the same as the behavior shown in Figure 38.60.

38.10 Software Resets

SSIE has three software reset bits to reset its states.

- SSIE software reset (SSIFCR.SSIRST)
- Transmit FIFO data register reset (SSIFCR.TFRST)
- Receive FIFO data register reset (SSIFCR.RFRST).

This section describes the procedures for the three types of software resets.

38.10.1 Software Reset Procedure

(1) SSIE Software Reset

For the SSIE software reset bit (SSIFCR.SSIRST), follow the procedure shown in Figure 38.61. After a reset, the same setting is applied when it is resumed. To change the settings of clocks and slave/master mode, follow the procedure to start

communication in Figure 38.53. See section 38.8.2. Transmission and section 38.8.3. Reception respectively for transmission and reception after communication is resumed.

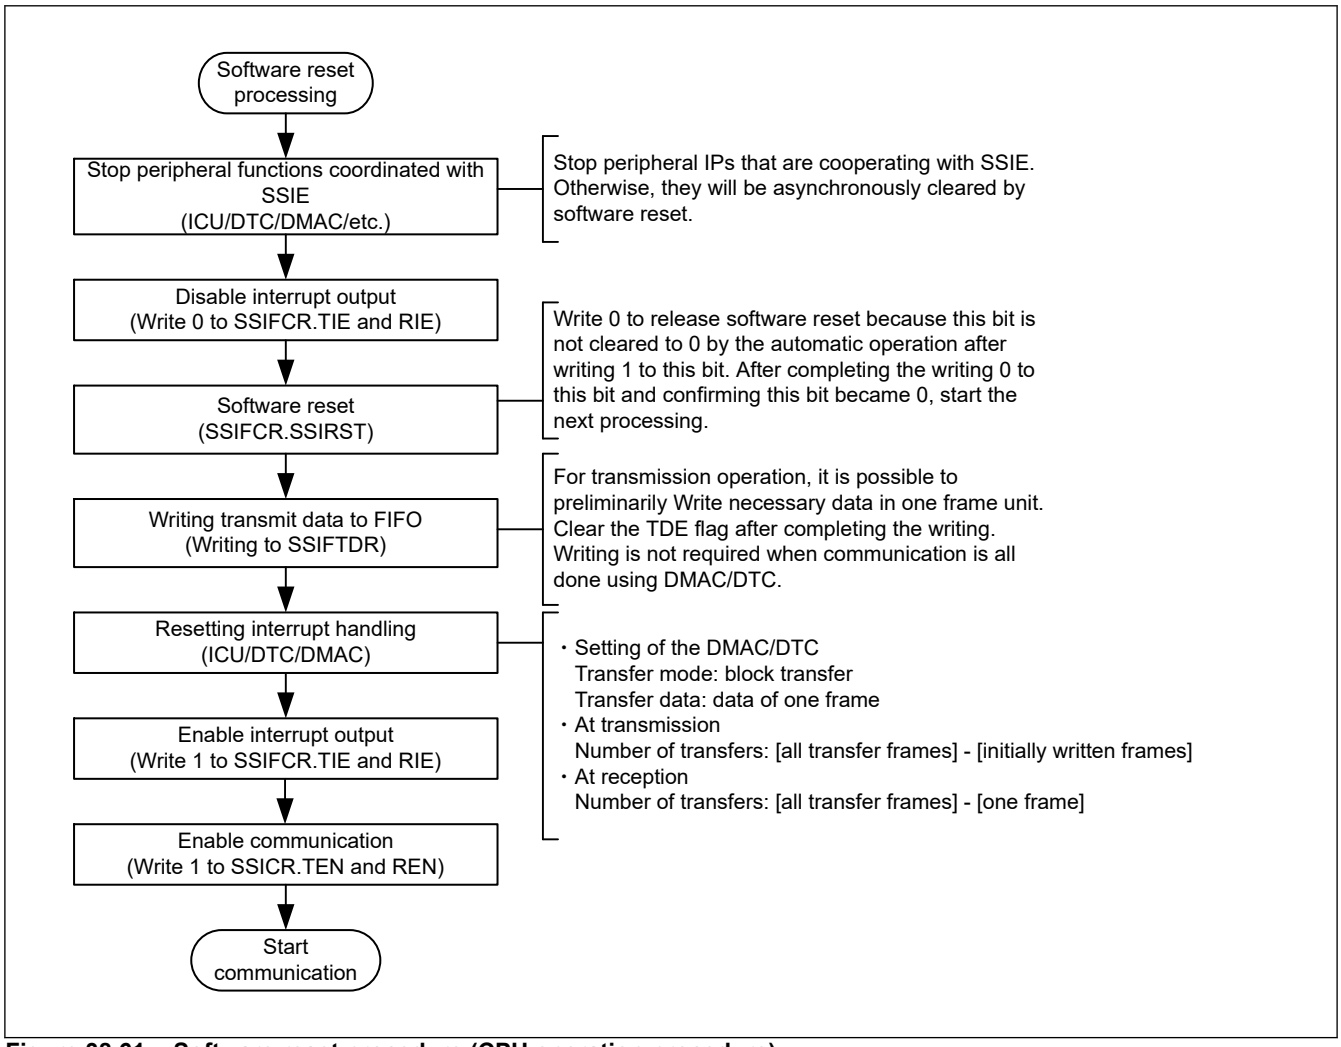

Figure 38.61 Software reset procedure (CPU operation procedure)

(2) Transmit FIFO data register reset

To perform a transmit FIFO data register reset, follow instructions in the procedure to start communication in Figure 38.53 and procedure to resume communication in Figure 38.58.

(3) Receive FIFO data register reset

To perform a receive FIFO data register reset, follow instructions in the procedure to start communication in Figure 38.53 and procedure to resume communication in Figure 38.58.

38.11 Notes

38.11.1 Notes for Slave-mode Communication

38.11.1.1 SSIBCK control

In slave-mode communication (SSICR.MST = 0), SSIE needs supply of SSIBCK. To stop BCK on the master side, make sure that SSIE is in the idle state (SSISR.IIRQ = 1). If BCK is stopped before SSIE becomes idle, take the procedure to start communication in Figure 38.53 or wait for an idle state by taking the procedure to resume communication in Figure 38.58.

38.11.1.2 SSILRCK/SSIFS pin

SSIE has the SSILRCK/SSIFS pin, which indicates the synchronization of communication. When SSIE is in slave mode (SSICR.MST = 0), the communication format SSIE uses must match that of the other-party device to communicate. SSIE uses the signal input by the SSILRCK/SSIFS pin only as a trigger to start communication.

38.11.2 Notes for Master-mode Communication

38.11.2.1 AUCKE control

In master-mode communication (SSICR.MST = 1), SSIE operates with the audio clock (AUDIO_MCK). To stop SSIE completely, make sure that SSIE is in the idle state (SSISR.IIRQ = 1) and then write 0 to SSIFCR.AUCKE.

38.11.2.2 LRCONT control

To stop the output to the SSILRCK/SSIFS pin with SSIOFR.LRCONT when SSIE is in the idle state in master-mode communication (SSICR.MST = 1), note the following: The output stops when the value of the SSIOFR.LRCONT bit is changed from 1 to 0. Make sure that the other-party device is not affected. For details, see Figure 38.44.

38.11.2.3 BCKASTP control

To stop the output to the SSIBCK pin with SSIOFR.BCKASTP in master-mode communication (SSICR.MST = 1) and while SSIE is in the idle state, note the following: The output stops when the value of the SSIOFR.BCKASTP bit is changed from 0 to 1. So, make sure that the other-party device is not affected. For details, see Figure 38.45.

The BCKASTP bit cannot be used when the other-party device (which is a slave) requires the clock output from the SSIBCK pin before and during communication.

38.11.3 Notes for Communication Flow

38.11.3.1 When an error interrupt is generated

SSIE has the following four errors.

- Transmit underflow error
- Transmit overflow error
- Receive underflow error
- Receive overflow error

When an underflow error or overflow error is generated, SSIE need to be restarted. Follow the procedure to halt communication in Figure 38.56 and error-handling procedure in Figure 38.57.

(1) Transmit Underflow Error

If a transmit underflow error occurs, review the number of times of writing data to the transmit FIFO data register (SSIFTDR) in response to a transmit data empty interrupt. After a transmit underflow error occurs, SSIE outputs 0s as data. To normally output the serial data written to the transmit FIFO data register (SSIFTDR) to the SSITXD0/SSIDATA0 pin, follow the procedure to halt communication in Figure 38.56 and error-handling procedure in Figure 38.57. After this error occurs, serial data is consumed as usual. If you resume communication, write the serial data from the beginning.

(2) Transmit Overflow Error

If a transmit overflow error occurs, review the number of times of writing data to the Transmit FIFO Data Register (SSIFTDR) in response to transmit data empty interrupts. The serial data written to the Transmit FIFO Data Register (SSIFTDR) that caused the transmit overflow error becomes invalid. This error can occur regardless of whether a transmission operation is being done. To recover from the error, follow the procedure to halt communication in Figure 38.56 and error-handling procedure in Figure 38.57. When you resume communication, deal with the invalid serial data appropriately.

(3) Receive Underflow Error

If a receive underflow error occurs, review the number of times of reading data from the receive FIFO data register (SSIFRDR) in response to receive data full interrupts. The values read from the receive FIFO data register (SSIFRDR) that caused the receive underflow error are undefined. This error can occur regardless of whether a reception operation is being done. To recover from the error, follow the procedure to halt communication in Figure 38.56 and error-handling procedure in Figure 38.57.

(4) Receive Overflow Error

If a receive overflow error occurs, review the number of times of reading data from the receive FIFO data register (SSIFRDR) in response to receive data full interrupts. The receive data that caused the receive overflow error cannot be stored in the receive FIFO data register (SSIFRDR). To recover from the error, follow the procedure to halt communication in Figure 38.56 and error-handling procedure in Figure 38.57.

38.11.3.2 Transmit data empty interrupt

The communication flow defined in SSIE uses the DTC/DMAC. If you do not use the DTC/DMAC, perform polling of the value 1 of SSIFSR.TDE to write data to SSIFTDR. The number of times of writing data to SSIFTDR by detecting the value 1 of SSIFSR.TDE must be in accordance with the free space size of the transmit FIFO data register specified by SSISCR.TDES. After as much transmit data as the free space size is written to SSIFTDR, the SSIFSR.TDE flag must be cleared. Continuous transmission is enabled by repeating data writing. If the SSIFSR.TDE flag is not cleared, the flag is not cleared automatically.

38.11.3.3 Receive data full interrupt

The communication flow defined in SSIE uses the DTC/DMAC. If you do not use the DTC/DMAC, perform polling of the value 1 of SSIFSR.RDF to read data from SSIFRDR. The number of times of reading data from SSIFRDR by detecting the value 1 of SSIFSR.RDF must be in accordance with the receive data storage capacity of the receive FIFO data register specified by SSISCR.RDFS. After received data is read from SSIFRDR, the SSIFSR.RDF flag must be cleared. Continuous reception is enabled by repeating data reading. If the SSIFSR.RDF flag is not cleared, the flag is not cleared automatically.

38.11.3.4 Switching transfer modes

1. For state transition from transmission, reception, and transmission and reception, disable transmission and reception (SSICR.TEN = 0, SSICR.REN = 0).
2. Confirm it is in the idle state (SSISR.IIRQ = 1).
3. In the idle state, set the SSICR.TEN bit or the SSICR.REN bit again and resume transfer.

38.11.3.5 Resume communication after halting SSIE

When communication of SSIE is halted according to the procedure to halt communication in Figure 38.56, resume communication according to the procedure to resume communication in Figure 38.58.

38.11.4 Write Access Restriction

38.11.4.1 SSICR register

If the TEN bit or REN bit is rewritten, make sure that the SSISR.IIRQ bit is in the desired status. If the value of the TEN or REN bit is changed by rewriting, subsequent operation is unpredictable. For example, when transmission or reception is enabled, check that SSISR.IIRQ is 0; when transmission or reception is disabled, check that SSISR.IIRQ is 1.

(1) TEN Bit and REN Bit

These bits enable/disable transmission and reception. When 1 is written to one of these bits, the corresponding communication operation starts in synchronization with a start trigger by the SSILRCK/SSIFS signal. For details, see section 38.8.2. Transmission, section 38.8.3. Reception, and section 38.8.4. Transmission and Reception. When 0 is written to this bit, the current communication operation stops at the next frame boundary. To use SSIE for both transmission and reception, always write 1 to these bits together. When stopping the communication using SSIE, always disable both transmission and reception (write 0 to the TEN and REN bits).

38.11.4.2 SSISR register

(1) Clearing TUIRQ and TOIRQ

After communication is enabled (by changing the value of SSICR.TEN bit from 0 to 1), the transmission error flags (TOIRQ and TUIRQ in the SSISR register) are cleared. If, however, the SSISR register is read continuously, the cleared status of the transmission error flags might be unable to be read.

(2) Clearing RUIRQ and ROIRQ

After communication is enabled (by changing the value of SSICR.REN bit from 0 to 1), the reception error flags (RUIRQ and ROIRQ in the SSISR register) are cleared. If, however, the SSISR register is read continuously, the cleared status of the reception error flags might be unable to be read.

38.11.4.3 Communication state

Writing to the bits with orange-shaded area in Table 38.17 is prohibited. If written, the operation performed immediately after writing is not guaranteed.

Table 38.17 Bits protected from writing during communication

Symbol	Address (BASE+)		+0								+1							
			31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

39. SD/MMC Host Interface (SDHI)

39.1 Overview

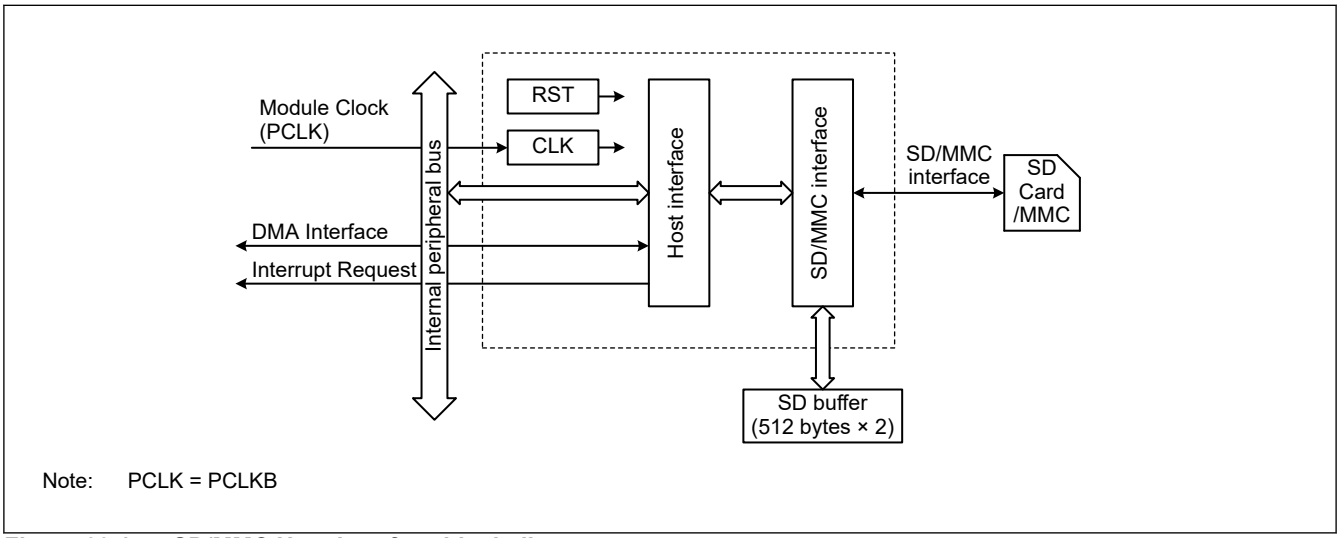
The Secure Digital Host Interface (SDHI) and MultiMediaCard (MMC) Interface provide the functionality required to connect a variety of external memory cards with the MCU. The SDHI supports both 1- and 4-bit buses for connecting different memory cards that support SD, SDHC, and SDXC formats. When developing host devices that are compliant with the SD Specifications, you must comply with the SD Host/Ancillary Product License Agreement (SD HALA).

The MMC interface supports 1-bit, 4-bit, and 8-bit MMC buses that provide eMMC 4.51 (JEDEC Standard JESD 84- B451) device access. This interface also provides backward compatibility and supports for high-speed SDR transfer modes.

Table 39.1 lists the SD/MMC Host Interface specifications and Figure 39.1 shows a block diagram.

Table 39.1 SD/MMC Host Interface specifications

Interface	Parameter	Specifications
SD	SD bus interface	• Compatible with SD memory card and SDIO card • Transfer bus mode selectable from 4-bit wide bus mode or 1-bit default bus mode • Compatible with SD, SDHC, and SDXC formats
SD and MMC shared	SDHI clock frequency	The SDHI clock is generated by dividing PCLKB by 2^n (n = 0 to 9)
	Error check functions	CRC7 (command/response), CRC16 (transfer data)
	Interrupt sources	Card access interrupt (SDHI_MMCn_ACCS), SDIO access interrupt (SDHI_MMCn_SDIO), Card detection interrupt (SDHI_MMCn_CARD) n = (0)
	DMA transfer sources	DMAC and DTC triggerable by the (SDHI_MMCn_ODMSDBREQ (n = 0, 1)) interrupt SD buffer is read and write accessible using the DMAC
	Other functions	• Card detect function • Write protect support
MMC	MMC bus interface	Transfer bus mode selectable from 1-bit, 4-bit, or 8-bit
	Transfer modes	Backward compatible mode or high-speed SDR mode selectable
	Other functions	e.MMC device access supported
TrustZone Filter	Security attribution can be set	



Note: PCLK = PCLKB

Figure 39.1 SD/MMC Host Interface block diagram

Table 39.2 SDHI I/O pins (n = 0) (1 of 2)

Channel	Pin name	I/O	Description
Ch n	SDnCLK	Output	SDHI clock

Table 39.2 SDHI I/O pins (n = 0) (2 of 2)

Channel	Pin name	I/O	Description
	SDnCMD	I/O	Command output, response input
	SDnDAT0	I/O	Data 0 (DAT0)
	SDnDAT1	I/O	Data 1 (DAT1), SDIO interrupt
	SDnDAT2	I/O	Data 2 (DAT2), SDIO Read wait
	SDnDAT3	I/O	Data 3 (DAT3), SD Card detect
	SDnDAT4	I/O	MMC Data 4 (DAT4)
	SDnDAT5	I/O	MMC Data 5 (DAT5)
	SDnDAT6	I/O	MMC Data 6 (DAT6)
	SDnDAT7	I/O	MMC Data 7 (DAT7)
	SDnCD	Input	SD card detection
	SDnWP	Input	SD card write protection

39.2 Register Descriptions

39.2.1 SD_CMD : Command Type Register

Base address: SDHI0 = 0x4009_2000

Offset address: 0x000

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CMD12AT[1:0]		TRSTP	CMDRW	CMDTP	RSPTP[2:0]			ACMD[1:0]		CMDIDX[5:0]					
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	CMDIDX[5:0]	Command Index Field Value Select These bits configure the command index field value. The examples shown include the bit values for the ACMD[1:0] bits. 0x06: CMD6 0x12: CMD18 0x4D: ACMD13	R/W
7:6	ACMD[1:0]	Command Type Select 0 0: CMD 0 1: ACMD Others: Setting prohibited	R/W
10:8	RSPTP[2:0]	Response Type Select*1 0 0 0: Normal mode Depending on the command, the response type and transfer method are selected in the ACMD[1:0] and CMDIDX[5:0] bits. At this time, the values for bits 15 to 11 in this register are invalid. 0 1 1: Extended mode and no response 1 0 0: Extended mode and R1, R5, R6, or R7 response 1 0 1: Extended mode and R1b response 1 1 0: Extended mode and R2 response 1 1 1: Extended mode and R3 or R4 response Others: Setting prohibited	R/W

Bit	Symbol	Function	R/W
11	CMDTP	Data Transfer Select*2 0: Do not include data transfer (bc, bcr, or ac) in command 1: Include data transfer (adtc) in command	R/W
12	CMDRW	Data Transfer Direction Select*3 0: Write (SD/MMC Host Interface → SD card/MMC) 1: Read (SD/MMC Host Interface ← SD card/MMC)	R/W
13	TRSTP	Block Transfer Select*3 0: Single block transfer 1: Multiple blocks transfer	R/W
15:14	CMD12AT[1:0]	CMD12 Automatic Issue Select*4 0 0: Automatically issue CMD12 during multiblock transfer 0 1: Do not automatically issue CMD12 during multiblock transfer Others: Setting prohibited	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Some commands cannot be used in normal mode.
Note 2. The CMDTP bit is only valid when the RSPTP[2:0] bits are 011b, 100b, 101b, 110b, or 111b.
Note 3. Bits CMDRW and TRSTP are only valid when the RSPTP[2:0] bits are 011b, 100b, 101b, 110b, or 111b, and the CMDTP bit is 1.
Note 4. The CMD12AT[1:0] bits are only valid when the RSPTP[2:0] bits are 011b, 100b, 101b, 110b, or 111b, and the TRSTP bit is 1.

The command type and response type are set in the SD_CMD register. The command type and transfer mode must be set when the RSPTP[2:0] bits are 011b, 100b, 101b, 110b, or 111b. The sequence starts when a value is written to this register. See Table 39.8 and Table 39.9 for setting examples. Do not write to the SD_CMD register when the SD_INFO2.CBSY flag is 1.

39.2.2 SD_ARG : SD Command Argument Register

Base address: SDHI0 = 0x4009_2000

Offset address: 0x008

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:																
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:																
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	—	These bits specify command format[39:8] (argument).	R/W

The SD_ARG register is used for setting the argument field value. Set the SD_ARG register before setting the SD_CMD register. The argument field value of the automatically issued CMD12 is 0x0000_0000 regardless of the SD_ARG register value.

39.2.3 SD_ARG1 : SD Command Argument Register 1

Base address: SDHI0 = 0x4009_2000

Offset address: 0x00C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:																
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	—	These bits specify command format[39:24] (argument).	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

The SD_ARG1 register is used for setting the argument field value. Set the SD_ARG1 register before setting the SD_CMD register. The argument field value of the automatically issued CMD12 is 0x0000_0000 regardless of the SD_ARG1 register value.

39.2.4 SD_STOP : Data Stop Register

Base address: SDHI0 = 0x4009_2000

Offset address: 0x010

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	SEC	—	—	—	—	—	—	—	STP
Value after reset:	0	0	0	0	0	0	0	0*1	0	0	0	0	0	0	0	0*1

Bit	Symbol	Function	R/W
0	STP	Transfer Stop Data transfer stops when this bit is set to 1.	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W
8	SEC	Block Count Register Value Select*2 0: Disable SD_SECCNT register value 1: Enable SD_SECCNT register value	R/W
31:9	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. The value is initialized by a reset and also on reset triggered by the SOFT_RST.SDRST flag.
Note 2. Do not rewrite this bit when the SD_INFO2.CBSY flag is 1.

The SD_STOP register stops data transfer. During a multiblock transfer sequence, the SD_SECCNT register value (number of blocks to be transferred) can be set to valid or invalid by setting the SD_STOP register.

STP bit (Transfer Stop)

When the STP bit is set to 1 during multiple block transfer, CMD12 is issued to halt the transfer through the SDHI. However, if a command sequence is halted because of a communications error or timeout, CMD12 is not issued. Although continued buffer access is possible even after STP is set to 1, the buffer access error bit (ILR or ILW) in SD_INFO2 is set accordingly.

When STP is set to 1 during transfer for single block write, the access end flag sets when SD_BUF becomes empty, and CMD12 is not issued. If SD_BUF does contain data, the access end flag sets on completion of reception of the busy state without CMD12 being issued.

When STP is set to 1 during transfer for single block read, the access end flag sets immediately after the STP bit is set, and CMD12 is not issued.

When STP is set to 1 during reception of the busy state after an R1b response, the access end flag sets on completion of reception of the busy state without CMD12 being issued.

When STP is set to 1 after a command sequence is completed, CMD12 is not issued and the access end flag does not set.

Set STP to 1 after the response end flag sets.

Set STP to 0 after the access end flag sets.

SEC bit (Block Count Register Value Select)

When SD_CMD is set in the following section to start the command sequence while the SEC bit is set to 1, CMD12 is automatically issued to stop multiblock transfer with the number of blocks set in SD_SECCNT.

CMD18 or CMD25 in normal mode (SD_CMD[10:8] = 000b)

SD_CMD[15:13] = 001b in extended mode (CMD12 is automatically issued, multiple block transfer)

When the command sequence is halted because of a communications error or timeout, CMD12 is not automatically issued.

39.2.5 SD_SECCNT : Block Count Register

Base address: SDHI0 = 0x4009_2000

Offset address: 0x014

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:																
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:																
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

When performing a multiblock transfer, SD_SECCNT is a read/write register used to set the number of blocks to be transferred. For example, when the register value is 0x0000_0001, 1 block is transferred. When the register value is 0x0000_FFFF, 65,535 blocks are transferred and when the register value is 0xFFFF_FFFF, 4,294,967,295 blocks are transferred. Do not set this register to 0x0000_0000. Do not rewrite the SD_SECCNT register when the SD_INFO2.CBSY flag is 1.

39.2.6 SD_RSPi : SD Card Response Register i (i = 10, 32, 54)

Base address: SDHI0 = 0x4009_2000

Offset address: 0x018 (SD_RSP10)
0x020 (SD_RSP32)
0x028 (SD_RSP54)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:																
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:																
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

39.2.7 SD_RSPj : SD Card Response Register j (j = 1, 3, 5)

Base address: SDHI0 = 0x4009_2000

Offset address: 0x01C (SD_RSP1)
0x024 (SD_RSP3)
0x02C (SD_RSP5)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:																
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	—	These bits store the response from the SD card/MMC.	R
31:16	—	These bits are read as 0.	R

39.2.8 SD_RSP76 : SD Card Response Register 76

Base address: SDHI0 = 0x4009_2000

Offset address: 0x030

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	SD_RSP76[23:16]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	SD_RSP76[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
23:0	SD_RSP76[23:0]	These bits store the response from the SD card/MMC.	R
31:24	—	These bits are read as 0.	R

39.2.9 SD_RSP7 : SD Card Response Register 7

Base address: SDHI0 = 0x4009_2000

Offset address: 0x034

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	SD_RSP7[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	SD_RSP7[7:0]	These bits store the response from the SD card/MMC.	R
31:8	—	These bits are read as 0.	R

SD_RSP10, SD_RSP32, SD_RSP54, SD_RSP1, SD_RSP3, SD_RSP5, SD_RSP76, and SD_RSP7 are read-only registers that store the response from the SD card/MMC. Depending on the type of response from the SD card/MMC, the SD/MMC Host Interface divides and stores the response among the four registers.

Table 39.3 lists the correspondence between the response type and its storage destination.

Table 39.3 Correspondence between response type and storage destination

Response type	SD_RSP10 register	SD_RSP32 register	SD_RSP54 register	SD_RSP1 register	SD_RSP3 register	SD_RSP5 register	SD_RSP76 register	SD_RSP7 register
R1	[39:8]	—	[39:8]*1	—	—	—	—	—
R1b	[39:8]	—	[39:8]*1	—	—	—	—	—
R2	[39:8]	[71:40]	[103:72]	—	—	—	[127:104]	—
R3	[39:8]	—	—	—	—	—	—	—
R4	[39:8]	—	—	—	—	—	—	—
R5	[39:8]	—	—	—	—	—	—	—
R6	[39:8]	—	—	—	—	—	—	—
R7	[39:8]	—	—	—	—	—	—	—

Note 1. The responses for CMD18 and CMD25 are stored in registers SD_RSP10 and SD_RSP54. Therefore, even if the SD_RSP10 register is overwritten with the response for the automatically issued CMD12, the response for CMD18 or CMD25 can be confirmed by reading the SD_RSP54 register.

39.2.10 SD_INFO1 : SD Card Interrupt Flag Register 1

Base address: SDHI0 = 0x4009_2000

Offset address: 0x038

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	SDD3MON	SDD3IN	SDD3RM	SDWPMON	—	SDCDMON	SDCDIN	SDCDRM	ACEND	—	RSPEND
Value after reset:	0	0	0	0	0	x	0	0	x	0	x	0	0	0*1	0	0*1

Bit	Symbol	Function	R/W
0	RSPEND	Response End Detection Flag 0: Response end not detected 1: Response end detected	R/(W)*2
1	—	This bit is read as 0. The write value should be 0.	R/W
2	ACEND	Access End Detection Flag 0: Access end not detected 1: Access end detected	R/(W)*2
3	SDCDRM	SDnCD Removal Flag 0: SD card/MMC removal not detected by the SDnCD pin 1: SD card/MMC removal detected by the SDnCD pin	R/(W)*2
4	SDCDIN	SDnCD Insertion Flag 0: SD card/MMC insertion not detected by the SDnCD pin 1: SD card/MMC insertion detected by the SDnCD pin	R/(W)*2

Bit	Symbol	Function	R/W
5	SDCDMON	SDnCD Pin Monitor Flag 0: SDnCD pin level is high*3 1: SDnCD pin level is low*3	R
6	—	This bit is read as 0. The write value should be 0.	R/W
7	SDWPMON	SDnWP Pin Monitor Flag 0: SDnWP pin level is high 1: SDnWP pin level is low	R
8	SDD3RM	SDnDAT3 Removal Flag 0: SD card/MMC removal not detected by the SDnDAT3 pin 1: SD card/MMC removal detected by the SDnDAT3 pin	R/(W)*2
9	SDD3IN	SDnDAT3 Insertion Flag 0: SD card/MMC insertion not detected by the SDnDAT3 pin 1: SD card/MMC insertion detected by the SDnDAT3 pin	R/(W)*2
10	SDD3MON	SDnDAT3 Pin Monitor Flag 0: SDnDAT3 pin level is low 1: SDnDAT3 pin level is high	R
31:11	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. The value is initialized by a reset and also on reset triggered by the SOFT_RST.SDRST flag.
Note 2. The flag does not change even if set to 1. Writing 0 changes the flag value to 0.
Note 3. The flag changes when the pin level continues for the period set in the SD_OPTION.CTOP[3:0] bits or longer.

The SD_INFO1 register indicates the detection of a response end or access end for a command sequence. The SD_INFO1 register also indicates the detection SD card/MMC insertion/removal and the write protection status.

During a multiblock transfer sequence, if CMD12 or CMD52 (SDIO abort) is issued, the ACEND flag sets to 1, but the RSPEND flag remains set to 0.

If the command sequence is stopped because of a communication error or timeout, the ACEND flag or RSPEND flag sets to 1.

After a reset is canceled, the SDD3MON bit, SDD3IN flag, and SDD3RM flag values are changed in accordance with the status of the SDnDAT3 (n = 0) pin, and their values are changed when data is being transferred in wide bus mode. These 3 bits are used only for SD card. Set flags to be cleared to 0. Set flags that are not being cleared to 1.

RSPEND flag (Response End Detection Flag)

The RSPEND flag indicates that a response end was detected.

[Setting conditions]

- When reception of the response is completed
- When transmission of a command without response is completed
- When reception of the busy state after R1b response is completed
- When reception of the response to CMD52 that was issued by setting the C52PUB bit to 1 is completed for transfer of multiple block read
- When reception of the response to CMD52 that was issued by setting the C52PUB bit to 1 is completed for transfer of multiple block write
- This bit is set when a command sequence is halted because of a communications error or timeout.

[Clearing conditions]

- When 0 is written to RSPEND
- When a command without data is issued.

Note: When a command is issued in absence of data transfer, the RSPEND flag becomes 1 after the command sequence ends.

ACEND flag (Access End Detection Flag)

The ACEND flag indicates that an access end was detected.

[Setting conditions]

- When read access to the buffer is completed for transfer of single block read
- When read access to the buffer for the last block of data is completed for transfer of multiple block read
- When read access to the buffer and reception of the response to CMD12 are completed for transfer of multiple block read with automatic issuing of CMD12
- When reception of the busy state after reception of the CRC status is completed for transfer of single block write
- When reception of the busy state after reception of the CRC status of the last block of data is completed for transfer of multiple block write
- When reception of the response busy state for CMD12 is completed for transfer of multiple block write with automatic issuing of CMD12
- When reception of the response to CMD12 that was issued by setting the STP bit to1 is completed for transfer of multiple block read
- When reception of the response busy state for CMD12 that was issued by setting the STP bit to1 is completed for transfer of multiple block write
- When reception of the response to CMD52 that was issued by setting the IOABT bit to 1 is completed for transfer of multiple block read
- When reception of the response to CMD52 that was issued by setting the IOABT bit to1 is completed for transfer of multiple block write
- This bit is set when a command sequence is halted because of a communications error or timeout.

[Clearing conditions]

- When 0 is written to ACEND
- When the access end bit is set to 1.

Note: The ACEND flag becomes 1 after the command sequence ends.

SDCDRM flag (SDnCD Removal Flag)

The SDCDRM flag indicates that SDnCD was removed.

[Setting condition]

- After a change in SDnCD from 0 to 1, Mcycle elapsed with SDnCD held at 1.

[Clearing conditions]

- When 0 is written to SDCDRM.

Note: Mcycle is set in bits [3:0] in SD_OPTION.

SDCDIN flag (SDnCD Insertion Flag)

The SDCDIN flag indicates that SDnCD was inserted.

[Setting condition]

- After a change in SDnCD from 1 to 0, Mcycle elapsed with SDnCD held at 0.

[Clearing conditions]

- When 0 is written to SDCDIN.

Note: Mcycle is set in bits [3:0] in SD_OPTION.

SDD3RM flag (SDnDAT3 Removal Flag)

The SDD3RM flag indicates that SDnDAT3 was removed.

[Setting condition]

- After a change in SDnDAT3 from 1 to 0, two cycles of PCLKB elapsed with SDnDAT3 held at 0.

[Clearing condition]

- When 0 is written to SDD3RM.

SDD3IN flag (SDnDAT3 Insertion Flag)

The SDD3IN flag indicates that SDnDAT3 was inserted.

[Setting condition]

- After a change in SDnDAT3 from 0 to 1, two cycles of PCLKB elapsed with SDnDAT3 held at 1.

[Clearing condition]

- When 0 is written to SDD3IN.

39.2.11 SD_INFO2 : SD Card Interrupt Flag Register 2

Base address: SDHI0 = 0x4009_2000

Offset address: 0x03C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ILA	CBSY	SD_CLK_CTRLEN	—	—	—	BWE	BRE	SDD0MON	RSPTO	ILR	ILW	DTO	ENDE	CRCE	CMDE
Value after reset:	0*1	0*1	1*1	0	x	0	0*1	0*1	x	0*1	0*1	0*1	0*1	0*1	0*1	0*1

Bit	Symbol	Function	R/W
0	CMDE	Command Error Detection Flag 0: Command error not detected 1: Command error detected	R/W*2
1	CRCE	CRC Error Detection Flag 0: CRC error not detected 1: CRC error detected	R/W*2
2	ENDE	End Bit Error Detection Flag 0: End bit error not detected 1: End bit error detected	R/W*2
3	DTO	Data Timeout Detection Flag 0: Data timeout not detected 1: Data timeout detected	R/W*2
4	ILW	SD_BUF0 Illegal Write Access Detection Flag 0: Illegal write access to the SD_BUF0 register not detected 1: Illegal write access to the SD_BUF0 register detected	R/W*2
5	ILR	SD_BUF0 Illegal Read Access Detection Flag 0: Illegal read access to the SD_BUF0 register not detected 1: Illegal read access to the SD_BUF0 register detected	R/W*2
6	RSPTO	Response Timeout Detection Flag 0: Response timeout not detected 1: Response timeout detected	R/W*2
7	SDD0MON	SDnDAT0 Pin Status Flag 0: SDnDAT0 pin is low 1: SDnDAT0 pin is high	R
8	BRE	SD_BUF0 Read Enable Flag 0: Disable read access to the SD_BUF0 register 1: Enable read access to the SD_BUF0 register	R/W*2

Bit	Symbol	Function	R/W
9	BWE	SD_BUF0 Write Enable Flag 0: Disable write access to the SD_BUF0 register 1: Enable write access to the SD_BUF0 register	R/W*2
10	—	This bit is read as 0. The write value should be 0.	R/W
11	—	The read value is undefined. The write value should be 1.	R/W
12	—	This bit is read as 0. The write value should be 0.	R/W
13	SD_CLK_CTRLEN	SD_CLK_CTRL Write Enable Flag 0: SD/MMC bus (CMD and DAT lines) is busy, so write access to the SD_CLK_CTRL.CLKEN and CLKSEL[7:0] bits is disabled 1: SD/MMC bus (CMD and DAT lines) is not busy, so write access to the SD_CLK_CTRL.CLKEN and CLKSEL[7:0] bits is enabled	R
14	CBSY	Command Sequence Status Flag 0: Command sequence complete 1: Command sequence in progress (busy)	R
15	ILA	Illegal Access Error Detection Flag 0: Illegal access error not detected 1: Illegal access error detected	R/W*2
31:16	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. The value is initialized by a reset and also on reset triggered by the SOFT_RST.SDRST flag.
Note 2. The flag does not change even if set to 1. Writing 0 changes the flag value to 0.

The SD_INFO2 register indicates the status of the SD buffer and the status of the SD card/MMC. Set flags to be cleared to 0. Set flags that are not being cleared to 1.

CMDE flag (Command Error Detection Flag)

The CMDE flag indicates that a command error was detected. The command sequence stops when a command error occurs. When the SDIO_MODE.C52PUB bit is set to 1 and CMD52 is automatically issued, if a communication error or response timeout occurs, the command sequence is not completed. Perform the error processing shown in section 39.3.12. IO_RW_EXTENDED Command (SD: CMD53/Multiple Block Read) or section 39.3.13. IO_RW_EXTENDED Command (SD: CMD53/Multiple Block Write), and complete the command sequence.

[Setting conditions]

- The command index of the transmitted command differs from the command index of the received response.
- The command index of a command issued within a command sequence differs from the command index of the received response.

[Clearing condition]

- When 0 is written to CMDE.

CRCE flag (CRC Error Detection Flag)

The CRCE flag indicates that a CRC error was detected. The command sequence stops when a CRC error occurs. When the SDIO_MODE.C52PUB bit is set to 1 and CMD52 is automatically issued, if a communication error or response timeout occurs, the command sequence is not completed. Perform the error processing shown in section 39.3.12. IO_RW_EXTENDED Command (SD: CMD53/Multiple Block Read) or section 39.3.13. IO_RW_EXTENDED Command (SD: CMD53/Multiple Block Write), and complete the command sequence.

[Setting conditions]

- When an error occurs in the CRC status.
- When a CRC error occurs in the read data.
- When a CRC error occurs in the response.
- A CRC error in the response to a command issued within a command sequence.

[Clearing condition]

- When 0 is written to CRCE.

ENDE flag (End Bit Error Detection Flag)

The ENDE flag indicates that an end bit error was detected. The command sequence is stopped when an end bit error occurs. When the SDIO_MODE.C52PUB bit is set to 1 and CMD52 is automatically issued, if a communication error or response timeout occurs, the command sequence is not completed. Perform the error processing shown in section 39.3.12. IO_RW_EXTENDED Command (SD: CMD53/Multiple Block Read) or section 39.3.13. IO_RW_EXTENDED Command (SD: CMD53/Multiple Block Write), and complete the command sequence.

[Setting conditions]

- When an error occurs in the response length (and the end bit is not detected).
- When an error occurs in the read data length (and the end bit is not detected among the valid bits).
- When an error occurs in the CRC status length (and the end bit is not detected).
- An error in the length of a response to a command issued within a command sequence, for example when the end bit is not detected.

[Clearing condition]

- When 0 is written to ENDE.

DTO flag (Data Timeout Detection Flag)

The DTO flag indicates that a data timeout was detected. The command sequence stops when a data timeout occurs.

[Setting conditions]

- After R1b response, the busy state (SDnDAT0 = 0) continues for longer than Ncycle.
- After CRC status, the busy state (SDnDAT0 = 0) continues for longer than Ncycle.
- After write data, the CRC status is not received though Ncycle has elapsed.
- After read command, read data is not received though a time longer than Ncycle has elapsed.
- After CMD12 is issued within a command sequence, the busy state (SDnDAT0 = 0) for longer than Ncycle continues.
- After the reception of read data, read data for the next block are not received though a time longer than Ncycle has elapsed.
- After release of the read wait state, read data for the next block are not received though a time longer than Ncycle has elapsed.

Note: Ncycle is set in bits [7:4] in SD_OPTION.

[Clearing condition]

- When 0 is written to DTO.

ILW flag (SD_BUF0 Illegal Write Access Detection Flag)

The ILW flag indicates that an SD_BUF0 illegal write access was detected.

[Setting conditions]

- When data is written to SD_BUF0 while it is not in the data read/write command state.
- When data is written to SD_BUF0 while SD_BUF is full.
- When data is written to SD_BUF0 while an error occurs in the CRC status or CRC status length.
- When data is written to SD_BUF0 while a busy state after the CRC status continues for longer than Ncycle.

Note: Ncycle is set in bits [7:4] in SD_OPTION.

[Clearing condition]

- When 0 is written to ILW.

ILR flag (SD_BUF0 Illegal Read Access Detection Flag)

The ILR flag indicates that an SD_BUF0 illegal read access was detected.

[Setting conditions]

- When SD_BUF is empty while SD_BUF0 is read.
- When data with a CRC error or END error is read from SD_BUF0.

[Clearing condition]

- When 0 is written to ILR.

RSPTO flag (Response Timeout Detection Flag)

The RSPTO flag indicates that a response timeout was detected. The command sequence is stopped when a response timeout occurs. When the SDIOMD.C52PUB bit is set to 1 and CMD52 is automatically issued, if a communication error or response timeout occurs, the command sequence is not completed. Perform the error processing shown in section 39.3.12. IO_RW_EXTENDED Command (SD: CMD53/Multiple Block Read) or section 39.3.13. IO_RW_EXTENDED Command (SD: CMD53/Multiple Block Write), and complete the command sequence.

[Setting condition]

- When a response is not received though a time longer than 640 cycles of SD/MMC clock has elapsed (including a response to a command issued within a command sequence).

[Clearing condition]

- When 0 is written to RSPTO.

SDD0MON flag (SDnDAT0 Pin Status Flag)

The SDD0MON flag indicates the status of the SDnDAT0 pin. If the data timeout (DTO) is set but the response timeout (RSPTO) is not set after the Erase command is issued, the end of the Erase sequence (SDD0MON = 1) is confirmed by polling DAT0.

If a communication error or timeout occurs during a write sequence, the DAT0 bit might retain the value 0.

While the SD/MMC clock is stopped, the DAT0 bit retains the value before the clock is stopped.

BRE flag (SD_BUF0 Read Enable Flag)

The BRE flag indicates that SD_BUF0 is enabled for reading.

[Setting conditions]

- When data set in SD_SIZE is stored in SD_BUF0 at single block transfer.
- When data set in SD_SIZE is stored in either bank 1 or bank 2 of SD_BUF0 at multiple block transfer.

[Clearing conditions]

- When 0 is written to BRE
- Reading of a block of data from SD_BUF0 by DMA transfer

When data is read from SD_BUF0 by the CPU, clear BRE then read the amount of data specified in SD_SIZE.

Even if a CRC error or an END error occurs while block data is read, data is stored in SD_BUF0 and BRE is set.

BWE flag (SD_BUF0 Write Enable Flag)

The BWE flag indicates that SD_BUF0 is enabled for writing.

[Setting conditions]

- When SD_BUF0 is empty at single block transfer.
- When either bank 1 or bank 2 of SD_BUF0 is empty at multiple block transfer.

[Clearing conditions]

- When 0 is written to BWE.
- Writing of a block of data to SD_BUF0 by DMA transfer.

When data is written to SD_BUF0 by the CPU, clear BWE and then write the amount of data specified in SD_SIZE.

SD_CLK_CTRLEN flag (SD_CLK_CTRL Write Enable Flag)

When a command sequence is started by writing to SD_CMD, the CBSY bit is set to 1 and, at the same time, the SD_CLK_CTRLEN bit is set to 0. The SD_CLK_CTRLEN bit is set to 1 after 8 cycles of SDCLK have elapsed after the CBSY bit clears to 0 on completion of the command sequence.

ILA flag (Illegal Access Error Detection Flag)

The ILA flag indicates that an illegal access error was detected.

[Setting conditions]

- Writing of data to SD_CMD within a command sequence (CBSY = 1).
- When SD_CMD[11] = 1 (command with data transfer) and SD_CMD[7:0] = 0000 1100b (CMD12) are set in SD_CMD.

[Clearing condition]

- When 0 is written to ILA.

39.2.12 SD_INFO1_MASK : SD INFO1 Interrupt Mask Register

Base address: SDHI0 = 0x4009_2000

Offset address: 0x040

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	SDD3INM	SDD3RMM	—	—	—	SDCDINM	SDCDRMM	ACENDM	—	RSPENDM
Value after reset:	0	0	0	0	0	0	1	1	0	0	0	1	1	1	0	1

Bit	Symbol	Function	R/W
0	RSPENDM	Response End Interrupt Request Mask 0: Do not mask response end interrupt request 1: Mask response end interrupt request	R/W
1	—	This bit is read as 0. The write value should be 0.	R/W
2	ACENDM	Access End Interrupt Request Mask 0: Do not mask access end interrupt request 1: Mask access end interrupt request	R/W
3	SDCDRMM	SDnCD Removal Interrupt Request Mask 0: Do not mask SD card/MMC removal interrupt request by the SDnCD pin 1: Mask SD card/MMC removal interrupt request by the SDnCD pin	R/W
4	SDCDINM	SDnCD Insertion Interrupt Request Mask 0: Do not mask SD card/MMC insertion interrupt request by the SDnCD pin 1: Mask SD card/MMC insertion interrupt request by the SDnCD pin	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W
8	SDD3RMM	SDnDAT3 Removal Interrupt Request Mask 0: Do not mask SD card/MMC removal interrupt request by the SDnDAT3 pin 1: Mask SD card/MMC removal interrupt request by the SDnDAT3 pin	R/W
9	SDD3INM	SDnDAT3 Insertion Interrupt Request Mask 0: Do not mask SD card/MMC insertion interrupt request by the SDnDAT3 pin 1: Mask SD card/MMC insertion interrupt request by the SDnDAT3 pin	R/W
31:10	—	These bits are read as 0. The write value should be 0.	R/W

The SD_INFO1_MASK register enables or disables interrupt requests from the status flags in the SD_INFO1 register. See Table 39.5, for details on the relationship between the status flags and the requested interrupt source.

39.2.13 SD_INFO2_MASK : SD INFO2 Interrupt Mask Register

Base address: SDHI0 = 0x4009_2000

Offset address: 0x044

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ILAM	—	—	—	—	—	BWEM	BREM	—	RSPTOM	ILRM	ILWM	DTOM	ENDEM	CRCEM	CMDEM
Value after reset:	1	0	0	0	1	0	1	1	0	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
0	CMDEM	Command Error Interrupt Request Mask 0: Do not mask command error interrupt request 1: Mask command error interrupt request	R/W
1	CRCEM	CRC Error Interrupt Request Mask 0: Do not mask CRC error interrupt request 1: Mask CRC error interrupt request	R/W
2	ENDEM	End Bit Error Interrupt Request Mask 0: Do not mask end bit detection error interrupt request 1: Mask end bit detection error interrupt request	R/W
3	DTOM	Data Timeout Interrupt Request Mask 0: Do not mask data timeout interrupt request 1: Mask data timeout interrupt request	R/W
4	ILWM	SD_BUF0 Register Illegal Write Interrupt Request Mask 0: Do not mask illegal write detection interrupt request for the SD_BUF0 register 1: Mask illegal write detection interrupt request for the SD_BUF0 register	R/W
5	ILRM	SD_BUF0 Register Illegal Read Interrupt Request Mask 0: Do not mask illegal read detection interrupt request for the SD_BUF0 register 1: Mask illegal read detection interrupt request for the SD_BUF0 register	R/W
6	RSPTOM	Response Timeout Interrupt Request Mask 0: Do not mask response timeout interrupt request 1: Mask response timeout interrupt request	R/W
7	—	This bit is read as 0. The write value should be 0.	R/W
8	BREM*1	BRE Interrupt Request Mask 0: Do not mask read enable interrupt request for the SD buffer 1: Mask read enable interrupt request for the SD buffer	R/W
9	BWEM*1	BWE Interrupt Request Mask 0: Do not mask write enable interrupt request for the SD_BUF0 register 1: Mask write enable interrupt request for the SD_BUF0 register	R/W
10	—	This bit is read as 0. The write value should be 0.	R/W
11	—	This bit is read as 1.The write value should be 1.	R/W
14:12	—	These bits are read as 0. The write value should be 0.	R/W
15	ILAM	Illegal Access Error Interrupt Request Mask 0: Do not mask illegal access error interrupt request 1: Mask illegal access error interrupt request	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. When the SD_INFO2_MASK.BWEM bit is 0 or the SD_INFO2_MASK.BREM bit is 0, set the SD_DMAEN.DMAEN bit to 0. When the SD_DMAEN.DMAEN bit is 1, set the SD_INFO2_MASK.BWEM bit to 1 and the SD_INFO2_MASK.BREM bit to 1.

The SD_INFO2_MASK register enables or disables interrupt requests from the status flags in the SD_INFO2 register. See Table 39.5 for details on the relationship between the status flags and the requested interrupt source.

39.2.14 SD_CLK_CTRL : SD Clock Control Register

Base address: SDHI0 = 0x4009_2000

Offset address: 0x048

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	CLKCTRLEN	CLKEN	CLKSEL[7:0]							
Value after reset:	0	0	0	0	0	0	0	0*1	0	0	1	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	CLKSEL[7:0]	SDHI Clock Frequency Select*2 0xFF PCLKB 0x00: PCLKB/2 0x01: PCLKB/4 0x02: PCLKB/8 0x04: PCLKB/16 0x08: PCLKB/32 0x10: PCLKB/64 0x20: PCLKB/128 0x40: PCLKB/256 0x80: PCLKB/512 Others: Setting prohibited	R/W
8	CLKEN	SD/MMC Clock Output Control*2 0: Disable SD/MMC clock output (fix SDnCLK signal low) 1: Enable SD/MMC clock output	R/W
9	CLKCTRLEN	SD/MMC Clock Output Automatic Control Select 0: Disable automatic control of SD/MMC clock output 1: Enable automatic control of SD/MMC clock output	R/W
31:10	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. The value is initialized by a reset and also on reset triggered by the SOFT_RST.SDRST flag.
Note 2. Bits CLKSEL[7:0] and CLKEN cannot be write accessed when the SD_INFO2.SD_CLK_CTRLEN flag is 0.

The SD_CLK_CTRL register controls the SD/MMC clock frequency settings and output. Set the CLKEN bit to 1 before writing to the SD_CMD register to start a command sequence. Do not write to the SD_CLK_CTRL register when the SD_INFO2.SD_CLK_CTRLEN flag is 0.

CLKCTRLEN bit (SD/MMC Clock Output Automatic Control Select)

The CLKCTRLEN bit enables or disables the automatic control function for SD/MMC clock output, which causes the SD/MMC clock to output only within a command sequence.

The timing with which SD/MMC clock output starts and stops is as follows:

- SD/MMC clock output starts after writing to SD_CMD
- SD/MMC clock output stops when 8 cycles of SD/MMC clock have elapsed after the end of the command sequence.

In addition, SD/MMC clock is fixed to 0 while SCLKEN of SD_CLK_CTRL is 0, regardless of the value of this bit.

39.2.15 SD_SIZE : Transfer Data Length Register

Base address: SDHI0 = 0x4009_2000

Offset address: 0x04C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	LEN[9:0]									
Value after reset:	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
9:0	LEN[9:0]	Transfer Data Size Setting These bits specify the transfer data size.*1	R/W
31:10	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Do not rewrite these bits when the SD_INFO2.CBSY flag is 1.

The SD_SIZE register sets the transfer data size.

LEN[9:0] bits (Transfer Data Size Setting)

When using single block transfer, the transfer data size can be set in the LEN[9:0] bits from 1 byte to 512 bytes. When CMD12 is automatically issued during a multiblock transfer sequence (CMD18 and CMD25), the transfer data size can only be set to 512 bytes. When CMD12 is not automatically issued during a multiblock transfer sequence, the transfer data size can be set to 32, 64, 128, 256, or 512 bytes. However, a 32-, 64-, 128-, or 256-byte multiblock read transfer can only be performed during an SDIO multiblock transfer (CMD53). Do not set these bits to 0 when using a command that includes data transfer.

39.2.16 SD_OPTION : SD Card Access Control Option Register

Base address: SDHI0 = 0x4009_2000

Offset address: 0x050

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	WIDTH	—	WIDTH8	—	—	—	—	TOUTMASK	TOP[3:0]				CTOP[3:0]			
Value after reset:	0*1	1	0*1	0	0	0	0	0*1	1*1	1*1	1*1	0*1	1*1	1*1	1*1	0*1

Bit	Symbol	Function	R/W
3:0	CTOP[3:0]	Card Detection Time Counter*2 0x0: PCLKB × 2^{10} 0x1: PCLKB × 2^{11} 0x2: PCLKB × 2^{12} 0x3: PCLKB × 2^{13} 0x4: PCLKB × 2^{14} 0x5: PCLKB × 2^{15} 0x6: PCLKB × 2^{16} 0x7: PCLKB × 2^{17} 0x8: PCLKB × 2^{18} 0x9: PCLKB × 2^{19} 0xA: PCLKB × 2^{20} 0xB: PCLKB × 2^{21} 0xC: PCLKB × 2^{22} 0xD: PCLKB × 2^{23} 0xE: PCLKB × 2^{24} 0xF: Setting prohibited	R/W
7:4	TOP[3:0]	Timeout Counter*2 0x0: SDHI clock × 2^{13} 0x1: SDHI clock × 2^{14} 0x2: SDHI clock × 2^{15} 0x3: SDHI clock × 2^{16} 0x4: SDHI clock × 2^{17} 0x5: SDHI clock × 2^{18} 0x6: SDHI clock × 2^{19} 0x7: SDHI clock × 2^{20} 0x8: SDHI clock × 2^{21} 0x9: SDHI clock × 2^{22} 0xA: SDHI clock × 2^{23} 0xB: SDHI clock × 2^{24} 0xC: SDHI clock × 2^{25} 0xD: SDHI clock × 2^{26} 0xE: SDHI clock × 2^{27} 0xF: Setting prohibited	R/W
8	TOUTMASK	Timeout Mask 0: Activate timeout 1: Inactivate timeout (do not set RSPTO and DTO bits of SD_INFO2 or CRCBSYTO, CRCTO, RDTO, BSYTO1, BSYTO0, RSPTO1 and RSPTO0 bits of SD_ERR_STS2) When timeout occurs because of an inactivated timeout, execute a software reset to terminate the command sequence.	R/W
12:9	—	These bits are read as 0. The write value should be 0.	R/W
13	WIDTH8	Bus Width*2 See bit 15 WIDTH bit.	R/W
14	—	This bit is read as 1. The write value should be 1.	R/W
15	WIDTH	Bus Width*2 WIDTH / WIDTH8 / Bus Width 0 / 1 / 8-bit width 0 / 0 / 4-bit width 1 / 0 / 1-bit width 1 / 1 / 1-bit width For 1-byte write transfers, set 4-bit or 1-bit width. Do not set 8-bit width.	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. The value is initialized by a reset and also on reset triggered by the SOFT_RST.SDRST flag.
Note 2. Do not rewrite these bits when the SD_INFO2.CBSY flag is 1.

The SD bus width and timeout counter are set in the SD_OPTION register.

39.2.17 SD_ERR_STS1 : SD Error Status Register 1

Base address: SDHI0 = 0x4009_2000

Offset address: 0x058

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	CRCTK[2:0]			CRCTKE	RDCRCE	RSPCRCE1	RSPCRCE0	—	—	CRCLENE	RDLENE	RSPLENE1	RSPLENE0	CMDE1	CMDE0
Value after reset:	0	0*1	1*1	0*1	0*1	0*1	0*1	0*1	0	0	0*1	0*1	0*1	0*1	0*1	0*1

Bit	Symbol	Function	R/W
0	CMDE0	Command Error Flag 0 0: No error exists in command index field value of a command*2 response 1: Error exists in command index field value of a command*2 response	R
1	CMDE1	Command Error Flag 1 0: No error exists in command index field value of a command*3 response 1: Error exists in command index field value of a command*3 response (with SD_CMD.CMDIDX[5:0] setting, an error that occurs with CMD12 issue is indicated in the CMDE0 flag)	R
2	RSPLENE0	Response Length Error Flag 0 0: No error exists in command*2 response length 1: Error exists in command*2 response length	R
3	RSPLENE1	Response Length Error Flag 1 0: No error exists in command*3 response length 1: Error exists in command*3 response length (with SD_CMD.CMDIDX[5:0] setting, an error that occurs with CMD12 issue is indicated in the RSPLENE0 flag)	R
4	RDLENE	Read Data Length Error Flag 0: No read data length error occurred 1: Read data length error occurred	R
5	CRCLENE	CRC Status Token Length Error Flag 0: No CRC status token length error occurred 1: CRC status token length error occurred	R
7:6	—	These bits are read as 0.	R
8	RSPCRCE0	Response CRC Error Flag 0 0: No CRC error detected in command*2 response 1: CRC error detected in command*2 response	R
9	RSPCRCE1	Response CRC Error Flag 1 0: No CRC error detected in command*3 response (with SD_CMD.CMDIDX[5:0] setting, an error that occurs with CMD12 issue is indicated in the RSPCRCE0 flag) 1: CRC error detected in command*3 response	R
10	RDCRCE	Read Data CRC Error Flag 0: No CRC error detected in read data 1: CRC error detected in read data	R
11	CRCTKE	CRC Status Token Error Flag 0: No error detected in CRC status token 1: Error detected in CRC status token	R
14:12	CRCTK[2:0]	CRC Status Token These bits store the CRC status token value (normal value is 010b).	R
15	—	This bit is read as 0.	R

Bit	Symbol	Function	R/W
31:16	—	These bits are read as 0.	R

Note 1. The value is initialized by a reset and also on reset triggered by the SOFT_RST.SDRST flag.
Note 2. CMD other than CMD12 when automatic issuing is enabled for multiple block transfer by the setting in SD_CMD, CMD12 when the STP bit in SD_STOP is set to 1, or CMD52 when the C52PUB or IOABT bit in SDIO_MODE is set to 1.
Note 3. CMD12 when automatic issuing is enabled for multiple block transfer by the setting in SD_CMD, CMD12 when the STP bit in SD_STOP is set to 1, or CMD52 when the C52PUB or IOABT bit in SDIO_MODE is set to 1.

The SD_ERR_STS1 register indicates the CRC status token, CRC error, end bit error, and command error.

39.2.18 SD_ERR_STS2 : SD Error Status Register 2

Base address: SDHI0 = 0x4009_2000

Offset address: 0x05C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	CRCB SYTO	CRCT O	RDTO	BSYT O1	BSYT O0	RSPT O1	RSPT O0
Value after reset:	0	0	0	0	0	0	0	0	0	0*1	0*1	0*1	0*1	0*1	0*1	0*1

Bit	Symbol	Function	R/W
0	RSPTO0	Response Timeout Flag 0 0: After command*2 was issued, response was received in less than 640 cycles of the SD/MMC clock 1: After command*2 was issued, response was not received in 640 or more cycles of the SD/MMC clock	R
1	RSPTO1	Response Timeout Flag 1 0: After command*3 was issued, response was received in less than 640 cycles of the SD/MMC clock 1: After command*3 was issued, response was not received after 640 or more cycles of the SD/MMC clock (with SD_CMD.CMDIDX[5:0] setting, an error that occurs with CMD12 issue is indicated in the RSPTO0 flag)	R
2	BSYTO0	Busy Timeout Flag 0 0: After R1b response was received, SD/MMC was released from the busy state during the specified period*4 1: After R1b response was received, SD/MMC was in the busy state after the specified period*4 elapsed	R
3	BSYTO1	Busy Timeout Flag 1 0: After CMD12 was automatically issued, SD/MMC was released from the busy state during the specified period*4 1: After CMD12 was automatically issued, SD/MMC was in the busy state after the specified period*4 elapsed (with SD_CMD.CMDIDX[5:0] setting, an error that occurs with CMD12 issue is indicated in the BSYTO0 flag)	R
4	RDTO	Read Data Timeout Flag When a read command is issued, this flag sets to 1 when read data is not received after the specified period*4 elapses. When read data is received, this flag sets to 1 when the next block of read data is not received after the specified period*4 elapses. When the SD/MMC exits the read wait state, this flag sets to 1 when the next block of read data is not received after the specified period*4 elapses.	R
5	CRCTO	CRC Status Token Timeout Flag 0: After CRC data was written to the SD card/MMC, a CRC status token was received during the specified period*4 1: After CRC data was written to the SD card/MMC, a CRC status token was not received after the specified period*4 elapsed	R

Bit	Symbol	Function	R/W
6	CRCBSYTO	CRC Status Token Busy Timeout Flag 0: After a CRC status token was received, the SD/MMC was released from the busy state during the specified period*4 1: After a CRC status token was received, the SD/MMC was in the busy state after the specified period*4 elapsed	R
31:7	—	These bits are read as 0.	R

Note 1. The value is initialized by a reset and also on reset triggered by the SOFT_RST.SDRST flag.
Note 2. CMD other than CMD12 when automatic issuing is enabled for multiple block transfer by the setting in SD_CMD, CMD12 when the STP bit in SD_STOP is set to 1, or CMD52 when the C52PUB or IOABT bit in SDIO_MODE is set to 1.
Note 3. CMD12 when automatic issuing is enabled for multiple block transfer by the setting in SD_CMD, CMD12 when the STP bit in SD_STOP is set to 1, or CMD52 when the C52PUB or IOABT bit in SDIO_MODE is set to 1.
Note 4. Set the SD_OPTION.TOP[3:0] bits to select the number of *n* cycles.

The SD_ERR_STS2 register indicates the timeout status.

39.2.19 SD_BUF0 : SD Buffer Register

Base address: SDHI0 = 0x4009_2000

Offset address: 0x060

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:																
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:																
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

When writing to the SD card, the write data is written to this register. When reading from the SD card, the read data is read from this register. This register is internally connected to two 512-byte buffers.

If both buffers are not empty when executing multiple block read, the SD card/MMC clock is stopped to suspend receiving data. When one of the buffers is empty, the SD card/MMC clock is supplied to resume receiving data.

39.2.20 SDIO_MODE : SDIO Mode Control Register

Base address: SDHI0 = 0x4009_2000

Offset address: 0x068

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	C52PUB	IOABT	—	—	—	—	—	RWREQ	—	INTEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	INTEN	SDIO Interrupt Acceptance Enable*1 0: Disable SDIO interrupt acceptance 1: Enable SDIO interrupt acceptance	R/W
1	—	This bit is read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
2	RWREQ	Read Wait Request 0: Allow SD/MMC to exit read wait state 1: Request for SD/MMC to enter read wait state	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W
8	IOABT	SDIO Abort If this bit is set to 1 during multiblock transfer triggered by CMD53, CMD52 is immediately issued, and the command sequence is aborted.	R/W
9	C52PUB	SDIO None Abort If this bit is set to 1 during multiblock transfer triggered by CMD53, CMD52 is issued after the transfer process is complete, and the command sequence is completed.	R/W
31:10	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Do not rewrite this bit when the SD_INFO2.CBSY flag is 1.

The SDIO_MODE register controls reception of the SDIO interrupt, CMD52 issuance during multiblock transfer, and read wait request. Do not set bits C52PUB and IOABT to 1 at the same time.

RWREQ bit (Read Wait Request)

When RWREQ is set to 1 in the CMD53 (multiple block) read sequence, the block transfer enters the read wait state between blocks.

[Read wait state releasing]

- The read wait state is released, when RWREQ is cleared to 0 in the read wait state.
- When IOABT is set to 1 in the read wait state, RWREQ is automatically cleared to 0 after CMD52 is issued, and then the read wait state is released.
- When C52PUB and RWREQ are set to 1 simultaneously in the CMD53 (multiple block) read sequence, the read wait state is not automatically released. Therefore, after the CMD52 response is received, clear RWREQ. You must set RWREQ and C52PUB simultaneously.

When RWREQ is set to 1 while the last block in the CMD53 (multiple block) read sequence is transferred, the read wait state is not entered and RWREQ is automatically cleared to 0 by setting access end. Set RWREQ to 1 after the response end flag sets.

IOABT bit (SDIO Abort)

When the IOABT bit is set to 1 in a CMD53 (multiple block) sequence, the CMD53 sequence is halted and CMD52 is issued. However, if a command sequence is halted because of a communication error or timeout, CMD52 is not issued. Although continued buffer access is possible even after IOABT is set to 1, the buffer access error bit (ILR or ILW) in SD_INFO2 is set accordingly. Set SD_ARG before setting IOABT to 1.

When IOABT is set to 1 during transfer for a single block write, the access end flag sets when SD_BUF0 becomes empty, and CMD52 is not issued. If SD_BUF0 contains data, the access end flag sets on completion of reception of the busy state without CMD52 being issued.

When IOABT is set to 1 during transfer for single block read, the access end flag sets immediately after IOABT is set, and CMD52 is not issued.

When IOABT is set to 1 during reception of the busy state after an R1b response, the access end flag sets on completion of reception of the busy state without CMD52 being issued.

When IOABT is set to 1 after a command sequence is completed, CMD52 is not issued and the access end flag does not set.

Set IOABT to 1 after the response end flag sets.

Set IOABT to 0 after the access end flag sets.

C52PUB bit (SDIO None Abort)

When the C52PUB bit is set to 1 in the CMD53 (multiple block) write sequence, CMD52 is automatically issued between blocks if SD_BUF0 becomes empty. C52PUB is automatically cleared to 0 after reception of the response to CMD52 is completed. Additionally, if C52PUB is set to 1 while the last block is being transferred, CMD52 is not issued. In this case, C52PUB is automatically cleared to 0 after the access end flag sets to 1.

When C52PUB and RWREQ are set to 1 in the CMD53 (multiple block) read sequence, the block transfer enters the read wait state between blocks and CMD52 is automatically issued. C52PUB is automatically cleared to 0 after reception of the response to CMD52 is completed. Additionally, if C52PUB is set to 1 while the last block is being transferred, CMD52 is not issued. In this case, C52PUB is automatically cleared to 0 after the access end flag sets to 1.

If C52PUB is set to 1 in the CMD53 (multiple block) read sequence, you must set RWREQ to 1 in addition to C52PUB.

Set SD_ARG before setting C52PUB to 1.

Set C52PUB to 1 after the response end flag sets.

39.2.21 SDIO_INFO1 : SDIO Interrupt Flag Register

Base address: SDHI0 = 0x4009_2000

Offset address: 0x06C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	EXWT	EXPUB52	—	—	—	—	—	—	—	—	—	—	—	—	—	IOIRQ
Value after reset:	0*1	0*1	0	0	0	0	0	0	0	0	0	0	0	x	x	0*1

Bit	Symbol	Function	R/W
0	IOIRQ	SDIO Interrupt Status Flag 0: No SDIO interrupt detected 1: SDIO interrupt detected	R/(W)*2
2:1	—	The read values are undefined. The write value should be 1.	R/W
13:3	—	These bits are read as 0. The write value should be 0.	R/W
14	EXPUB52	EXPUB52 Status Flag Indicates the status of the EXPUB52.	R/(W)*2
15	EXWT	EXWT Status Flag Indicates the status of the EXWT.	R/(W)*2
31:16	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. The value is initialized by a reset and also on reset triggered by the SOFT_RST.SDRST flag.
Note 2. Only 0 can be written to clear the bit.

The SDIO_INFO1 register indicates the status of the SDIO card access. Set flags to be cleared to 0. Set flags that are not being cleared to 1.

IOIRQ flag (SDIO Interrupt Status Flag)

The IOIRQ flag indicates that an SDIO interrupt occurred.

[Setting condition]

- When SDIO interrupt from an SDIO card is received while INTEN in SDIO_MODE is set to 1.

[Clearing condition]

- When 0 is written to IOIRQ.*1

Note 1. Before clearing this bit, access the SDIO card to negate the SDIO interrupt signal from the SDIO card. If the interrupt signal is not negated, this bit can be set again.

EXPUB52 flag (EXPUB52 Status Flag)

The EXPUB52 flag indicates the EXPUB52 status.

[Setting conditions]

- While the last block in the CMD53 (multiple block) sequence is transferred, C52PUB in SDIO_MODE is set to 1.
- While C52PUB is set to 1 in the CMD53 (multiple block) write sequence, the last block is transferred.

[Clearing condition]

- When 0 is written to EXPUB52.

EXWT flag (EXWT Status Flag)

The EXWT flag indicates the EXWT status.

[Setting condition]

- While the last block in the CMD53 (multiple block) read sequence is transferred, RWREQ in SDIO_MODE is set to 1.

[Clearing condition]

- When 0 is written to EXWT.

39.2.22 SDIO_INFO1_MASK : SDIO INFO1 Interrupt Mask Register

Base address: SDHI0 = 0x4009_2000

Offset address: 0x070

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	EXWTM	EXPUB52M	—	—	—	—	—	—	—	—	—	—	—	—	—	IOIRQM
Value after reset:	1	1	0	0	0	0	0	0	0	0	0	0	0	1	1	1

Bit	Symbol	Function	R/W
0	IOIRQM	IOIRQ Interrupt Mask Control 0: Do not mask IOIRQ interrupts 1: Mask IOIRQ interrupts	R/W
2:1	—	These bits are read as 1.The write value should be 1.	R/W
13:3	—	These bits are read as 0. The write value should be 0.	R/W
14	EXPUB52M	EXPUB52 Interrupt Request Mask Control 0: Do not mask EXPUB52 interrupt requests 1: Mask EXPUB52 interrupt requests	R/W
15	EXWTM	EXWT Interrupt Request Mask Control 0: Do not mask EXWT interrupt requests 1: Mask EXWT interrupt requests	R/W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

The SDIO_INFO1_MASK register enables or disables interrupt requests from the status flags in the SDIO_INFO1 register. See Table 39.5 for details on the relationship between the status flags and the requested interrupt source.

39.2.23 SD_DMAEN : DMA Mode Enable Register

Base address: SDHI0 = 0x4009_2000

Offset address: 0x1B0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DMAEN	—
Value after reset:	0	0	0	1	0	0	0	0	0	0	0	1	0	0	0	0

Bit	Symbol	Function	R/W
0	—	This bit is read as 0. The write value should be 0.	R/W
1	DMAEN	DMA Transfer Enable*1 *2 0: Disable use of DMA transfer to access SD_BUF0 register 1: Enable use of DMA transfer to access SD_BUF0 register	R/W
3:2	—	These bits are read as 0. The write value should be 0.	R/W
4	—	This bit is read as 1. The write value should be 1.	R/W
11:5	—	These bits are read as 0. The write value should be 0.	R/W
12	—	This bit is read as 1. The write value should be 1.	R/W
31:13	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Do not rewrite this bit when the SD_INFO2.CBSY bit is 1.
Note 2. When the SD_INFO2_MASK.BWEM bit is 0 or the SD_INFO2_MASK.BREM bit is 0, set the SD_DMAEN.DMAEN bit to 0. When the SD_DMAEN.DMAEN bit is 1, set the SD_INFO2_MASK.BWEM bit to 1 and the SD_INFO2_MASK.BREM bit to 1.

The SD_DMAEN register enables or disables DMA transfers.

DMAEN bit (DMA Transfer Enable)

When using DMA transfer to access the SD buffer, set the DMAEN bit to 1 before setting the SD_CMD register.

39.2.24 SOFT_RST : Software Reset Register

Base address: SDHI0 = 0x4009_2000

Offset address: 0x1C0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SDRST
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1

Bit	Symbol	Function	R/W
0	SDRST	Software Reset Control 0: Reset SD/MMC Host Interface software 1: Cancel reset of SD/MMC Host Interface software	R/W
2:1	—	These bits are read as 1. The write value should be 1.	R/W
31:3	—	These bits are read as 0. The write value should be 0.	R/W

Table 39.4 lists the bits and flags initialized by SD/MMC Host Interface software reset.

Table 39.4 Bits and flags initialized by SD/MMC Host Interface software reset

Register	Bit/flag
SD_STOP	SEC, STP
SD_INFO1	RSPEND, ACEND
SD_INFO2	CMDE, CRCE, ENDE, DTO, ILW, ILR, RSPTO, BRE, BWE, SD_CLK_CTRLEN, CBSY, ILA
SD_CLK_CTRL	CLKEN
SD_OPTION	CTOP[3:0], TOP[3:0], TOUTMASK, WIDTH8, WIDTH
SD_ERR_STS1	CMDE0, CMDE1, RSPLENE0, RSPLENE1, RDLENE, CRCLENE, RSPCRCE0, RSPCRCE1, RDCRCE, CRCTKE, CRCTK[2:0]
SD_ERR_STS2	RSPTO0, RSPTO1, BSYTO0, BSYTO1, RDTO, CRCTO, CRCBSYTO
SDIO_INFO1	IOIRQ, EXPUB52, EXWT
SDIF_MODE	NOCHKCR

39.2.25 SDIF_MODE : SD Interface Mode Setting Register

Base address: SDHI0 = 0x4009_2000

Offset address: 0x1CC

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	NOCHKCR	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0*1	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	—	These bits are read as 0. The write value should be 0.	R/W
8	NOCHKCR	CRC Check Mask CRC check mask bit for MMC test commands. Set when CRC16 or CRC status value check is not executed. 0: Enable CRC check 1: Disable CRC Check (ignore CRC16 valued when reading and ignore CRC status value when writing)	R/W
31:9	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. The value is initialized by a reset and also on reset triggered by the SOFT_RST.SDRST flag.

NOCHKCR bit (CRC Check Mask)

The NOCHKCR bit is used for MMC test commands. This bit is set when CRC16 or CRC status value check is not executed.

39.2.26 EXT_SWAP : Swap Control Register

Base address: SDHI0 = 0x4009_2000

Offset address: 0x1E0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	BRSWP	BWSWP	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	—	These bits are read as 0. The write value should be 0.	R/W
6	BWSWP	SD_BUF0 Swap Write*1 0: Normal write operation 1: Swap the byte endian order before writing to SD_BUF0 register	R/W
7	BRSWP	SD_BUF0 Swap Read*1 0: Normal read operation 1: Swap the byte endian order before reading SD_BUF0 register	R/W
31:8	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Do not rewrite this bit when the SD_INFO2.CBSY flag is 1.

The EXT_SWAP register selects whether or not the byte endian order is swapped when accessing the SD_BUF0 register. See section 39.3.1. SD/MMC Interface for details on the differences in accessing the SD_BUF0 register based on the EXT_SWAP register value.

39.3 Operation

39.3.1 SD/MMC Interface

When data is read from the SD card/MMC, the process is as follows:

1. The SD/MMC Host Interface receives data from the SD card/MMC through the SDnDAT signal (see Figure 39.2 and Figure 39.3).
2. The received data is stored in SD_BUF of the MMC Host Interface (see Figure 39.4).
3. The data stored in SD_BUF is read from SD_BUF0 (see Figure 39.5).

When data is written to the SD card/MMC, the specified procedure is reversed.

When accessing SD_BUF0, pay attention to the transfer order in SDnDAT and the store order in SD_BUF. If required, you can change the byte endian of the data read from or written to SD_BUF0 using the SDSWAP register. See Figure 39.6.

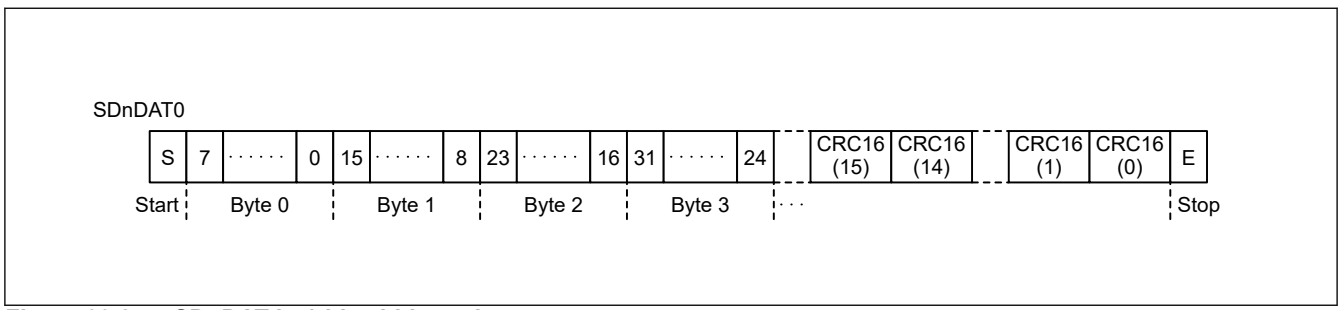


Figure 39.2 SDnDAT in 1-bit width mode

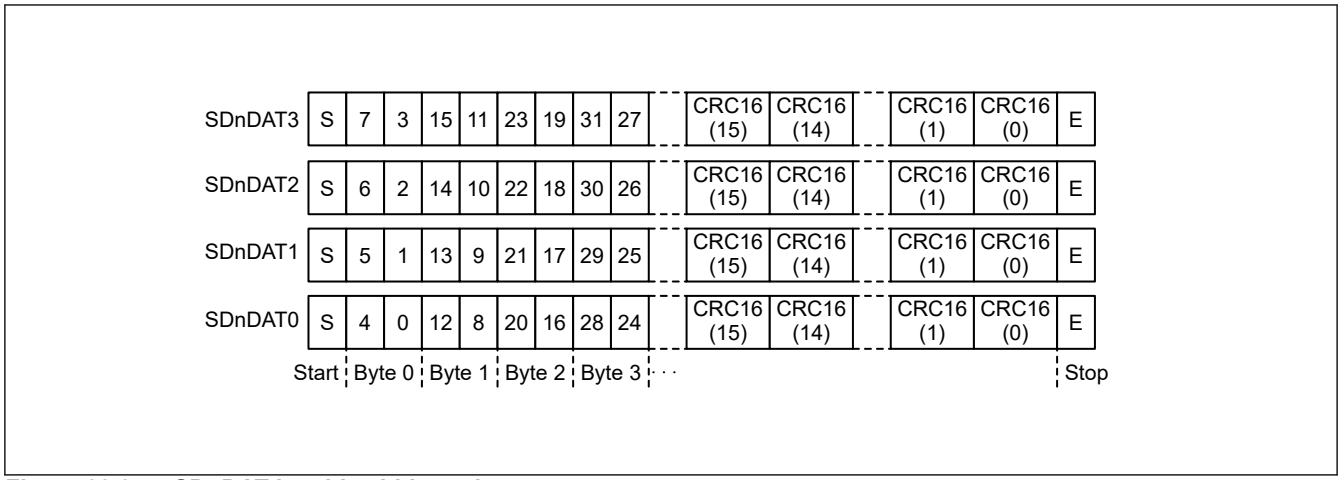

Figure 39.3 SDnDAT in 4-bit width mode

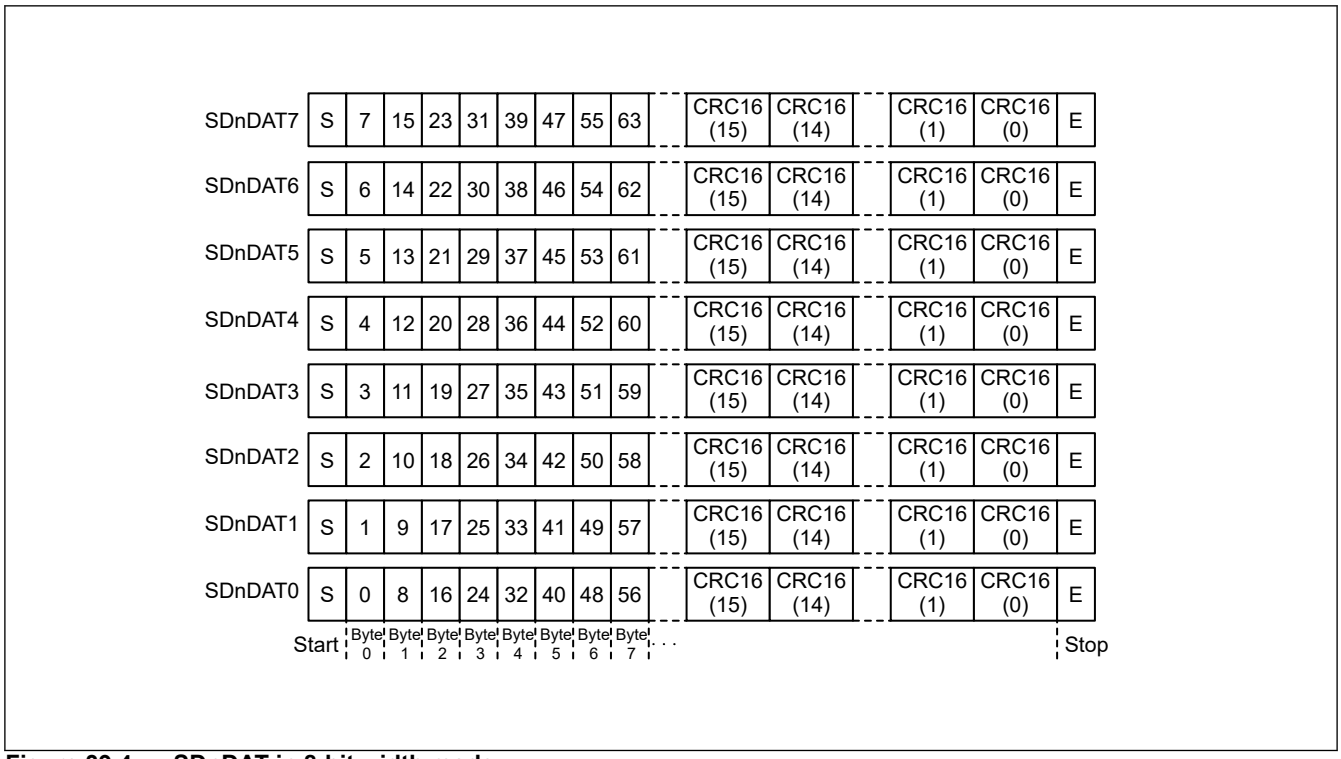

Figure 39.4 SDnDAT in 8-bit width mode

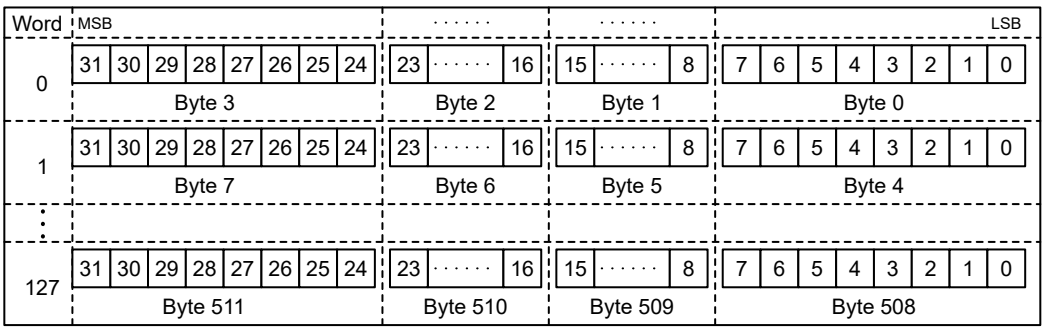

Figure 39.5 SD_BUF store data

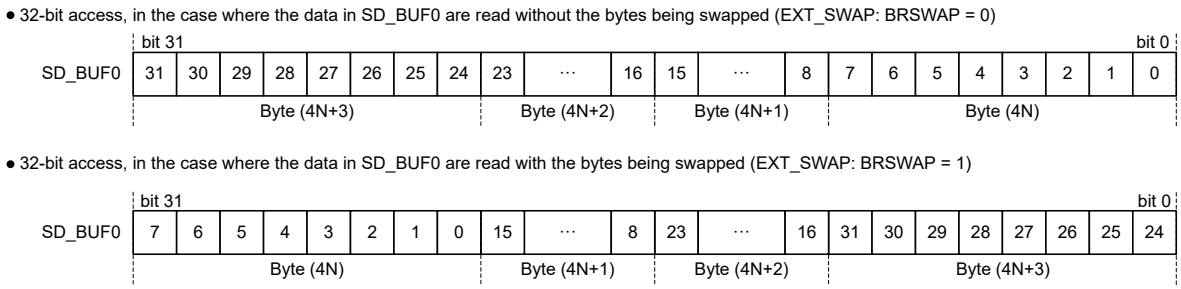

Figure 39.6 Read from SD_BUF0

39.3.2 Card Detect/Write Protect

39.3.2.1 Card detect

The SD/MMC Host Interface has two types of card detect functions.

(1) Card detect with SDnCD (n = 0)

Figure 39.7 shows the timing for card detect using SDnCD. SDnCD is connected to the card socket and pulled up on the host device. The resistance of the pull-up resistor is determined by the specification of the SD/MMC host device.

(2) Card insertion

SDnCD is pulled down when a card is inserted. At this point, if SDnCD is pulled down for the Mcycle period (set in SD_OPTION), SDCDIN in SD_INFO1 is set to 1. It is cleared by writing 0.

(3) Card removal

SDnCD is pulled up when a card is removed. At this point, if SDnCD is pulled up for the Mcycle period (set in SD_OPTION), SDCDRM in SD_INFO1 is set to 1. It is cleared by writing 0.

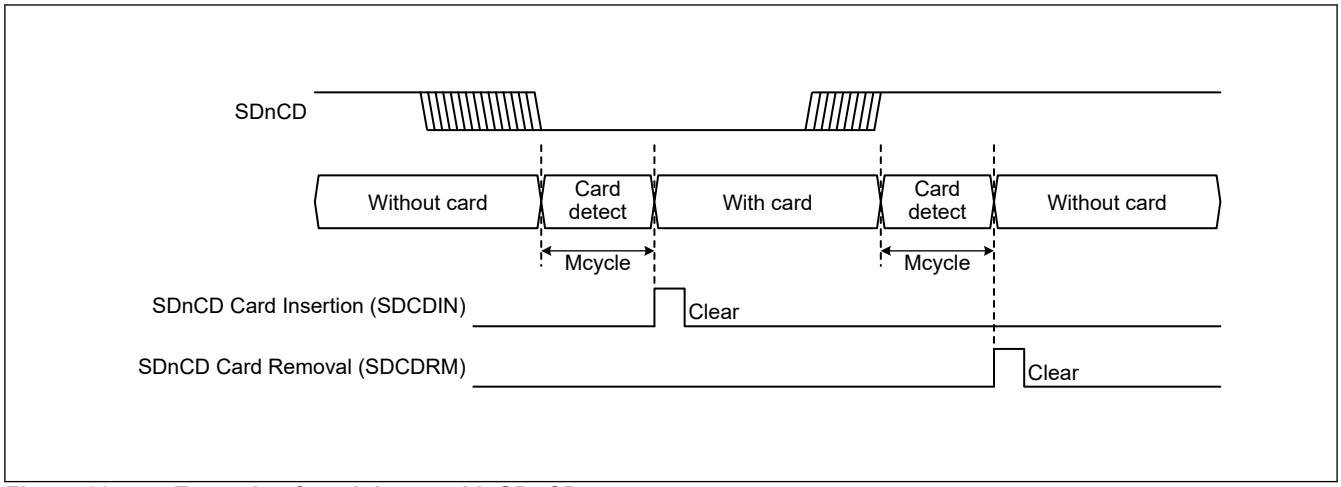

Figure 39.7 Example of card detect with SDnCD

(4) SD card detect with SDnDAT3 (n = 0)

Figure 39.8 shows the timing when the SD card is detected with SDnDAT3. In addition, SDnDAT3 is pulled down by the host device, and the resistance value for pulling down is determined by the specification of the SD host device.

(5) Card insertion

When an SD card is inserted, SDnDAT3 is pulled up and SDD3IN in SD_INFO1 is set to 1. It is cleared by writing 0.

(6) Card removal

When an SD card is removed, SDnDAT3 is pulled down and SDD3RM in SD_INFO1 is set to 1. It is cleared by writing 0.

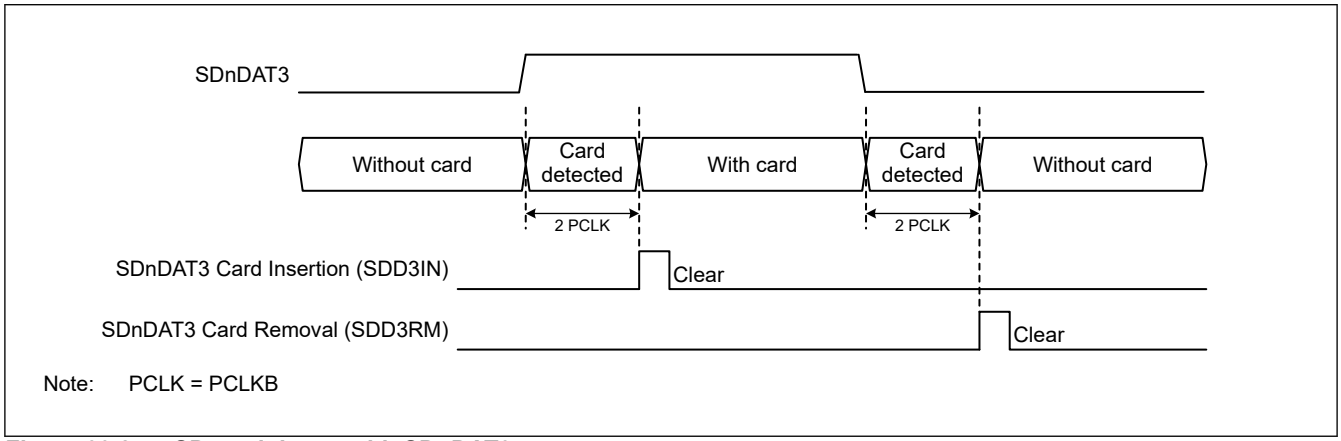

Figure 39.8 SD card detect with SDnDAT3

39.3.2.2 Write protect

The SD/MMC Host Interface has two types of write protect functions.

(1) Write protect with SDnWP (n = 0)

SDnWP is connected to the card socket and pulled up or pulled down by the card insertion. The selection of pulling up or pulling down and the resistance value is determined by the specification of the SD host device. When the SDnWP state is reflected to SDWPMON in SD_INFO1, the write protect state is set after the SD card is inserted.

(2) Write protect with command

The internal write protection of the card and the lock/unlock operation of the card are realized by the command.

39.3.3 Interrupt Request and DMA Transfer Request

39.3.3.1 Interrupts

Table 39.5 lists the SDHI interrupt sources. The SDHI requests an interrupt when:

- The status flags in registers SD_INFO1, SD_INFO2, and SDIO_INFO1 set to 1.
- The associated bits in the SD_INFO1_MASK, SD_INFO2_MASK, and SDIO_INFO1_MASK registers are 0.

When clearing the status flags in registers SD_INFO1, SD_INFO2, and SDIO_INFO1, write 0 to the status flags to be cleared and write 1 to the status flags that are not being cleared.

Table 39.5 Interrupt sources

Interrupt sources	Status flag register		Interrupt mask register		Interrupt name
	Register symbol	Bit symbol	Register symbol	Bit symbol	Ch n (n = 0)
Card Access Interrupt (CACI)	SD_INFO1	ACEND	SD_INFO1_MASK	ACENDM	SDHI_MMCn_ACCS
		RSPEND		RSPENDM	
	SD_INFO2	ILA	SD_INFO2_MASK	ILAM	
		BWE		BWEM	
		BRE		BREM	
		RSPTO		RSPTOM	
		ILR		ILRM	
		ILW		ILWM	
		DTO		DTOM	
		ENDE		ENDEM	
		CRCE		CRCEM	
		CMDE		CMDEM	
SDIO Access Interrupt (SDACI)	SDIO_INFO1	EXWT	SDIO_INFO1_MASK	EXWTM	SDHI_MMCn_SDIO
		EXPUB52		EXPUB52M	
		IOIRQ		IOIRQM	
Card Detect Interrupt (CDETI)	SD_INFO1	SDD3IN	SD_INFO1_MASK	SDD3INM	SDHI_MMCn_CARD
		SDD3RM		SDD3RMM	
		SDCDIN		SDCDINM	
		SDCDRM		SDCDRMM	

39.3.3.2 DMA transfer requests (SDHI_MMCn_ODMSDBREQ, n = 0)

The SD/MMC Host Interface has two types of DMA transfer requests.

(1) SD_BUF write DMA transfer request

- When the BWE bit in SD_INFO2 is set to 1 while the DMAEN bit in SD_DMAEN is set to 1, the SD_BUF write DMA transfer request is asserted.
- The SD_BUF write DMA transfer request is negated when the last data in one block (based on the transfer data size set in SD_SIZE) is transferred. The SD_BUF write DMA transfer request is also negated by clearing the SDRST bit in SOFT_RST to 0 or setting the STP bit in SD_STOP to 1. However, if a communications error or timeout occurs at the DMA transfer, the SD_BUF write DMA transfer request is not negated.
- The BWE bit in SD_INFO2 is cleared after transfer of the last data in one block following a request for writing to SD_BUF by DMA transfer.
- The number of DMA transfers must be n × one block. (n = integer, one block = the transfer data size set in SD_SIZE)
- When the IOABT bit in SDIO_MODE is set to 1, the SD_BUF write DMA transfer request is negated.

- The DMA transfer request is also negated by clearing the DMAEN bit to 0. However, the DMA transfer request is asserted again when the DMAEN bit is set to 1 before writing to SD_CMD.
- Because the BWE bit in SD_INFO2 is not cleared in response to setting the STP/IOABT bit, or to a communications error or timeout, clear the bit to 0 before issuing the next command. The next request to write to SD_BUF by DMA transfer is not issued while the BWE bit is set.

(2) SD_BUF read DMA transfer request

- When the BRE bit in SD_INFO2 is set to 1 while the DMAEN bit in the SD_DMAEN register is set to 1, the SD_BUF read DMA transfer request is asserted.
- The SD_BUF read DMA transfer request is negated when the last data in one block (based on the transfer data size set in SD_SIZE) is transferred. The SD_BUF read DMA transfer request is also negated by clearing the SDRST bit in SOFT_RST to 0 or setting the STP bit in SD_STOP to 1. However, if a communications error or timeout occurs at the DMA transfer, the SD_BUF read DMA transfer request is not negated.
- The BRE bit in SD_INFO2 is cleared after transfer of the last data in one block following a request to write to SD_BUF by DMA transfer.
- The number of DMA transfers must be n × one block. (n = integer, one block = the transfer data size set in SD_SIZE)
- When the IOABT bit in SDIO_MODE is set to 1, the SD_BUF read DMA transfer request is negated.
- The DMA transfer request is also negated by clearing the DMAEN bit to 0. However, the DMA transfer request is asserted again when the DMAEN bit is set to 1 before writing to SD_CMD.
- Because the BRE bit in SD_INFO2 is not cleared in response to setting the STP/IOABT bit or in response to a communications error or timeout, clear the bit to 0 before issuing the next command. The next request to write to SD_BUF by DMA transfer is not issued while the BRE bit is set.

39.3.4 Communication Errors and Timeouts

When a communication error or timeout error occurs, depending on the type of error, the associated status flag in the SD_INFO2 register sets to 1. Also, depending on the source of the error, the associated flag in the SD_ERR_STS1 or SD_ERR_STS2 register sets to 1.

The status flags in registers SD_ERR_STS1 and SD_ERR_STS2 clear to 0 by writing to the SD_CMD register, or by setting the SOFT_RST.SDRST bit to 0.

Table 39.6 Communication errors

Communication error	Interrupt flag register		Error status register		This occurs when…
	Register symbol	Bit symbol	Register symbol	Bit symbol	
End bit error	SD_INFO2	ENDE	SD_ERR_STS1	CRCLENE	The CRC status token length is in error
				RDLENE	The read data length is in error
				RSPLENE1	The response length is in error*1
				RSPLENE0	The response length is in error*2
CRC error		CRCE		CRCTKE	The CRC status token is in error
				RDCRCE	There is a CRC error in the read data
				RSPCRCE1	There is a CRC error in the response*1
				RSPCRCE0	There is a CRC error in the response*2
Command error		CMDE		CMDE1	The command index field value for the transmitted command and received response do not match*1
				CMDE0	The command index field value for the transmitted command and received response do not match*2

Note 1. CMD12 when automatic issuing is enabled for multiple block transfer by the setting in SD_CMD, CMD12 when the STP bit in SD_STOP is set to 1, or CMD52 when the C52PUB or IOABT bit in SDIO_MODE is set to 1.
Note 2. CMD other than CMD12 when automatic issuing is enabled for multiple block transfer by the setting in SD_CMD, CMD12 when the STP bit in SD_STOP is set to 1, or CMD52 when the C52PUB or IOABT bit in SDIO_MODE is set to 1.

Table 39.7 Timeouts

Timeout	Interrupt flag register		Error status register		This occurs when…
	Register symbol	Bit symbol	Register symbol	Bit symbol	
Response timeout	SD_INFO2	RSPTO	SD_ERR_STS2	RSPTO1	A response is not received even after a minimum of 640 SDHI clock cycles elapse*1
				RSPTO0	A response is not received even after a minimum of 640 SDHI clock cycles elapse*2
Data timeout (excluding response timeout)		DTO		CRCBSYTO	After the CRC status token is received, the SDHI is busy for at least the period set*3
				CRCTO	After the write data is transmitted, the CRC status token is not received even after at least the period set*3 elapses
				RDTO	After the read command is issued, the read data is not received even after at least the period set*3 elapses
					After the read data is received, the next block read data is not received even after at least the period set*3 elapses
					After the SDHI exits the read wait state, the next block read data is not received even after at least the period set*3 elapses
				BSYTO1	After CMD12 is issued during the command sequence, the SDHI is busy for at least the period set*3
				BSYTO0	After the R1b response is received, the SDHI is busy for at least the period set*3 (a command other than CMD12 is issued during the command sequence)

Note 1. CMD12 when automatic issuing is enabled for multiple block transfer by the setting in SD_CMD, CMD12 when the STP bit in SD_STOP is set to 1, or CMD52 when the C52PUB or IOABT bit in SDIO_MODE is set to 1.
Note 2. CMD other than CMD12 when automatic issuing is enabled for multiple block transfer by the setting in SD_CMD, CMD12 when the STP bit in SD_STOP bit is set to 1, or CMD52 when the C52PUB or IOABT bit in SDIO_MODE is set to 1.
Note 3. The period is set in the SD_OPTION.TOP[3:0] bits.

39.3.5 Command without Data Transfer (SD/MMC)

Figure 39.9 and Figure 39.10 show example flows.

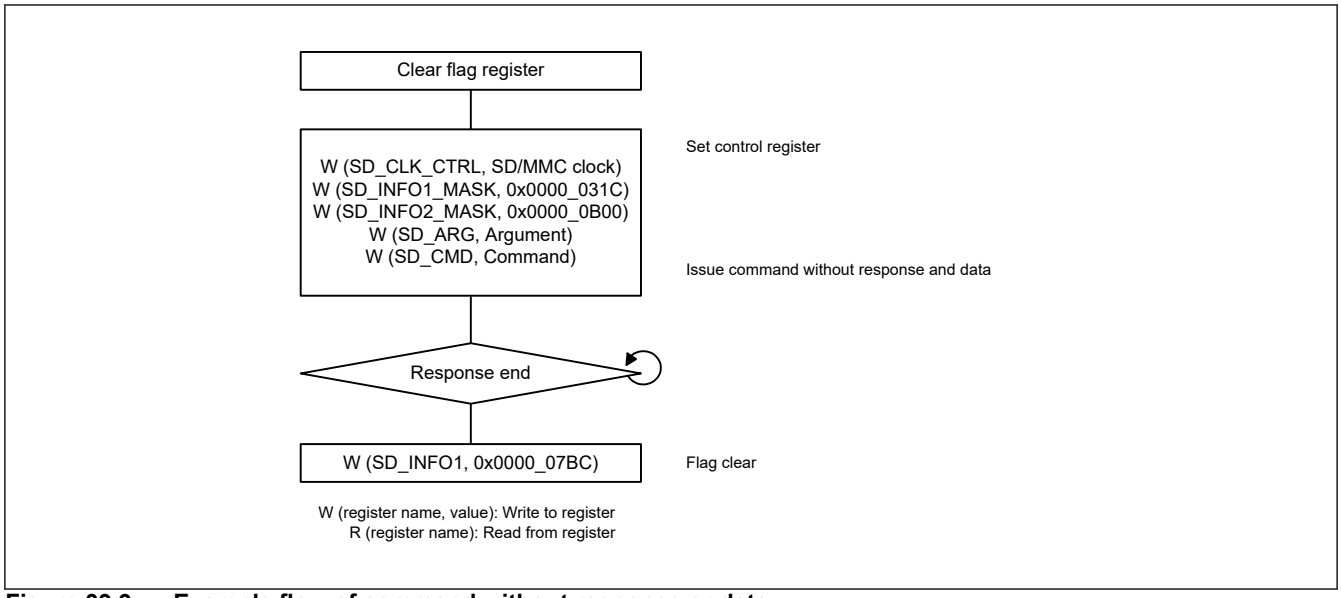

Figure 39.9 Example flow of command without response or data

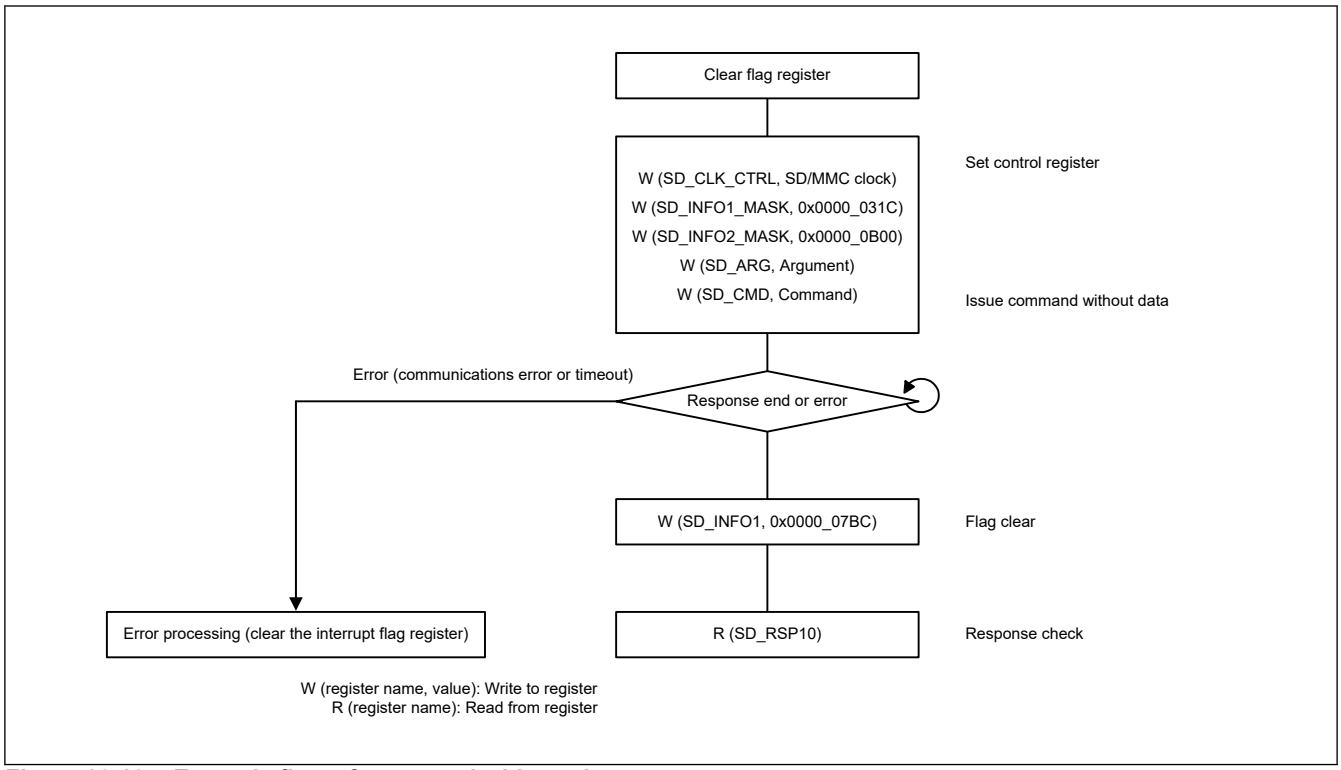

Figure 39.10 Example flow of command without data

39.3.5.1 Operation for command without data transfer

The following legend is used for description of register read/write.

W (register name, value): Write to register

R (register name): Read from register

The operation is described in the following section.

(1) Command without response and data

a. Flag register clear
First, clear the bits in the flag register. (SD_INFO1 and SD_INFO2)

b. Control register set
Set the SD/MMC clock and interrupt masking. (SD_CLK_CTRL, SD_INFO1_MASK, and SD_INFO2_MASK)

c. Command issue
Set CMD argument in SD_ARG and write to SD_CMD.
Accordingly, CMD is issued, and the operation is started.

d. Flag clear
When transmission of a command is completed, RSPEND (response end) in SD_INFO1 is set to 1 to generate an interrupt. Clear RSPEND to 0.

(2) Command without data

a. Flag register clear
First, clear the bits in the flag register. (SD_INFO1 and SD_INFO2)

b. Control register set
Set the SD/MMC clock and interrupt masking. (SD_CLK_CTRL, SD_INFO1_MASK, and SD_INFO2_MASK)

c. Command issue
Set CMD argument in SD_ARG and write to the SD_CMD.
Accordingly, CMD is issued, and the operation is started.

d. Flag clear
When a response is received, RSPEND (response end) in SD_INFO1 is set to 1 to generate an interrupt. Clear RSPEND to 0.

e. Read a response from SD_RSP10. Additionally, perform error processing (clear the interrupt flag register) if a communication error or timeout occurs.

39.3.6 Single Block Read (SD/MMC)

Figure 39.11 shows an example flow of a single block read operation.

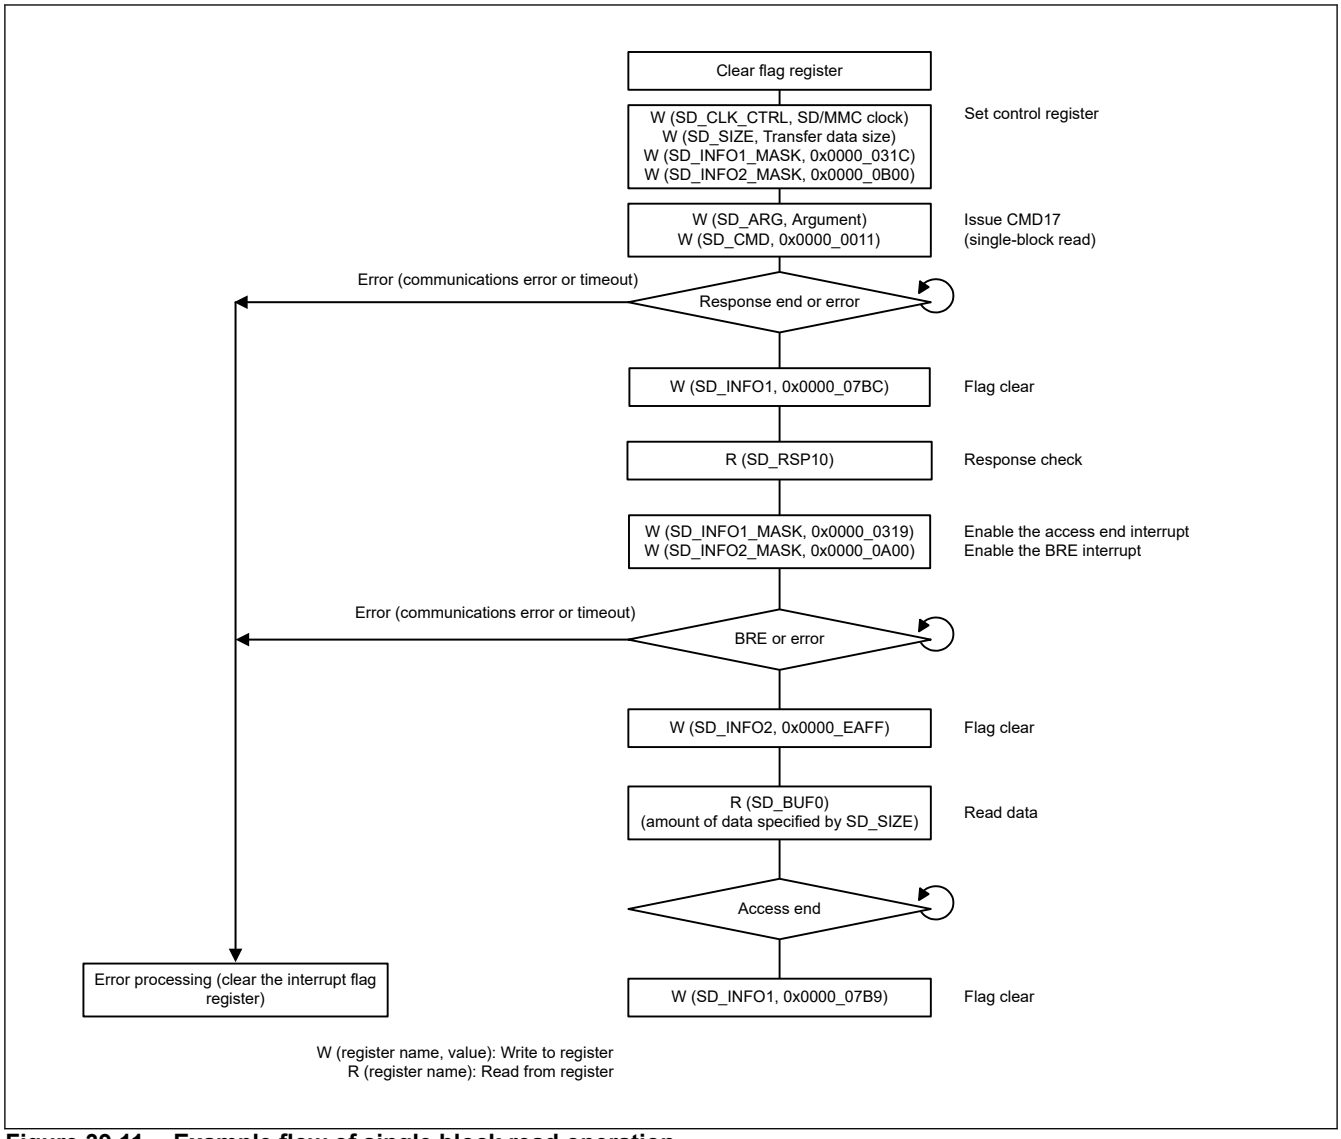

Figure 39.11 Example flow of single block read operation

39.3.6.1 Single block read operation

The operation of the single block read is described as follows:

a. Flag register clear
First, clear the bits in the flag register (SD_INFO1 and SD_INFO2).

b. Control register set
Set the SD/MMC clock, transfer data size, interrupt mask (SD_CLK_CTRL, SD_SIZE, SD_INFO1_MASK, and SD_INFO2_MASK).

c. Command issue (CMD17)
Set CMD17 argument in SD_ARG and write 0x0000_0011 to SD_CMD. CMD17 is issued and the single block read operation is started.

d. Response check
On receiving the response, RSPEND (response end) in SD_INFO1 is set to 1 to generate an interrupt. Clear RSPEND to 0 and read the response from SD_RSP10. If the result of response decoding is an error, the command sequence can be halted by setting the STP bit in SD_STP or the IOABT bit in SDIO_MODE to 1. In addition, this causes CMD12 and CMD52 to not be issued. If the ACEND bit (access end) in SD_INFO1 is set, halting the command sequence also leads to the generation of an interrupt.

e. Data receive from SD card/MMC and data read

Write 0x0000_0319 to SD_INFO1_MASK to enable the access end interrupt. In addition, write 0x0000_0A00 to SD_INFO2_MASK to enable the BRE interrupt. When the data received from the SD card/MMC is completed, the BRE bit in SD_INFO2 is set to 1 to generate an interrupt. Clear the BRE bit to 0 and read the amount of data specified in SD_SIZE from SD_BUF0.
A communication error or timeout might be generated if data is being received while reading of SD_BUF0 is in progress.

f. Operation complete
When the data read from SD_BUF0 is completed, ACEND (access end) in SD_INFO1 is set to 1 to generate an interrupt. Clear ACEND to 0 to end the single block read operation.
Additionally, perform error processing (clear the interrupt flag register) if a communication error or timeout occurs.

39.3.7 Single Block Write (SD/MMC)

Figure 39.12 shows an example flow of a single block write operation.

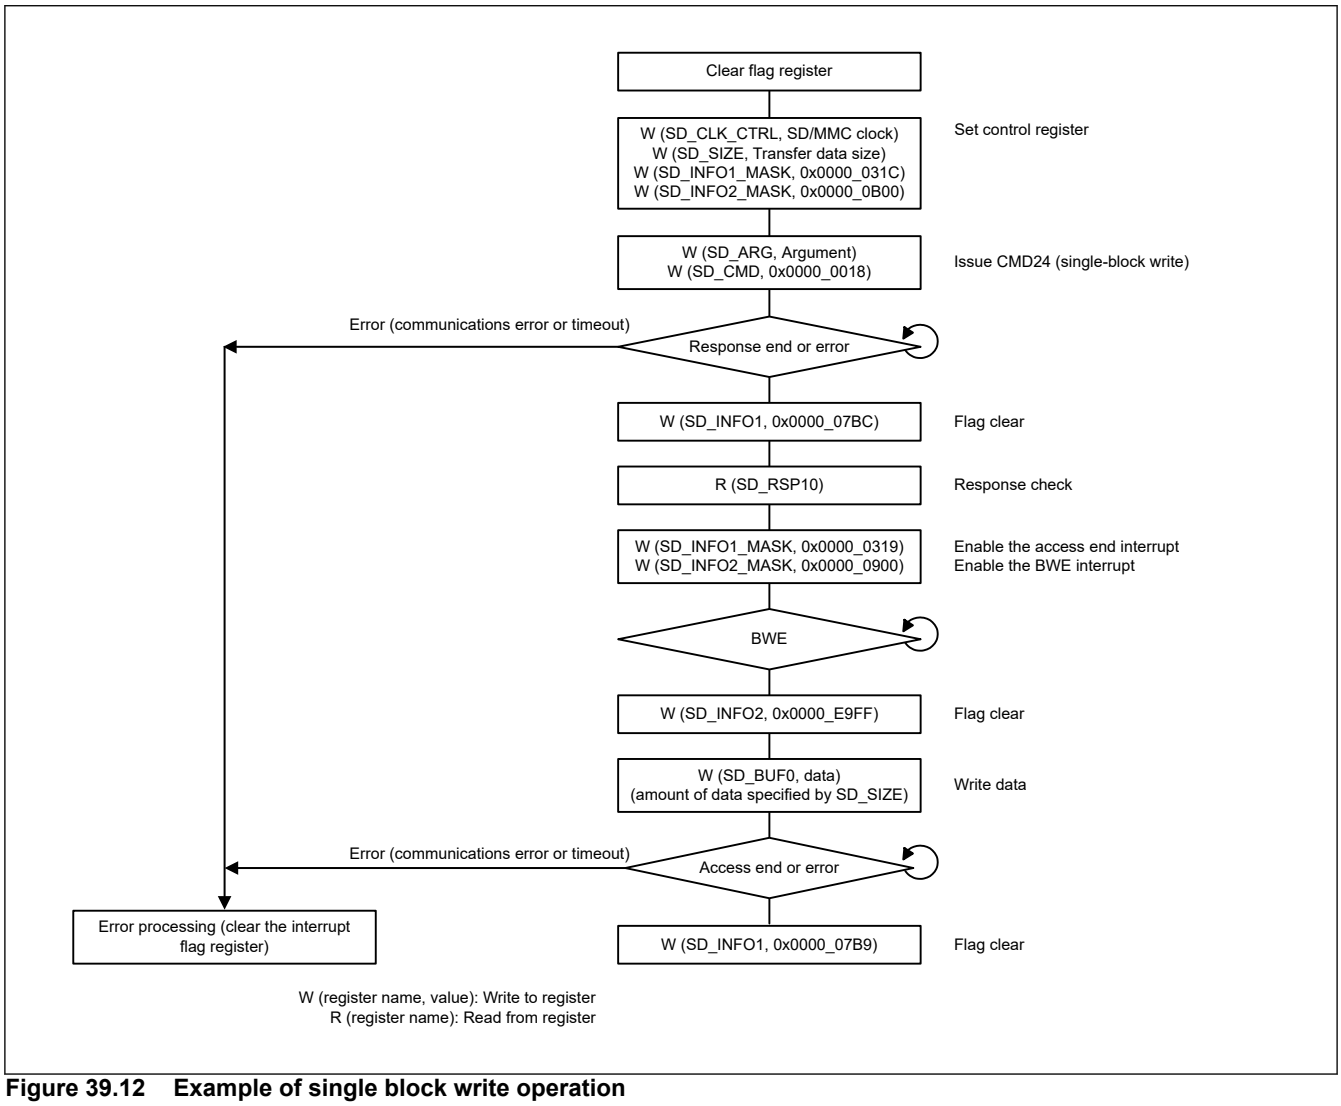

Figure 39.12 Example of single block write operation

39.3.7.1 Single block write operation

The operation of the single block write is described as follows:

a. Flag register clear
First, clear the bits in the flag register (SD_INFO1 and SD_INFO2).

b. Control register set

Set the SD/MMC clock, transfer data size, interrupt mask (SD_CLK_CTRL, SD_SIZE, SD_INFO1_MASK, and SD_INFO2_MASK).

c. Command issue (CMD24)
Set CMD24 argument in SD_ARG and write 0x0000_0018 to SD_CMD. CMD24 is issued and the single block write operation is started.

d. Response check
On receiving the response, RSPEND (response end) in SD_INFO1 is set to 1 to generate an interrupt. Clear RSPEND to 0 and read the response from SD_RSP10. If the result of response decoding is an error, the command sequence can be halted by setting the STP bit in SD_STP or the IOABT bit in SDIO_MODE to 1. In addition, this causes CMD12 and CMD52 to not be issued. If the ACEND bit (access end) in SD_INFO is set, halting the command sequence also leads to the generation of an interrupt.

e. Data write and data transmit to SD card/MMC
Write 0x0000_0319 to SD_INFO1_MASK to enable the access end interrupt. In addition, write 0x0000_0900 to SD_INFO2_MASK to enable the BWE interrupt. When SD_BUF0 is ready for the data to be written, the BWE bit in SD_INFO2 is set to 1 to generate an interrupt. Clear the BWE bit to 0 and write the amount of data specified in SD_SIZE to SD_BUF0. When the data write to SD_BUF0 is completed, data is transmitted to the SD card. Then, the CRC status and busy state are received from the SD card/MMC.
However, a communications error or timeout might be generated if data is being transmitted after writing to SD_BUF0.

f. Operation complete
When the CRC status and busy state are received from the SD card/MMC, ACEND (access end) in SD_INFO1 is set to 1 to generate an interrupt. Clear the ACEND bit to 0 to end the single block write operation.
In addition, perform error processing (clear the interrupt flag register) if a communication error or timeout occurs.

39.3.8 Multiple Block Read (SD/MMC)

Figure 39.13 shows an example flow of a multiple block read operation.

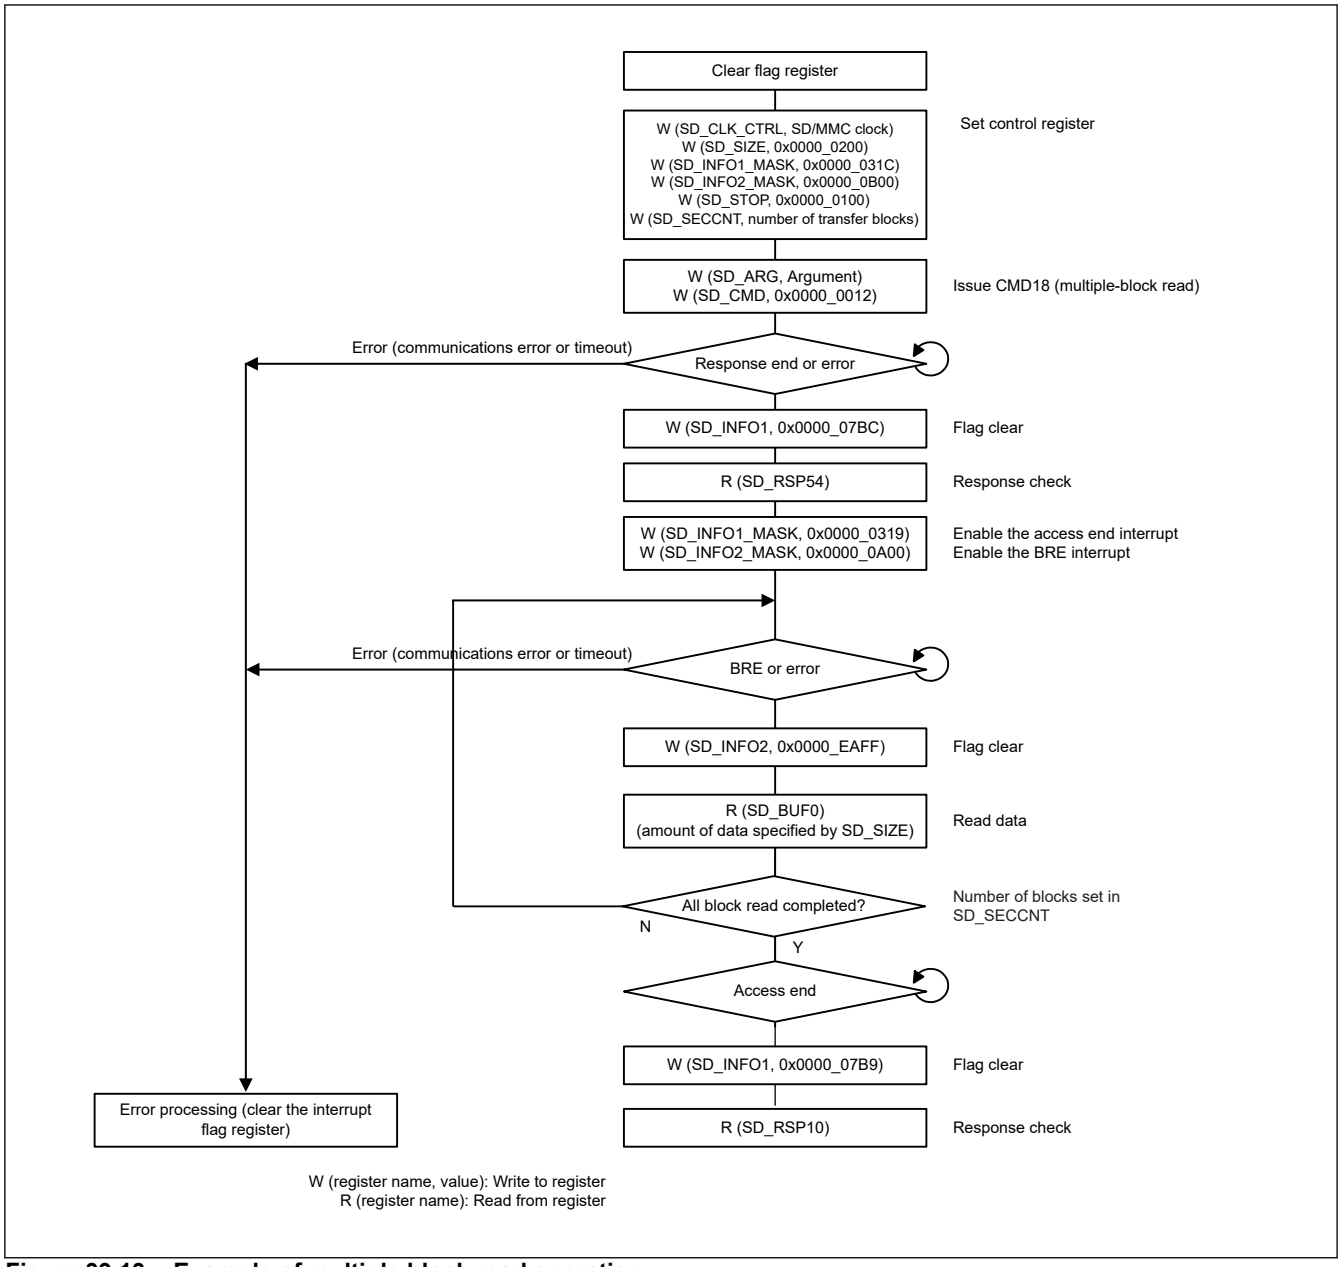

Figure 39.13 Example of multiple block read operation

39.3.8.1 Multiple block read operation

The operation of the multiple block read is described as follows:

a. Flag register clear
First, clear the bits in the flag register (SD_INFO1 and SD_INFO2).

b. Control register set
Set the SD/MMC clock, transfer data size, interrupt mask (SD_CLK_CTRL, SD_SIZE, SD_INFO1_MASK, and SD_INFO2_MASK).
Set SEC in SD_STOP to 1, and set the number of transfer blocks in SD_SECCNT.

c. Command issue (CMD18)
Set CMD18 argument in SD_ARG and write 0x0000_0012 to SD_CMD. CMD18 is issued and the multiple block read operation is started.

d. Response check
On receiving the response, RSPEND (response end) in SD_INFO1 is set to 1 to generate an interrupt. Clear RSPEND to 0 and read the response from SD_RSP54. If the result of response decoding is an error, the command sequence can be

halted by setting the STP bit in SD_STP to 1. Setting the STP bit to 1 also causes CMD12 to be issued and the response received. If the command sequence is halted because the access end interrupt is enabled, an interrupt is generated when the ACEND bit (access end) bit in SD_INFO1 sets to 1 on completion of response reception. Clear the ACEND bit to 0 and read the response.

e. Data receive from SD card/MMC and data read
Write 0x0000_0319 to SD_INFO1_MASK to enable the access end interrupt. In addition, write 0x0000_0A00 to SD_INFO2_MASK to enable the BRE interrupt. When one-block data received from the SD card/MMC is completed, the BRE bit in SD_INFO2 is set to 1 to generate an interrupt. Clear the BRE bit to 0 and read the amount of data specified in SD_SIZE from SD_BUF0. Doing this repeats transfer of the number of blocks set in SD_SECCNT. However, a communication error or timeout might be generated if data is being received while reading of SD_BUF0 is in progress. CMD12 is automatically issued to stop multiblock transfer with the number of blocks that is set to SD_SECCNT and the response is received. At this point, CMD12 argument is automatically set to 0x0000_0000.

f. Operation complete
When all-block data read and the CMD12 response received are completed, ACEND (access end) in SD_INFO1 is set to 1 to generate an interrupt. Clear ACEND to 0 to read the response. This is the end of multiple block read operation. In addition, perform error processing (clear the interrupt flag register) if a communication error or timeout occurs.

39.3.9 Multiple Block Write (SD/MMC Using Internal Timer)

Figure 39.14 shows an example flow of a multiple block write using internal timer.

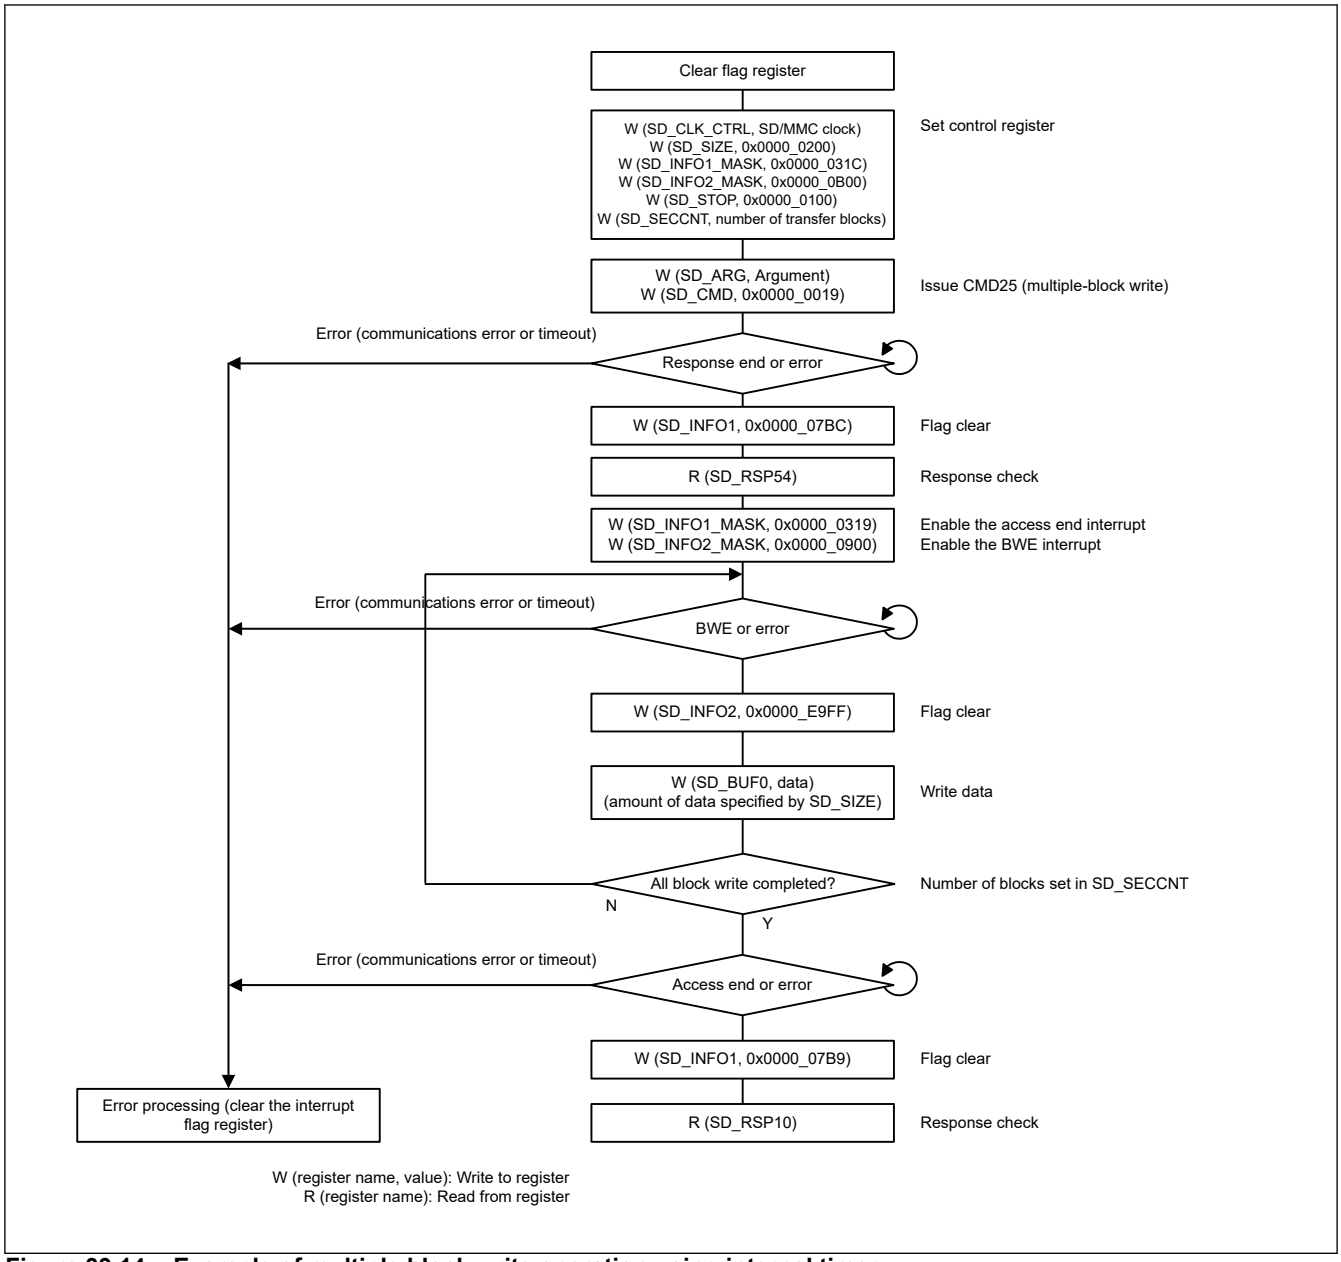

Figure 39.14 Example of multiple block write operation using internal timer

39.3.9.1 Multiple block write operation using internal timer

The operation of the multiple block write is described as follows:

a. Flag register clear
First, clear the bits in the flag register (SD_INFO1 and SD_INFO2).

b. Control register set
Set the SD/MMC clock, transfer data size, interrupt mask (SD_CLK_CTRL, SD_SIZE, SD_INFO1_MASK, and SD_INFO2_MASK).
Set the SEC bit in SD_STOP to 1, and set the number of transfer blocks in SD_SECCNT.

c. Command issue (CMD25)
Set CMD25 argument in SD_ARG and write 0x0000_0019 to SD_CMD. CMD25 is issued and the multiple block write operation is started.

d. Response check
On receiving the response, the RSPEND bit (response end) in SD_INFO1 is set to 1 to generate an interrupt.
Clear the RSPEND bit to 0 and read the response from SD_RSP54. If the result of response decoding is an error, the command sequence can be halted by setting the STP bit in SD_STP to 1. Setting the STP bit to 1 also causes CMD12 to

be issued and the response received. If the command sequence is halted because the access end interrupt is enabled, an interrupt is generated by when the ACEND bit (access end) bit in SD_INFO1 sets to 1 on completion of response reception. Clear the ACEND bit to 0 and read the response.

e. Data write and data transmit to SD card/MMC
Write 0x0000_0319 to SD_INFO1_MASK to enable the access end interrupt. In addition, write 0x0000_0900 to SD_INFO2_MASK to enable the BWE interrupt. When SD_BUF0 is ready for the data to be written, the BWE bit in the SD_INFO2 resister is set to 1 to generate an interrupt. Clear the BWE bit to 0 and write the amount of data specified in SD_SIZE to SD_BUF0. When the data write to SD_BUF0 is completed, data is transmitted to the SD card/MMC. The CRC status and busy state are received from the SD card/MMC. This repeats transfer of the number of blocks set in SD_SECCNT. However, a communication error or timeout might be generated if data is being received while writing to SD_BUF0 is in progress. CMD12 is automatically issued to stop multiblock transfer with the number of blocks which is set to SD_SECCNT and the response is received. At this point, CMD12 argument is automatically set to 0x0000_0000.

f. Operation complete
When all-block data transmit and the CRC status receive are completed, the ACEND bit (access end) in SD_INFO1 is set to 1 to generate an interrupt. Clear the ACEND bit to 0 to read the response. This is the end of multiple block write operation. Additionally, perform error processing (clear the interrupt flag register) if a communications error or timeout occurs.

39.3.10 Multiple Block Write (MMC using external timer)

Figure 39.15 shows an example flow of a multiple block write using an external timer.

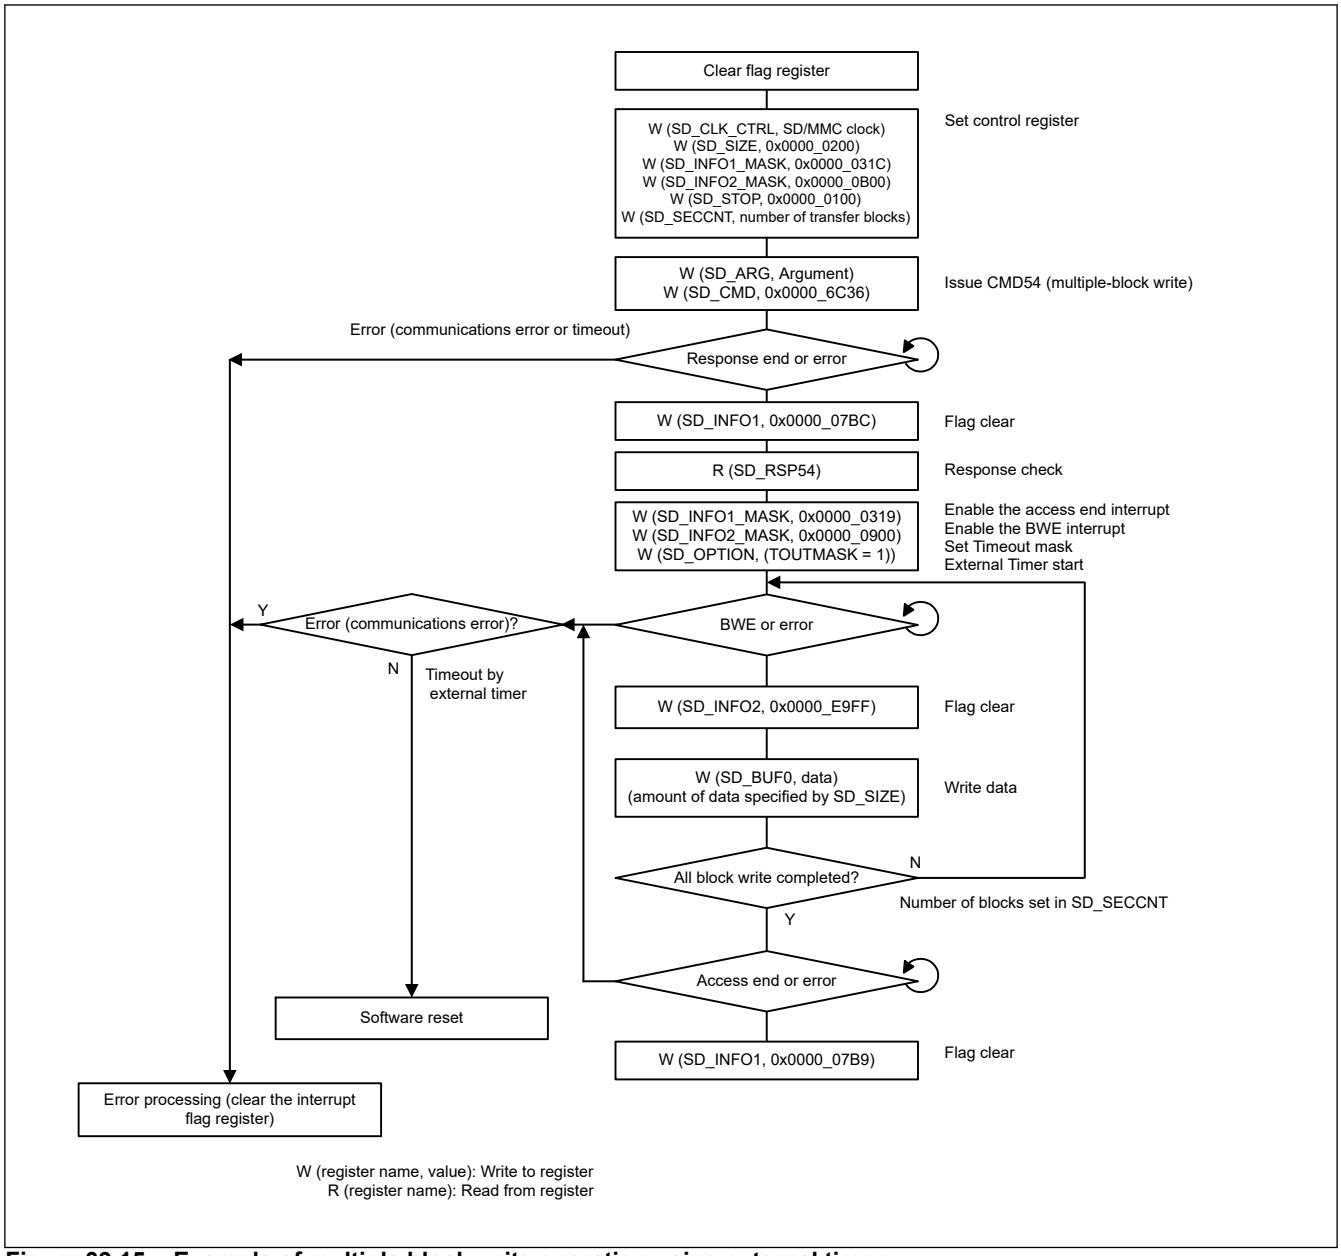

Figure 39.15 Example of multiple block write operation using external timer

39.3.10.1 Multiple block write operation using external timer

The operation of the multiple block write is described as follows:

a. Flag register clear
First, clear the bits in the flag register (SD_INFO1 and SD_INFO2).

b. Control register set
Set the MMC clock, transfer data size, interrupt mask (SD_CLK_CTRL, SD_SIZE, SD_INFO1_MASK, and SD_INFO2_MASK).
Set the SEC bit in SD_STOP to 1, and set the number of transfer blocks in SD_SECCNT.

c. Command issue (CMD54)
Set CMD54 Argument in SD_ARG and write 0x0000_6C36 to SD_CMD. CMD54 is issued and the multiple block write operation is started.

d. Response check
On receiving the response, the RSPEND bit (response end) in SD_INFO1 is set to 1 to generate an interrupt. Clear the RSPEND bit to 0 and read the response from SD_RSP54. If the result of response decoding is an error, the command sequence can be halted by setting the STP bit in SD_STP to 1. Setting the STP bit to 1 also causes CMD12 to be issued

and the response received. If the command sequence is halted because the access end interrupt is enabled, an interrupt is generated by when the ACEND bit (access end) bit in SD_INFO1 sets to 1 on completion of response reception. Clear the ACEND bit to 0 and read the response.

e. Data write and data transmit to MMC
Write 0x0000_0319 to SD_INFO1_MASK to enable the access end interrupt, write 0x0000_0900 to SD_INFO2_MASK to enable the BWE interrupt and set 1 to TOUTMASK of SD_OPTION to inactivate timeout. In addition, start external timer. When SD_BUF0 is ready for the data to be written, the BWE bit in the SD_INFO2 resister is set to 1 to generate an interrupt. Clear the BWE bit to 0 and write the amount of data specified in SD_SIZE to SD_BUF0. When the data write to SD_BUF0 is completed, data is transmitted to the MMC. The CRC status and busy state are received from the MMC. Doing this repeats transfer of the number of blocks set in SD_SECCNT. However, a communication error or timeout might be generated if data is being received while writing to SD_BUF0 is in progress.

f. Operation complete
When all-block data transmit and the CRC status receive are completed, the ACEND bit (access end) in SD_INFO1 is set to 1 to generate an interrupt. Clear the ACEND bit to 0 to read the response. This is the end of multiple block write operation. Additionally, perform error processing (clear the interrupt flag register) if a communications error or timeout occurs when receiving response. Execute software reset if a timeout by external timer occurs when transmitting data.

39.3.11 IO_RW_DIRECT Command (SD: CMD52)

Figure 39.16 shows an example flow of an IO_DIRECT command (CMD52) operation.

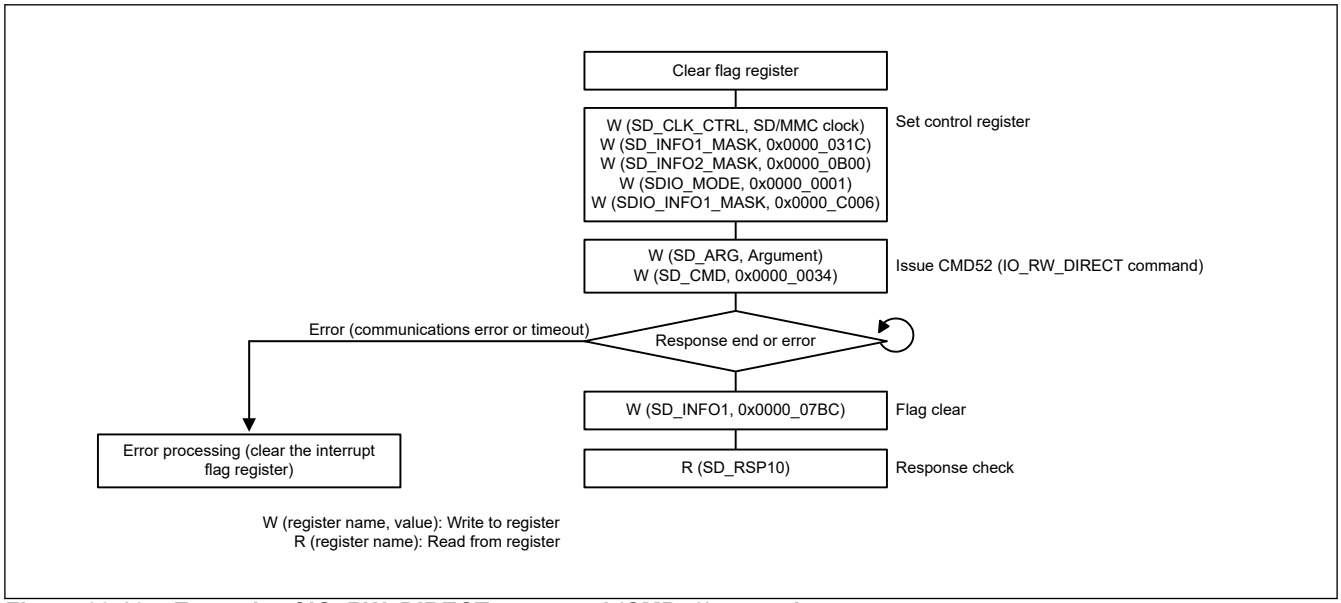

Figure 39.16 Example of IO_RW_DIRECT command (CMD52) operation

39.3.12 IO_RW_EXTENDED Command (SD: CMD53/Multiple Block Read)

Figure 39.17 shows an example flow for a CMD53 multiple block read operation.

39.4 Usage Notes

39.4.1 SD_BUF Illegal Write Access (SD/MMC)

When writing data to SD_BUF0 after the single block write or multi block write command is issued, the data of the size specified in SD_SIZE must be written.

If the data exceeds the size specified in SD_SIZE is written, the ERR4 bit in SD_INFO2 is set to 1. In addition, the data written to SD_BUF0 might not be transmitted and the SD_CLK_CTRLEN bit in SD_INFO2 is held at the value of 0. If this occurs, clearing the SDRST bit in SOFT_RST to 0 and then restoring its value to 1 clears the SD_CLK_CTRLEN bit to 1.

However, this does not apply to the single byte or three bytes when the SD_SIZE setting is odd, or to the fraction of bytes when the SD_SIZE setting is even (the 2 bytes that are not in a 4-byte unit), because the portion of dummy data writing is regarded as excess data and ignored.

39.4.2 Block Number Constraint for Multiple Block Read (SD)

When performing a multiple block read of one or two blocks, depending on the timing with which the SD card response register is read, the response value might not be read properly. To prevent this, do one of the following:

1. When receiving one or two blocks of data, use single block reading.
2. Read the response to CMD18 from SD_RSP54.

39.4.2.1 Mechanism of incorrect reading

Figure 39.25 shows the processing flows of the SDHI (hardware) operation and software operation when a multiple block read is performed on two blocks. As shown in the incorrect operation in Figure 39.25, when an interrupt is generated on reception of the CMD18 response and the timing with which the SD card response register (SD_RSP10) is read by the interrupt is delayed, the data during the CMD12 response reception or the CMD12 response might be read. This problem does not occur for multiple block reads of three or more blocks, because CMD12 is not issued until the block of data is read. The problem also does not occur for multiple block writes, because the CMD25 response is read before the block of data is sent.

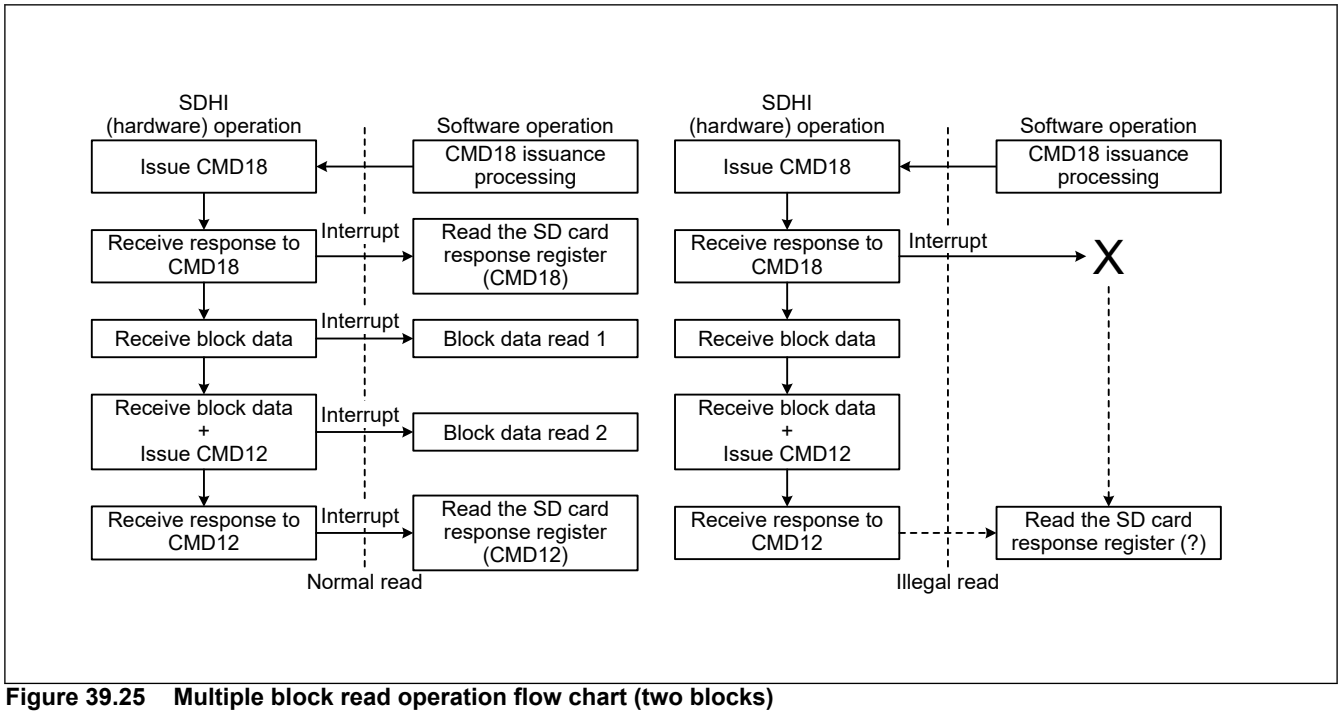

Figure 39.25 Multiple block read operation flow chart (two blocks)

39.4.3 Automatic Control of SD/MMC Clock Output (SD/MMC)

In the SD Card/MMC standard, 74 cycles of SD/MMC clock must be output before initialization of the card. For this reason, use automatic control of SD/MMC clock output after 74 cycles of SD/MMC clock are output. In addition, if

automatic control of SD/MMC clock output was in use, SD/MMC clock output is stopped on completion of the sequence for a communications error or timeout. When state transitions within the SD card/MMC are necessary after completion of the sequence, release automatic control of SD/MMC clock output and restart supply of the SD/MMC clock to the SD card/MMC.

39.4.4 Control of the C52PUB Setting for Multiple Block Write (SD)

If the C52PUB bit in SDIO_MODE is set to 1 during a sequence of multiple block write because of CMD53, CMD52 is not issued until SD_BUF becomes empty. For this reason, set the C52PUB bit after suspending writing to SD_BUF by using one of the following procedures, as appropriate:

(a) When DMA transfer is not in use

1. Before setting the C52PUB bit, suspend writing to SD_BUF by making the setting in SD_INFO2 to disable BWE interrupts.
2. Set the C52PUB bit in SDIO_MODE to 1 (so that CMD52 is issued when SD_BUF becomes empty).
3. After the RSPEND interrupt processing in SD_INFO1 because the issuing of CMD52 is completed, restart writing to SD_BUF by making the setting in SD_INFO2 to enable BWE interrupts.

(b) When DMA transfer is in use

1. Every time DMA transfer of the value set in SD_SIZE × n blocks (where n = 1, 2,…) proceeds, suspend writing to SD_BUF by DMA transfer before the C52PUB bit is set.
2. Set the C52PUB bit in SDIO_MODE to 1 (so that CMD52 is issued when SD_BUF becomes empty).
3. After the RSPEND interrupt processing in SD_INFO1 because the issuing of CMD52 is completed, restart writing to SD_BUF by DMA transfer.

39.4.5 Notes on SD_CLK_CTRL Register Settings (SD/MMC)

When the SD_CLK_CTRLEN bit in SD_INFO2 is 0, SD_CLK_CTRL cannot be written to. Before writing to SD_CLK_CTRL, you must check that the SD_CLK_CTRLEN bit in SD_INFO2 is 1.

39.4.6 Specification Limitations

1. The Suspend/Resume operation of the SDIO is not supported.
2. The SPI bus is not supported. (SD/MMC)
3. The shared bus and 8-bit SD bus of the embedded SDIO are not supported.
4. Stream transfer of MMC is not supported.
5. High Priority Interrupt (HPI) of MMC is not supported.
6. Boot Operation/Alternative Boot Operation of MMC is not supported.
7. Open-ended multiple block transfer of MMC is not supported.

39.4.7 STP Bit Setting during Multiple Block Read (SD/MMC)

During execution of multiple block read with automatic CMD12 execution by setting the SEC bit in SD_STOP to 1, even if the STP bit in SD_STOP is set to 1 to forcibly stop the execution, the command sequence might not stop depending on the timing of setting the STP bit.

To avoid this, when setting the STP bit in SD_STOP to 1 during multiple block transfer, clear the SEC bit in SD_STOP to 0 at the same time. (Even when the SD_CLK_CTRLEN bit in SD_INFO2 is 0, change the SEC bit from 1 to 0.)

When the command sequence does not stop because the SEC bit was not cleared to 0, the command sequence can be stopped by clearing the SDRST bit in SOFT_RST to 0.

When forcibly terminating the CMD53 multiple block transfer through the IOABT bit in SDIO_MODE, you must leave the SEC bit in SD_STOP as 1.

39.4.8 Register Setting Notes

1. All registers in section 39.2. Register Descriptions are accessed in 32-bit access-only.
2. When setting registers, set them after the I/O Port Register setting.

40. Cyclic Redundancy Check (CRC)

40.1 Overview

The Cyclic Redundancy Check (CRC) generates CRC codes to detect errors in the data. The bit order of CRC calculation results can be switched for LSB-first or MSB-first communication. Additionally, various CRC-generation polynomials are available.

Table 40.1 lists the CRC calculator specifications and Figure 40.1 shows a block diagram.

Table 40.1 CRC calculator specifications

Item	Description	
Data size	8-bit	32-bit
Data for CRC calculation*1	CRC code generated for data in 8n-bit units (where n is a natural number)	CRC code generated for data in 32n-bit units (where n is a natural number)
CRC processor unit	Operation executed on 8 bits in parallel	Operation executed on 32 bits in parallel
CRC generating polynomial	One of three generating polynomials that is selectable: [8-bit CRC] • $X^8 + X^2 + X + 1$ (CRC-8) [16-bit CRC] • $X^{16} + X^{15} + X^2 + 1$ (CRC-16) • $X^{16} + X^{12} + X^5 + 1$ (CRC-CCITT).	One of two generating polynomials that is selectable: [32-bit CRC] • $X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^8 + X^7 + X^5 + X^4 + X^2 + X + 1$ (CRC-32) • $X^{32} + X^{28} + X^{27} + X^{26} + X^{25} + X^{23} + X^{22} + X^{20} + X^{19} + X^{18} + X^{14} + X^{13} + X^{11} + X^{10} + X^9 + X^8 + X^6 + 1$ (CRC-32C).
CRC calculation switching	The bit order of CRC calculation results can be switched for LSB-first or MSB-first communication	
Module-stop function	Module-stop state can be set to reduce power consumption	
TrustZone Filter	Security attribution can be set	

Note 1. This function cannot divide data used in CRC calculations. Write data in 8-bit or 32-bit units.

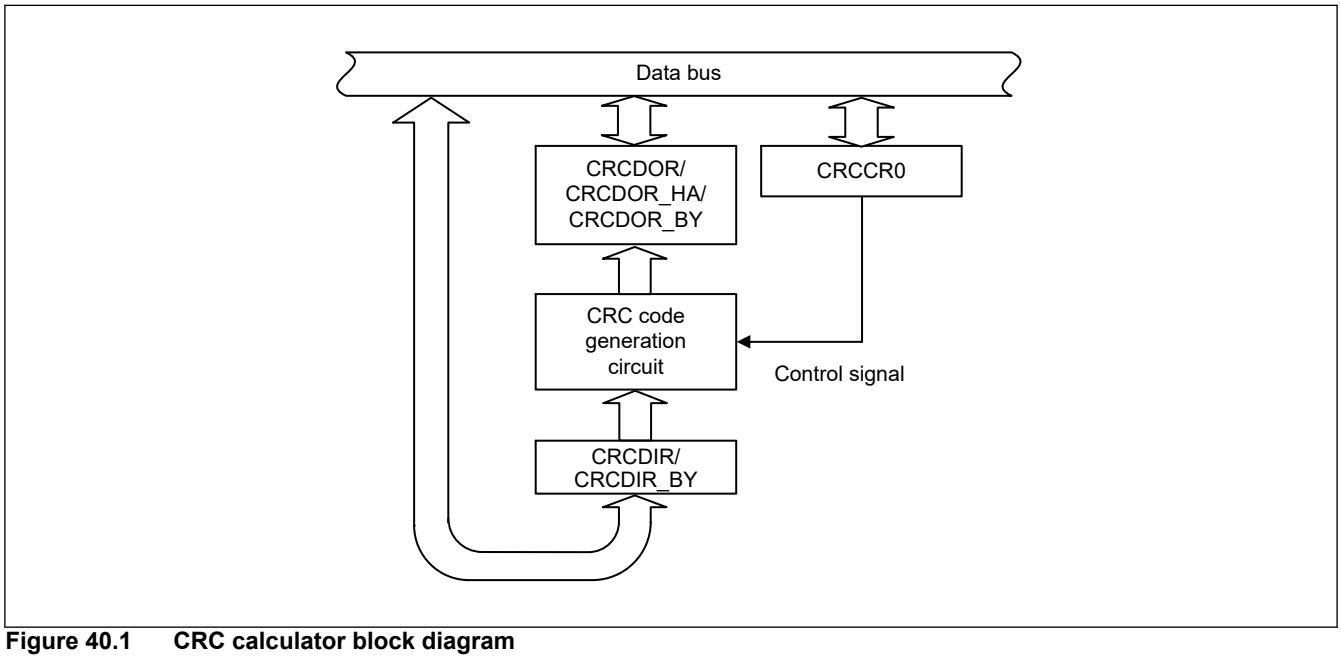

Figure 40.1 CRC calculator block diagram

40.2 Register Descriptions

40.2.1 CRCCR0 : CRC Control Register 0

Base address: CRC = 0x4010_8000

Offset address: 0x00

Bit position:	7	6	5	4	3	2	1	0
Bit field:	DORCLR	LMS	—	—	—	GPS[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	GPS[2:0]	CRC Generating Polynomial Switching 0 0 1: 8-bit CRC-8 ($X^8 + X^2 + X + 1$) 0 1 0: 16-bit CRC-16 ($X^{16} + X^{15} + X^2 + 1$) 0 1 1: 16-bit CRC-CCITT ($X^{16} + X^{12} + X^5 + 1$) 1 0 0: 32-bit CRC-32 ($X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^8 + X^7 + X^5 + X^4 + X^2 + X + 1$) 1 0 1: 32-bit CRC-32C ($X^{32} + X^{28} + X^{27} + X^{26} + X^{25} + X^{23} + X^{22} + X^{20} + X^{19} + X^{18} + X^{14} + X^{13} + X^{11} + X^{10} + X^9 + X^8 + X^6 + 1$) Others: No calculation is executed	R/W
5:3	—	These bits are read as 0. The write value should be 0.	R/W
6	LMS	CRC Calculation Switching 0: Generate CRC code for LSB-first communication 1: Generate CRC code for MSB-first communication	R/W
7	DORCLR	CRCDOR/CRCDOR_HA/CRCDOR_BY Register Clear 0: No effect 1: Clear the CRCDOR/CRCDOR_HA/CRCDOR_BY register	W

GPS[2:0] bits (CRC Generating Polynomial Switching)

The GPS[2:0] bits select the CRC generating polynomial.

LMS bit (CRC Calculation Switching)

The LMS bit selects the bit order of generated CRC code. Transmit the lower byte of the CRC code first for LSB-first communication and the upper byte first for MSB-first communication. For details on transmitting and receiving CRC code, see section 40.3. Operation.

DORCLR bit (CRCDOR/CRCDOR_HA/CRCDOR_BY Register Clear)

Write 1 to the DORCLR bit to set the CRCDOR/CRCDOR_HA/CRCDOR_BY register to 0x00000000. This bit is read as 0. Only 1 can be written to it.

40.2.2 CRCDIR/CRCDIR_BY : CRC Data Input Register

Base address: CRC = 0x4010_8000

Offset address: 0x04

Bit position:	31	0
Bit field:		
Value after reset:	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	

Bit	Symbol	Function	R/W
31:0	n/a	CRC input data The CRCDIR register is a 32-bit read/write register to write data for CRC-32 or CRC-32C calculation. The CRCDIR_BY (CRCDIR[31:24]) is an 8-bit read/write register to write data for CRC-8, CRC-16, or CRC-CCITT calculation.	R/W

40.2.3 CRCDOR/CRCDOR_HA/CRCDOR_BY : CRC Data Output Register

Base address: CRC = 0x4010_8000

Offset address: 0x08

Bit position:	31																												0
Bit field:																													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	n/a	CRC output data The CRCDOR register is a 32-bit read/write register for CRC-32 or CRC-32C calculation. The CRCDOR_HA (CRCDOR[31:16]) register is a 16-bit read/write register for CRC-16 or CRC-CCITT calculation. The CRCDOR_BY (CRCDOR[31:24]) register is an 8-bit read/write register for CRC-8 calculation. Because its initial value is 0x00000000, rewrite the CRCDOR/CRCDOR_HA/CRCDOR_BY register to perform the calculations using a value other than the initial value. Data written to the CRCDIR/CRCDIR_BY register is CRC calculated and the result is stored in the CRCDOR/CRCDOR_HA/CRCDOR_BY register. If the CRC code is calculated following the transferred data and the result is 0x00000000, there is no CRC error.	R/W

40.3 Operation

40.3.1 Basic Operation

The CRC calculator generates CRC codes for use in LSB-first or MSB-first transfer.

The following examples show CRC code generation for input data (0xF0) using the 16-bit CRC-CCITT generating polynomial ($X^{16} + X^{12} + X^5 + 1$). In these examples, the value of the CRC Data Output Register (CRCDOR_HA) is cleared before CRC calculation.

When an 8-bit CRC (with the polynomial $X^8 + X^2 + X + 1$) is in use, the valid bits of the CRC code are obtained in CRCDOR_BY. When a 32-bit CRC is in use, the valid bits of the CRC code are obtained in CRCDOR.

Figure 40.2 and Figure 40.3 show the LSB-first and MSB-first data transmission examples respectively. Figure 40.4 and Figure 40.5 show the LSB-first and MSB-first data reception examples.

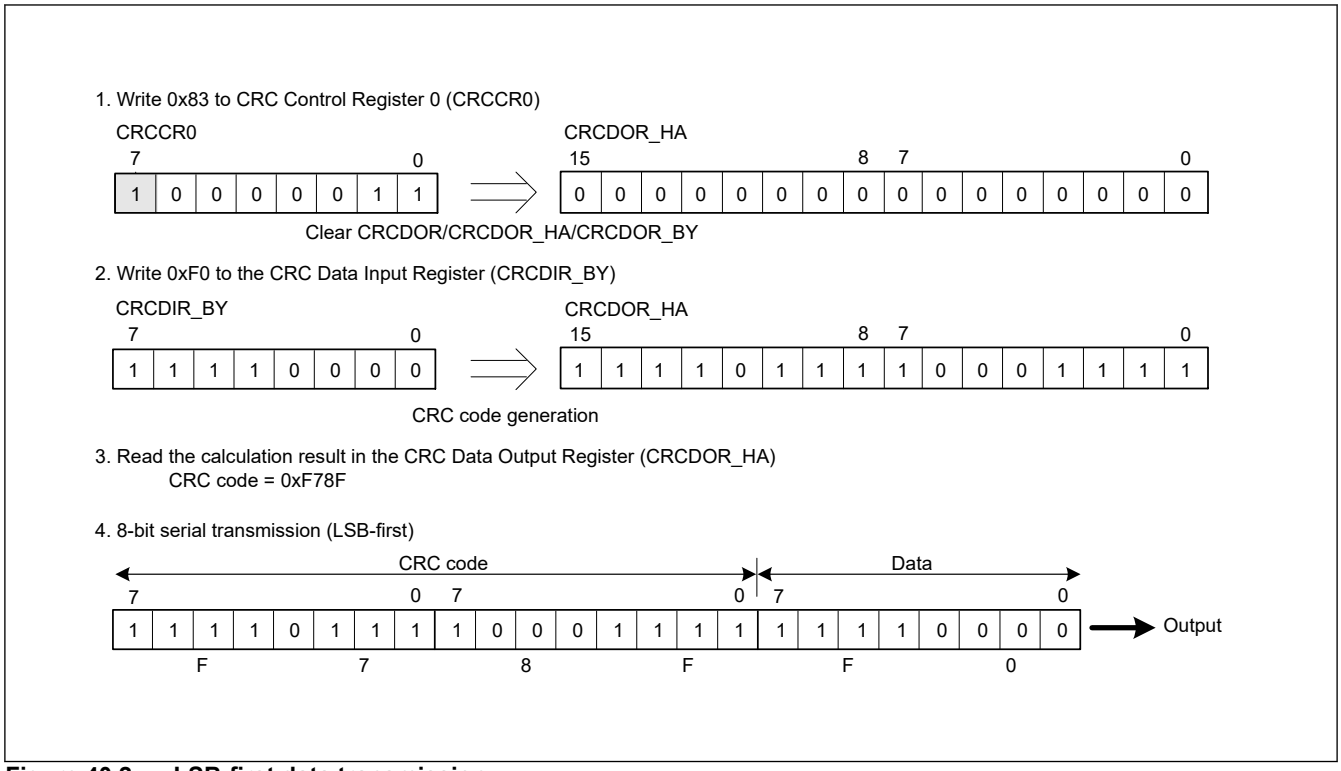

Figure 40.2 LSB-first data transmission

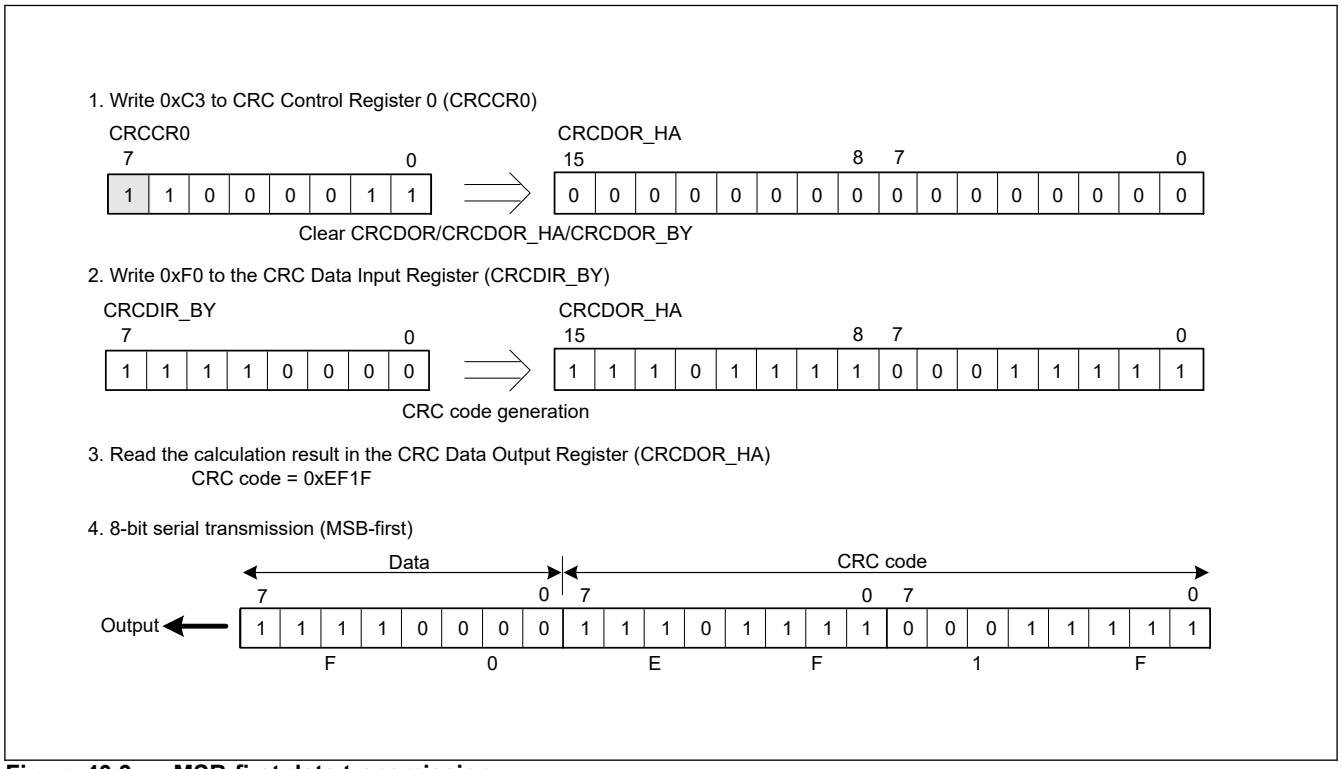

Figure 40.3 MSB-first data transmission

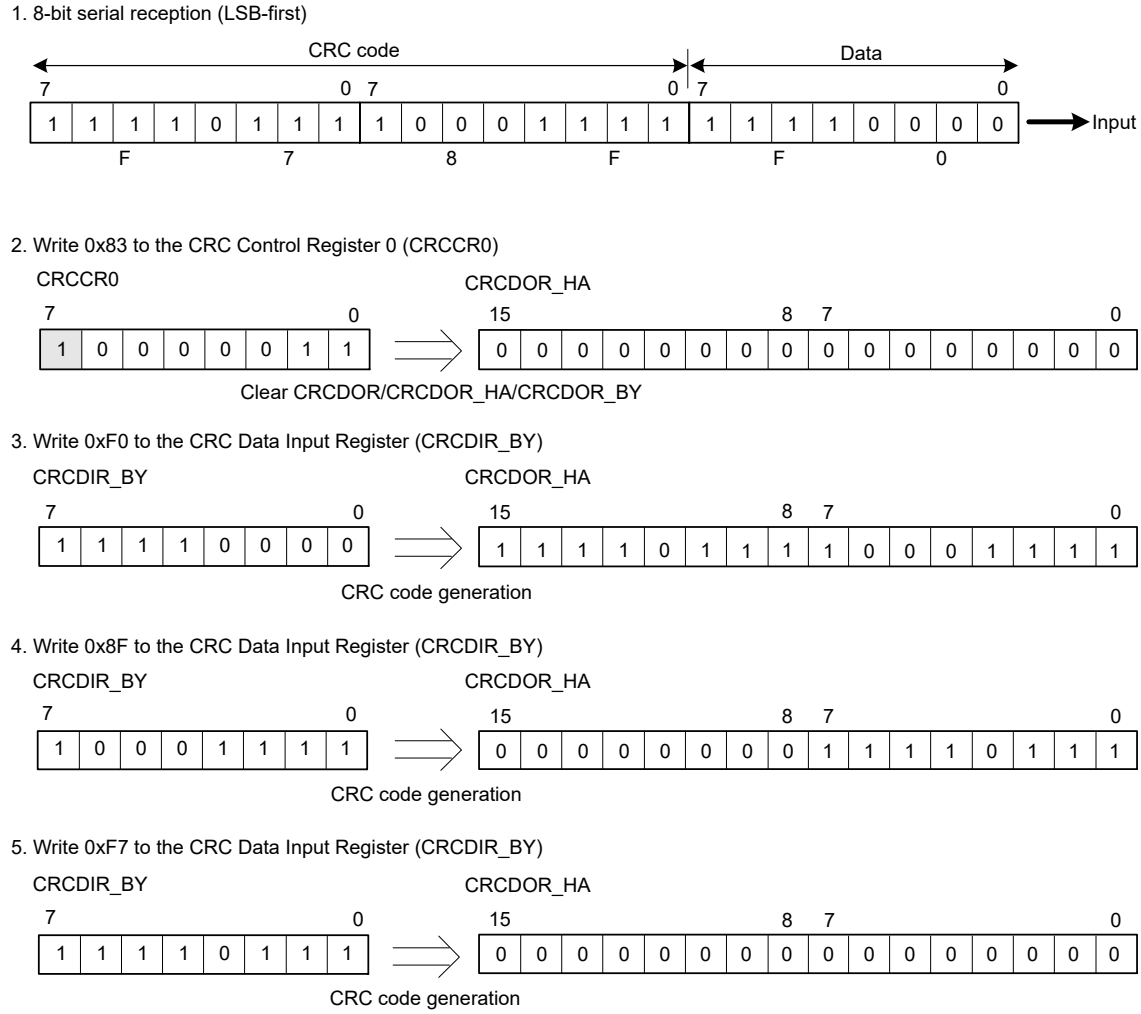

Figure 40.4 LSB-first data reception

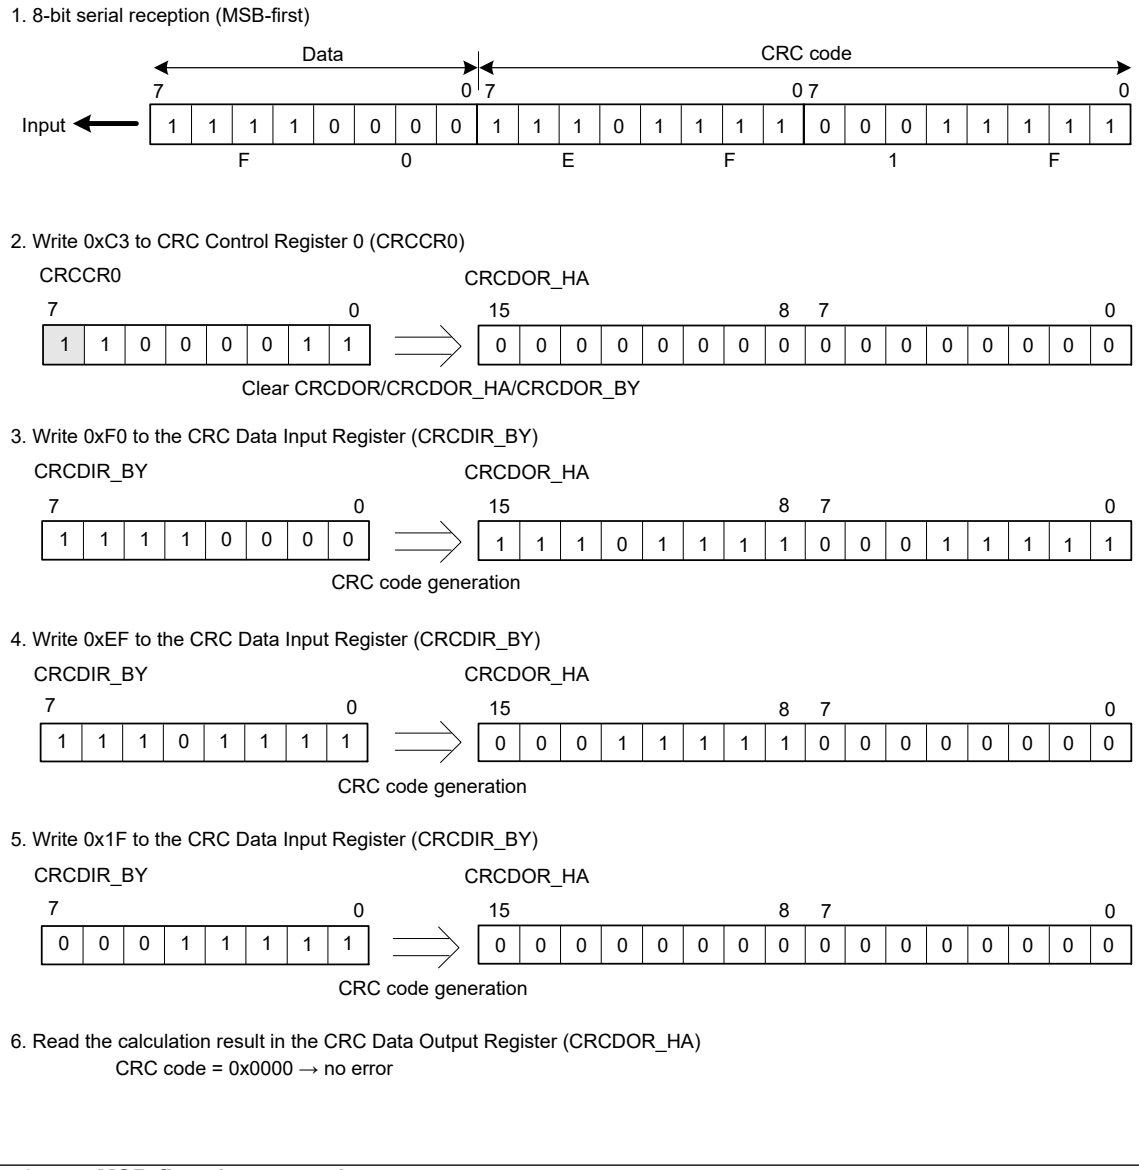

Figure 40.5 MSB-first data reception

40.4 Usage Notes

40.4.1 Settings for the Module-Stop State

The Module Stop Control Register C (MSTPCRC) can enable or disable CRC calculator operation. The CRC calculator is initially stopped after a reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

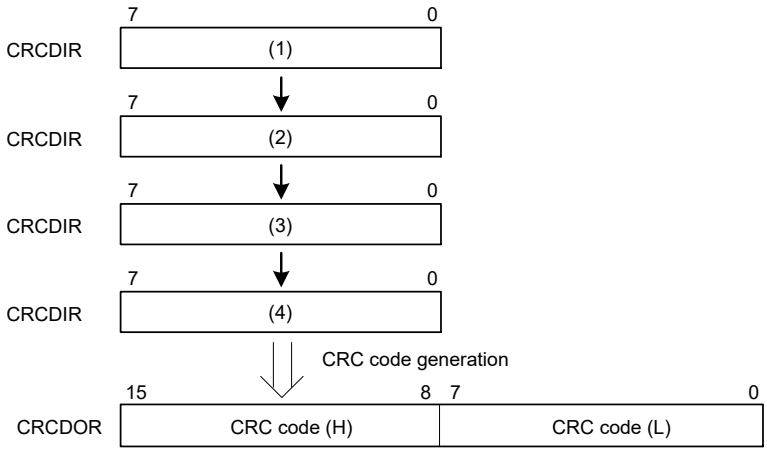
40.4.2 Note on Transmission

The transmission sequence for the CRC code differs based on whether the transmission is LSB-first or MSB-first. Figure 40.6 shows an LSB-first and MSB-first data transmission.

When transmitting 32-bit data (for operation executed on 8 bits in parallel)

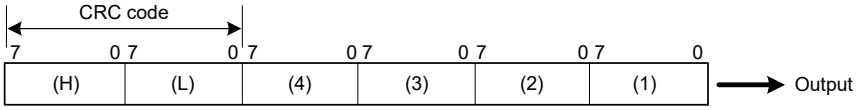
1. CRC code

After specifying the method for generation calculation, write data to CRCDIR in order of (1), (2), (3), and (4).



2. Transmit data

(i) When transmission is LSB-first



(ii) When transmission is MSB-first

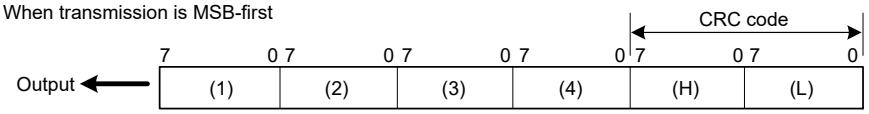


Figure 40.6 LSB-first and MSB-first data transmission

41. Boundary Scan

41.1 Overview

The boundary scan function provides a serial I/O interface based on the JTAG (Joint Test Action Group), IEEE Std.1149.1, and IEEE Standard Test Access Port and Boundary Scan Architecture. Table 41.1 lists the boundary scan specifications, Figure 41.1 shows a block diagram, and Table 41.2 lists the I/O pins.

Table 41.1 Boundary scan specifications

Parameter	Specifications
Execution condition	Boundary scan must be executed when the RES pin is driven low.
Test modes	• BYPASS mode • EXTEST mode • SAMPLE/PRELOAD mode • CLAMP mode • HIGHZ mode • IDCODE mode

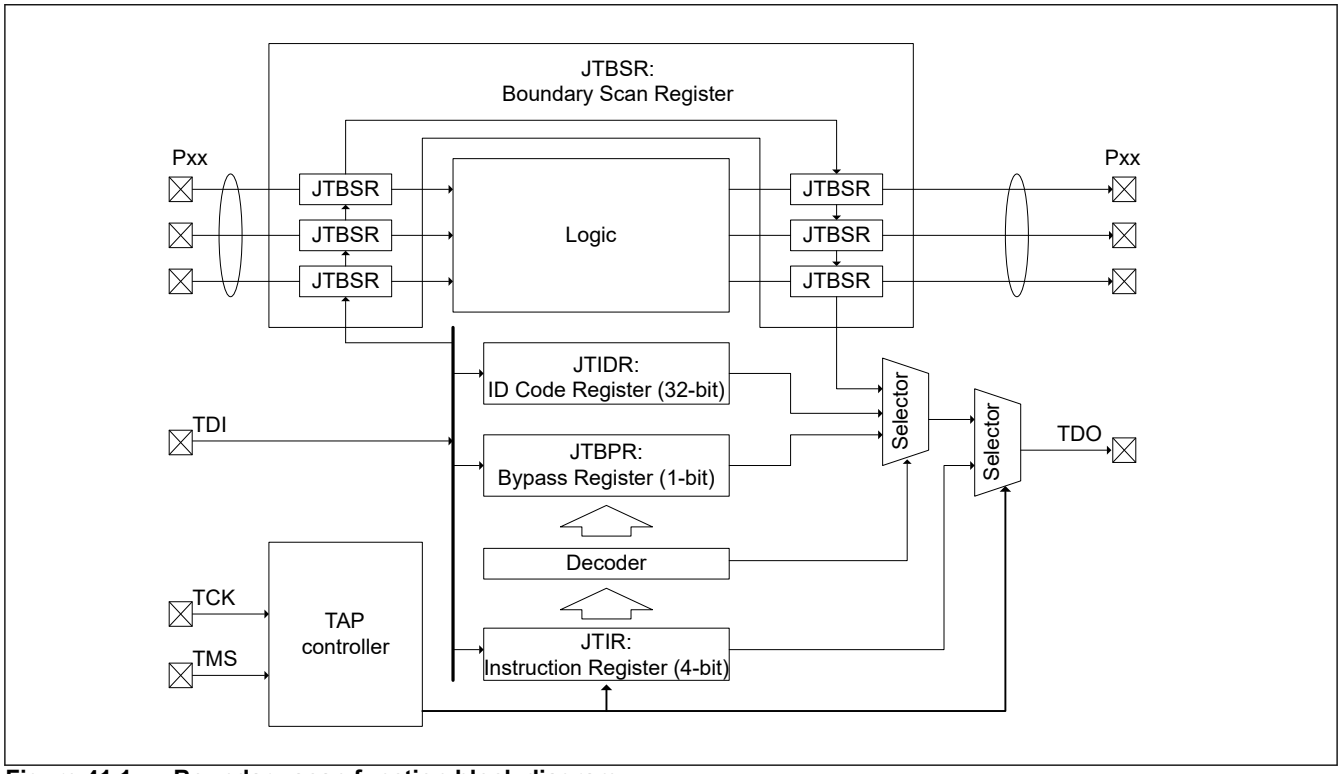

Figure 41.1 Boundary scan function block diagram

Table 41.2 Boundary scan I/O pins

Pin name	I/O	Description
TCK	Input	Test clock input pin Clock signal for boundary scan. The input clock duty cycle is 50% when the boundary scan function is used.
TMS	Input	Test mode select pin
TDI	Input	Test data input pin
TDO	Output	Test data output pin

Note: This device does not support the TRST pin for the JTAG interface.

41.2 Register Descriptions

Table 41.3 lists the boundary scan registers.

Table 41.3 Boundary scan registers

Register name	Symbol	Value after reset
Instruction Register	JTIR	0xE
ID Code Register	JTIDR	0x0841_2447
Bypass Register	JTBPR	Undefined
Boundary Scan Register	JTBSR	Undefined

Usage notes for the boundary scan registers:

- Instructions can be input to the Instruction Register (JTIR) through the TDI pin by serial transfer.
- The Bypass Register (JTBPR), which is a 1-bit register, is connected between the TDI and TDO pins in BYPASS mode.
- The Boundary Scan Register (JTBSR), which is configured according to the BSDL description, is connected between the TDI and TDO pins when test data is being shifted in.

Table 41.4 shows the availability of serial transfer for the registers.

Table 41.4 Serial transfer for registers

Register name	Serial input	Serial output
Instruction Register (JTIR)	Available	Available
ID Code Register (JTIDR)	Available	Available
Bypass Register (JTBPR)	Available	Available
Boundary Scan Register (JTBSR)	Available	Available

41.2.1 JTIR : Instruction Register

Bit position:	3	2	1	0
Bit field:	TS[3:0]			
Value after reset:	1	1	1	0

Bit	Symbol	Function	R/W
3:0	TS[3:0]	Test Bit Set The command configuration for these bits	—

TS[3:0]	Instruction
0x0	EXTEST
0x1	SAMPLE/PRELOAD
0x3	IDCODE (Renesas code)
0x5	CLAMP
0x6	HIGHZ
0xF	BYPASS
Others	Reserved

JTAG instructions can be transferred to the JTIR register by serial input from the TDI pin. The JTIR register is initialized when a power-on reset occurs, or when the TAP controller is in the Test-Logic-Reset state.

41.2.2 JTIDR : ID Code Register

Bit position:	31																												0
Bit field:	DID[31:0]																												
Value after reset:	0	0	0	0	1	0	0	0	0	1	0	0	0	0	0	0	1	0	1	0	0	1	0	0	0	1	0	0	0	1	1	1

Bit	Symbol	Function	R/W
31:0	DID[31:0]	Device ID These bits store the fixed value that indicates the device IDCODE (0x0841_2447).	—

The JTIDR register data is output from the TDO pin when the IDCODE instruction is executed. After a reset release, the DID[31:0] of JTIDR changes into the Arm® debug code. See the *Arm® CoreSight™ SoC-400 Technical Reference Manual* (ARM DDI 0480F).

41.2.3 JTBPR : Bypass Register

The JTBPR register is a 1-bit register and is connected between the TDI and TDO pins when the JTIR register is set to BYPASS mode. The JTBPR register cannot be read from or written to by the CPU.

41.2.4 JTBSR : Boundary Scan Register

The JTBSR register is a shift register for controlling the external input and output pins of this device, and is distributed across the pads. To apply the JTBSR register in boundary-scan testing, issue the EXTEST, SAMPLE/PRELOAD, CLAMP, and HIGHZ instructions. The BSDL file describes the associations between the JTBSR register bits and the pins of this device. The value after reset is undefined.

41.3 Operation

During a reset, the JTAG ports, TCK, TMS, TDI, and TDO, are assigned as default pin functions. The TCK, TMS, and TDI pins are pulled up by the pull-up resistors. Boundary scan testing can be executed after the setup time elapses when POR is negated and RES is driven low.

41.3.1 TAP Controller

Figure 41.2 shows the state transition diagram of the TAP controller. All transitions are controlled by the TMS signal.

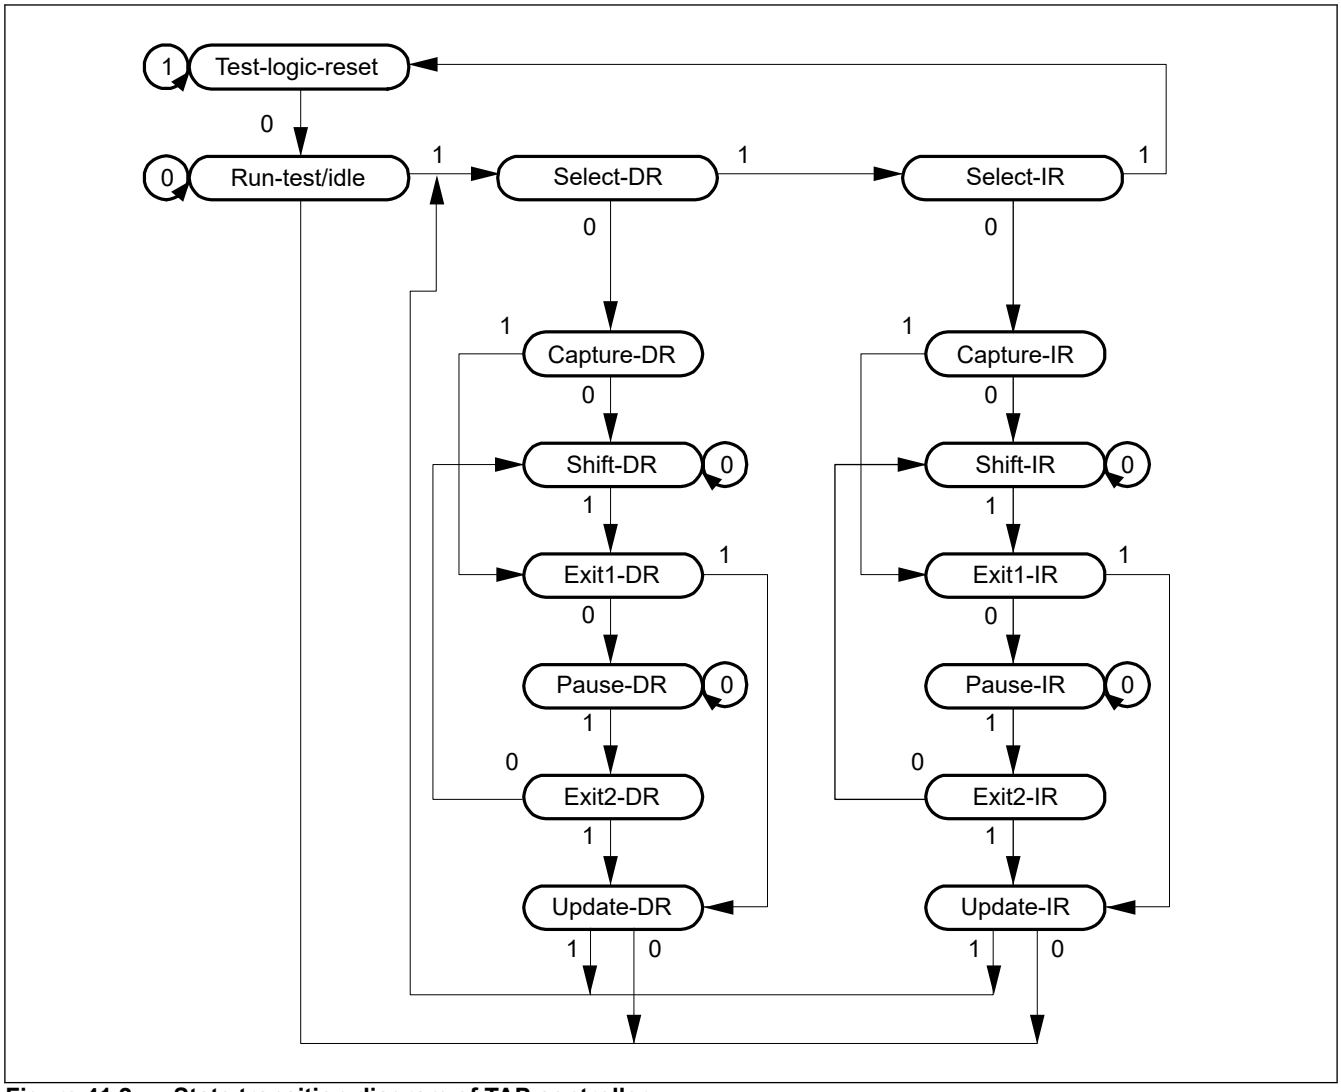

Figure 41.2 State transition diagram of TAP controller

41.3.2 Commands

(1) BYPASS

The BYPASS instruction drives the Bypass Register (JTBPR). This instruction shortens the shift path, facilitating the transfer of serial data to other LSIs on a printed circuit board at higher speeds. While this instruction is being executed, the test circuit has no effect on the system circuits.

The JTBPR register is connected between the TDI and TDO pins. Bypass operation is initiated from the Shift-DR operation. The TDO is low in the first clock cycle in the Shift-DR state. In the subsequent clock cycles, values input to the TDI pin are output from the TDO pin.

(2) EXTEST

The EXTEST instruction is used to test external circuits when this device is installed on the printed circuit board. If this instruction is executed, output pins are used to output test data (specified in the SAMPLE/PRELOAD instruction) from the Boundary Scan Register (JTBSR) to the other devices, and input pins are used to input the test result.

(3) SAMPLE/PRELOAD

The SAMPLE/PRELOAD instruction is used to input data from the internal circuits of this device to the JTBSR register, output data from the scan path, and reload the data to the scan path. While this instruction is executed, input signals are directly input to this device and output signals are also directly output to the external circuits. This device system circuit is not affected by this instruction.

In SAMPLE operation, the JTBSR register latches a snapshot of the data transferred from the input pins to the internal circuit or data transferred from the internal circuit to the output pins. The latched data is read from the scan path. The JTBSR register latches the data snapshot on the rising edge of the TCK pin in the Capture-DR state. The data snapshot is only transferred from the internal circuit to the output pins during a reset.

In PRELOAD operation, the initial value is written from the scan path to the parallel output latch of the JTBSR register prior to the EXTEST instruction execution. If EXTEST is executed without executing this PRELOAD operation, undefined values are output from the beginning to the end (transfer to the output latch) of the EXTEST sequence. (In the EXTEST instruction, output parallel latches are always output to the output pins.)

(4) IDCODE

When the IDCODE instruction is selected, the ID Code Register (JTIDR) value is output to the TDO pin in the Shift-DR state of the TAP controller. In this case, the JTIDR register value is output LSB-first. During this instruction execution, the test circuit does not affect the system circuit.

(5) CLAMP

When the CLAMP instruction is selected, output pins output the JTBSR register value that was specified in the SAMPLE/PRELOAD instruction in advance. While the CLAMP instruction is selected, the status of the JTBSR register is maintained regardless of the TAP controller state.

The JTBPR register is connected between the TDI and TDO pins, leading to the same operation as when the BYPASS instruction is selected.

(6) HIGHZ

When the HIGHZ instruction is selected, all output pins enter high-impedance state. While the HIGHZ instruction is selected, the JTBSR register is maintained regardless of the state of the TAP controller.

The JTBPR register is connected between the TDI and TDO pins, leading to the same operation as when the BYPASS instruction is selected.

41.4 Usage Notes

The boundary scan function is subject to the following constraints:

- The boundary scan must be executed when the RES pin is driven low
- Serial data input/output is in LSB order, as shown in Figure 41.3

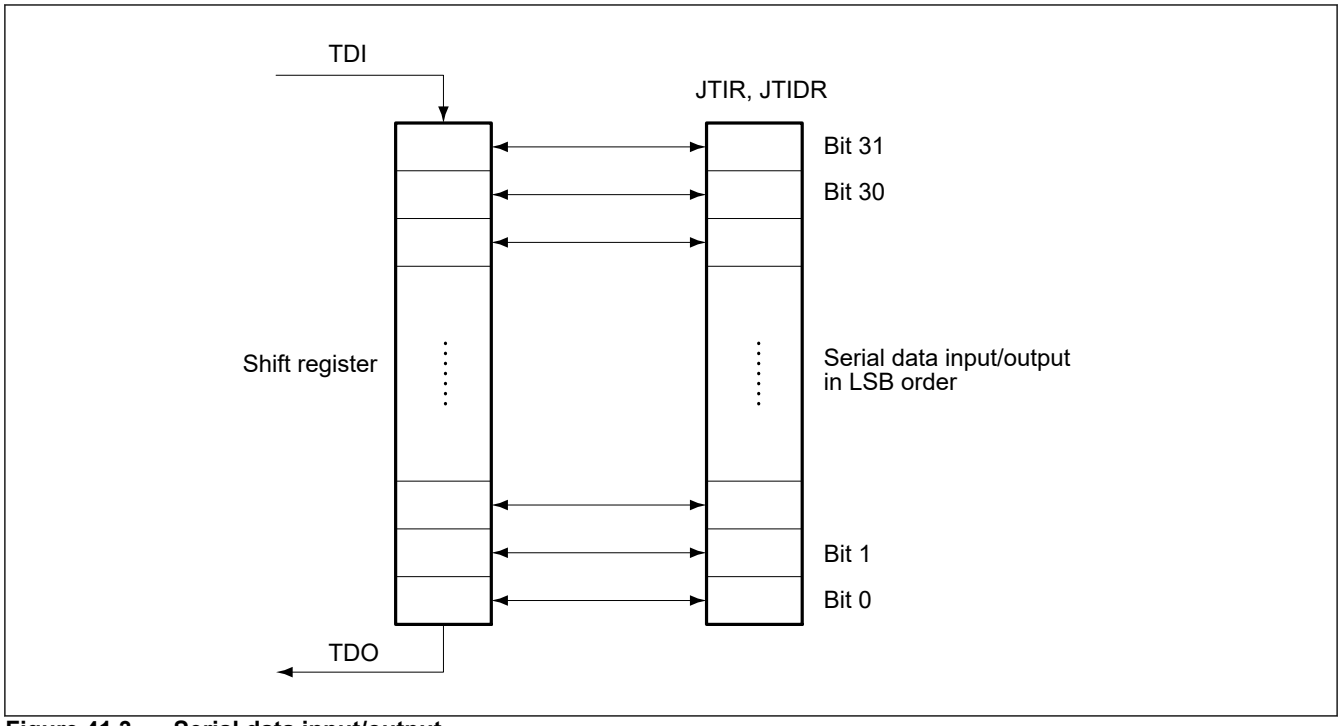

Figure 41.3 Serial data input/output

The following pins cannot be boundary-scanned:

- Power supply pins (VCC, VCL, VCL0, VSS, VBATT, AVCC0, AVSS0, VCC_USB, VSS_USB, VSS1_USBHS, VSS2_USBHS, PVSS_USBHS, and AVSS_USBHS)
- Analog reference pins (VREFH0, VREFL0, VREFH, VREFL)
- Clock pins (EXTAL, XTAL, XCIN, and XCOUT)
- Reset pin (RES)
- USB-dedicated pins (USB_DP, USB_DM, USBHS_DP, and USBHS_DM)
- The boundary-scan pins (TCK, TMS, TDI, and TDO).

42. Secure Cryptographic Engine (SCE9)

42.1 Overview

The Secure Cryptographic Engine (SCE9) consists of the access management circuit, encryption engine, and random number generation circuit. In combination with the SCE9 library, the SCE9 can prevent eavesdropping (to maintain confidentiality), falsification of information (to ensuret integrity), and impersonation (to verify authenticity).

Because key information required for encryption and decryption is stored only in the SCE9 and all accesses from the outside can be blocked, SCE9 enables building a more robust security system.

Only access control circuit, random number generation circuit, and unique ID are supported. The operation of other circuits is not guaranteed.

Table 42.1 lists the SCE9 specifications. Figure 42.1 shows the SCE9 block diagram.

Table 42.1 SCE9 specifications (1 of 2)

Parameter	Specifications
Access control	Access management circuit ● In case of irregular access to the SCE9 due to a tampered program or CPU runaway, this circuit blocks all subsequent accesses and stops data output from the SCE9
Encryption engine	AES: Compliant with NIST FIPS PUB 197 ● Key length: 128, 192, or 256 bits ● Data block size: 128 bits ● Encryption usage modes ECB, CBC, CTR: Compliant with NIST SP 800-38A CMAC: Compliant with NIST SP 800-38B CCM: Compliant with NIST SP 800-38C GCM: Compliant with NIST SP 800-38D XTS: Compliant with NIST SP 800-38E GCTR ● Throughput for 128-bit data 11 PCLKA cycles for 128-bit key 13 PCLKA cycles for 192-bit key 15 PCLKA cycles for 256-bit key*1 AES-GCM ● AES-GCM is realized by combining AES-GCTR and GHASH. Key management ● Wrapped keys are only valid within the SCE9
Random number generation	128-bit true random number generation circuit
Signature generation and verification	RSA ● Support for 1024-bit, 2048-bit, 3072-bit, and 4096-bit key sizes ● Signature generation, signature verification, public-key encryption, private-key decryption DSA ● Support for DSA key sizes: – (1024-bit, 160-bit) – (2048-bit, 224-bit) – (2048-bit, 256-bit) ● Signature generation, signature verification ECC ● Support for curve – NIST P-192, P-224, P-256, and P-384 – Brainpool P256r1, P384r1, and P512r1 ● Signature generation, signature verification
Message digest computation	HASH ● SHA224 and SHA256

Table 42.1 SCE9 specifications (2 of 2)

Parameter	Specifications
Hardware Unique Key	• A read-only, 256-bit Hardware Unique Key (HUK) is exclusively accessible by the SCE access management circuit through a dedicated bus. • Key derivation functions (KDFs) combine the Hardware Unique Key with the key generation information. The derived keys implement the key wrapping for user key secure storage. • The HUK uniqueness prevents the illicit cloning and copying of keys to another MCU of the MCU group. • The HUK itself is stored in wrapped (encrypted, non-plain) format in an isolated memory area. Therefore it is protected from illicit access and copy.
Unique ID	• A read-only, 128-bit ID unique to an MCU (Unique ID) is accessible from the access management circuit. • Key derivation functions (KDFs) combine the Unique ID with the key generation information. Such derived keys are used to unwrap the HUK within the SCE boundary.
Low power consumption	Setting of the module-stop state is possible

Note 1. This does not include the overhead of calling SCE9 library functions.

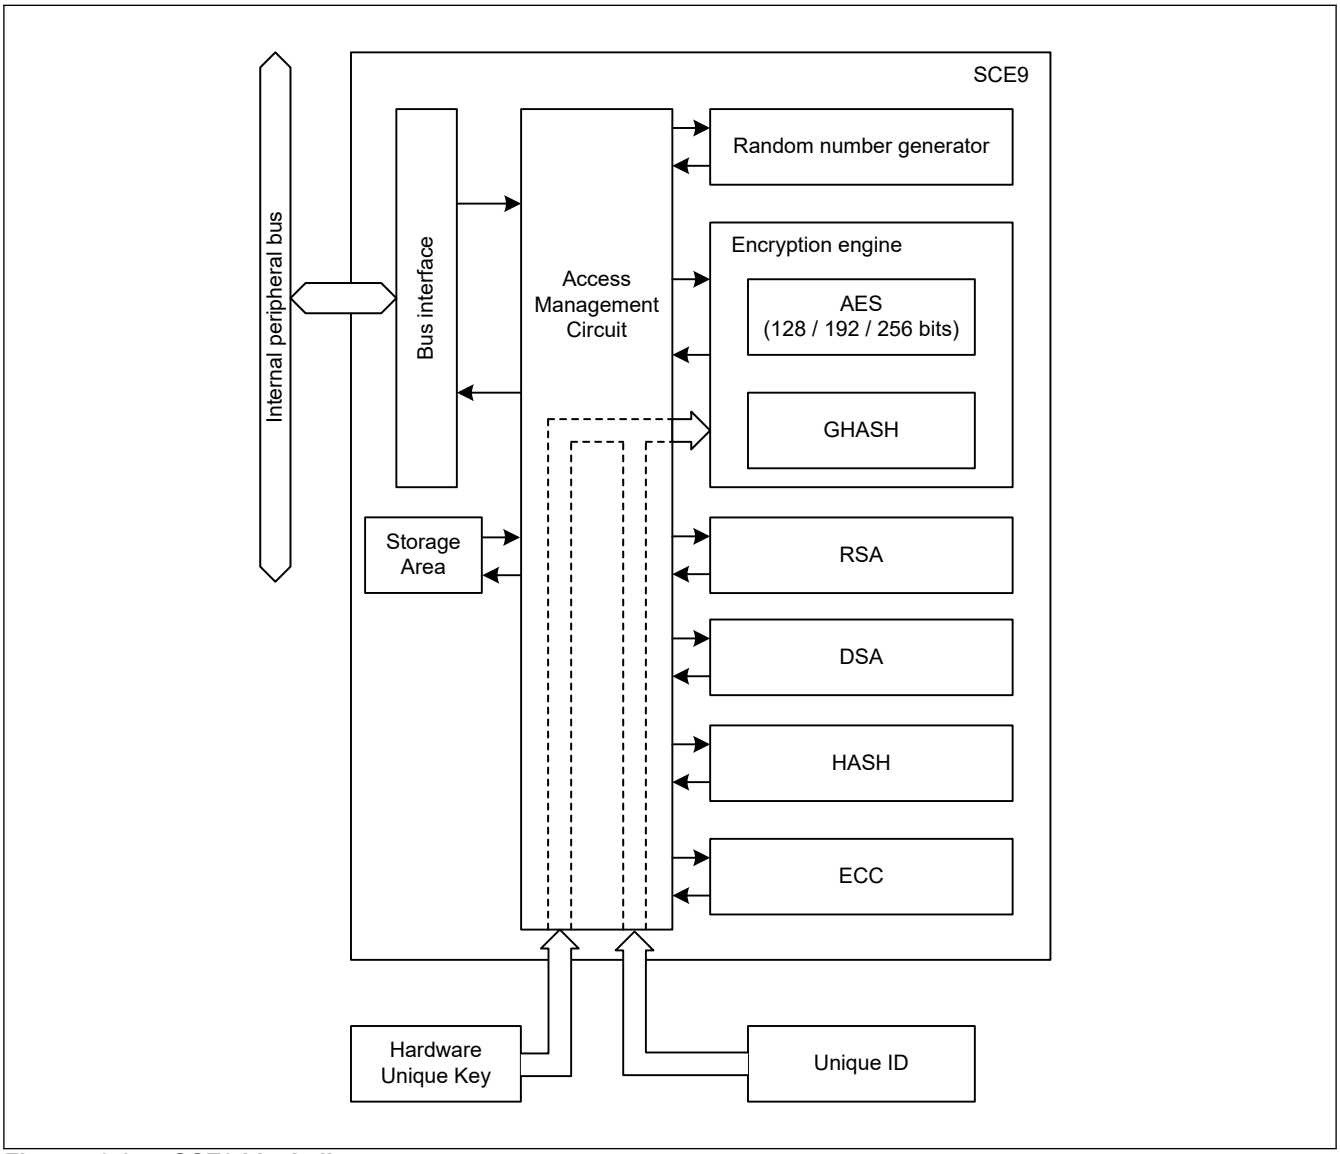

Figure 42.1 SCE9 block diagram

42.2 Operation

42.2.1 Encryption Engine

Figure 42.2 shows conceptual diagram of the encryption engine installed in the SCE9.

The encryption engine uses the key generation information, and converts the plaintext data to ciphertext or ciphertext data to plaintext through the hardware.

The encryption/decryption process can be completed without exposing the key data and the process's intermediate data to the outside of the SCE9.

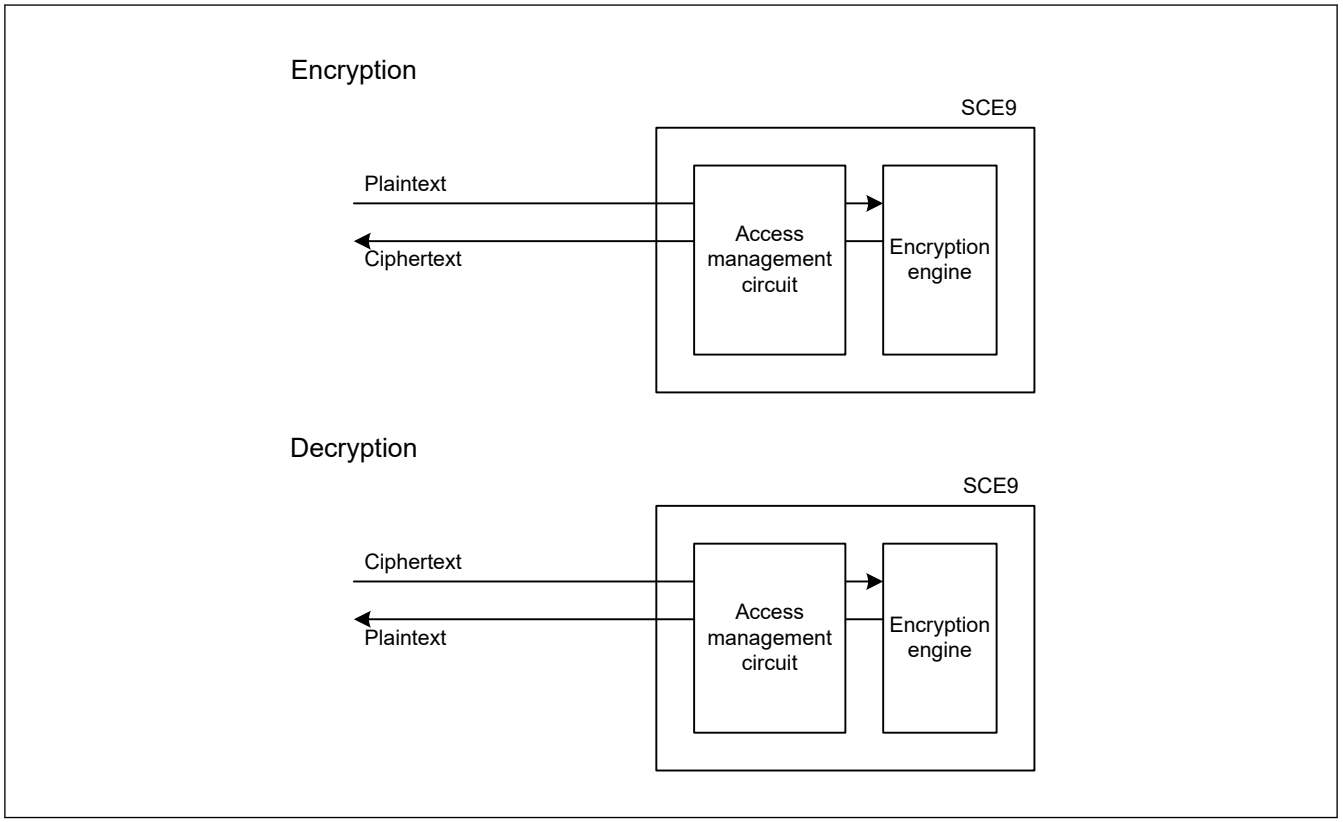

Figure 42.2 Conceptual diagram of the encryption engine

42.2.2 Encryption and Decryption

Follow the procedure below to encrypt and decrypt the data:

1. Enter the key generation information to the SCE9 and restore the key data.
2. Enter the target data to the SCE9. Plaintext data is converted to ciphertext and ciphertext data to plaintext.
3. Read the converted data.

The encryption engine has input and output buffers, and can perform encryption/decryption in parallel with data input/output. Figure 42.3 shows the encryption engine timing.

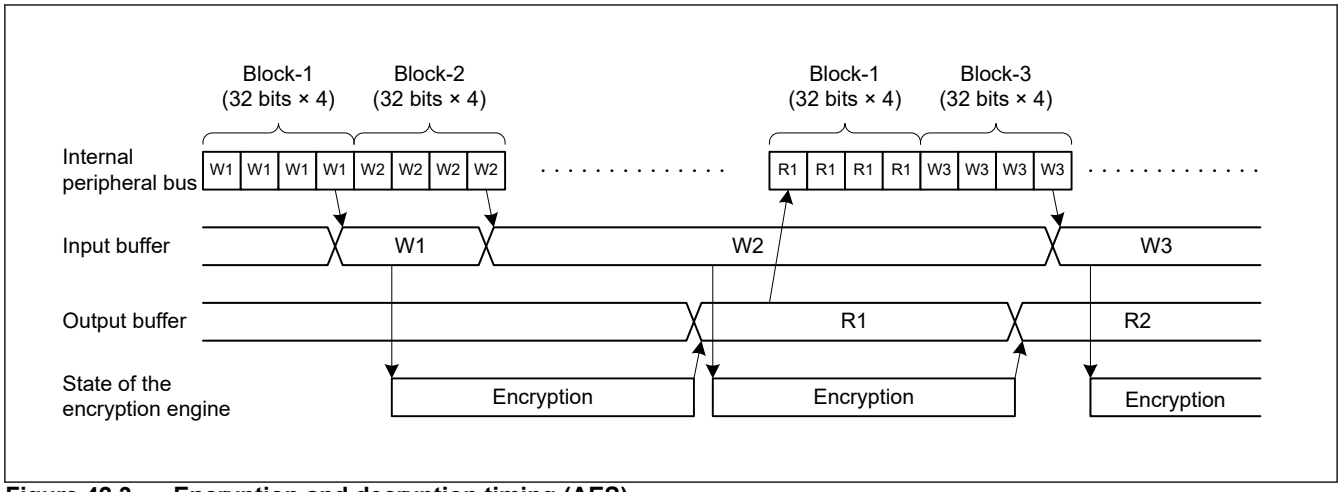

Figure 42.3 Encryption and decryption timing (AES)

42.3 Usage Notes

42.3.1 Software Standby Mode

When Software Standby mode is entered while the encryption engine is in process, proper processing cannot be resumed after cancelling Software Standby mode. Software Standby mode should therefore be entered while the encryption engine is not running.

42.3.2 Module-Stop Function Setting

SCE9 operation can be disabled or enabled using Module Stop Control Register C (MSTPCRC). The SCE9 module is initially stopped after reset. Releasing the module-stop state enables access to the registers.

43. 12-Bit A/D Converter (ADC12)

43.1 Overview

The MCU includes 12-bit successive approximation A/D converter (ADC12) units. Analog input channels are selectable up to 13 in unit 0 and up to 16 in unit 1. Each 3 analog input of unit 0 and unit 1 is assigned to the same port (AN000/AN100, AN001/AN101, and AN002/AN102), and up to 26 ports are available as analog input. The temperature sensor output and an internal reference voltage are selectable for conversion in each unit 0 and unit 1.

The A/D conversion accuracy is selectable from 12-bit, 10-bit, 8-bit conversion, making it possible to optimize the trade-off between speed and resolution in generating a digital value.

The ADC12 supports the following operating modes:

- Single scan mode to convert analog inputs of selected channels in ascending order of channel number
- Continuous scan mode to convert analog inputs of selected channels continuously in ascending order of channel number
- Group scan mode to divide analog inputs of channels into two groups (group A and B) and convert the analog inputs of selected channels for each group in ascending order of channel number.

In group scan mode, select two groups (group A and B). You can individually select the scan start conditions for each group (group A, B) and start scanning of each group at different times. In addition, when group A priority control operation is set, the ADC12 accepts group A scan start during group B A/D conversion, suspending group B conversion. This allows you to assign higher priority to A/D conversion start for group A.

In double trigger mode, the analog input of a selected channel is converted in single scan mode or group scan mode (group A), and data converted by the first and second A/D conversion start triggers are stored in different registers, providing duplexing of A/D converted data.

Self-diagnosis is performed once at the beginning of each scan, and one of the three reference voltage values generated in ADC12 is A/D converted.

The temperature sensor output and the internal reference voltage is selectable at the same time as the analog input of the channel. First A/D conversion is performed for the analog input of the channel, next the temperature sensor output and then for the internal reference voltage.

The ADC12 also provides a compare function (window A and window B). The compare function specifies the upper reference value for window A and lower reference value for window B, and outputs an interrupt when the A/D converted value of the selected channel meets the comparison conditions.

The A/D data storage buffer is a ring buffer consisting of 16 buffers to sequentially store A/D converted data.

Table 43.1lists the ADC12 specifications and Table 43.2 list the functions. Figure 43.1 shows a block diagram of ADC12 and Table 43.3 lists the I/O pins.

Table 43.1 ADC12 specifications (1 of 3)

Parameter	Specifications
Number of units	two units
Input channels	Up to 26 channels (AN000 to AN010, AN012, AN013, AN100 to AN102, AN116 to AN128)*4 Extended
Analog function	Temperature sensor output, , internal reference voltage
Conversion method	Successive approximation method
Resolution	12-bit, 10-bit, 8-bit
Conversion time	0.4 µs/channel (when 12-bit A/D conversion clock PCLKC (ADCLK) is operating at 50 MHz)
A/D conversion clock	Peripheral module clock PCLKA and A/D conversion clock PCLKC (ADCLK) can be set with the following division ratios: PCLKA to PCLKC (ADCLK) frequency ratio = 1:1, 2:1, 4:1, 8:1, 1:2, 1:4

Table 43.1 ADC12 specifications (2 of 3)

Parameter	Specifications
Data registers[*1]	● 26 registers for analog input ● One register for A/D-converted data duplication in double trigger mode ● Two registers for A/D-converted data duplication during extended operation in double trigger mode ● One register for temperature sensor output ● One register for internal reference voltage ● One register for self-diagnosis ● A/D conversion results are stored in A/D data registers ● 12-bit, 10-bit, 8-bit accuracy for A/D conversion results ● A/D-converted value addition mode, in which the sum of all A/D-converted results is stored in the A/D data registers as a value with the conversion accuracy bit count + extended bits ● Double-trigger mode (selectable in single scan and group scan modes): – The first unit of A/D-converted analog input data on one selected channel is stored in the data register for the channel, and the second unit is stored in the duplication register. ● Extended operation in double trigger mode (available for specific triggers): – A/D-converted analog input data on one selected channel is stored in the duplication register provided for the associated trigger.
Operating modes[*2]	● Single scan mode: – A/D conversion is performed only once on the analog inputs of arbitrarily selected channels , on the temperature sensor output, on the internal reference voltage. ● Continuous scan mode: A/D conversion is performed repeatedly on the analog inputs of the selected channels on the temperature sensor output, and on the internal reference voltage. ● Group scan mode: – Analog inputs of selected channels, the temperature sensor output, and the internal reference voltage are divided into groups A and B. Then A/D conversion of the analog inputs selected on a group basis is performed once. – The scan start conditions can be independently selected for group A, B, allowing A/D conversion of group A, B to be started independently. ● Group scan mode (when group priority operation is selected): – If a priority group trigger is input during scanning of a lower-priority group, the scanning of the lower-priority group is stopped and then scanning of the priority group is started. The order of priority is group A > group B. – It is possible to select whether to restart scanning (rescan) of the lower-priority group upon completion of the priority group scan. It is also possible to specify rescanning to be started from the first channel of the selected channels or from the channel for which A/D conversion has not been completed.
Conditions for A/D conversion start	● Software trigger ● Synchronous triggers from the Event Link Controller (ELC) ● Asynchronous triggering by the external trigger pins, ADTRG0 (unit 0) and ADTRG1 (unit 1)
Functions	● Variable sampling state count ● Self-diagnosis of A/D converter ● Selectable A/D-converted value addition mode or average mode ● Analog input disconnection detection function (discharge and precharge functions) ● Double-trigger mode (duplication of A/D conversion data) ● Automatic clear function for A/D data registers ● Digital comparison of values in the comparison register and data register, and comparison between values in the data registers ● Interleave function ● Ring buffer

Table 43.1 ADC12 specifications (3 of 3)

Parameter	Specifications
Interrupt sources	• In single scan mode (double trigger deselected), an A/D scan end interrupt request (ADC12i_ADI (i = 0, 1)) and ELC event signal (ADC12i_ADI (i = 0, 1)) can be generated on completion of single scan. – A compare interrupt request (ADC12i_CMPAI (i = 0, 1)/ADC12i_CMPBI (i = 0, 1)) can be generated in response to a match with a digital comparison condition. – A window compare ELC event signal (ADC12i_WCMPM (i = 0, 1)) can be generated in response to a match with a digital comparison condition. – A window compare ELC event signal (ADC12i_WCMPUM (i = 0, 1)) can be generated in response to a mismatch with a digital comparison condition. • In single scan mode (double trigger selected), an A/D scan end interrupt request (ADC12i_ADI (i = 0, 1)) and ELC event signal (ADC12i_ADI (i = 0, 1)) is generated on completion of two scans. • In continuous scan mode, an A/D scan end interrupt request (ADC12i_ADI (i = 0, 1)) and ELC event signal (ADC12i_ADI (i = 0, 1)) is generated on completion of all the selected channel scans. • In group scan mode (double trigger deselected), an A/D scan end interrupt request (ADC12i_ADI (i = 0, 1)) and ELC event signal (ADC12i_ADI (i = 0, 1)) is generated on completion of group A scan, and an A/D scan end interrupt request for group B (ADC12i_GBADI (i = 0, 1)) can be generated on completion of group B scan. • In group scan mode (double trigger selected), an A/D scan end interrupt request (ADC12i_ADI (i = 0, 1)) and ELC event signal (ADC12i_ADI (i = 0, 1)) is generated on completion of two group A scans, and an A/D scan end interrupt request for group B (ADC12i_GBADI (i = 0, 1)) can be generated on completion of group B scan. • ADC12i_ADI (i = 0, 1), ADC12i_GBADI (i = 0, 1), ADC12i_WCMPM (i = 0, 1), and ADC12i_WCMPUM (i = 0, 1) can activate the Data Transfer Controller (DTC).
ELC interface	• An event is generated upon completion of group A scan in group-scan mode. • An event is generated upon completion of group B scan in group-scan mode. • An event is generated when all scans complete. • Scan can be started by a trigger from the ELC. • An event is generated according to conditions of the compare function window in single-scan mode.
Reference voltage	• Unit 0: VREFH0 is the analog reference voltage. VREFL0 is the analog reference ground. • Unit 1: VREFH is the analog reference voltage. VREFL is the analog reference ground.
Module-stop function	Module-stop state can be set to reduce power consumption.*3
TrustZone Filter	Security attribution can be set for each units

Note 1. Changing the A/D conversion accuracy also changes the A/D conversion time. For details, see section 43.3.7. Analog Input Sampling and Scan Conversion Time.
Note 2. When selecting the temperature sensor output and the internal reference voltage, do not use continuous scan mode or group scan mode.
Note 3. For details, see section 10, Low Power Modes.
Note 4. AN000 & AN100, AN001 & AN101, and AN002 & AN102 are assigned to the same port pin.

Table 43.3 lists the ADC12 I/O pins.

Table 43.3 ADC12 I/O pins (unit 0)

Pin name	I/O	Function
AVCC0	Input	Analog block power supply pin (Connect to VCC when ADC12/DAC12 is not used.)
AVSS0	Input	Analog block power supply ground pin (Connect to VSS when ADC12/DAC12 is not used.)
VREFH0	Input	Analog reference voltage supply pin
VREFL0	Input	Analog reference ground pin
AN000 to AN010, AN012, AN013*1	Input	Analog input pins 0 to 10, 12, 13
ADTRG0	Input	External trigger input pin for starting A/D conversion

Note 1. AN000 & AN100, AN001 & AN101, and AN002 & AN102 are assigned to the same port pin.

Table 43.4 ADC12 I/O pins (unit 1)

Pin name	I/O	Function
AVCC0	Input	Analog block power supply pin
AVSS0	Input	Analog block power supply ground pin
VREFH	Input	Reference power supply pin
VREFL	Input	Reference power supply ground pin
AN100 to AN102, AN116 to AN128*1	Input	Analog input pins 0 to 2, 16 to 28
ADTRG1	Input	External trigger input pin for starting A/D conversion

Note 1. AN000 & AN100, AN001 & AN101, and AN002 & AN102 are assigned to the same port pin.

43.2 Register Descriptions

43.2.1 ADDRn : A/D Data Registers n (n = 0 to 10, 12, 13)

Base address: ADC12m = 0x4017_0000 + 0x0200 × m (m = 0, 1)

Offset address: 0x020 + 0x2 × n (n = 0 to 10, 12, 13, m = 0)
0x020 + 0x2 × n (n = 0 to 2, 16 to 28, m = 1)

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ADDR [15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	ADDR [15:0]	Converted Value 15 to 0 Functions vary depending on the selected mode and accuracy. See Table 43.5 and Table 43.6.	R

ADDRn registers are 16-bit read-only registers to store A/D conversion results.

The following conditions determine the formats for data in the A/D data registers:

- Setting of the A/D Data Register Format Select bit (ADCER.ADRFMT) (flush-left or flush-right)
- The setting in the A/D Conversion Accuracy Select bits (ADCER.ADPRC[1:0]) (12-bit, 10-bit, 8-bit is selectable.)
- Setting of the Addition/Average Count Select bits (ADADC.ADC[2:0]) (1, 2, 3, 4, or 16 times)
- Setting of the Average Mode Enable bit (ADADC.AVEE) (addition or average).

This section describes the data formats for these conditions in different modes.

(1) When A/D-converted value addition/average mode is not selected

Table 43.5 shows the example of bit assignment for 12-bit accuracy.

Table 43.5 Example of bit assignment for 12-bit accuracy

Accuracy	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	These bits are read as 0.				Converted Value 11 to 0: 12-bit A/D-converted value											
Left-justified data with 12-bit accuracy	Converted Value 11 to 0: 12-bit A/D-converted value												These bits are read as 0.			

(2) When A/D-converted value average mode is selected

A/D-converted value average mode can be selected when 2 or 4 times is specified in the A/D-converted value addition mode. When A/D converted value average mode is selected, these registers indicate the mean of A/D-converted values on a specific channel. The value is stored in the A/D data register based on the setting of the A/D Data Register Format Select bit in the same way as for normal A/D conversion.

(3) When A/D-converted value addition mode is selected

For 12-bit, 10-bit, 8-bit accuracy, 1, 2, 3, or 4 times can be selected in the A/D-converted value addition mode. A/D conversion results are stored in the A/D data register as a 2-bit-extended value of the specified conversion accuracy.

For 12-bit accuracy, 16 times can also be selected in the A/D-converted value addition mode. In A/D-converted value addition mode, these registers indicate the value that is obtained by adding A/D-converted values on a specific channel. A/D conversion results are stored in the A/D data register as a 4-bit-extended value of the specified conversion accuracy.

When A/D-converted value addition mode is selected, the value is stored in the A/D data register based on the settings of the A/D Data Register Format Select bits.

Table 43.6 shows example of the bit assignment for 12-bit accuracy.

Table 43.6 Example of bit assignment for 12-bit accuracy when A/D-converted value addition mode is selected

Accuracy		b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	When 16 conversion times is specified	Added Value 15 to 0: 16-bit sum of A/D conversion results															
	When 1, 2, 3, or 4 conversion times is specified	These bits are read as 0.		Added Value 13 to 0: 14-bit sum of A/D conversion results													
Left-justified data with 12-bit accuracy	When 1, 2, 3, or 4 conversion times is specified	Added Value 15 to 0: 16-bit sum of A/D conversion results															
	When 16 conversion times is specified	Added Value 13 to 0: 14-bit sum of A/D conversion results														These bits are read as 0.	

43.2.2 ADDBLDR : A/D Data Duplexing Register

Base address: ADC12m = 0x4017_0000 + 0x0200 × m (m = 0, 1)

Offset address: 0x018

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ADDBLDR [15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	ADDBLDR [15:0]	Converted Value 15 to 0 Functions vary depending on the selected mode and accuracy. See Table 43.7 and Table 43.8.	R

ADDBLDR register is a 16-bit read-only register to store A/D conversion results in response to a second trigger in double-trigger mode.

The following conditions determine the formats for data in the A/D data registers:

- Setting of the A/D Data Register Format Select bit (ADCER.ADRFMT) (flush-left or flush-right)
- The setting in the A/D Conversion Accuracy Select bits (ADCER.ADPRC[1:0]) (12-bit, 10-bit, 8-bit is selectable.)
- Setting of the Addition/Average Count Select bits (ADADC.ADC[2:0]) (1, 2, 3, 4, or 16 times)
- Setting of the Average Mode Enable bit (ADADC.AVEE) (addition or average).

This section describes the data formats for these conditions in different modes.

(1) When A/D-converted value addition/average mode is not selected

Table 43.7 shows the example of bit assignment for 12-bit accuracy.

Table 43.7 Example of bit assignment for 12-bit accuracy

Accuracy	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	These bits are read as 0.				Converted Value 11 to 0: 12-bit A/D-converted value											
Left-justified data with 12-bit accuracy	Converted Value 11 to 0: 12-bit A/D-converted value												These bits are read as 0.			

(2) When A/D-converted value average mode is selected

A/D-converted value average mode can be selected when 2 or 4 times is specified in the A/D-converted value addition mode. When A/D converted value average mode is selected, this register indicates the mean of A/D-converted values on a

specific channel. The value is stored in the A/D data register based on the setting of the A/D Data Register Format Select bit in the same way as for normal A/D conversion.

(3) When A/D-converted value addition mode is selected

For 12-bit, 10-bit, 8-bit accuracy, 1, 2, 3, or 4 times can be selected in the A/D-converted value addition mode. A/D conversion results are stored in the A/D data register as a 2-bit-extended value of the specified conversion accuracy.

For 12-bit accuracy, 16 times can also be selected in the A/D-converted value addition mode. In A/D-converted value addition mode, this register indicates the value that is obtained by adding A/D-converted values on a specific channel. A/D conversion results are stored in the A/D data register as a 4-bit-extended value of the specified conversion accuracy.

When A/D-converted value addition mode is selected, the value is stored in the A/D data register based on the settings of the A/D Data Register Format Select bits.

Table 43.8 shows example of the bit assignment for 12-bit accuracy.

Table 43.8 Example of bit assignment for 12-bit accuracy when A/D-converted value addition mode is selected

Accuracy		b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	When 16 conversion times is specified	Added Value 15 to 0: 16-bit sum of A/D conversion results															
	When 1, 2, 3, or 4 conversion times is specified	These bits are read as 0.		Added Value 13 to 0: 14-bit sum of A/D conversion results													
Left-justified data with 12-bit accuracy	When 1, 2, 3, or 4 conversion times is specified	Added Value 15 to 0: 16-bit sum of A/D conversion results															
	When 16 conversion times is specified	Added Value 13 to 0: 14-bit sum of A/D conversion results														These bits are read as 0.	

43.2.3 ADDBLDRn : A/D Data Duplexing Register n (n = A, B)

Base address: ADC12m = 0x4017_0000 + 0x0200 × m (m = 0, 1)

Offset address: 0x084 (n = A)
0x086 (n = B)

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ADDBLDR [15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	ADDBLDR [15:0]	Converted Value 15 to 0 Functions vary depending on the selected mode and accuracy. See Table 43.9 and Table 43.10.	R

ADDBLDRn registers are 16-bit read-only registers to store A/D conversion results in response to respective triggers during extended operation in double-trigger mode.

The following conditions determine the formats for data in the A/D data registers:

- Setting of the A/D Data Register Format Select bit (ADCER.ADRFMT) (flush-left or flush-right)
- The setting in the A/D Conversion Accuracy Select bits (ADCER.ADPRC[1:0]) (12-bit, 10-bit, 8-bit is selectable.)
- Setting of the Addition/Average Count Select bits (ADADC.ADC[2:0]) (1, 2, 3, 4, or 16 times)
- Setting of the Average Mode Enable bit (ADADC.AVEE) (addition or average).

This section describes the data formats for these conditions in different modes.

(1) When A/D-converted value addition/average mode is not selected

Table 43.9 shows the example of bit assignment for 12-bit accuracy.

Table 43.9 Example of bit assignment for 12-bit accuracy

Accuracy	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	These bits are read as 0.				Converted Value 11 to 0: 12-bit A/D-converted value											
Left-justified data with 12-bit accuracy	Converted Value 11 to 0: 12-bit A/D-converted value												These bits are read as 0.			

(2) When A/D-converted value average mode is selected

A/D-converted value average mode can be selected when 2 or 4 times is specified in the A/D-converted value addition mode. When A/D converted value average mode is selected, these registers indicate the mean of A/D-converted values on a specific channel. The value is stored in the A/D data register based on the setting of the A/D Data Register Format Select bit in the same way as for normal A/D conversion.

(3) When A/D-converted value addition mode is selected

For 12-bit, 10-bit, 8-bit accuracy, 1, 2, 3, or 4 times can be selected in the A/D-converted value addition mode. A/D conversion results are stored in the A/D data register as a 2-bit-extended value of the specified conversion accuracy.

For 12-bit accuracy, 16 times can also be selected in the A/D-converted value addition mode. In A/D-converted value addition mode, these registers indicate the value that is obtained by adding A/D-converted values on a specific channel. A/D conversion results are stored in the A/D data register as a 4-bit-extended value of the specified conversion accuracy.

When A/D-converted value addition mode is selected, the value is stored in the A/D data register based on the settings of the A/D Data Register Format Select bits.

Table 43.10 shows example of the bit assignment for 12-bit accuracy.

Table 43.10 Example of bit assignment for 12-bit accuracy when A/D-converted value addition mode is selected

Accuracy		b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	When 16 conversion times is specified	Added Value 15 to 0: 16-bit sum of A/D conversion results															
	When 1, 2, 3, or 4 conversion times is specified	These bits are read as 0.		Added Value 13 to 0: 14-bit sum of A/D conversion results													
Left-justified data with 12-bit accuracy	When 1, 2, 3, or 4 conversion times is specified	Added Value 15 to 0: 16-bit sum of A/D conversion results															
	When 16 conversion times is specified	Added Value 13 to 0: 14-bit sum of A/D conversion results														These bits are read as 0.	

43.2.4 ADTSDR : A/D Temperature Sensor Data Register

Base address: ADC12m = 0x4017_0000 + 0x0200 × m (m = 0, 1)

Offset address: 0x01A

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ADTSDR [15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	ADTSDR [15:0]	Converted Value 15 to 0 Functions vary depending on the selected mode and accuracy. See Table 43.11 and Table 43.12.	R

ADTSDR register is a 16-bit read-only register to store A/D conversion result of the temperature sensor output.

The following conditions determine the formats for data in the A/D data registers:

- Setting of the A/D Data Register Format Select bit (ADCER.ADRFMT) (flush-left or flush-right)
- The setting in the A/D Conversion Accuracy Select bits (ADCER.ADPRC[1:0]) (12-bit, 10-bit, 8-bit is selectable.)
- Setting of the Addition/Average Count Select bits (ADADC.ADC[2:0]) (1, 2, 3, 4, or 16 times)
- Setting of the Average Mode Enable bit (ADADC.AVEE) (addition or average).

This section describes the data formats for these conditions in different modes.

(1) When A/D-converted value addition/average mode is not selected

Table 43.11 shows the example of bit assignment for 12-bit accuracy.

Table 43.11 Example of bit assignment for 12-bit accuracy

Accuracy	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	These bits are read as 0.				Converted Value 11 to 0: 12-bit A/D-converted value											
Left-justified data with 12-bit accuracy	Converted Value 11 to 0: 12-bit A/D-converted value												These bits are read as 0.			

(2) When A/D-converted value average mode is selected

A/D-converted value average mode can be selected when 2 or 4 times is specified in the A/D-converted value addition mode. When A/D converted value average mode is selected, this register indicates the mean of A/D-converted values on a specific channel. The value is stored in the A/D data register based on the setting of the A/D Data Register Format Select bit in the same way as for normal A/D conversion.

(3) When A/D-converted value addition mode is selected

For 12-bit, 10-bit, 8-bit accuracy, 1, 2, 3, or 4 times can be selected in the A/D-converted value addition mode. A/D conversion results are stored in the A/D data register as a 2-bit-extended value of the specified conversion accuracy.

For 12-bit accuracy, 16 times can also be selected in the A/D-converted value addition mode. In A/D-converted value addition mode, this register indicates the value that is obtained by adding A/D-converted values on a specific channel. A/D conversion results are stored in the A/D data register as a 4-bit-extended value of the specified conversion accuracy.

When A/D-converted value addition mode is selected, the value is stored in the A/D data register based on the settings of the A/D Data Register Format Select bits.

Table 43.12 shows example of the bit assignment for 12-bit accuracy.

Table 43.12 Example of bit assignment for 12-bit accuracy when A/D-converted value addition mode is selected (1 of 2)

Accuracy		b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	When 16 conversion times is specified	Added Value 15 to 0: 16-bit sum of A/D conversion results															
	When 1, 2, 3, or 4 conversion times is specified	These bits are read as 0.	Added Value 13 to 0: 14-bit sum of A/D conversion results														

Table 43.12 Example of bit assignment for 12-bit accuracy when A/D-converted value addition mode is selected (2 of 2)

Accuracy		b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Left-justified data with 12-bit accuracy	When 1, 2, 3, or 4 conversion times is specified	Added Value 15 to 0: 16-bit sum of A/D conversion results															
	When 16 conversion times is specified	Added Value 13 to 0: 14-bit sum of A/D conversion results														These bits are read as 0.	

43.2.5 ADOCDR : A/D Internal Reference Voltage Data Register

Base address: ADC12m = 0x4017_0000 + 0x0200 × m (m = 0, 1)

Offset address: 0x01C

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ADOCDR [15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	ADOCDR [15:0]	Converted Value 15 to 0 Functions vary depending on the selected mode and accuracy. See Table 43.13 and Table 43.14.	R

ADOCDR register is a 16-bit read-only register to store A/D conversion result of the internal reference voltage.

The following conditions determine the formats for data in the A/D data registers:

- Setting of the A/D Data Register Format Select bit (ADCER.ADRFMT) (flush-left or flush-right)
- The setting in the A/D Conversion Accuracy Select bits (ADCER.ADPRC[1:0]) (12-bit, 10-bit, 8-bit is selectable.)
- Setting of the Addition/Average Count Select bits (ADADC.ADC[2:0]) (1, 2, 3, 4, or 16 times)
- Setting of the Average Mode Enable bit (ADADC.AVEE) (addition or average).

This section describes the data formats for these conditions in different modes.

(1) When A/D-converted value addition/average mode is not selected

Table 43.13 shows the example of bit assignment for 12-bit accuracy.

Table 43.13 Example of bit assignment for 12-bit accuracy

Accuracy	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	These bits are read as 0.				Converted Value 11 to 0: 12-bit A/D-converted value											
Left-justified data with 12-bit accuracy	Converted Value 11 to 0: 12-bit A/D-converted value												These bits are read as 0.			

(2) When A/D-converted value average mode is selected

A/D-converted value average mode can be selected when 2 or 4 times is specified in the A/D-converted value addition mode. When A/D converted value average mode is selected, this register indicates the mean of A/D-converted values on a specific channel. The value is stored in the A/D data register based on the setting of the A/D Data Register Format Select bit in the same way as for normal A/D conversion.

(3) When A/D-converted value addition mode is selected

For 12-bit, 10-bit, 8-bit accuracy, 1, 2, 3, or 4 times can be selected in the A/D-converted value addition mode. A/D conversion results are stored in the A/D data register as a 2-bit-extended value of the specified conversion accuracy.

For 12-bit accuracy, 16 times can also be selected in the A/D-converted value addition mode. In A/D-converted value addition mode, this register indicates the value that is obtained by adding A/D-converted values on a specific channel. A/D conversion results are stored in the A/D data register as a 4-bit-extended value of the specified conversion accuracy.

When A/D-converted value addition mode is selected, the value is stored in the A/D data register based on the settings of the A/D Data Register Format Select bits.

Table 43.14 shows example of the bit assignment for 12-bit accuracy.

Table 43.14 Example of bit assignment for 12-bit accuracy when A/D-converted value addition mode is selected

Accuracy		b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	When 16 conversion times is specified	Added Value 15 to 0: 16-bit sum of A/D conversion results															
	When 1, 2, 3, or 4 conversion times is specified	These bits are read as 0.		Added Value 13 to 0: 14-bit sum of A/D conversion results													
Left-justified data with 12-bit accuracy	When 1, 2, 3, or 4 conversion times is specified	Added Value 15 to 0: 16-bit sum of A/D conversion results															
	When 16 conversion times is specified	Added Value 13 to 0: 14-bit sum of A/D conversion results														These bits are read as 0.	

43.2.6 ADRD : A/D Self-Diagnosis Data Register

Base address: ADC12m = 0x4017_0000 + 0x0200 × m (m = 0, 1)

Offset address: 0x01E

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	DIAGST[1:0]		—	—	AD[11:0]											
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
11:0	AD[11:0]	Converted Value 11 to 0 12-bit A/D-converted value	R
13:12	—	These bits are read as 0.	R
15:14	DIAGST[1:0]	Self-Diagnosis Status For details on self-diagnosis, see section 43.2.15. ADCER : A/D Control Extended Register. 0 0: Self-diagnosis not executed after power-on. 0 1: Self-diagnosis was executed using the 0 V voltage. 1 0: Self-diagnosis was executed using the reference voltage*1 × 1/2. 1 1: Self-diagnosis was executed using the reference voltage *1.	R

Note: The example of the bit assignment for the right-justified data with 12-bit accuracy is indicated.
Note 1. The reference voltage refers to VREFH0 for unit 0 and to VREFH for unit 1.

ADRD is a 16-bit read-only register that holds the A/D conversion results based on the self-diagnosis of the ADC12. In addition to the AD[11:0] bits indicating the A/D-converted value, it includes the Self-Diagnosis Status bit (DIAGST[1:0]).

The settings of the A/D data register format and the A/D conversion accuracy determines the formats for data in this register.

The A/D-converted value addition and average modes cannot be applied to the A/D self-diagnosis function. For details on self-diagnosis, see section 43.2.15. ADCER : A/D Control Extended Register.

This section describes the data formats for each condition. The register diagram and the register bit table shown in this section indicate example of the bit assignment for the left and right-justified data with 12-bit accuracy.

Table 43.15 Bit assignment for each right-justified accuracy

Accuracy	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	DIAGST[1:0]		—		AD[11:0]											

Table 43.16 Bit assignment for each left-justified accuracy

Accuracy	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Left-justified data with 12-bit accuracy	AD[11:0]												—		DIAGST[1:0]	

43.2.7 ADCSR : A/D Control Register

Base address: ADC12m = 0x4017_0000 + 0x0200 × m (m = 0, 1)

Offset address: 0x000

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ADST	ADCS[1:0]		—	—	—	TRGE	EXTRG	DBLE	GBADIE	—	DBLANS[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
4:0	DBLANS[4:0]	Double Trigger Channel Select These bits select one analog input channel for double-trigger operation. The setting is only valid in double-trigger mode.	R/W
5	—	This bit is read as 0. The write value should be 0.	R/W
6	GBADIE	Group B Scan End Interrupt and ELC Event Enable Group B scan only works in group scan mode. 0: Disable ADC12i_GBADI (i = 0, 1) interrupt generation on group B scan completion. 1: Enable ADC12i_GBADI (i = 0, 1) interrupt generation on group B scan completion.	R/W
7	DBLE	Double Trigger Mode Select 0: Deselect double-trigger mode. 1: Select double-trigger mode.	R/W
8	EXTRG	Trigger Select*1 0: Start A/D conversion by the synchronous trigger (ELC). 1: Start A/D conversion by the asynchronous trigger (ADTRG0).	R/W
9	TRGE	Trigger Start Enable 0: Disable A/D conversion to be started by the synchronous or asynchronous trigger 1: Enable A/D conversion to be started by the synchronous or asynchronous trigger	R/W
10	—	These bits are read as 0. The write value should be 0.	R/W
11	—	These bits are read as 0. The write value should be 0.	R/W
12	—	These bits are read as 0. The write value should be 0.	R/W
14:13	ADCS[1:0]	Scan Mode Select 0 0: Single scan mode 0 1: Group scan mode 1 0: Continuous scan mode 1 1: Setting prohibited	R/W
15	ADST	A/D Conversion Start 0: Stop A/D conversion process. 1: Start A/D conversion process.	R/W

Note 1. To start A/D conversion using an external pin (asynchronous trigger):
After a high-level signal is input to the external pin (ADTRG0), write 1 to both the TRGE and EXTRG bits in the ADCSR register and drive the ADTRG0 pin low. With these settings, the scan conversion process starts on detection of the falling edge of ADTRG0. The pulse width of the low-level input must be at least PCLKA 1.5 clock cycles.

The ADCSR register sets double-trigger mode and A/D conversion start trigger, enables or disables scan end interrupt, selects the scan mode, and starts or stops A/D conversion.

DBLANS[4:0] bits (Double Trigger Channel Select)

The DBLANS[4:0] bits select one channel for A/D conversion data duplication in double-trigger mode. This can be selected by setting the binary value of the channel number to be duplicated. The A/D conversion results of the analog input of the channel selected in the DBLANS[4:0] bits are stored in A/D Data Register y when conversion is started by the first trigger, and in the A/D Data Duplexing Register when conversion is started by the second trigger.

In double-trigger mode, the channels selected in the ADANSA0 and ADANSA1 registers, are invalid, and the channel selected in the DBLANS[4:0] bits is A/D converted instead.

When double-trigger mode is used in group scan mode, double-trigger control is only applied to group A and not to group B. Therefore, multiple channel analog input can be selected for group B even in double-trigger mode.

Only set the DBLANS[4:0] bits when the ADST bit is 0. Do not set the DBLANS[4:0] bits at the same time that you write 1 to the ADST bit.

To enter A/D-converted value addition/average mode when in double-trigger mode, select the channel using the DBLANS[4:0] bits in the ADANSA0 and ADANSA1 registers.

A/D-converted data from the self-diagnosis function temperature sensor output and internal reference voltage cannot be used in double-trigger mode.

GBADIE bit (Group B Scan End Interrupt and ELC Event Enable)

The GBADIE bit enables or disables group B scan end interrupt (ADC12i_GBADI (i = 0, 1)) in group scan mode.

DBLE bit (Double Trigger Mode Select)

The DBLE bit selects or deselects double-trigger mode. Double-trigger mode can only be operated by the synchronous trigger (ELC) selected in the ADSTRGR.TRSA[5:0] bits.

Double-trigger operation is as follows:

1. The ADC12i_ADI (i = 0, 1) interrupt is not output on completion of the first conversion but on completion of the second conversion.
2. The A/D conversion results from the duplication channel (selected in DBLANS[4:0]) started by the first trigger are stored in A/D Data Register y and those started by the second trigger are stored in the A/D Data Duplexing Register.

When the DBLE bit is set (double-trigger mode is selected), the channels specified in the ADANSA0 and ADANSA1 registers are invalid. Double-trigger mode is deselected by setting DBLE to 0. Setting DBLE to 1 again enables the same double-trigger operation described in 1. and 2. for first time scanning with the first trigger.

Do not select double-trigger mode in continuous scan mode. Software triggering cannot be used in double-trigger mode. Always set the ADST bit to 0 before setting the DBLE bit. Do not set the DBLE bit at that same time as writing 1 to the ADST bit.

EXTRG bit (Trigger Select)

The EXTRG bit selects the synchronous or asynchronous trigger as the trigger for starting A/D conversion.

In group scan mode, the setting of this bit takes effect on the trigger selected for group A. For group B, A/D conversion is started by the selected synchronous trigger regardless of this bit setting.

TRGE bit (Trigger Start Enable)

The TRGE bit enables or disables A/D conversion by the synchronous and asynchronous triggers. In group scan mode, set this bit to 1.

ADCS[1:0] bits (Scan Mode Select)

The ADCS[1:0] bits select the scan mode.

In single scan mode, A/D conversion is performed for the analog inputs of the channels selected in the ADANSA0 and ADANSA1 registers, in ascending order of channel number. When 1 cycle of A/D conversion completes for all the selected channels, the scan conversion stops.

In continuous scan mode, when the ADCSR.ADST bit is 1, A/D conversion is performed for the analog inputs of the channels selected with the ADANSA0 and ADANSA1 registers , in ascending order of channel number. When 1 cycle of A/D conversion completes for all the selected channels, A/D conversion repeats from the first channel. If the ADCSR.ADST bit is set to 0 during continuous scan, A/D conversion stops even if scanning is in progress.

In group scan mode:

- Group A scanning is started by the synchronous trigger (ELC) selected in the TRSA[5:0] bits in the ADSTRGR register. A/D conversion is performed on group A analog inputs of the channels selected in the ADANSA0 and ADANSA1 registers, in ascending order of channel number. When 1 cycle of A/D conversion completes for all the selected channels, A/D conversion stops.
- Group B scanning is started by the synchronous trigger (ELC) selected in the ADSTRGR.TRSB[5:0] bits. A/D conversion is performed on group B analog inputs of the channels selected in the ADANSB0 and ADANSB1 registers, in ascending order of channel number. When 1 cycle of A/D conversion completes for all the selected channels, A/D conversion stops.

If the conversion processes in group A and group B occur at the same time, those conversions cannot be controlled separately. In this case, set group A Priority Control Setting bit (ADGSPCR.PGS) in the A/D Group Scan Priority Control Register (ADGSPCR) to 1 to assign a priority to group A conversion.

In group scan mode, select different channels and triggers for group A and group B.

Only set the ADCS[1:0] bits when the ADST bit is 0. Do not set the ADCS[1:0] bits at the same time that you write 1 to the ADST bit.

Table 43.17 Selectable targets for A/D conversion depending on scan and double-trigger mode settings

Scan mode setting	Double-trigger mode setting	Targets for A/D conversion				
		Self-diagnosis	Analog input (group A)	Analog input (group B)	Temperature sensor output	Internal reference voltage
Single scan	DBLE = 0	✓	✓	—	✓	✓
	DBLE = 1	—	✓ (1 ch only)	—	—	—
Continuous scan	DBLE = 0	✓	✓	—	✓	✓
	DBLE = 1	—	—	—	—	—
Group scan	DBLE = 0	✓	✓	✓	✓	✓
	DBLE = 1	—	✓ (1 ch only)	✓	✓	✓

Note: ✓: Selectable, —: Not selectable

ADST bit (A/D Conversion Start)

The ADST bit starts or stops the A/D conversion process. Before the ADST bit is set to 1, set the A/D conversion clock, the conversion mode, and the conversion target analog input.

[Setting conditions]

- 1 is written.
- The synchronous trigger (ELC) selected in the ADSTRGR.TRSA[5:0] bits is detected when ADCSR.EXTRG is 0 and ADCSR.TRGE is 1.
- The synchronous trigger (ELC) selected in the ADSTRGR.TRSB[5:0] bits is detected when ADCSR.TRGE is set to 1 in group scan mode.
- The asynchronous trigger is detected when the ADCSR.TRGE and ADCSR.EXTRG bits are set to 1 and the ADSTRGR.TRSA[5:0] bits are set to 0x00.
- When group priority operation mode is enabled (ADCSR.ADCS[1:0] = 01b and ADGSPCR.PGS = 1), the ADGSPCR.GBRP bit is set to 1, and each time A/D conversion on the group with the lowest priority is started.

[Clearing conditions]

- 0 is written.

- The A/D conversion of all the selected channels, the temperature sensor output the internal reference voltage completes in single scan mode.
- Group A scan completes in group scan mode.
- Group B scan completes in group scan mode.
- When group priority operation mode is enabled (ADCSR.ADCS[1:0] = 01b and ADGSPCR.PGS = 1), the ADGSPCR.GBRSCN bit is set to 1, and A/D conversion on the group with the lowest priority started by trigger completes.

Note: When group priority operation mode is enabled (ADCSR.ADCS[1:0] = 01b and ADGSPCR.PGS = 1), do not set the ADST bit to 1.
Note: When group priority operation mode is enabled (ADCSR.ADCS[1:0] = 01b and ADGSPCR.PGS = 1), do not set the ADST bit to 0. When forcing A/D conversion to terminate, follow the procedure for clearing the ADST bit.

43.2.8 ADANSA0 : A/D Channel Select Register A0

Base address: ADC12m = 0x4017_0000 + 0x0200 × m (m = 0, 1)

Offset address: 0x004

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	ANSA13	ANSA12	—	ANSA10	ANSA9	ANSA8	ANSA7	ANSA6	ANSA5	ANSA4	ANSA3	ANSA2	ANSA1	ANSA0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
10:0	ANSA10 to ANSA0	A/D Conversion Channels Select Bit 10 (ANSA10) is associated with ANm10 and bit 0 (ANSA0) is associated with ANm00. 0: Do not select associated input channel. 1: Select associated input channel.	R/W
11	—	This bit is read as 0. The write value should be 0.	R/W
13:12	ANSA13 to ANSA12	A/D Conversion Channels Select Bit 13 (ANSA13) is associated with ANm13 and bit 12 (ANSA12) is associated with ANm12. 0: Do not select associated input channel. 1: Select associated input channel.	R/W
15:14	—	These bits are read as 0. The write value should be 0.	R/W

Note: ANSAn (n = 3 to 10, 12, 13) are only for unit 0.

ADANSA0 register selects analog input channels for A/D conversion. In group scan mode, this register selects group A channels.

Only set the ADANSA0 register when the ADCSR.ADST bit is 0.

ANSAn bits (A/D Conversion Channels Select)

The ADANSA0 register selects any combination of analog input channels for A/D conversion. The channels and the number of channels can be arbitrarily set.

In double trigger mode, the channels selected in the ADANSA0 register are invalid, and the channel selected in the ADCSR.DBLANS[4:0] bits is selected in group A instead.

When group scan mode is selected, do not select the channels specified in A/D Channel Select Register B0 (ADANSB0) and A/D Channel Select Register B1 (ADANSB1).

43.2.9 ADANSA1 : A/D Channel Select Register A1

Base address: ADC12m = 0x4017_0000 + 0x0200 × m (m = 0, 1)

Offset address: 0x006

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	ANSA28	ANSA27	ANSA26	ANSA25	ANSA24	ANSA23	ANSA22	ANSA21	ANSA20	ANSA19	ANSA18	ANSA17	ANSA16

Bit	Symbol	Function	R/W
12:0	ANSA28 to ANSA16	A/D Conversion Channels Select Bit 12 (ANSA28) is associated with ANm28 and bit 0 (ANSA16) is associated with ANm16. 0: Do not select associated input channel. 1: Select associated input channel.	R/W
15:13	—	These bits are read as 0. The write value should be 0.	R/W

Note: ANSAn (n = 16 to 28) are only for unit 1.

ADANSA1 register selects analog input channels for A/D conversion. In group scan mode, this register selects group A channels.

Only set the ADANSA1 register when the ADCSR.ADST bit is 0.

ANSAn bits (A/D Conversion Channels Select)

The ADANSA1 register selects any combination of analog input channels for A/D conversion. The channels and the number of channels can be arbitrarily set.

In double trigger mode, the channels selected in the ADANSA1 register are invalid, and the channel selected in the ADCSR.DBLANS[4:0] bits is selected in group A instead.

When group scan mode is selected, do not select the channels specified in A/D Channel Select Register B0 (ADANSB0) and A/D Channel Select Register B1 (ADANSB1).

43.2.10 ADANSB0 : A/D Channel Select Register B0

Base address: ADC12m = 0x4017_0000 + 0x0200 × m (m = 0, 1)

Offset address: 0x014

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	ANSB13	ANSB12	—	ANSB10	ANSB9	ANSB8	ANSB7	ANSB6	ANSB5	ANSB4	ANSB3	ANSB2	ANSB1	ANSB0

Bit	Symbol	Function	R/W
10:0	ANSB10 to ANSB0	A/D Conversion Channels Select Bit 10 (ANSB10) is associated with ANm10 and bit 0 (ANSB0) is associated with ANm00. 0: Do not select associated input channel. 1: Select associated input channel.	R/W
11	—	This bit is read as 0. The write value should be 0.	R/W
13:12	ANSB13 to ANSB12	A/D Conversion Channels Select Bit 13 (ANSB13) is associated with ANm13 and bit 12 (ANSB12) is associated with ANm12. 0: Do not select associated input channel. 1: Select associated input channel.	R/W
15:14	—	These bits are read as 0. The write value should be 0.	R/W

Note: ANSBn (n = 3 to 10, 12, 13) are only for unit 0.

ADANSB0 selects analog input channels for A/D conversion in group B when group scan mode is selected. The ADANSB0 register is not used in any scan mode other than group scan mode.

Only set the ADANSB0 register when the ADCSR.ADST bit is 0.

ANSBn bits (A/D Conversion Channels Select)

The ADANSB0 register selects any combination of analog input channels in group B for A/D conversion when group scan mode is selected. The ADANSB0 register is used for group scan mode only and not for any other modes.

Do not select channels specified in group A as selected in the ADANSA0 and ADANSA1 registers or the ADCSR.DBLANS[4:0] bits in double-trigger mode.

43.2.11 ADANSB1 : A/D Channel Select Register B1

Base address: ADC12m = 0x4017_0000 + 0x0200 × m (m = 0, 1)

Offset address: 0x016

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	ANSB28	ANSB27	ANSB26	ANSB25	ANSB24	ANSB23	ANSB22	ANSB21	ANSB20	ANSB19	ANSB18	ANSB17	ANSB16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
12:0	ANSB28 to ANSB16	A/D Conversion Channels Select Bit 12 (ANSB28) is associated with ANm28 and bit 0 (ANSB16) is associated with ANm16. 0: Do not select associated input channel. 1: Select associated input channel.	R/W
15:13	—	These bits are read as 0. The write value should be 0.	R/W

Note: ANSBn (n = 16 to 28) are only for unit 1.

ADANSB1 selects analog input channels for A/D conversion in group B when group scan mode is selected. The ADANSB1 register is not used in any scan mode other than group scan mode.

Only set the ADANSB1 register when the ADCSR.ADST bit is 0.

ANSBn bits (A/D Conversion Channels Select)

The ADANSB1 register selects any combination of analog input channels in group B for A/D conversion when group scan mode is selected. The ADANSB1 register is used for group scan mode only and not for any other modes.

Do not select channels specified in group A as selected in the ADANSA0 and ADANSA1 registers or the ADCSR.DBLANS[4:0] bits in double-trigger mode.

43.2.12 ADADS0 : A/D-Converted Value Addition/Average Channel Select Register 0

Base address: ADC12m = 0x4017_0000 + 0x0200 × m (m = 0, 1)

Offset address: 0x008

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	ADS13	ADS12	—	ADS10	ADS9	ADS8	ADS7	ADS6	ADS5	ADS4	ADS3	ADS2	ADS1	ADS0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
10:0	ADS10 to ADS0	A/D-Converted Value Addition/Average Channel Select Bit 10 (ADS10) is associated with ANm10 and bit 0 (ADS0) is associated with ANm00. 0: Do not select associated input channel. 1: Select associated input channel.	R/W
11	—	This bit is read as 0. The write value should be 0.	R/W
13:12	ADS13 to ADS12	A/D-Converted Value Addition/Average Channel Select Bit 13 (ADS13) is associated with ANm13 and bit 12 (ADS12) is associated with ANm12. 0: Do not select associated input channel. 1: Select associated input channel.	R/W
15:14	—	These bits are read as 0. The write value should be 0.	R/W

Note: ADSn (n = 3 to 10, 12, 13) are only for unit 0.

ADSn bits (A/D-Converted Value Addition/Average Channel Select)

The ADSn bits determine which A/D-converted channels are subject to A/D-converted value addition/averaging. When an ADSn bit associated with a channel selected for A/D conversion is set to 1, A/D conversion of the analog input of the respective channel is performed successively 1, 2, 3, 4, or 16 times, as specified in the ADC[2:0] bits in the ADADC register.

When the ADADC.AVEE bit is 0, the value obtained by addition is stored in the A/D data register. When the ADADC.AVEE bit is 1, the mean value of the results obtained by addition is stored in the A/D data register.

The ADSn bits apply only to channels that are selected for A/D conversion in:

- The ANSAn bits in the ADANSA0 register or the DBLANS[4:0] bits in the ADCSR register
- The ANSBn bits in the ADANSB0 register

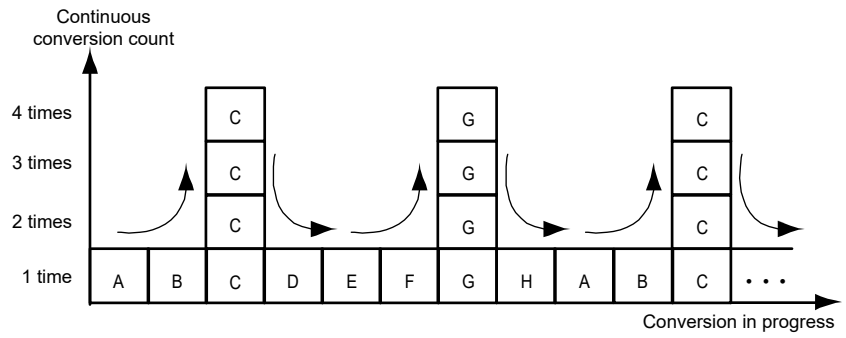
For channels on which the A/D conversion is performed and for which addition/average mode is not selected, a normal 1-time conversion is executed, and the conversion result is stored in the A/D data register.

Only set ADADS0 register bits when the ADCSR.ADST bit is 0.

Figure 43.3 shows a scanning operation sequence in which the ADADS0 register bits (channel c and g) are set to 1. In this figure:

- Addition mode is selected (ADADC.AVEE = 0)
- The number of conversions is set to 4 (ADADC.ADC[1:0] = 11b)
- The analog input channels (a to h) are selected by ADANSA0 register in continuous scan mode (ADCSR.ADCS[1:0] = 10b).

The conversion process begins with analog input A (channel a). The analog input C (channel c) conversion is performed successively 4 times and the added value is returned to A/D Data Register c (ADDRc). Next, the analog input D (channel d) conversion process is started. The analog input G (channel g) is performed successively 4 times and the added value is returned to A/D Data Register g (ADDRg). After conversion of analog input H (channel h), the conversion operation repeats in the same sequence starting with analog input A (channel a).



Note: A to H are analog inputs (channel a to h)

Figure 43.3 Scan conversion sequence with ADADC.ADC[2:0] = 011b, set 1 for analog inputs C and G by ADADS0/1

43.2.13 ADADS1 : A/D-Converted Value Addition/Average Channel Select Register 1

Base address: ADC12m = 0x4017_0000 + 0x0200 × m (m = 0, 1)

Offset address: 0x00A

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	ADS28	ADS27	ADS26	ADS25	ADS24	ADS23	ADS22	ADS21	ADS20	ADS19	ADS18	ADS17	ADS16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
12:0	ADS28 to ADS16	A/D-Converted Value Addition/Average Channel Select Bit 12 (ADS28) is associated with ANm28 and bit 0 (ADS16) is associated with ANm16. 0: Do not select associated input channel. 1: Select associated input channel.	R/W
15:13	—	These bits are read as 0. The write value should be 0.	R/W

Note: ADSn (n = 16 to 28) are only for unit 1.

ADSn bits (A/D-Converted Value Addition/Average Channel Select)

The ADSn bits determine which A/D-converted channels are subject to A/D-converted value addition/averaging. When an ADSn bit associated with a channel selected for A/D conversion is set to 1, A/D conversion of the analog input of the respective channel is performed successively 1, 2, 3, 4, or 16 times, as specified in the ADC[2:0] bits in the ADADC register.

When the ADADC.AVEE bit is 0, the value obtained by addition is stored in the A/D data register. When the ADADC.AVEE bit is 1, the mean value of the results obtained by addition is stored in the A/D data register.

The ADSn bits apply only to channels that are selected for A/D conversion in:

- The ANSAn bits in the ADANSA1 register or the DBLANS[4:0] bits in the ADCSR register
- The ANSBn bits in the ADANSB1 register.

For channels on which the A/D conversion is performed and for which addition/average mode is not selected, a normal 1-time conversion is executed, and the conversion result is stored in the A/D data register.

Only set ADADS1 register when the ADCSR.ADST bit is 0.

43.2.14 ADADC : A/D-Converted Value Addition/Average Count Select Register

Base address: ADC12m = 0x4017_0000 + 0x0200 × m (m = 0, 1)

Offset address: 0x00C

Bit position:	7	6	5	4	3	2	1	0
Bit field:	AVEE	—	—	—	—	ADC[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	ADC[2:0]	Addition/Average Count Select 0 0 0: 1-time conversion (no addition, same as normal conversion) 0 0 1: 2-time conversion (1 addition) 0 1 0: 3-time conversion (2 additions) 0 1 1: 4-time conversion (3 additions) 1 0 1: 16-time conversion (15 additions) Others: Setting prohibited	R/W
6:3	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
7	AVEE	Average Mode Select 0: Enable addition mode 1: Enable average mode	R/W

ADADC sets the addition or average mode and addition count for A/D conversion. Table 43.18 lists the settable combinations of ADADC register.

Table 43.18 Settable combinations of ADADC register

Mode select (AVEE)	Resolution	Conversion time				
		1-time	2-time	3-time	4-time	16-time
Addition mode (AVEE = 0)	8-bit	✓	✓	✓	✓	—
	10-bit	✓	✓	✓	✓	—
	12-bit	✓	✓	✓	✓	✓
Average mode (AVEE = 1)	8, 10, 12 bits	—	✓	—	✓	—

Note: ✓: Selectable, —: Not selectable

ADC[2:0] bits (Addition/Average Count Select)

The ADC[2:0] bits set the addition count in all channels for which A/D conversion and addition/average mode are selected, including the channel selected in double trigger mode with the ADCSR.DBLANS[4:0] bits. The count also applies to A/D conversion of the temperature sensor output and the internal reference voltage.
When self-diagnosis is executed (ADCER.DIAGM = 1), do not set the ADC[2:0] bits to any value other than 000b.

AVEE bit (Average Mode Select)

The AVEE bit selects addition or average mode in all channels for which A/D conversion and addition/average mode are selected, including the channels selected in double-trigger mode in the ADCSR.DBLANS[4:0] bits, temperature sensor output, internal reference voltage.

43.2.15 ADCER : A/D Control Extended Register

Base address: ADC12m = 0x4017_0000 + 0x0200 × m (m = 0, 1)

Offset address: 0x00E

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ADRFMT	—	—	—	DIAGM	DIAGLD	DIAGVAL[1:0]		—	—	ACE	—	—	ADPRC[1:0]		—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	—	These bits are read as 0. The write value should be 0.	R/W
2:1	ADPRC[1:0]	A/D Conversion Accuracy Specify 0 0: 12-bit accuracy 0 1: 10-bit accuracy 1 0: 8-bit accuracy 1 1: Setting prohibited	R/W
4:3	—	These bits are read as 0. The write value should be 0.	R/W
5	ACE	A/D Data Register Automatic Clearing Enable 0: Disable automatic clearing 1: Enable automatic clearing	R/W
7:6	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
9:8	DIAGVAL[1:0]	Self-Diagnosis Conversion Voltage Select 0 0: Setting prohibited when self-diagnosis is enabled 0 1: 0 volts 1 0: Reference voltage*1 × 1/2 1 1: Reference voltage*1	R/W
10	DIAGLD	Self-Diagnosis Mode Select 0: Select rotation mode for self-diagnosis voltage 1: Select mixed mode for self-diagnosis voltage	R/W
11	DIAGM	Self-Diagnosis Enable 0: Disable ADC12 self-diagnosis 1: Enable ADC12 self-diagnosis	R/W
14:12	—	These bits are read as 0. The write value should be 0.	R/W
15	ADRFMT	A/D Data Register Format Select 0: Select right-justified for the A/D data register format 1: Select left-justified for the A/D data register format	R/W

Note 1. The reference voltage refers to VREFH0 for unit 0 and to VREFH for unit 1.

ADPRC[1:0] bit (A/D Conversion Accuracy Specify)

The ADPRC[1:0] bits set the A/D conversion accuracy. Changing the A/D conversion accuracy also changes the bit width of valid data stored in the result register and the A/D conversion time. For details, see section 43.3.7. Analog Input Sampling and Scan Conversion Timesection 45.3.6, Analog Input Sampling and Scan Conversion Time. Only set the ADPRC[1:0] bits while the ADCSR.ADST bit is 0.

ACE bit (A/D Data Register Automatic Clearing Enable)

The ACE bit enables or disables automatic clearing (all 0) of the ADDRy, ADRD, ADDBLDR, ADDBLDRA, ADDBLDRB, ADTSDR, or ADOCDR register after any of these registers is read by the CPU or DTC. Automatic clearing of the A/D data registers enables detection of failures that are not updated in the A/D data registers. For details, see section 43.3.8. Usage Example of A/D Data Register Automatic Clearing Function.

DIAGVAL[1:0] bits (Self-Diagnosis Conversion Voltage Select)

The DIAGVAL[1:0] bits select the voltage value used in self-diagnosis fixed voltage mode. For details, see the DIAGLD bit description.

Do not execute self-diagnosis by setting the DIAGLD bit to 1 when the DIAGVAL[1:0] bits are set to 00b.

DIAGLD bit (Self-Diagnosis Mode Select)

The DIAGLD bit selects whether the three voltage values are rotated, or the fixed voltage is used in self-diagnosis.

Setting the DIAGLD bit to 0 selects conversion of the voltages in rotation mode, where 0 V, the reference voltage × 1/2, and the reference voltage are converted, in that order. After reset and when self-diagnosis voltage rotation mode is selected, self-diagnosis is executed from 0 V. The self-diagnosis voltage value does not return to 0 V when scan conversion completes. When scan conversion is restarted, rotation starts at the voltage value following the previous value.

Setting the DIAGLD bit to 1 selects fixed voltage, in which the fixed voltage specified in the ADCER.DIAGVAL[1:0] bits is converted. If fixed mode is switched to rotation mode, rotation starts at the fixed voltage value.

Only set the DIAGLD bit when the ADCSR.ADST bit is 0.

DIAGM bit (Self-Diagnosis Enable)

The DIAGM bit enables or disables self-diagnosis.

Self-diagnosis is used to detect a failure of the ADC12. In self-diagnosis mode, one of the three voltage values (0 V, the reference voltage × 1/2, or the reference voltage) is converted. When conversion completes, information on the converted voltage and the conversion result is stored into the A/D Self-Diagnosis Data Register (ADRD). The ADRD register can be read to determine whether the conversion result falls within the normal or abnormal range.

Self-diagnosis is executed once at the beginning of each scan, and one of the three voltages is converted. In double trigger mode (ADCSR.DBLE = 1), self-diagnosis (DIAGM = 0) is deselected. When self-diagnosis is selected in group scan mode, self-diagnosis is executed separately for group A and group B.

Only set the DIAGM bit when the ADCSR.ADST bit is 0.

ADRFMT bit (A/D Data Register Format Select)

The ADRFMT bit specifies flush-right or flush-left for data to be stored in the ADDRy, ADDBLDR, ADDBLDRA, ADDBLDRB, ADTSDR, ADOCDR, ADCMPDR0/1, ADWINLLB, ADWINULB, or ADRD register.

Only set the ADRFMT bit when the ADCSR.ADST bit is 0.

43.2.16 ADSTRGR : A/D Conversion Start Trigger Select Register

Base address: ADC12m = 0x4017_0000 + 0x0200 × m (m = 0, 1)

Offset address: 0x010

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	TRSA[5:0]						—	—	TRSB[5:0]					
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	TRSB[5:0]	A/D Conversion Start Trigger Select for Group B Select the A/D conversion start trigger for group B in group scan mode.	R/W
7:6	—	These bits are read as 0. The write value should be 0.	R/W
13:8	TRSA[5:0]	A/D Conversion Start Trigger Select Select the A/D conversion start trigger in single scan mode and continuous scan mode. In group scan mode, the A/D conversion start trigger for group A is selected.	R/W
15:14	—	These bits are read as 0. The write value should be 0.	R/W

TRSB[5:0] bits (A/D Conversion Start Trigger Select for Group B)

The TRSB[5:0] bits select the trigger to start scanning of the analog input selected in group B. The TRSB[5:0] bits must only be set in group scan mode and are not used in any other scan mode. For the scan conversion start trigger for group B, setting a software trigger or an asynchronous trigger is prohibited. In group scan mode, set the TRSB[5:0] bits to a value other than 0x00 and set the ADCSR.TRGE bit to 1.

When group A is given priority in group scan mode, setting the ADGSPCR.GBRP bit to 1 allows group B to continuously operate in single scan mode. When setting the ADGSPCR.GBRP bit to 1, set the TRSB[5:0] bits to 0x3F. The issuance period for a conversion trigger must be more than or equal to the actual scan conversion time (t_{SCAN}). If the issuance period is less than t_{SCAN}, A/D conversion by the trigger might have no effect.

Table 43.19 lists the A/D conversion startup sources selected in the TRSB[5:0] bits.

Table 43.19 Selection of A/D conversion start sources in the TRSB[5:0] bits (1 of 2)

Source	Remarks	TRSB[5]	TRSB[4]	TRSB[3]	TRSB[2]	TRSB[1]	TRSB[0]
Trigger source deselected state	—	1	1	1	1	1	1
ELC_AD00 (unit 0) and ELC_AD10 (unit 1)	ELC	0	0	1	0	0	1
ELC_AD01 (unit 0) and ELC_AD11 (unit 1)	ELC	0	0	1	0	1	0

Table 43.19 Selection of A/D conversion start sources in the TRSB[5:0] bits (2 of 2)

Source	Remarks	TRSB[5]	TRSB[4]	TRSB[3]	TRSB[2]	TRSB[1]	TRSB[0]
ELC_AD00 (unit 0) and ELC_AD10 (unit 1), ELC_AD01 (unit 0) and ELC_AD11 (unit 1)	ELC	0	0	1	0	1	1

TRSA[5:0] bits (A/D Conversion Start Trigger Select)

The TRSA[5:0] bits select the trigger to start A/D conversion in single scan mode and continuous scan mode, or the trigger to start scanning of group A analog inputs in group scan mode. When scanning is executed in group scan mode or double trigger mode, software trigger or asynchronous trigger is prohibited.

- When using a synchronous trigger (ELC), set the TRGE bit in the ADCSR register to 1 and set the EXTRG bit in the ADCSR register to 0.
- When using the asynchronous trigger (ADTRG0), set the TRGE bit in the ADCSR register to 1 and set the EXTRG bit in the ADCSR register to 1.
- Software trigger (ADCSR.ADST) is enabled regardless of the settings of the ADCSR.TRGE bit, the ADCSR.EXTRG bit, or the TRSA[5:0] bits.

The issuance period for a conversion trigger must be more than or equal to the actual scan conversion time (tSCAN). If the issuance period is less than tSCAN, A/D conversion by a trigger might have no effect.

Table 43.20 lists the A/D conversion start sources selected in the TRSA[5:0] bits.

Table 43.20 Selection of A/D activation sources in the TRSA[5:0] bits

Source	Remarks	TRSA[5]	TRSA[4]	TRSA[3]	TRSA[2]	TRSA[1]	TRSA[0]
Trigger source deselected state	—	1	1	1	1	1	1
ADTRGn (n = 0, 1)	Input pin for the trigger	0	0	0	0	0	0
ELC_AD00 (unit 0) and ELC_AD10 (unit 1)	ELC	0	0	1	0	0	1
ELC_AD01 (unit 0) and ELC_AD11 (unit 1)	ELC	0	0	1	0	1	0
ELC_AD00 (unit 0) and ELC_AD10 (unit 1), ELC_AD01 (unit 0) and ELC_AD11 (unit 1)	ELC	0	0	1	0	1	1

43.2.17 ADEXICR : A/D Conversion Extended Input Control Registers

Base address: ADC12m = 0x4017_0000 + 0x0200 × m (m = 0, 1)

Offset address: 0x012

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	OCSB	TSSB	OCSA	TSSA	—	—	—	—	—	—	OCSAD	TSSAD
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TSSAD	Temperature Sensor Output A/D-Converted Value Addition/Average Mode Select 0: Do not select addition/average mode for temperature sensor output. 1: Select addition/average mode for temperature sensor output.	R/W
1	OCSAD	Internal Reference Voltage A/D-Converted Value Addition/Average Mode Select 0: Do not select addition/average mode for internal reference voltage. 1: Select addition/average mode for internal reference voltage.	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W
8	TSSA	Temperature Sensor Output A/D Conversion Select 0: Disable A/D conversion of temperature sensor output 1: Enable A/D conversion of temperature sensor output	R/W
9	OCSA	Internal Reference Voltage A/D Conversion Select 0: Disable A/D conversion of internal reference voltage 1: Enable A/D conversion of internal reference voltage	R/W
10	TSSB	Temperature Sensor Output A/D Conversion Select for Group B 0: Disable A/D conversion of temperature sensor output 1: Enable A/D conversion of temperature sensor output	R/W
11	OCSB	Internal Reference Voltage A/D Conversion Select for Group B 0: Disable A/D conversion of internal reference voltage 1: Enable A/D conversion of internal reference voltage	R/W
15:12	—	These bits are read as 0. The write value should be 0.	R/W

TSSAD bit (Temperature Sensor Output A/D-Converted Value Addition/Average Mode Select)

When the TSSAD bit is set to 1, A/D conversion of the temperature sensor output is selected and performed successively the number of times specified in the ADC[2:0] bits in ADADC. When the ADADC.AVEE bit is 0, the value obtained by addition (integration) is returned to the A/D Temperature Sensor Data Register (ADTSDR). When the ADADC.AVEE bit is 1, the mean value is returned to ADTSDR.

Only set the TSSAD bit while the ADCSR.ADST bit is 0.

OCSAD bit (Internal Reference Voltage A/D-Converted Value Addition/Average Mode Select)

When the OCSAD bit is set to 1, A/D conversion of the internal reference voltage is selected and performed successively the number of times specified in the ADC[2:0] bits in ADADC. When the ADADC.AVEE bit is 0, the value obtained by addition (integration) is returned to the A/D Internal Reference Voltage Data Register (ADOCDR). When the ADADC.AVEE bit is 1, the mean value is returned to ADOCDR.

Only set the OCSAD bit while the ADCSR.ADST bit is 0.

TSSA bit (Temperature Sensor Output A/D Conversion Select)

The TSSA bit selects A/D conversion of the temperature sensor output for group A in single scan mode, continuous scan mode, or group scan mode. When A/D conversion of the temperature sensor output is selected and performed, set the ADCSR.DBLE bit to 0.

Only set the TSSA bit while the ADCSR.ADST bit is 0.

OCSA bit (Internal Reference Voltage A/D Conversion Select)

The OCSA bit selects A/D conversion of the internal reference voltage for group A in single scan mode, continuous scan mode, or group scan mode. When A/D conversion of the internal reference voltage is selected and performed, set the ADCSR.DBLE bit to 0.

Only set the OCSA bit while the ADCSR.ADST bit is 0. In addition, wait for 400 ns or more after the OCSA bit is set to 1 before starting A/D conversion.

TSSB bit (Temperature Sensor Output A/D Conversion Select for Group B)

The TSSB bit selects A/D conversion of the temperature sensor output for group B in group scan mode. Only set the TSSB bit while the ADCSR.ADST bit is 0. Do not set the TSSB bit to 1 while the TSSA bit is 1.

OCSB bit (Internal Reference Voltage A/D Conversion Select for Group B)

The OCSB bit selects A/D conversion of the internal reference voltage for group B in group scan mode. Only set the OCSB bit while the ADCSR.ADST bit is 0. Do not set the OCSB bit to 1 while the OCSA bit is 1. Moreover, start the A/D conversion after waiting for 400 ns or more after the OCSB bit is set to 1.

43.2.18 ADSSTRn/ADSSTRL/ADSSTRT/ADSSTRO : A/D Sampling State Register (n = 0 to 10, 12, 13)

Base address: ADC12m = 0x4017_0000 + 0x0200 × m (m = 0, 1)

Offset address: 0x0E0 + 0x1 × n (n = 0 to 10, 12, 13, m = 0)
0x0E0 + 0x1 × n (n = 0 to 2, m = 1)
0x0DD (ADSSTRL)
0x0DE (ADSSTRT)
0x0DF (ADSSTRO)

Bit position:	7	6	5	4	3	2	1	0
Bit field:	SST[7:0]							
Value after reset:	0	0	0	0	1	0	1	1

Bit	Symbol	Function	R/W
7:0	SST[7:0]	Sampling Time Setting These bits set the sampling time in the range from 5 to 255 states.	R/W

The ADSSTRn register sets the sampling time for analog input.

The sampling time can be adjusted if the impedance of the analog input signal source is too high to secure sufficient sampling time, or if the ADCLK clock is slow. The set value indicates the time for one ADCLK cycle, and the required sampling time is specified by the voltage conditions. For details, see section 53.5. ADC12 Characteristics.

The lower limit of the sampling time setting depends on the frequency ratio:

- If the frequency ratio of PCLKA to PCLKC (ADCLK) = 1:1, 2:1, 4:1, or 8:1 the sampling time must be set to a value of more than 5 states
- If the frequency ratio of PCLKA to PCLKC (ADCLK) = 1:2 or 1:4, the sampling time must be set to a value of more than 6 states.

Table 43.21 shows the relationship between the A/D Sampling State Register and the associated channels. For details, see section 43.3.7. Analog Input Sampling and Scan Conversion Time.

Only set the SST[7:0] bits when the ADCSR.ADST bit is 0.

Table 43.21 Relationship between A/D sampling state register and associated channels (1 of 2)

Bit name	Associated channels
ADSSTRn.SST[7:0] bits (n = 0 to 10, 12, 13(unit 0), 0 to 2(unit 1))*1	AN000 to AN010, AN012, AN013, AN100 to AN102
ADSSTRL.SST[7:0] bits	AN116 to AN128
ADSSTRT.SST[7:0] bits	Temperature sensor output

Table 43.21 Relationship between A/D sampling state register and associated channels (2 of 2)

Bit name	Associated channels
ADSSTRO.SST[7:0] bits	Internal reference voltage

Note 1. When the self-diagnosis function is selected, the sampling time set in the ADSSTR0.SST[7:0] bits is applied.

43.2.19 ADDISCR : A/D Disconnection Detection Control Register

Base address: ADC12m = 0x4017_0000 + 0x0200 × m (m = 0, 1)

Offset address: 0x07A

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	PCHG	ADNDIS[3:0]			
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	ADNDIS[3:0]	Disconnection Detection Assist Setting 0x0: The disconnection detection assist function is disabled 0x1: Setting prohibited Others: The number of states for the discharge or precharge period.	R/W
4	PCHG	Precharge/discharge select 0: Discharge 1: Precharge	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W

The ADDISCR register selects either precharge or discharge, and the period of precharge or discharge for the A/D disconnection detection assist function. Only set the ADDISCR register when the ADCSR.ADST bit is 0. When the temperature sensor output or internal reference voltage is converted, the A/D converter executes discharge automatically.

Disable the disconnection detection assist function if any of the following functions are used:

- The temperature sensor
- The internal reference voltage
- A/D self-diagnosis

ADNDIS[3:0] bits (Disconnection Detection Assist Setting)

The ADNDIS[3:0] bits specify the period of precharge or discharge. When ADNDIS[3:0] = 0000b, the disconnection detection assist function is disabled. Setting the ADNDIS[3:0] bits to 0001b is prohibited. Except when ADNDIS[3:0] = 0000b or 0001b, the specified value indicates the number of states for the period of precharge or discharge. When the ADNDIS[3:0] bits are set to any values other than 0000b or 0001b, the disconnection detection assistance function is enabled.

PCHG bit (Precharge/discharge select)

The PCHG bit selects either precharge or discharge.

43.2.20 ADGSPCR : A/D Group Scan Priority Control Register

Base address: ADC12m = 0x4017_0000 + 0x0200 × m (m = 0, 1)

Offset address: 0x080

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	GBRP	LGRRS	—	—	—	—	—	—	—	—	—	—	—	—	GBRSCN	PGS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PGS	Group Priority Operation Setting*1 0: Operate without group priority control. 1: Operate with group priority control.	R/W
1	GBRSCN	Lower-Priority Group Restart Setting (enabled only when PGS = 1 and reserved when PGS = 0.) 0: Disable rescanning of the group that was stopped in group priority operation 1: Enable rescanning of the group that was stopped in group priority operation.	R/W
13:2	—	These bits are read as 0. The write value should be 0.	R/W
14	LGRRS	Restart Channel Select Enabled only when PGS = 1 and GBRSCN = 1. 0: Start rescanning from the first channel for scanning 1: Start rescanning from the channel for which A/D conversion is not completed.	R/W
15	GBRP	Single Scan Continuous Start*2 (enabled only when PGS = 1 and reserved when PGS = 0.) 0: Single scan is not continuously activated. 1: Single scan for the group with the lower-priority is continuously activated.	R/W

Note 1. The ADCSR.ADCS[1:0] bits must be set to 01b (group scan mode) before setting PGS to 1. Operation is not guaranteed if these bits are set to any other value.

Note 2. When the GBRP bit is set to 1, single scan is performed continuously for the group with the lower-priority regardless of the setting in the GBRSCN bit.

PGS bit (Group Priority Operation Setting)

The PGS bit controls group priority operation in group scan mode. Set the PGS bit to 1 to enable group priority operation.

The ADCSR.ADCS[1:0] bits must be set to 01b (group scan mode) before setting the PGS bit to 1. Operation is not guaranteed if the bits are set to any other value.

When the PGS bit is set to 0, a clear operation must be performed by software as described in section 43.6.3. Constraints on Stopping A/D Conversion. When the PGS bit is set to 1, use the settings described in section 43.3.4.3. Group Priority Operation.

GBRSCN bit (Lower-Priority Group Restart Setting)

The GBRSCN bit controls the restarting of scan operation in group priority operation.

When the GBRSCN bit is set to 1, if the scan operation of a lower-priority group is stopped by a trigger input of a priority group, the lower-priority group scanning is restarted on completion of the priority group scanning. If a trigger of a lower-priority group is input during scanning of the priority group, the lower-priority group scanning is started on completion of the priority group scanning.

When the GBRSCN bit is set to 0, triggers input during scanning are ignored. Set the GBRSCN bit while the ADCSR.ADST bit is 0.

LGRRS bit (Restart Channel Select)

This bit sets the channel from which rescanning is to be started in group priority operation. The setting of the LGRRS bit is valid when the PGS and GBRSCN bits are 1.

If the LGRRS bit is 0, scanning of a lower-priority group that was stopped in group priority operation is restarted from the first channel after scanning of the priority group completes.

If the LGRRS bit is 1, scanning of a lower-priority group that was stopped in group priority operation is restarted (upon completion of scanning of the priority group) from the channel for which A/D conversion is not complete. If A/D conversion of the addition setting channel was not completed the specified number of times when scanning stopped, A/D conversion of the addition setting channel is performed again the specified number of times when scanning restarts.

Set the LGRRS bit while the ADCSR.ADST bit is 0.

GBRP bit (Single Scan Continuous Start)

The GBRP bit is set when a single scan operation is to be performed continuously on the group with the lower-priority.

Setting the GBRP bit to 1 starts a single scan of the group with the lower-priority. On completion of the scan, another single scan of the group with the lower-priority is started automatically. If scanning has been stopped during group priority

operation, single scan of the group with the lower-priority is automatically restarted on completion of the A/D conversion of the priority group.

Before setting the GBRP bit to 1, disable input of a trigger for the lower-priority group. If the GBRP bit is set to 1, rescanning is performed only on the group with the lower-priority even if the GBRSCN bit is set to 0.

43.2.21 ADCMPCR : A/D Compare Function Control Register

Base address: ADC12m = 0x4017_0000 + 0x0200 × m (m = 0, 1)

Offset address: 0x090

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CMPAIE	WCMPE	CMPBIE	—	CMPAE	—	CMPBE	—	—	—	—	—	—	—	CMPAB[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	CMPAB[1:0]	Window A/B Composite Conditions Setting These bits are valid when both window A and window B are enabled (CMPAE = 1 and CMPBE = 1). 0 0: Output ADC12i_WCMPM (i = 0, 1) when window A OR window B comparison conditions are met. Otherwise, output ADC12i_WCMPUM (i = 0, 1). 0 1: Output ADC12i_WCMPM (i = 0, 1) when window A EXOR window B comparison conditions are met. Otherwise, output ADC12i_WCMPUM (i = 0, 1). 1 0: Output ADC12i_WCMPM (i = 0, 1) when window A AND window B comparison conditions are met. Otherwise, output ADC12i_WCMPUM (i = 0, 1). 1 1: Setting prohibited.	R/W
8:2	—	These bits are read as 0. The write value should be 0.	R/W
9	CMPBE	Compare Window B Operation Enable 0: Disable compare window B operation. Disable ADC12i_WCMPM (i = 0, 1) and ADC12i_WCMPUM (i = 0, 1) outputs. 1: Enable compare window B operation.	R/W
10	—	This bit is read as 0. The write value should be 0.	R/W
11	CMPAE	Compare Window A Operation Enable 0: Disable compare window A operation. Disable ADC12i_WCMPM (i = 0, 1) and ADC12i_WCMPUM (i = 0, 1) outputs. 1: Enable compare window A operation.	R/W
12	—	This bit is read as 0. The write value should be 0.	R/W
13	CMPBIE	Compare B Interrupt Enable 0: Disable ADC12i_CMPBI (i = 0, 1) interrupt when comparison conditions (window B) are met. 1: Enable ADC12i_CMPBI (i = 0, 1) interrupt when comparison conditions (window B) are met.	R/W
14	WCMPE	Window Function Setting 0: Disable window function Window A and window B operate as a comparator to compare the single value on the lower side with the A/D conversion result. 1: Enable window function Window A and window B operate as a comparator to compare the two values on the upper and lower sides with the A/D conversion result.	R/W
15	CMPAIE	Compare A Interrupt Enable 0: Disable ADC12i_CMPAI (i = 0, 1) interrupt when comparison conditions (window A) are met. 1: Enable ADC12i_CMPAI (i = 0, 1) interrupt when comparison conditions (window A) are met.	R/W

CMPAB[1:0] bits (Window A/B Composite Conditions Setting)

The CMPAB[1:0] bits are valid when both window A and window B are enabled (CMPAE = 1 and CMPBE = 1) in single scan mode. These bits specify the compare function match/mismatch event output conditions and monitoring conditions of ADWINMON.MONCOMB. Only set the CMPAB[1:0] bits while the ADCSR.ADST bit is 0.

CMPBE bit (Compare Window B Operation Enable)

The CMPBE bit enables or disables the compare window B operation. Set the CMPBE bit while the ADCSR.ADST bit is 0.

Set this bit to 0 before setting the following registers:

- A/D Channel Select Registers A0, A1, B0, B1 (ADANSA0, ADANSA1, ADANSB0, ADANSB1)
- OCSB, TSSB, OCSA, or TSSA bits in the A/D Conversion Extended Input Control Register (ADEXICR)
- CMPCHB[5:0] bits in the Window B Channel Select Register (ADCMPBNSR)

CMPAE bit (Compare Window A Operation Enable)

The CMPAE bit enables or disables the compare window A operation. Set the CMPAE bit while the ADCSR.ADST bit is 0.

Set this bit to 0 before setting the following registers:

- A/D Channel Select Registers A0, A1, B0, B1 (ADANSA0, ADANSA1, ADANSB0, ADANSB1)
- OCSB, TSSB, OCSA, or TSSA bits in the A/D Conversion Extended Input Control Register (ADEXICR)
- Window A Channel Select Registers 0 and 1 (ADCMPANSR0 and ADCMPANSR1)
- Window A Extended Input Select Register (ADCMPANSER)

CMPBIE bit (Compare B Interrupt Enable)

The CMPBIE bit enables or disables the ADC12i_CMPBI (i = 0, 1) interrupt output when the comparison conditions (window B) are met.

WCMPE bit (Window Function Setting)

The WCMPE bit enables or disables the window function. Set the WCMPE bit while the ADCSR.ADST bit is 0.

CMPAIE bit (Compare A Interrupt Enable)

The CMPAIE bit enables or disables the ADC12i_CMPAI (i = 0, 1) interrupt output when the comparison conditions (window A) are met.

43.2.22 ADCMPANSR0 : A/D Compare Function Window A Channel Select Register 0

Base address: ADC12m = 0x4017_0000 + 0x0200 × m (m = 0, 1)

Offset address: 0x094

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	CMPCHA13	CMPCHA12	—	CMPCHA10	CMPCHA9	CMPCHA8	CMPCHA7	CMPCHA6	CMPCHA5	CMPCHA4	CMPCHA3	CMPCHA2	CMPCHA1	CMPCHA0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
10:0	CMPCHA10 to CMPCHA0	Compare Window A Channel Select Bit 10 (CMPCHA10) is associated with ANm10 and bit 0 (CMPCHA0) is associated with ANm00. 0: Disable compare function for associated input channel 1: Enable compare function for associated input channel	R/W
11	—	This bit is read as 0. The write value should be 0.	R/W
13:12	CMPCHA13 to CMPCHA12	Compare Window A Channel Select Bit 13 (CMPCHA13) is associated with ANm13 and bit 12 (CMPCHA12) is associated with ANm12. 0: Disable compare function for associated input channel 1: Enable compare function for associated input channel	R/W
15:14	—	These bits are read as 0. The write value should be 0.	R/W

Note: CMPCHAn (n = 3 to 10, 12, 13) are only for unit 0.

CMPCHAn bits (Compare Window A Channel Select)

The compare function is enabled by writing 1 to the CMPCHAn bits with the same number as the A/D conversion channel selected in the ADANSA0.ANSAn bits and the ADANSB0.ANSBn bits.

Set the CMPCHAn bits while the ADCSR.ADST bit is 0.

43.2.23 ADCMPANSR1 : A/D Compare Function Window A Channel Select Register 1

Base address: ADC12m = 0x4017_0000 + 0x0200 × m (m = 0, 1)

Offset address: 0x096

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	CMPCHA28	CMPCHA27	CMPCHA26	CMPCHA25	CMPCHA24	CMPCHA23	CMPCHA22	CMPCHA21	CMPCHA20	CMPCHA19	CMPCHA18	CMPCHA17	CMPCHA16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
12:0	CMPCHA28 to CMPCHA16	Compare Window A Channel Select Bit 12 (CMPCHA28) is associated with ANm28 and bit 0 (CMPCHA16) is associated with ANm16. 0: Disable compare function for associated input channel 1: Enable compare function for associated input channel	R/W
15:13	—	These bits are read as 0. The write value should be 0.	R/W

Note: CMPCHAn (n = 16 to 28) are only for unit 1.

CMPCHAn bits (Compare Window A Channel Select)

The compare function is enabled by writing 1 to the CMPCHAn bits with the same number as the A/D conversion channel selected in the ADANSA1.ANSA bits and the ADANSB1.ANSB bits.

Set the CMPCHAn bits while the ADCSR.ADST bit is 0.

43.2.24 ADCMPANSER : A/D Compare Function Window A Extended Input Select Register

Base address: ADC12m = 0x4017_0000 + 0x0200 × m (m = 0, 1)

Offset address: 0x092

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	CMPOCA	CMPTSA
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CMPTSA	Temperature Sensor Output Compare Select 0: Exclude the temperature sensor output from the compare Window A target range. 1: Include the temperature sensor output in the compare Window A target range.	R/W
1	CMPOCA	Internal Reference Voltage Compare Select 0: Exclude the internal reference voltage from the compare Window A target range. 1: Include the internal reference voltage in the compare Window A target range.	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W

CMPTSA bit (Temperature Sensor Output Compare Select)

The compare Window A function is enabled by setting the CMPTSA bit to 1 while the ADEXICR.TSSA bit or the ADEXICR.TSSB bit is 1. Set the CMPTSA bit while the ADCSR.ADST bit is 0.

CMPOCA bit (Internal Reference Voltage Compare Select)

The compare window A function is enabled by setting the CMPOCA bit to 1 when the ADEXICR.OCSA and ADEXICR.OCSB bit is 1. Set the CMPOCA bit when the ADCSR.ADST bit is 0.

43.2.25 ADCMPLR0 : A/D Compare Function Window A Comparison Condition Setting Register 0

Base address: ADC12m = 0x4017_0000 + 0x0200 × m (m = 0, 1)

Offset address: 0x098

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	CMPLCHA13	CMPLCHA12	—	CMPLCHA10	CMPLCHA9	CMPLCHA8	CMPLCHA7	CMPLCHA6	CMPLCHA5	CMPLCHA4	CMPLCHA3	CMPLCHA2	CMPLCHA1	CMPLCHA0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
10:0	CMPLCHA10 to CMPLCHA0	Compare Window A Comparison Condition Select These bits set comparison conditions for channels to which Window A comparison conditions are applied. Bit 10 (CMPLCHA10) is associated with ANm10 and bit 0 (CMPLCHA0) is associated with ANm00. Comparison conditions are shown in Figure 43.4. 0: When window function is disabled (ADCMPCR.WCMPE = 0): ADCMPDR0 value > A/D-converted value When window function is enabled (ADCMPCR.WCMPE = 1): A/D-converted value < ADCMPDR0 value, or ADCMPDR1 value < A/D-converted value 1: When window function is disabled (ADCMPCR.WCMPE = 0): ADCMPDR0 value < A/D-converted value When window function is enabled (ADCMPCR.WCMPE = 1): ADCMPDR0 value < A/D-converted value < ADCMPDR1 value	R/W
11	—	This bit is read as 0. The write value should be 0.	R/W
13:12	CMPLCHA13 to CMPLCHA12	Compare Window A Comparison Condition Select These bits set comparison conditions for channels to which Window A comparison conditions are applied. Bit 13 (CMPLCHA13) is associated with ANm13 and bit 12 (CMPLCHA12) is associated with ANm12. Comparison conditions are shown in Figure 43.4. 0: When window function is disabled (ADCMPCR.WCMPE = 0): ADCMPDR0 value > A/D-converted value When window function is enabled (ADCMPCR.WCMPE = 1): A/D-converted value < ADCMPDR0 value, or ADCMPDR1 value < A/D-converted value 1: When window function is disabled (ADCMPCR.WCMPE = 0): ADCMPDR0 value < A/D-converted value When window function is enabled (ADCMPCR.WCMPE = 1): ADCMPDR0 value < A/D-converted value < ADCMPDR1 value	R/W
15:14	—	These bits are read as 0. The write value should be 0.	R/W

Note: CMPLCHAn (n = 3 to 10, 12, 13) are only for unit 0.

CMPLCHAn bits (Compare Window A Comparison Condition Select)

The CMPLCHAn bits specify the comparison conditions for channels to which Window A comparison conditions are applied. These bits can be set for each analog input to be compared. When the comparison result of each analog input meets the set condition, the ADCMPSR0.CMPSTCHAn flag sets to 1 and a compare interrupt (ADC12i_CMPAI (i = 0, 1)) is generated.

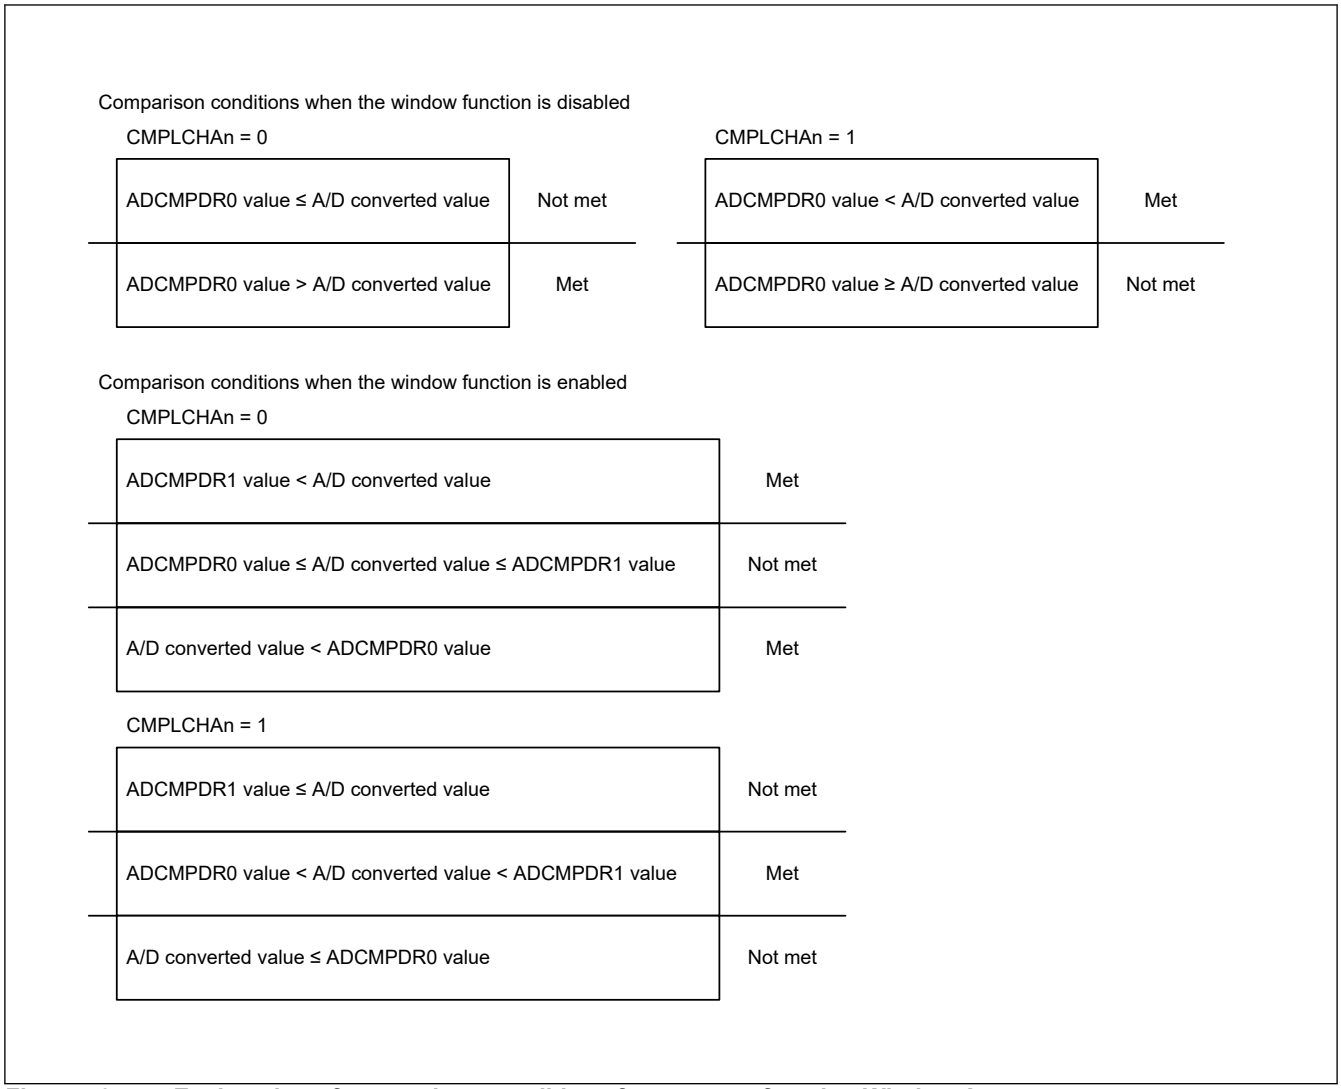


Figure 43.4 Explanation of comparison conditions for compare function Window A

43.2.26 ADCMPLR1 : A/D Compare Function Window A Comparison Condition Setting Register 1

Base address: ADC12m = 0x4017_0000 + 0x0200 × m (m = 0, 1)

Offset address: 0x09A

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	CMPLCHA28	CMPLCHA27	CMPLCHA26	CMPLCHA25	CMPLCHA24	CMPLCHA23	CMPLCHA22	CMPLCHA21	CMPLCHA20	CMPLCHA19	CMPLCHA18	CMPLCHA17	CMPLCHA16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
12:0	CMPLCHA28 to CMPLCHA16	Compare Window A Comparison Condition Select These bits set comparison conditions for channels to which Window A comparison conditions are applied. Bit 12 (CMPLCHA28) is associated with ANm28 and bit 0 (CMPLCHA16) is associated with ANm16. Comparison conditions are shown in Figure 43.4. 0: When window function is disabled (ADCMPCR.WCMPE = 0): ADCMPDR0 value > A/D-converted value When window function is enabled (ADCMPCR.WCMPE = 1): A/D-converted value < ADCMPDR0 value, or ADCMPDR1 value < A/D-converted value 1: When window function is disabled (ADCMPCR.WCMPE = 0): ADCMPDR0 value < A/D-converted value When window function is enabled (ADCMPCR.WCMPE = 1): ADCMPDR0 value < A/D-converted value < ADCMPDR1 value	R/W
15:13	—	These bits are read as 0. The write value should be 0.	R/W

Note: CMPLCHAn (n = 16 to 28) are only for unit 1.

CMPLCHAn bits (Compare Window A Comparison Condition Select)

The CMPLCHAn bits specify the comparison conditions for analog channels to which window A comparison conditions are applied. These bits can be set for each analog input to be compared. When the comparison result of each analog input meets the set condition, the ADCMPSR1.CMPSTCHAn bit is set to 1 and a compare interrupt (ADC12i_CMPAI (i = 0, 1)) is generated.

43.2.27 ADCMPLER : A/D Compare Function Window A Extended Input Comparison Condition Setting Register

Base address: ADC12m = 0x4017_0000 + 0x0200 × m (m = 0, 1)

Offset address: 0x093

1	CMPLOCA	Compare Window A Internal Reference Voltage Comparison Condition Select Comparison conditions are shown in Figure 43.4. 0: When window function is disabled (ADCMPCR.WCMPE = 0) : ADCMPDR0 value > A/D-converted value When window function is enabled (ADCMPCR.WCMPE = 1): A/D-converted value < ADCMPDR0 value, or A/D-converted value > ADCMPDR1 value 1: When window function is disabled (ADCMPCR.WCMPE = 0): ADCMPDR0 value < A/D-converted value When window function is enabled (ADCMPCR.WCMPE = 1): ADCMPDR0 value < A/D-converted value < ADCMPDR1 value	R/W

Bit	Symbol	Function	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W

CMPLTSA bit (Compare Window A Temperature Sensor Output Comparison Condition Select)

The CMPLTSA bit specifies comparison conditions when the temperature sensor output is the target for the Window A comparison condition. When the temperature sensor output comparison result meets the set condition, the ADCMPSER.CMPSTTSA flag sets to 1 and a compare interrupt (ADC12i_CMPAI (i = 0, 1)) is generated.

CMPLOCA bit (Compare Window A Internal Reference Voltage Comparison Condition Select)

The CMPLOCA bit specifies comparison conditions when the internal reference voltage is the target for the Window A comparison condition. When the internal reference voltage comparison result meets the set condition, the ADCMPSER.CMPSTOCA flag sets to 1 and a compare interrupt (ADC12i_CMPAI (i = 0, 1)) is generated.

43.2.28 ADCMPDRn : A/D Compare Function Window A Lower-Side/Upper-Side Level Setting Register (n = 0, 1)

Base address: ADC12m = 0x4017_0000 + 0x0200 × m (m = 0, 1)

Offset address: 0x09C + (0x2 × n)

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:																
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The ADCMPDRy (y = 0, 1) register specifies the reference data when the compare window A function is used. ADCMPDR0 sets the lower reference for window A, and ADCMPDR1 sets the upper reference for window A.

ADCMPDRy are read/write registers.

ADCMPDRy are writable even during A/D conversion. The reference data can be dynamically changed by rewriting register values during A/D conversion*1.

Set these registers so that the upper reference is not less than the lower reference (ADCMPDR1 ≥ ADCMPDR0). ADCMPDR1 are not used when the window function is disabled.

Note 1. The lower and the upper references are changed when each register is written. For example, when the upper reference value is changed and the lower reference value is being changed, the MCU compares the upper reference (after rewrite), and the lower reference (before rewrite) with the A/D conversion result. See Figure 43.5. If the comparison during the rewriting of these two references is erroneous, then rewrite these reference values when both ADCSR.ADST and the target Compare Window Operation Enable bit (ADCMPCR.CMPAE or ADCMPCR.CMPBE) are 0.

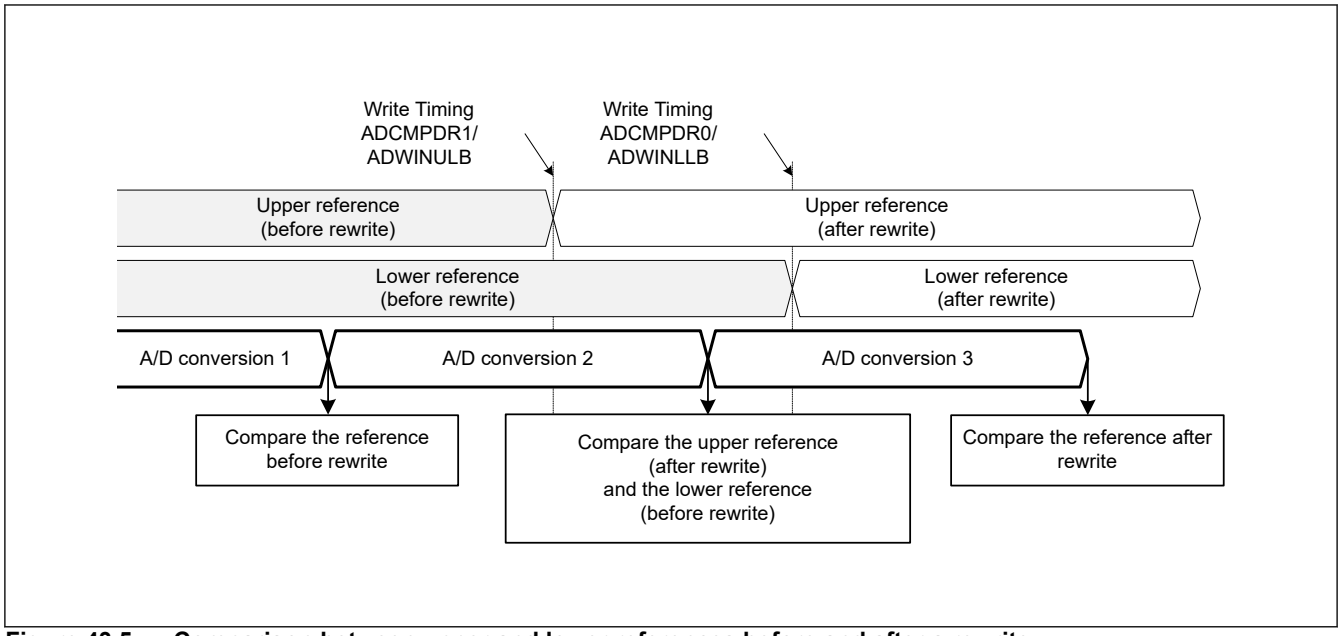

Figure 43.5 Comparison between upper and lower references before and after a rewrite

The ADCMPDRy registers use different formats depending on the following conditions:

- The value of A/D Data Register Format Select bit (flush-right or flush-left)
- The value of the A/D Conversion Accuracy Select bit (12-bit, 10-bit, 8-bit)
- The value of A/D-Converted Value Addition/Average Channel Select bits (A/D-converted value addition mode selected or not selected).

The data formats for each condition are shown as follows:

1. When A/D-converted value addition mode is not selected
   - Flush-right data with 12-bit accuracy — Lower 12 bits ([11:0]) are valid
   - Flush-right data with 10-bit accuracy — Lower 10 bits ([9:0]) are valid
   - Flush-right data with 8-bit accuracy — Lower 8 bits ([7:0]) are valid
   - Flush-left data with 12-bit accuracy — Upper 12 bits ([15:4]) are valid
   - Flush-left data with 10-bit accuracy — Upper 10 bits ([15:6]) are valid
   - Flush-left data with 8-bit accuracy — Upper 8 bits ([15:8]) are valid
2. When A/D-converted value addition mode is selected
   - Flush-right data with 12-bit accuracy — Lower 14 bits ([13:0]) are valid
   - Flush-right data with 10-bit accuracy — Lower 12 bits ([11:0]) are valid
   - Flush-right data with 8-bit accuracy — Lower 10 bits ([9:0]) are valid
   - Flush-left data with 12-bit accuracy — Upper 14 bits ([15:2]) are valid
   - Flush-left data with 10-bit accuracy — Upper 12 bits ([15:4]) are valid
   - Flush-left data with 8-bit accuracy — Upper 10 bits ([15:6]) are valid

43.2.29 ADWINnLB : A/D Compare Function Window B Lower-Side/Upper-Side Level Setting Register (n = L, U)

Base address: ADC12m = 0x4017_0000 + 0x0200 × m (m = 0, 1)

Offset address: 0x0A8 (n = L)
0x0AA (n = U)

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:																
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The ADWINULB and ADWINLLB registers specify the reference data when the compare window B function is used. ADWINLLB sets the lower reference for window B, and ADWINULB sets the upper reference for window B.

ADWINnLB are read/write registers.

ADWINnLB are writable even during A/D conversion. The reference data can be dynamically changed by rewriting register values during A/D conversion*1.

Set these registers so that the upper reference is not less than the lower reference (ADWINULB ≥ ADWINLLB). ADWINULB are not used when the window function is disabled.

Note 1. The lower and the upper references are changed when each register is written. For example, when the upper reference value is changed and the lower reference value is being changed, the MCU compares the upper reference (after rewrite), and the lower reference (before rewrite) with the A/D conversion result. See Figure 43.6. If the comparison during the rewriting of these two references is erroneous, then rewrite these reference values when both ADCSR.ADST and the target Compare Window Operation Enable bit (ADCMPCR.CMPAE or ADCMPCR.CMPBE) are 0.

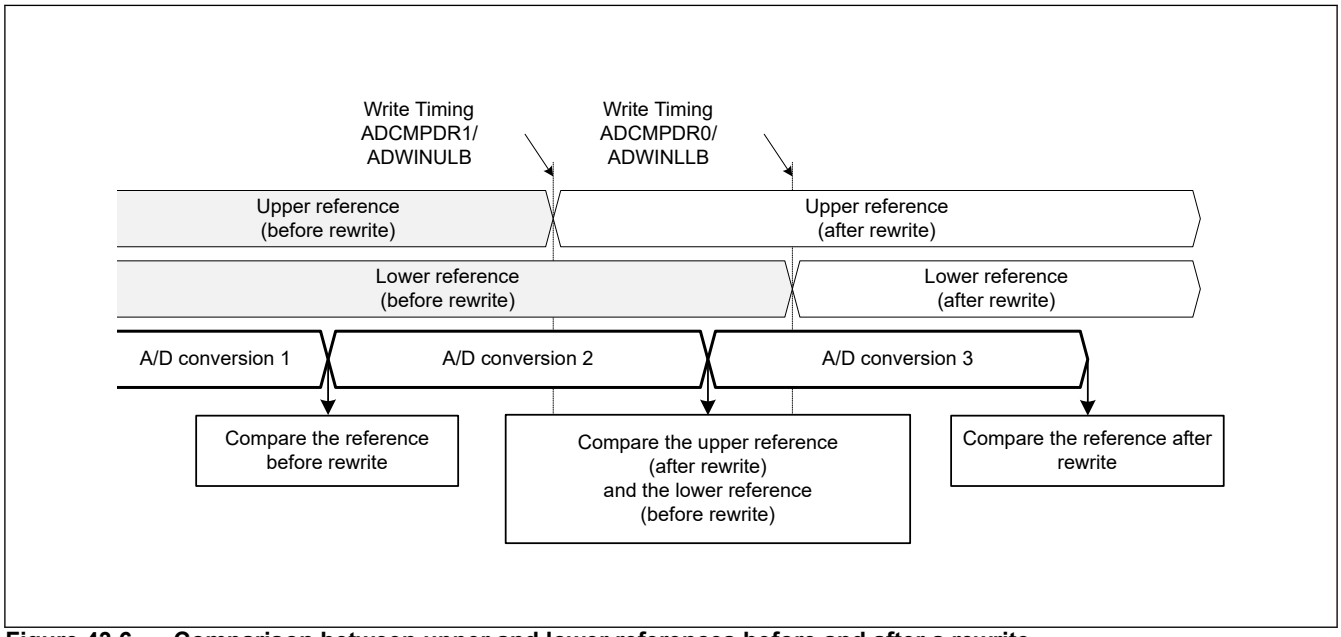

Figure 43.6 Comparison between upper and lower references before and after a rewrite

The ADWINnLB registers use different formats depending on the following conditions:

- The value of A/D Data Register Format Select bit (flush-right or flush-left)
- The value of the A/D Conversion Accuracy Select bit (12-bit, 10-bit, 8-bit)
- The value of A/D-Converted Value Addition/Average Channel Select bits (A/D-converted value addition mode selected or not selected).

The data formats for each condition are shown as follows:

1. When A/D-converted value addition mode is not selected

- Flush-right data with 12-bit accuracy — Lower 12 bits ([11:0]) are valid
- Flush-right data with 10-bit accuracy — Lower 10 bits ([9:0]) are valid
- Flush-right data with 8-bit accuracy — Lower 8 bits ([7:0]) are valid
- Flush-left data with 12-bit accuracy — Upper 12 bits ([15:4]) are valid
- Flush-left data with 10-bit accuracy — Upper 10 bits ([15:6]) are valid
- Flush-left data with 8-bit accuracy — Upper 8 bits ([15:8]) are valid

2. When A/D-converted value addition mode is selected
   - Flush-right data with 12-bit accuracy — Lower 14 bits ([13:0]) are valid
   - Flush-right data with 10-bit accuracy — Lower 12 bits ([11:0]) are valid
   - Flush-right data with 8-bit accuracy — Lower 10 bits ([9:0]) are valid
   - Flush-left data with 12-bit accuracy — Upper 14 bits ([15:2]) are valid
   - Flush-left data with 10-bit accuracy — Upper 12 bits ([15:4]) are valid
   - Flush-left data with 8-bit accuracy — Upper 10 bits ([15:6]) are valid

43.2.30 ADCMPSR0 : A/D Compare Function Window A Channel Status Register 0

Base address: ADC12m = 0x4017_0000 + 0x0200 × m (m = 0, 1)

Offset address: 0x0A0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	CMPSTCHA13	CMPSTCHA12	—	CMPSTCHA10	CMPSTCHA9	CMPSTCHA8	CMPSTCHA7	CMPSTCHA6	CMPSTCHA5	CMPSTCHA4	CMPSTCHA3	CMPSTCHA2	CMPSTCHA1	CMPSTCHA0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
10:0	CMPSTCHA10 to CMPSTCHA0	Compare Window A Flag When Window A operation is enabled (ADCMPCR.CMPAE = 1b), these bits indicate the comparison result of channels to which Window A comparison conditions are applied. Bit 10 (CMPSTCHA10) is associated with ANm10 and bit 0 (CMPSTCHA0) is associated with ANm00. 0: Comparison conditions are not met. 1: Comparison conditions are met.	R/W
11	—	This bit is read as 0. The write value should be 0.	R/W
13:12	CMPSTCHA13 to CMPSTCHA12	Compare Window A Flag When Window A operation is enabled (ADCMPCR.CMPAE = 1b), these bits indicate the comparison result of channels to which Window A comparison conditions are applied. Bit 13 (CMPSTCHA13) is associated with ANm13 and bit 12 (CMPSTCHA12) is associated with ANm12. 0: Comparison conditions are not met. 1: Comparison conditions are met.	R/W
15:14	—	These bits are read as 0. The write value should be 0.	R/W

Note: CMPSTCHAn (n = 3 to 10, 12, 13) are only for unit 0.

CMPSTCHAn flags (Compare Window A Flag)

The CMPSTCHAn flags indicate the comparison results for channels to which Window A comparison conditions are applied. When a comparison condition set in ADCMPLR0.CMPLCHA is met at the end of A/D conversion, the associated CMPSTCHAn flag sets to 1. When the ADCMPCR.CMPAIE bit is 1, a compare interrupt request (ADC12i_CMPAI (i = 0, 1)) is generated when this flag sets to 1.

Writing 1 to the CMPSTCHAn flags is invalid.

[Setting condition]

- The condition set in ADCMPLR0.CMPLCHA is met when ADCMPCR.CMPAE = 1.

[Clearing condition]

- Writing 0 after reading 1.

43.2.31 ADCMPSR1 : A/D Compare Function Window A Channel Status Register1

Base address: ADC12m = 0x4017_0000 + 0x0200 × m (m = 0, 1)

Offset address: 0x0A2

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	CMPSTCHA28	CMPSTCHA27	CMPSTCHA26	CMPSTCHA25	CMPSTCHA24	CMPSTCHA23	CMPSTCHA22	CMPSTCHA21	CMPSTCHA20	CMPSTCHA19	CMPSTCHA18	CMPSTCHA17	CMPSTCHA16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
12:0	CMPSTCHA28 to CMPSTCHA16	Compare Window A Flag When Window A operation is enabled (ADCMPCR.CMPAE = 1), these bits indicate the comparison result of channels to which Window A comparison conditions are applied. Bit 12 (CMPSTCHA28) is associated with ANm28 and bit 0 (CMPSTCHA16) is associated with ANm16. 0: Comparison conditions are not met. 1: Comparison conditions are met.	R/W
15:13	—	These bits are read as 0. The write value should be 0.	R/W

Note: CMPSTCHAn (n = 16 to 28) are only for unit 1.

CMPSTCHAn flags (Compare Window A Flag)

The CMPSTCHAn flags indicate the comparison results for channels to which Window A comparison conditions are applied. When the comparison condition set in ADCMPLR1.CMPLCHA is met at the end of A/D conversion, the associated CMPSTCHAn flag sets to 1. When the ADCMPCR.CMPAIE bit is 1, a compare interrupt request (ADC12i_CMPAI (i = 0, 1)) is generated when this flag sets to 1.

Writing 1 to the CMPSTCHAn flags is invalid.

[Setting condition]

- The condition set in ADCMPLR1.CMPLCHA is met when ADCMPCR.CMPAE = 1.

[Clearing condition]

- Writing 0 after reading 1.

43.2.32 ADCMPSER : A/D Compare Function Window A Extended Input Channel Status Register

Base address: ADC12m = 0x4017_0000 + 0x0200 × m (m = 0, 1)

Offset address: 0x0A4

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	CMPSTOCA	CMPSTTSA
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CMPSTTSA	Compare Window A Temperature Sensor Output Compare Flag When Window A operation is enabled (ADCMPCR.CMPAE = 1), this bit indicates the temperature sensor output comparison result. 0: Comparison conditions are not met. 1: Comparison conditions are met.	R/W

Bit	Symbol	Function	R/W
1	CMPSTOCA	Compare Window A Internal Reference Voltage Compare Flag When Window A operation is enabled (ADCMPCR.CMPAE = 1), this bit indicates the internal reference voltage comparison result. 0: Comparison conditions are not met. 1: Comparison conditions are met.	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W

The ADCMPSER register stores compare results of compare function window A.

CMPSTTSA flag (Compare Window A Temperature Sensor Output Compare Flag)

The CMPSTTSA flag indicates the temperature sensor output comparison result. When the comparison condition set in ADCMPLER.CMPLTSA is met at the end of A/D conversion, this flag sets to 1. When the ADCMPCR.CMPAIE bit is 1, a compare interrupt request (ADC12i_CMPAI (i = 0, 1)) is generated when this flag sets to 1.

Writing 1 to the CMPSTTSA flag is invalid.

[Setting condition]

- The condition set in ADCMPLER.CMPLTSA is met when ADCMPCR.CMPAE = 1.

[Clearing condition]

- Writing 0 after reading 1.

CMPSTOCA flag (Compare Window A Internal Reference Voltage Compare Flag)

The CMPSTOCA flag indicates the internal reference voltage comparison result. When the comparison condition set in ADCMPLER.CMPLOCA is met at the end of A/D conversion, this flag sets to 1. When the ADCMPCR.CMPAIE bit is 1, a compare interrupt request (ADC12i_CMPAI (i = 0, 1)) is generated when this flag sets to 1.

Writing 1 to the CMPSTOCA flag is invalid.

[Setting condition]

- The condition set in ADCMPLER.CMPLOCA is met when ADCMPCR.CMPAE = 1.

[Clearing condition]

- Writing 0 after reading 1.

43.2.33 ADCMPBNSR : A/D Compare Function Window B Channel Select Register

Base address: ADC12m = 0x4017_0000 + 0x0200 × m (m = 0, 1)

Offset address: 0x0A6

</table>

CMPCHB[5:0] bits (Compare Window B Channel Select)

The CMPCHB[5:0] bits specify the channels to be compared with the compare Window B conditions from AN000 to AN010, AN012, AN013, AN100 to AN102, AN116 to AN128, the temperature sensor, the internal reference voltage. The compare Window B function is enabled by specifying the hexadecimal number of the A/D conversion channel selected in the ADANSA0, ADANSA1, ADANSB0, ADANSB1 registers.

Set the CMPCHB[5:0] bits while the ADCSR.ADST bit is 0.

CMPLB bit (Compare Window B Comparison Condition Setting)

The CMPLB bit specifies the comparison conditions for channels for Window B. When the comparison result of an analog input meets the set condition, the associated ADCMPBSR.CMPSTB flag sets to 1 and a compare interrupt request (ADC12i_CMPBI (i = 0, 1)) is generated.

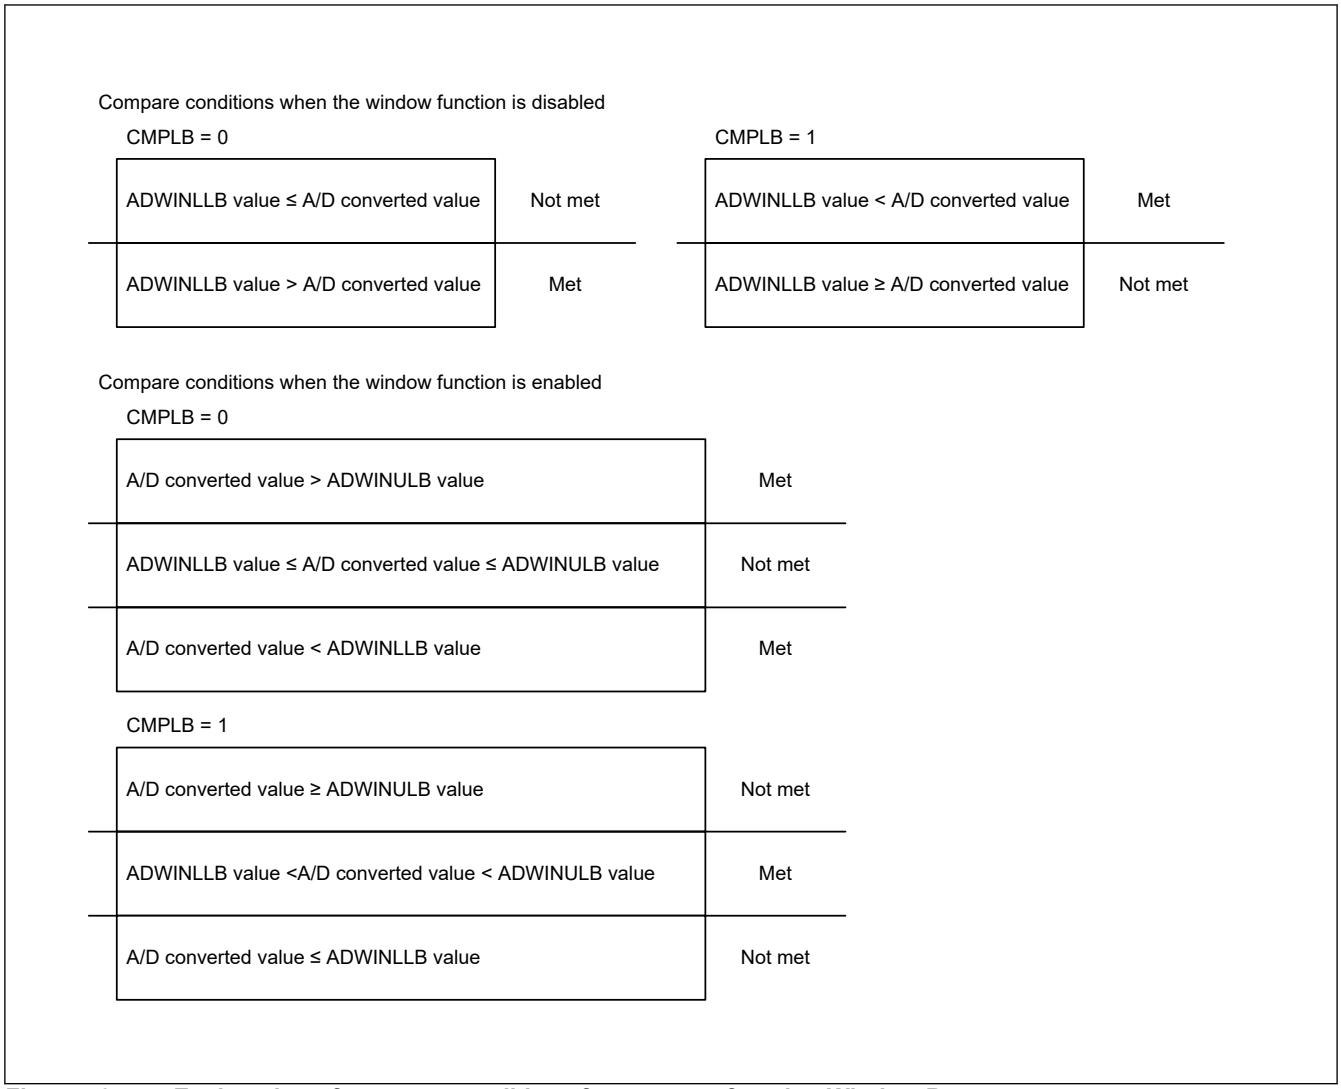

Figure 43.7 Explanation of compare conditions for compare function Window B

43.2.34 ADCMPBSR : A/D Compare Function Window B Status Register

Base address: ADC12m = 0x4017_0000 + 0x0200 × m (m = 0, 1)

Offset address: 0x0AC

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	CMPSTB
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CMPSTB	Compare Window B Flag When Window B operation is enabled (ADCMPCR.CMPBE = 1), this bit indicates the comparison result of channels to which Window B comparison conditions are applied,temperature sensor output, internal reference voltage. 0: Comparison conditions are not met. 1: Comparison conditions are met.	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W

CMPSTB flag (Compare Window B Flag)

The CMPSTB flag indicates the comparison result of channels to which Window B comparison conditions are applied, the temperature sensor output, internal reference voltage. When the comparison condition set in ADCMPBNSR.CMPLB is met

at the end of A/D conversion, this flag sets to 1. When the ADCMPCR.CMPBIE bit is 1, a compare interrupt request (ADC12i_CMPBI (i = 0, 1)) is generated when this flag sets to 1.

Writing 1 to the CMPSTB flag is invalid.

[Setting condition]

- The condition set in ADCMPBNSR.CMPLB is met when ADCMPCR.CMPBE = 1.

[Clearing condition]

- Writing 0 after reading 1.

43.2.35 ADWINMON : A/D Compare Function Window A/B Status Monitor Register

Base address: ADC12m = 0x4017_0000 + 0x0200 × m (m = 0, 1)

Offset address: 0x08C

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	MONCMPB	MONCMPA	—	—	—	MONCOMB
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MONCOMB	Combination Result Monitor This bit indicates the combination result. This bit is valid when both Window A and Window B operations are enabled. 0: Window A/B composite conditions are not met. 1: Window A/B composite conditions are met.	R
3:1	—	These bits are read as 0.	R
4	MONCMPA	Comparison Result Monitor A 0: Window A comparison conditions are not met. 1: Window A comparison conditions are met.	R
5	MONCMPB	Comparison Result Monitor B 0: Window B comparison conditions are not met. 1: Window B comparison conditions are met.	R
7:6	—	These bits are read as 0.	R

MONCOMB bit (Combination Result Monitor)

The read-only MONCOMB bit indicates the combined result of comparison condition results A and B based on the combination condition set in the ADCMPCR.CMPAB[1:0] bits.

[Setting condition]

- The combined result meets the combination condition set in the ADCMPCR.CMPAB[1:0] bits when ADCMPCR.CMPAE = 1 and ADCMPCR.CMPBE = 1.

[Clearing conditions]

- The combined result does not meet the combination condition set in the ADCMPCR.CMPAB[1:0] bits.
- ADCMPCR.CMPAE = 0 or ADCMPCR.CMPBE = 0.

MONCMPA bit (Comparison Result Monitor A)

The read-only MONCMPA bit is read as 1 when the A/D-converted value of the Window A target channel meets the condition set in ADCMPLR0/ADCMPLR1 and ADCMPLER. Otherwise, it is read as 0.

[Setting condition]

- The A/D-converted value meets the condition set in the ADCMPLR0/ADCMPLR1 and ADCMPLER registers when ADCMPCR.CMPAE = 1.

[Clearing conditions]

- The A/D-converted value does not meet the condition set in the ADCMPLR0/ADCMPLR1 and ADCMPLER registers when ADCMPCR.CMPAE = 1.
- ADCMPCR.CMPAE = 0 (automatically cleared when the ADCMPCR.CMPAE value changes from 1 to 0).

MONCMPB bit (Comparison Result Monitor B)

The read-only MONCMPB bit is read as 1 when the A/D-converted value of the Window B target channel meets the condition set in the ADCMPBNSR.CMPLB bit. Otherwise, it is read as 0.

[Setting condition]

- The A/D-converted value meets the condition set in ADCMPBNSR.CMPLB when ADCMPCR.CMPBE = 1.

[Clearing conditions]

- The A/D-converted value does not meet the condition set in ADCMPBNSR.CMPLB when ADCMPCR.CMPBE = 1.
- ADCMPCR.CMPBE = 0 (automatically cleared when the ADCMPCR.CMPBE value changes from 1 to 0).

43.2.36 ADBUFEN : A/D Data Buffer Enable Register

Base address: ADC12m = 0x4017_0000 + 0x0200 × m (m = 0, 1)

Offset address: 0x0D0

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	BUFEN
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	BUFEN	Data Buffer Enable 0: The data buffer is not used. 1: The data buffer is used.	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W

The ADBUFEN register sets whether to enable the data buffer.

BUFEN bit (Data Buffer Enable)

This bit enables the use of the data buffer.

When BUFEN = 1b, A/D conversion result (addition result) other than self-diagnosis result is stored in ADBUFn.

Disable the data storage operation (BUFEN = 0b) before reading ADBUFPTR.

Do not use the data buffer for data duplexing, or group scan.

43.2.37 ADBUFPTR : A/D Data Buffer Pointer Register

Base address: ADC12m = 0x4017_0000 + 0x0200 × m (m = 0, 1)

Offset address: 0x0D2

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	PTROVF	BUFPTR[3:0]			
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	BUFPTR[3:0]	Data Buffer Pointer These bits indicate the number of data buffer to which the next A/D converted data is transferred.	R/W

Bit	Symbol	Function	R/W
4	PTROVF	Pointer Overflow Flag 0: The data buffer pointer has not overflowed. 1: The data buffer pointer has overflowed.	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W

ADBUFPTR is a register that indicates the data buffer pointer and overflow status.

BUFPTR[3:0] bit (Data Buffer Pointer)

These bits indicate the number of data buffer to which the next A/D converted data is transferred.

When data has been transferred to data buffer 15, the pointer value becomes 0000b and the PTROVF bit is set to 1.

When the next data has been transferred, the data in data buffer 0 is overwritten.

Writing 0x00 to this register clears the value of these bits. Writing a value other than 0x00 is disabled.

PTROVF bit (Pointer Overflow Flag)

This bit indicates whether the data buffer pointer has overflowed. This bit is set to 1 when the pointer value becomes 0000b (overflow).

Writing 0x00 to this register clears this bit value. Writing a value other than 0x00 is disabled.

43.2.38 ADBUFn : A/D Data Buffer Registers n (n = 0 to 15)

Base address: ADC12m = 0x4017_0000 + 0x0200 × m (m = 0, 1)

Offset address: 0x0B0 + 0x2 × n (n = 0 to 15))

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ADBUF[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	ADBUF[15:0]	Converted Value 15 to 0 Functions vary depending on the selected mode and accuracy. See Table 43.22 and Table 43.23.	R

ADBUFn registers are 16-bit read-only registers that sequentially store all A/D conversion results. The automatic clear function is not applied to these registers.

ADBUFn settings are the same as the A/D data register format settings.

The following conditions determine the formats for data in the ADBUFn registers:

- Setting of the Register Format Select bit (ADCER.ADRFMT) (flush-left or flush-right)
- Setting of the Addition/Average Count Select bits (ADADC.ADC[2:0]) (1, 2, 3, 4, or 16 times)
- Setting of the Average Mode Enable bit (ADADC.AVEE) (addition or average).

This section describes the data formats for these conditions in different modes.

(1) When A/D-converted value addition/average mode is not selected

Table 43.22 shows the bit assignment for each accuracy.

Table 43.22 Bit assignment for each accuracy (1 of 2)

Accuracy	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	These bits are read as 0.				Converted Value 11 to 0: 12-bit A/D-converted value											

Table 43.22 Bit assignment for each accuracy (2 of 2)

Accuracy	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Left-justified data with 12-bit accuracy	Converted Value 11 to 0: 12-bit A/D-converted value												These bits are read as 0.			

(2) When A/D-converted value average mode is selected

A/D-converted value average mode can be selected when 2 or 4 times is specified in the A/D-converted value addition mode. When A/D converted value average mode is selected, This register indicatesThese registers indicate the mean of A/D-converted values on a specific channel. The value is stored in the A/D data register based on the setting of the A/D Data Register Format Select bit in the same way as for normal A/D conversion.

(3) When A/D-converted value addition mode is selected

For 12-bit, 10-bit, 8-bit accuracy, 1, 2, 3, or 4 times can be selected in the A/D-converted value addition mode. A/D conversion results are stored in the A/D data register as a 2-bit-extended value of the specified conversion accuracy.

For 12-bit accuracy, 16 times can also be selected in the A/D-converted value addition mode. In A/D-converted value addition mode, this register indicatesthese registers indicate the value that is obtained by adding A/D-converted values on a specific channel. A/D conversion results are stored in the A/D data register as a 4-bit-extended value of the specified conversion accuracy.

When A/D-converted value addition mode is selected, the value is stored in the A/D data register based on the settings of the A/D Data Register Format Select bits.

Table 43.23 shows the bit assignment for each accuracy.

Table 43.23 Bit assignment for each accuracy when A/D-converted value addition mode is selected

Accuracy		b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	When 16 conversion times is specified	Added Value 15 to 0: 16-bit sum of A/D conversion results															
	When 1, 2, 3, or 4 conversion times is specified	These bits are read as 0.	Added Value 13 to 0: 14-bit sum of A/D conversion results														
Left-justified data with 12-bit accuracy	When 1, 2, 3, or 4 conversion times is specified	Added Value 15 to 0: 16-bit sum of A/D conversion results															
	When 16 conversion times is specified	Added Value 13 to 0: 14-bit sum of A/D conversion results														These bits are read as 0.	

43.3 Operation

43.3.1 Scanning Operation

In scanning, A/D conversion is performed sequentially on the analog inputs of the specified channels.

Scan conversion is performed in any of the three operating modes:

- Single scan mode
- Continuous scan mode
- Group scan mode

In single scan mode, one or more specified channels are scanned once. In continuous scan mode, one or more specified channels are scanned repeatedly until software sets the ADCSR.ADST bit to 0. In group scan mode, the selected channels in group A, B are scanned once after scan starts in response to the respective synchronous trigger.

In single scan mode and continuous scan mode, A/D conversion is performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n. In group scan mode, A/D conversion is performed for the ANn channels in group A selected in the ADANSA0 and ADANSA1 registers, and for the

ANn channels in group B selected in the ADANSB0 and ADANSB1 registers, starting from the channel with the smallest number n.

When self-diagnosis is selected, it is executed once at the beginning of each scan and one of the three reference voltages is converted.

The temperature sensor output and internal reference voltage can be selected at the same time as the analog input of the channels, and A/D conversion is performed on the analog input of channels, temperature sensor output, and internal reference voltage, in that order.

Double trigger mode can be used with single scan mode or group scan mode. With double trigger mode enabled (ADCSR.DBLE = 1), A/D conversion data of a channel selected in the ADCSR.DBLANS[4:0] bits is duplicated only if the conversion is started by the synchronous trigger (ELC) selected in the ADSTRGR.TRSA[5:0] bits. In group scan mode, only group A can use double trigger mode.

In the extended operation of double trigger mode, the A/D conversion operation is generated from the synchronous trigger combination selected in the ADSTRGR.TRSA[5:0] bits. In addition to normal double trigger mode operation, A/ D conversion data with odd number trigger (ELC_AD00 (unit 0) and ELC_AD10 (unit 1)) is stored in A/D Data Duplexing Register A (ADDBLDRA), and A/D conversion data with even number trigger (ELC_AD01 (unit 0) and ELC_AD11 (unit 1)) is stored in A/D Data Duplexing Register B (ADDBLDRB). In the extended operation of double trigger mode, when one of the trigger combinations occurs at the same time, the data duplexing register settings for the specified triggers do not work, and A/D conversion data is stored in A/D Data Duplexing Register B (ADDBLDRB).

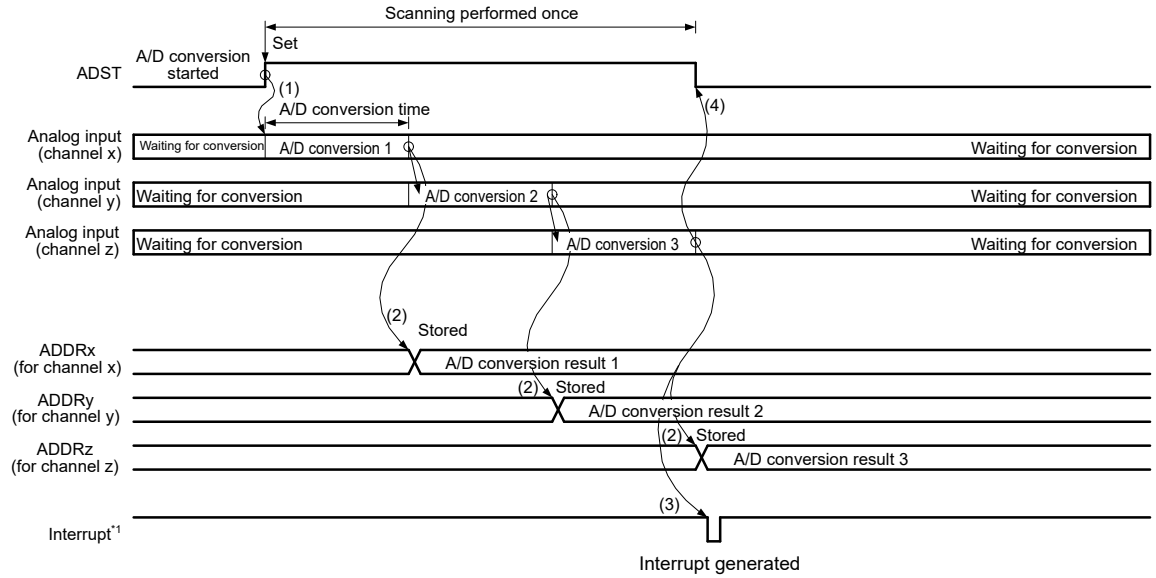
The ADC12 ignores a synchronous trigger that occurs during the A/D conversion started by another synchronous trigger.

43.3.2 Single Scan Mode

43.3.2.1 Basic Operation

In basic operation of single scan mode, A/D conversion is performed once on the analog input of the specified channels as follows:

1. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, a synchronous trigger input (ELC), or an asynchronous trigger input, A/D conversion is performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
2. Each time A/D conversion of a single channel is completed, the A/D conversion result is stored in the associated A/D data register (ADDRy).
3. When A/D conversion of all the selected channels is completed, an ADC12i_ADI (i = 0, 1) interrupt request is generated .
4. The ADST bit remains 1 (A/D conversion start) during A/D conversion and is automatically set to 0 when A/D conversion of all the selected channels is completed. The ADC12 then enters a wait state.



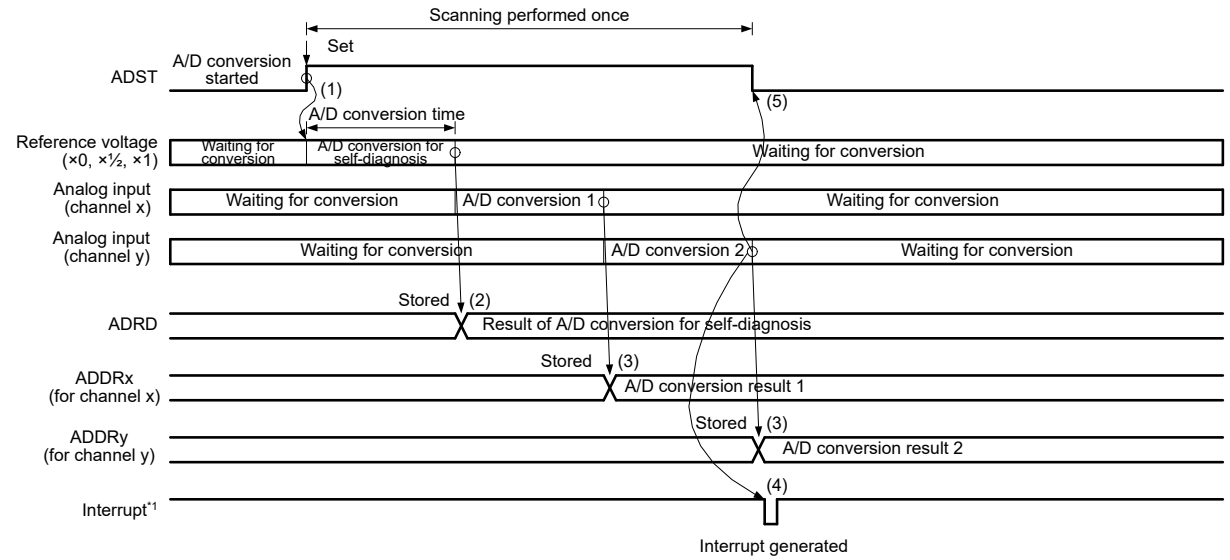
Note: x, y, and z (x < y < z) are the selected channel numbers by ADANSA0/1.
Note 1. ADC12i_ADI (i = 0, 1)

Figure 43.8 Example basic operation in single scan mode when the analog inputs (channel x to z) are selected

43.3.2.2 Channel Selection and Self-Diagnosis

When channels and self-diagnosis are selected, A/D conversion is first performed for the reference voltage VREFH0, VREFH (×0, ×1/2, or ×1) , then A/D conversion is performed once on the analog input of the selected channels as follows:

1. A/D conversion for self-diagnosis is first started when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger input, a synchronous trigger input (ELC), or an asynchronous trigger input.
2. When A/D conversion for self-diagnosis is completed, the A/D conversion result is stored in the A/D Self-Diagnosis Data Register (ADRD). A/D conversion is then performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
3. Each time A/D conversion of a single channel is completed, the A/D conversion result is stored in the associated A/D data register (ADDRy).
4. When A/D conversion of all the selected channels is completed, an ADC12i_ADI (i = 0, 1) interrupt request is generated .
5. The ADCSR.ADST bit remains 1 (A/D conversion start) during A/D conversion and is automatically set to 0 when A/D conversion of all the selected channels is completed. The ADC12 then enters a wait state.



Note: x and y (x < y) are the selected channel numbers by ADANSA0/1.
Note 1. ADC12i_ADI (i = 0, 1)

Figure 43.9 Example basic operation in single scan mode when the analog inputs (channel x and y) are selected with self- diagnosis

43.3.2.3 A/D Conversion of Temperature Sensor Output or Internal Reference Voltage

When the channels and temperature sensor output or internal reference voltage are selected at the same time, A/D conversion is performed first on the analog input of the selected channels, and once on the temperature sensor output or internal reference voltage. When both temperature sensor output and internal reference voltage are selected, A/D conversion of the temperature sensor output and internal reference voltage is performed, in that order. With the channels deselected, selecting only the temperature sensor output or internal reference voltage is also possible.

The operation is as follows:

1. When a software trigger, synchronous trigger (ELC), or asynchronous trigger sets the ADCSR.ADST bit to 1 (A/D conversion start), A/D conversion is performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
2. On completion of A/D conversion on the channels, the result is stored in the associated A/D Data Register y (ADDRy), and then A/D conversion of the temperature sensor output starts.
3. On completion of A/D conversion of the temperature sensor output, the result is stored in the associated A/D Temperature Sensor Data Register (ADTSDR), and then A/D conversion of the internal reference voltage starts.
4. On completion of A/D conversion of the internal reference voltage, the result is stored in the associated A/D Internal Reference Voltage Data Register (ADOCDR), and an ADC12i_ADI (i = 0, 1) interrupt request is generated (no register setting).
5. The ADCSR.ADST bit remains 1 (A/D conversion start) during A/D conversion, and is automatically cleared to 0 on completion of A/D conversion. Then, the ADC12 enters a wait state.

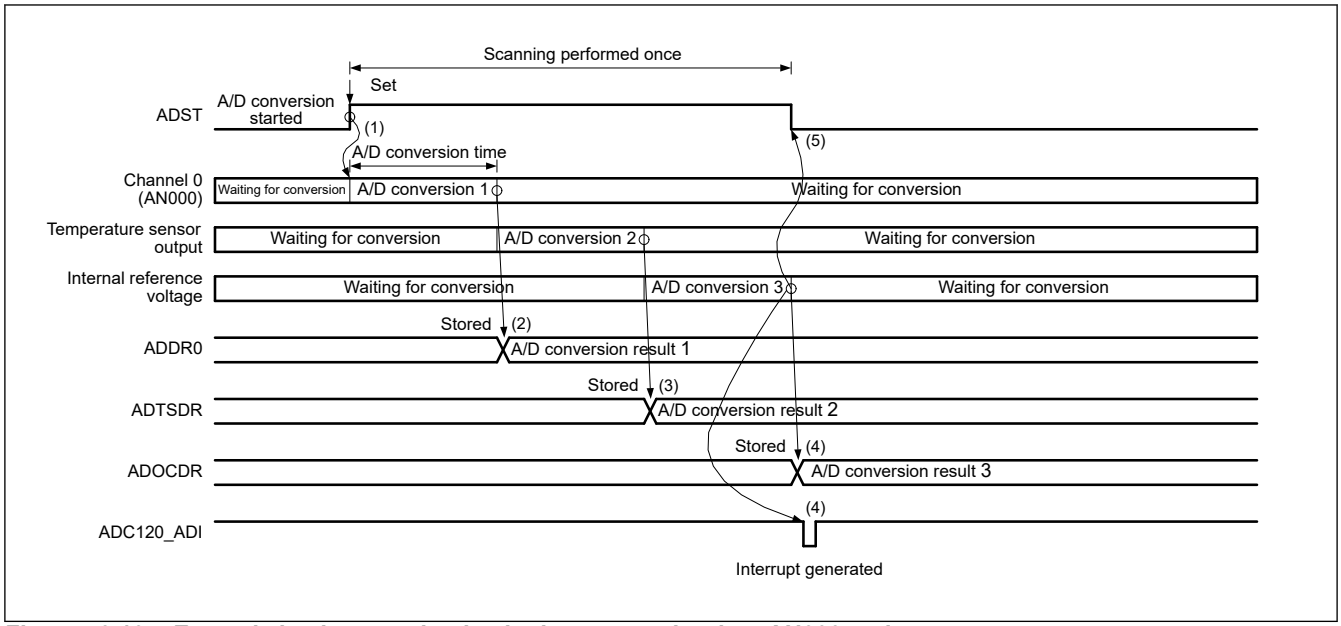


Figure 43.10 Example basic operation in single scan mode when AN000 and temperature sensor output or internal reference voltage are selected

43.3.2.4 A/D Conversion in Double-Trigger Mode

When double trigger mode is selected in single scan mode, two rounds of single scan operation started by a synchronous trigger (ELC) are performed in sequence.

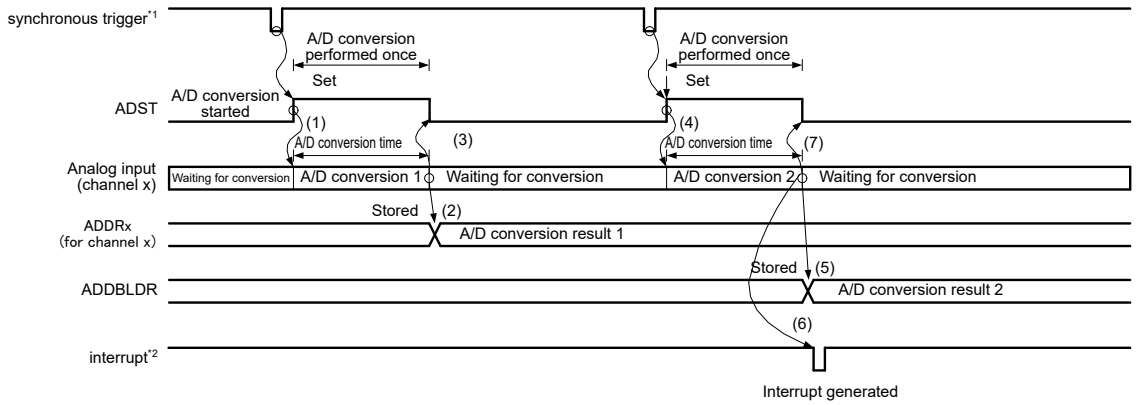
Deselect self-diagnosis and set the temperature sensor output A/D conversion select bit (ADEXICR.TSSA and ADEXICR.TSSB) and the internal reference voltage A/D conversion select bit (ADEXICR.OCSA and ADEXICR.OCSB) to 0.

Duplication of A/D conversion data is enabled by setting the channel numbers to be duplicated in the ADCSR.DBLANS[4:0] bits and setting the ADCSR.DBLE bit to 1. When the ADCSR.DBLE bit is set to 1, channel selection using the ADANSA0 and ADANSA1 registers is invalid.

In double trigger mode, select a synchronous trigger (ELC) with the ADSTRGR.TRSA[5:0] bits. Additionally, set the ADCSR.EXTRG bit to 0 and the ADCSR.TRGE bit to 1. Do not use a software trigger.

The operation is as follows:

1. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by a synchronous trigger input (ELC), A/D conversion starts on the single channel selected in the ADCSR.DBLANS[4:0] bits.
2. Each time A/D conversion of a single channel is completed, the A/D conversion result is stored in the associated A/D Data Register y (ADDRy).
3. The ADCSR.ADST bit is automatically set to 0 and the ADC12 enters a wait state. An ADC12i_ADI (i = 0, 1) interrupt request is not generated .
4. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by the second trigger input, A/D conversion starts on the single channel selected in the ADCSR.DBLANS[4:0] bits.
5. When A/D conversion is completed, the result is stored in the A/D Data Duplexing Register (ADDBLDR), which is exclusively used in double-trigger mode.
6. An ADC12i_ADI (i = 0, 1) interrupt request is generated.
7. The ADCSR.ADST bit remains 1 (A/D conversion start) during A/D conversion and is automatically set to 0 when A/D conversion is completed. Then the ADC12 enters a wait state.



Note: x is the selected channel number by ADANSA0/1.
Note 1. ELC_AD00 (unit 0) and ELC_AD10 (unit 1)/ELC_AD01 (unit 0) and ELC_AD11 (unit 1)
Note 2. ADC12i_ADI (i = 0, 1)

Figure 43.11 Example operation in single scan mode when double-trigger mode is selected and the analog input (channel x) is duplicated

43.3.2.5 Extended Operations When Double-Trigger Mode Is Selected

When double trigger mode is selected in single scan mode, and a synchronous trigger (ELC_AD00 (unit 0) and ELC_AD10 (unit 1)/ELC_AD01 (unit 0) and ELC_AD11 (unit 1)) is selected as the trigger for the start of A/D conversion, two rounds of single scan operation are performed.

Deselect self-diagnosis and set the temperature sensor output A/D conversion select bit (ADEXICR.TSSA and ADEXICR.TSSB), and the internal reference voltage A/D conversion select bit (ADEXICR.OCSA and ADEXICR.OCSB) to 0.

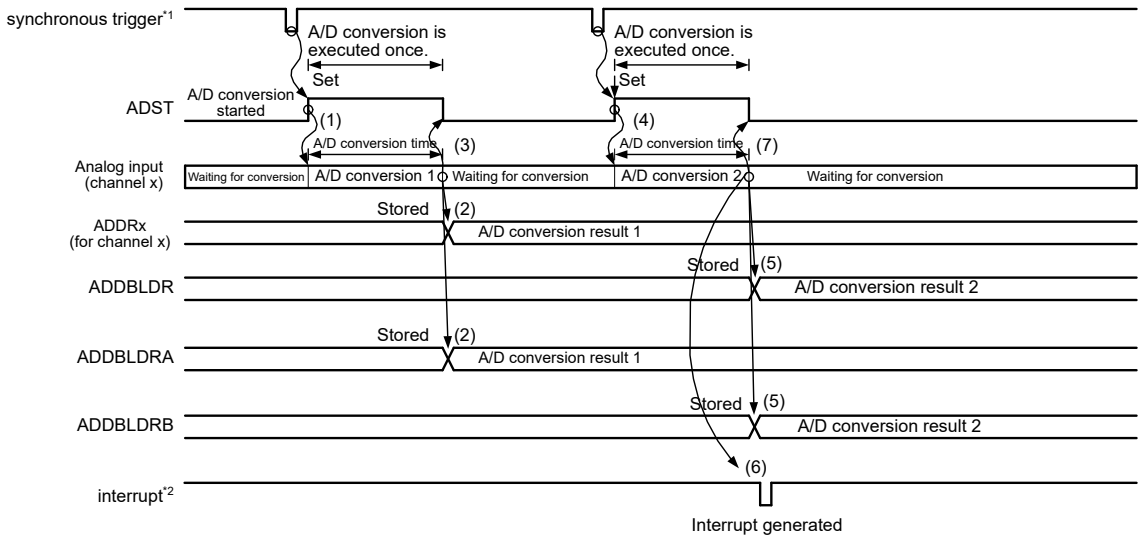
Duplication of A/D conversion data is enabled by setting the channel number to be duplicated to the ADCSR.DBLANS[4:0] bits and setting the ADCSR.DBLE bit to 1. When the ADCSR.DBLE bit is set to 1, channel selection using the ADANSA0 and ADANSA1 registers is invalid.

In extended double trigger mode, select a synchronous trigger combination ELC_AD00 (unit 0) and ELC_AD10 (unit 1)/ ELC_AD01 (unit 0) and ELC_AD11 (unit 1) by setting the ADSTRGR.TRSA[5:0] bits to 0x0B, set the ADCSR.EXTRG bit to 0, and set the ADCSR.TRGE bit to 1. Do not use a software trigger.

The operation is as follows:

1. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by a synchronous trigger input (ELC_AD00 (unit 0) and ELC_AD10 (unit 1)/ELC_AD01 (unit 0) and ELC_AD11 (unit 1)), A/D conversion starts on the single channel selected in the ADCSR.DBLANS[4:0] bits.
2. When A/D conversion completes, the A/D conversion result is stored in the associated A/D Data Register (ADDRy) and in A/D Data Duplexing Register A (ADDBLDRA) or A/D Data Duplexing Register B (ADDBLDRB) when the ELC_ADi0 or ELC_ADi1 trigger is input respectively (i = 1).
3. The ADCSR.ADST bit is automatically set to 0 and the ADC12 enters a wait state. An ADC12i_ADI (i = 0, 1) interrupt request is not generated.
4. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by the second trigger (ELC_AD00 (unit 0) and ELC_AD10 (unit 1)/ELC_AD01 (unit 0) and ELC_AD11 (unit 1)), A/ D conversion starts on the single channel selected in the ADCSR.DBLANS[4:0] bits.
5. When A/D conversion completes, the A/D conversion result is stored in the A/D Data Duplexing Register (ADDBLDR) and in A/D Data Duplexing Register A (ADDBLDRA) or A/D Data Duplexing Register B (ADDBLDRB) when the ELC_ADi0 or ELC_ADi1 trigger is input respectively (i = 1).
6. An ADC12i_ADI (i = 0, 1) interrupt request is generated.

7. The ADCSR.ADST bit remains 1 (A/D conversion start) during A/D conversion and is automatically set to 0 when A/D conversion completes. The ADC12 then enters a wait state.



Note: x is the selected channel number by ADANSA0/1.
Note 1. ELC_AD00 (unit 0) and ELC_AD10 (unit 1)/ELC_AD01 (unit 0) and ELC_AD11 (unit 1)
Note 2. ADC12i_ADI (i = 0, 1)

Figure 43.12 Example extended operation in double trigger mode with duplication selected for the analog input (channel x) and ELC_AD00 (unit 0) and ELC_AD10 (unit 1)/ELC_AD01 (unit 0) and ELC_AD11 (unit 1)

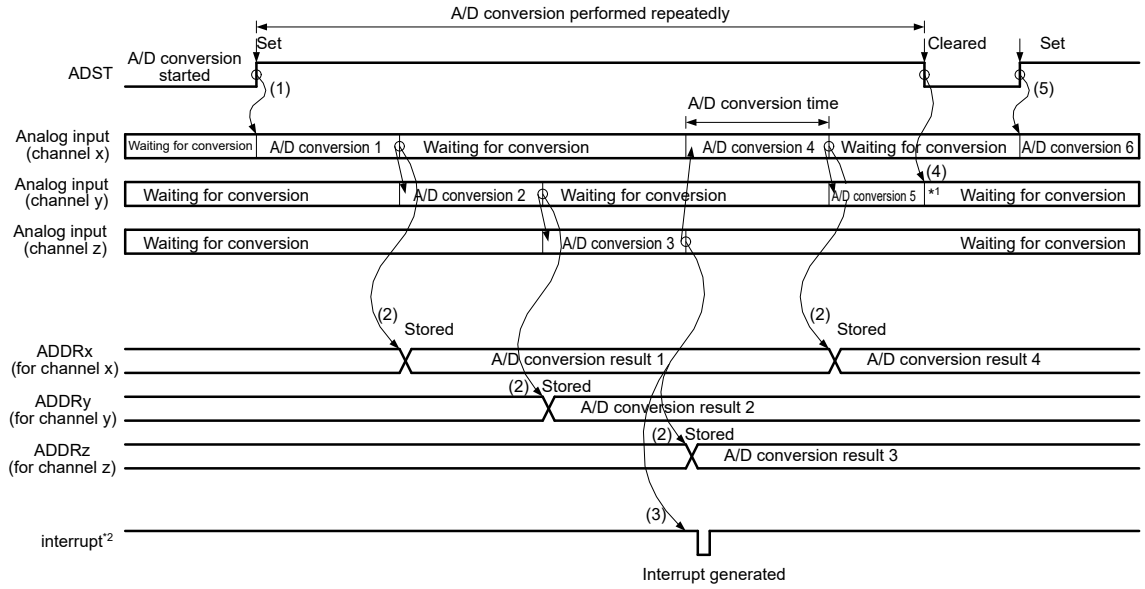
43.3.3 Continuous Scan Mode

43.3.3.1 Basic Operation

In continuous scan mode, A/D conversion is performed repeatedly on the analog input of the specified channels.

The operation is as follows:

1. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, a synchronous trigger input (ELC), or an asynchronous trigger input, A/D conversion is performed for ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
2. Each time A/D conversion of a single channel is completed, the A/D conversion result is stored in the associated A/D Data Register (ADDRy).
3. When A/D conversion of all the selected channels is completed, an ADC12i_ADI (i = 0, 1) interrupt request is generated. The ADC12 sequentially starts A/D conversion for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
4. The ADCSR.ADST bit is not automatically cleared, and steps 2. and 3. are repeated as long as ADCSR.ADST remains 1 (A/ D conversion start). When the ADCSR.ADST bit is set to 0 (A/D conversion stop), A/D conversion stops and the ADC12 enters a wait state.
5. When the ADCSR.ADST bit is later set to 1 (A/D conversion start), A/D conversion starts again for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.



Note: x, y, and z (x < y < z) are the selected channel numbers by ADANSA0/1.
Note 1. Data for A/D conversion 5 is ignored.
Note 2. ADC12i_ADI (i = 0, 1)

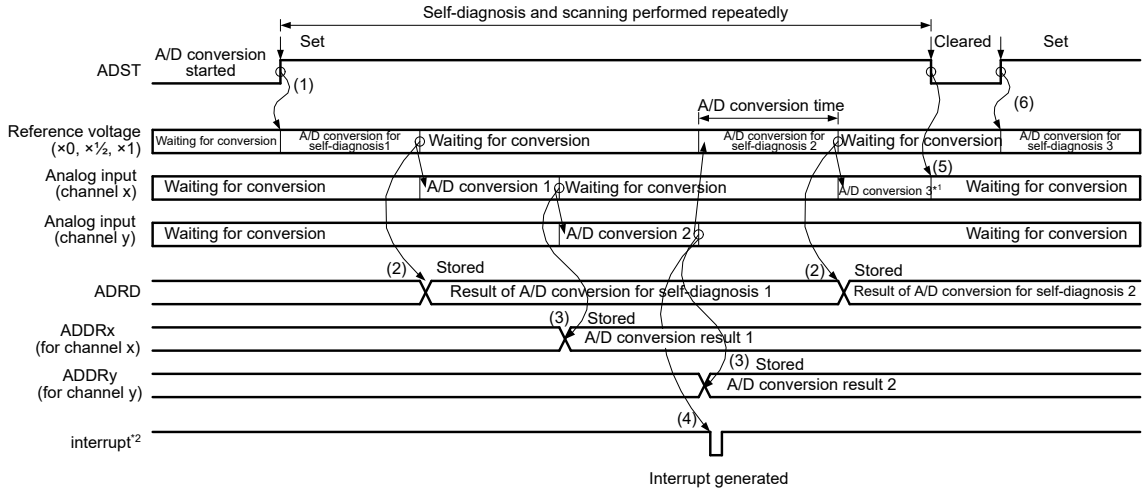
Figure 43.13 Example basic operation in continuous scan mode when the analog inputs (channel x to z) are selected

43.3.3.2 Channel Selection and Self-Diagnosis

When channels and self-diagnosis are selected at the same time, A/D conversion is first performed for the reference voltage VREFH0, VREFH (×0, ×1/2, or ×1) supplied to the ADC12, and A/D conversion is performed on the analog input of the selected channels. This sequence is repeated as described in the section that follows.

The operation is as follows:

1. A/D conversion for self-diagnosis is first started when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger input, a synchronous trigger input (ELC), or an asynchronous trigger input.
2. When A/D conversion for self-diagnosis is completed, the A/D conversion result is stored in the A/D Self-Diagnosis Data Register (ADRD). A/D conversion is then performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
3. Each time A/D conversion of a single channel is completed, the A/D conversion result is stored in the corresponding A/D Data Register (ADDRy).
4. When A/D conversion of all the selected channels is completed, an ADC12i_ADI (i = 0, 1) interrupt request is generated. At the same time, the ADC12 starts A/D conversion for self-diagnosis and then on the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
5. The ADCSR.ADST bit is not automatically cleared, and steps 2. to 4. are repeated as long as the ADCSR.ADST bit remains 1. When the ADST bit is set to 0 (A/D conversion stop), A/D conversion stops and the ADC12 enters a wait state.
6. When the ADST bit is later set to 1 (A/D conversion start), the A/D conversion for self-diagnosis is started again.



Note: x and y (x < y) are the selected channel numbers by ADANSA0/1.
Note 1. Data for A/D conversion 3 is ignored.
Note 2. ADC12i_ADI (i = 0, 1)

Figure 43.14 Example basic operation in continuous scan mode when the analog inputs (channel x and y) are selected with self-diagnosis

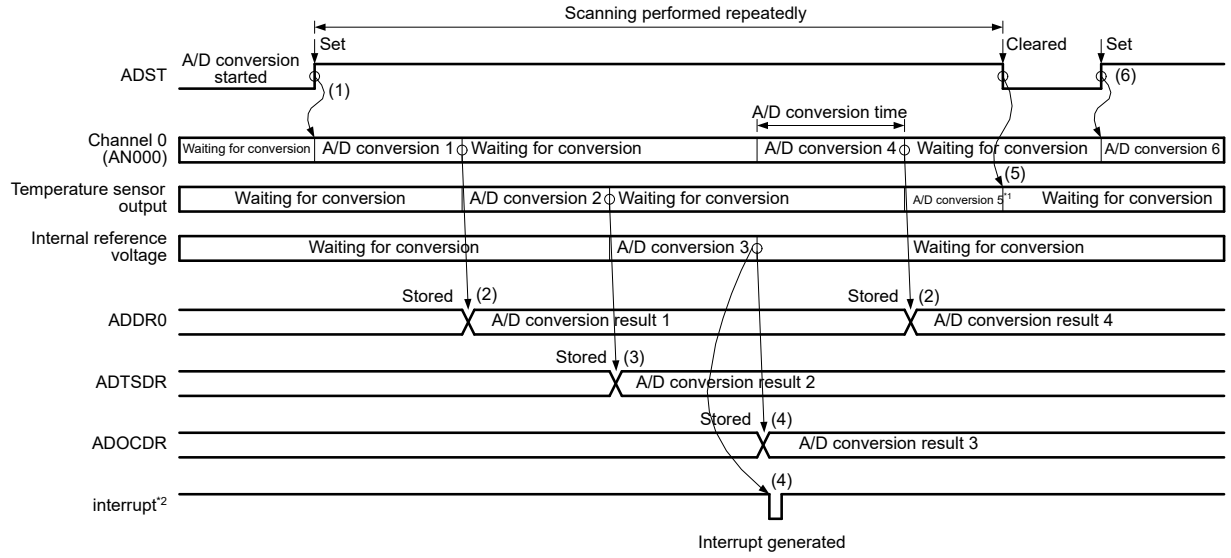
43.3.3.3 A/D Conversion of Temperature Sensor Output or Internal Reference Voltage

When the channels and temperature sensor output or internal reference voltage are selected at the same time, A/D conversion is first performed on the analog input of the selected channels, and then the A/D conversion of the temperature sensor output or internal reference voltage is repeated. When both the temperature sensor output and internal reference voltage are selected, A/D conversion of the temperature sensor output and internal reference voltage is performed, in that order.

With the channels deselected, selecting only the temperature sensor output or internal reference voltage is also possible.

The operation is as follows:

1. When a software trigger, synchronous trigger (ELC), or asynchronous trigger sets the ADCSR.ADST bit to 1 (A/D conversion start), A/D conversion is performed for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the smallest number n.
2. On completion of A/D conversion on the channels, the result is stored in the associated A/D Data Register y (ADDRy), and then A/D conversion of temperature sensor output starts.
3. On completion of A/D conversion of the temperature sensor output, the result is stored in the associated A/D Temperature Sensor Data Register (ADTSDR), and then A/D conversion of the internal reference voltage starts.
4. On completion of A/D conversion of the internal reference voltage, the result is stored in the associated A/D Internal Reference Voltage Data Register (ADOCDR), and an ADC12i_ADI (i = 0, 1) interrupt request is generated. In addition, the ADC12 continuously starts A/D conversion for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the lowest number n.
5. The ADCSR.ADST bit is not cleared automatically, and steps 2 to 4 are repeated as long as this bit remains set to 1. When the ADCSR.ADST bit is set to 0 (A/D conversion stop), A/D conversion stops and the ADC12 enters a wait state.
6. When the ADCSR.ADST bit is then set to 1 (A/D conversion start), A/D conversion starts again for the ANn channels selected in the ADANSA0 and ADANSA1 registers, starting from the channel with the lowest number n.



Note 1. Data for A/D conversion 5 is ignored.
Note 2. ADC12i_ADI (i = 0, 1)

Figure 43.15 Example basic operation in continuous scan mode when AN000 and temperature sensor output or internal reference voltage are selected

43.3.4 Group Scan Mode

43.3.4.1 Basic Operation

In group scan mode, A/D conversion is performed once on the analog input of all the specified channels in group A and B after scanning is started by a synchronous trigger (ELC). The scan operation of each group is similar to the scan operation in single scan mode.

The synchronous triggers can be selected in the ADSTRGR.TRSA[5:0] bits for group A and in the ADSTRGR.TRSB[5:0] bits for group B. Use different triggers for group A and B to prevent simultaneous A/D conversion of the two groups. Do not use a software trigger.

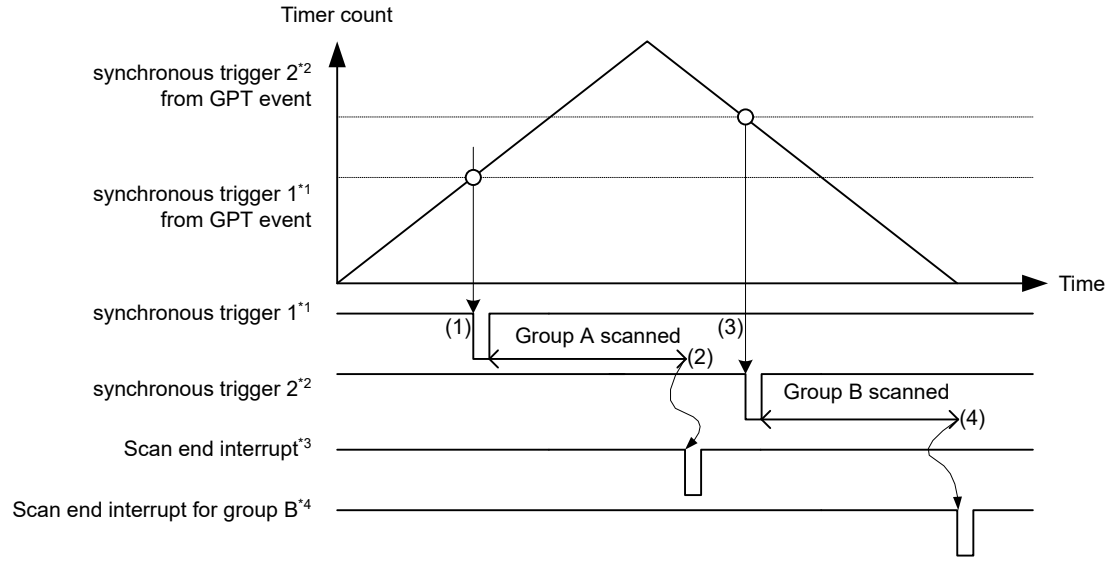
The group A channels to be A/D-converted are selected using the ADANSA0 and ADANSA1 registers and the ADEXICR.TSSA and OCSA bits. The group B channels to be A/D-converted are selected using the ADANSB0 and ADANSB1 registers and the ADEXICR.TSSB and OCSB bits. Group A and B cannot use the same channels.

When self-diagnosis is selected in group scan mode, self-diagnosis is separately executed for Group A and B.

The following sequence describes operation in group scan mode using a synchronous trigger from the ELC. In this example, the ELC_AD00 (unit 0) and ELC_AD10 (unit 1) trigger from the ELC is used to start conversion of group A and the ELC_AD01 (unit 0) and ELC_AD11 (unit 1) trigger from the ELC is used to start conversion of group B. In addition, ELC_AD00 (unit 0) and ELC_AD10 (unit 1) and ELC_AD01 (unit 0) and ELC_AD11 (unit 1) are selected for the GPT event in the associated ELC.ELSRn registers.

The operation is as follows:

1. Scanning of group A is started by ELC_AD00 (unit 0) and ELC_AD10 (unit 1).
2. When group A scanning completes, an ADC12i_ADI (i = 0, 1) interrupt is generated (no register setting).
3. Scanning of group B is started by ELC_AD01 (unit 0) and ELC_AD11 (unit 1).
4. When group B scanning completes, an ADC12i_GBADI (i = 0, 1) interrupt is generated if the ADCSR.GBADIE bit is 1 (ADC12i_GBADI (i = 0, 1) interrupt when scanning completion is enabled).



Note 1. ELC_AD00 (unit 0) and ELC_AD10 (unit 1)
Note 2. ELC_AD01 (unit 0) and ELC_AD11 (unit 1)
Note 3. ADC12i_ADI (i = 0, 1)
Note 4. ADC12i_GBADI (i = 0, 1)

Figure 43.16 Example basic operation in group scan mode when synchronous triggers from the ELC are used

43.3.4.2 A/D Conversion in Double-Trigger Mode

When double trigger mode is selected in group scan mode, two rounds of single scan operation started by a synchronous trigger (ELC) are performed as a sequence for group A. For group B, single scan operation started by a synchronous trigger (ELC) is performed once.

In group scan mode, the synchronous trigger can be selected in the ADSTRGR.TRSA[5:0] bits for group A and in the ADSTRGR.TRSB[5:0] bits for group B. Use different triggers for groupA, B to prevent simultaneous A/D conversion of the two groups. Do not use a software trigger or an asynchronous trigger.

When an ELC_AD00 (unit 0) and ELC_AD10 (unit 1)/ELC_AD01 (unit 0) and ELC_AD11 (unit 1) is selected as group A synchronous triggers by setting the ADSTRGR.TRSA[5:0] bits to 0x0B, operation proceeds in extended double trigger mode.

The group A channel to be A/D-converted is selected using the DBLANS[4:0] bits in the ADCSR register, while the group B channels to be A/D-converted are selected using the ADANSB0 and ADANSB1 registers. Group A, B cannot use the same channels.

When double-trigger mode is selected in group scan mode, set the A/D conversion select bits for both the temperature sensor output (ADEXICR.TSSA) and the internal reference voltage (ADEXICR.OCSA) to 0 (deselected).

Self-diagnosis cannot be selected when double trigger mode is selected in group scan mode.

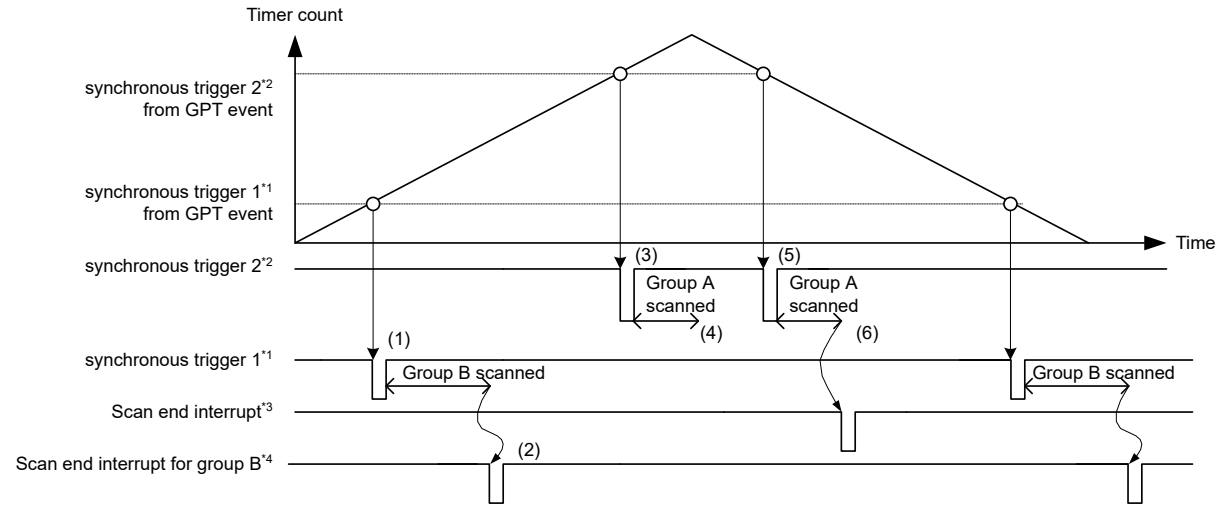
Duplication of A/D conversion data is enabled by setting the channel numbers to be duplicated in the ADCSR.DBLANS[4:0] bits and setting the ADCSR.DBLE bit to 1.

The following sequence describes operation in group scan mode with double trigger mode selected and using a synchronous trigger from the ELC. In this example, the ELC_AD00 (unit 0) and ELC_AD10 (unit 1) trigger is used to start conversion of group A and the ELC_AD01 (unit 0) and ELC_AD11 (unit 1) trigger is used to start conversion of group B. In addition, ELC_AD00 (unit 0) and ELC_AD10 (unit 1) and ELC_AD01 (unit 0) and ELC_AD11 (unit 1) are selected for the GPT event in the associated ELC.ELSRn registers.

The operation is as follows:

1. Scanning of group B is started by the ELC_AD00 (unit 0) and ELC_AD10 (unit 1) trigger from the ELC.

2. When group B scanning completes, an ADC12i_GBADI (i = 0, 1) interrupt is generated if the GBADIE bit in ADCSR is 1 (ADC12i_GBADI (i = 0, 1) interrupt when scanning completion is enabled).
3. The first scan of group A is started by the first ELC_AD01 (unit 0) and ELC_AD11 (unit 1) trigger.
4. When the first scan of group A completes, the conversion result is stored in the associated A/D Data Register y (ADDRy); an ADC12i_ADI (i = 0, 1) interrupt request is not generated.
5. The second scan of group A is started by the second ELC_AD01 (unit 0) and ELC_AD11 (unit 1) trigger.
6. When the second scan of group A completes, the conversion result is stored in ADDBLDR. An ADC12i_ADI (i = 0, 1) interrupt is generated.



Note 1. ELC_AD00 (unit 0) and ELC_AD10 (unit 1)
Note 2. ELC_AD01 (unit 0) and ELC_AD11 (unit 1)
Note 3. ADC12i_ADI (i = 0, 1)
Note 4. ADC12i_GBADI (i = 0, 1)

Figure 43.17 Example basic operation in group scan mode with double-trigger mode when synchronous triggers from the ELC are used

43.3.4.3 Group Priority Operation

Group priority operation is performed by setting the ADGSPCR.PGS bit to 1 in group-scan mode. The priority of groups is group A > group B.

When setting the PGS bit in the ADGSPCR register to 1, follow the procedure described in Figure 43.18. If the procedure is not followed, A/D conversion operation and stored data are not guaranteed.

As the basic operation in group-scan mode, a trigger input generated during A/D conversion of group A, B is ignored, and the A/D conversion operation of each group is similar to the operation in single-scan mode.

In group priority operation, if a trigger for a priority group is input during scanning of a lower-priority group, A/D conversion for the lower-priority group is stopped and A/D conversion for the priority group is performed.

If the setting of the ADGSPCR.GBRSCN bit is 0, the lower-priority group enters a wait state when A/D conversion for the priority group completes. A trigger input of the lower-priority group generated during A/D conversion is ignored.

If the setting of the ADGSPCR.GBRSCN bit is 1, A/D conversion for the lower-priority group automatically restarts upon completion of A/D conversion for the priority group. A trigger input of the lower-priority group generated during A/D conversion on the priority group takes effect, and A/D conversion for the lower-priority group is automatically performed upon completion of A/D conversion on the priority group.

If the ADGSPCR.GBRSCN bit is 1 and the ADGSPCR.LGRRS bit is 0, A/D conversion for the lower-priority group is restarted from the first channel. If the setting of the ADGSPCR.LGRRS bit is 1, A/D conversion for the lower-priority group is restarted from the channel for which the conversion stopped. However, if the self-diagnosis function is used, the A/D conversion is restarted from the channel for which the conversion stopped after self-diagnosis completed.

Table 43.24 summarizes operations in response to the input of a trigger during A/D conversion with the settings of the ADGSPCR.GBRSCN bit.

If the setting of the ADGSPCR.GBRP bit is 1, A/D conversion operation for the lowest-priority group is to continuously perform single scans.

For the trigger settings in group-scan mode, select a synchronous trigger for group A by using the ADSTRGR.TRSA[5:0] bits, a synchronous trigger for group B by using the ADSTRGR.TRSB[5:0] bits. Each trigger must be different from each other. Set the ADSTRGR.TRSB[5:0] bits to 0x3F when setting the ADGSPCR.GBRP bit to 1.

The channels to be scanned must be selected in the registers shown in section 43.3.4. Group Scan Mode.

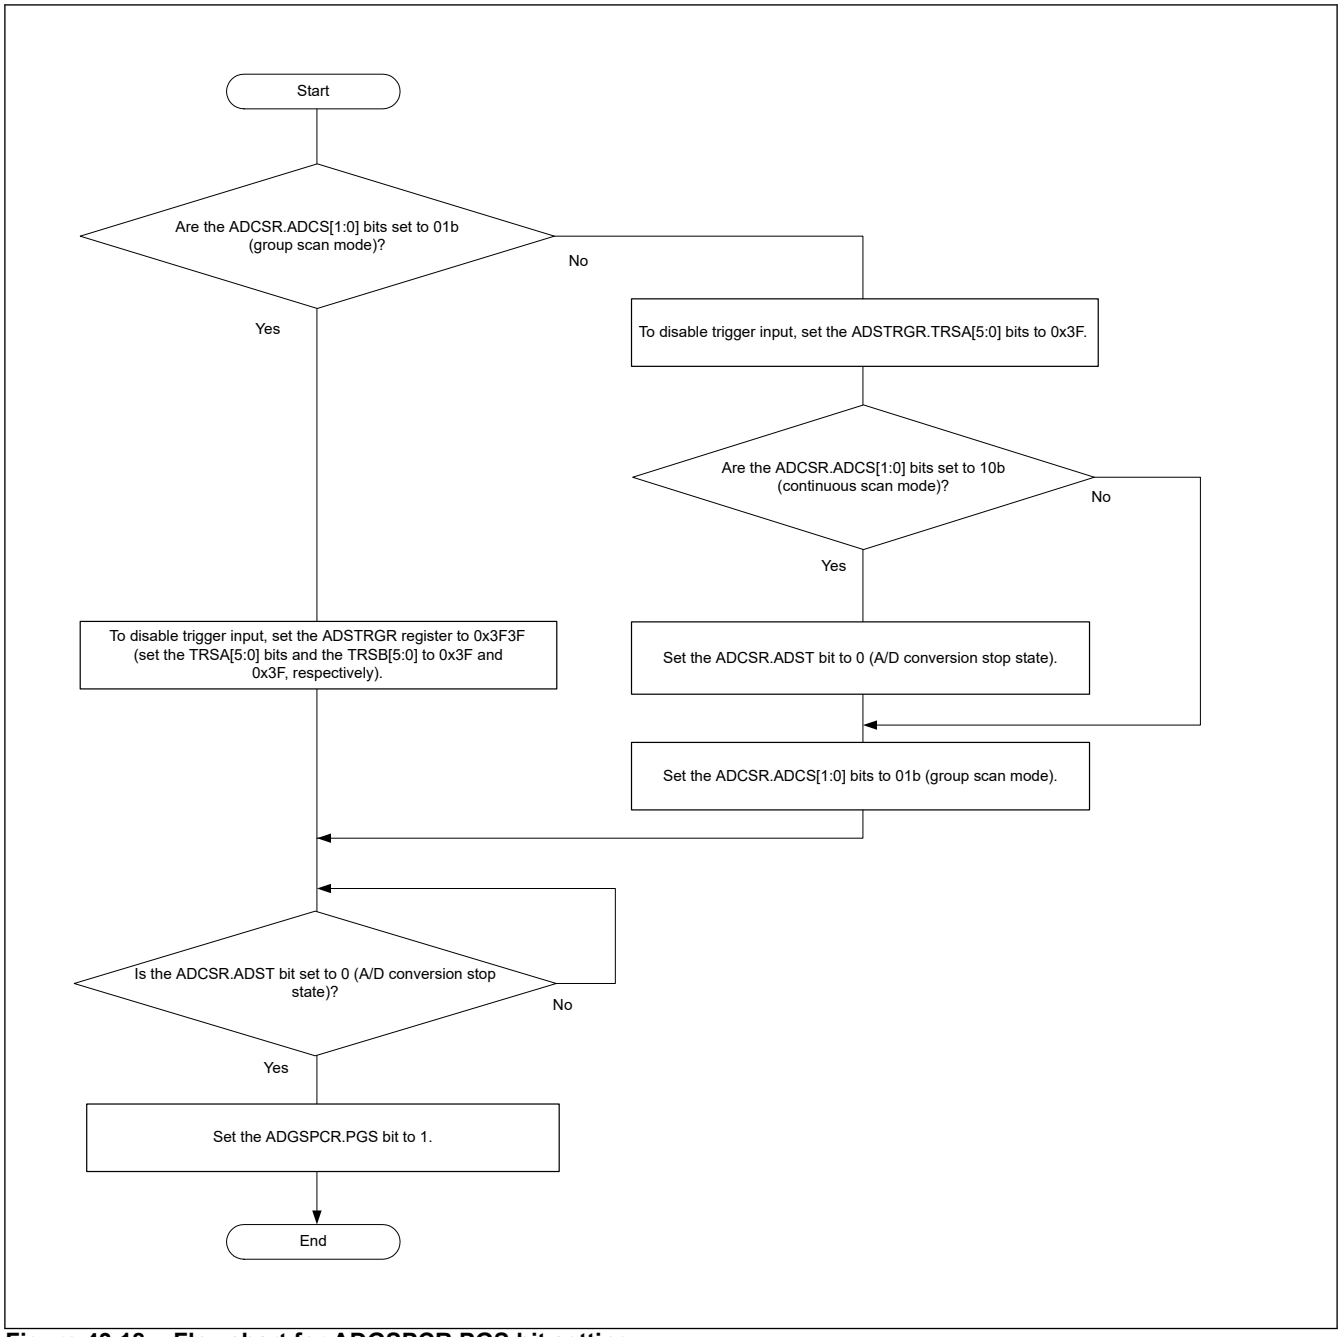


Figure 43.18 Flowchart for ADGSPCR.PGS bit setting

Table 43.24 Control of A/D conversion operations according to ADGSPCR.GBRSCN bit setting

A/D conversion operation	Trigger input	ADGSPCR.GBRSCN = 0	ADGSPCR.GBRSCN = 1
When A/D conversion for group A is in progress	Input of trigger for group A	Trigger input is ineffective.	Trigger input is ineffective.
	Input of trigger for group B	Trigger input is ineffective.	A/D conversion for group B is performed after A/D conversion for group A completes.
When A/D conversion for group B is in progress	Input of trigger for group A	A/D conversion for group B is discontinued and A/D conversion for group A starts.	• A/D conversion for group B is discontinued and A/D conversion for group A starts. • A/D conversion for group B starts after A/D conversion for group A completes.
	Input of trigger for group B	Trigger input is ineffective.	Trigger input is ineffective.

To use group priority operation mode, select the operation mode to be implemented and set the registers according to the following table.

Table 43.25 Group priority operation setting and operation mode for two groups (ADGSPCR.PGS = 1)

ADGSPCR			Operation category
GBRSCN	LGRRS	GBRP	
0	x	0	Group priority operation for two groups (groups A and B) • When a trigger of group A is input, A/D conversion for group B is terminated (and will not be restarted).
1	0	0	Group priority operation for two groups (groups A and B) • After A/D conversion for group B stopped, when A/D conversion for group A completes, A/D conversion for the group B channels selected in the ADANSB0 and ADANSB1 registers restarts according to the conversion order of smaller channel number.
1	1	0	Group priority operation for two groups (groups A and B) • After A/D conversion for group B stopped, when A/D conversion for group A completes, A/D conversion for the group B channels selected in the ADANSB0/1 register restarts according to the conversion order of smaller channel number, beginning from the channel for which A/D conversion stopped.*1
x	0	1	Group priority operation for two groups (groups A and B) • Single scanning for group B is continuously performed without a start trigger input. After A/D conversion for group B stopped, when A/D conversion for group A completes, single scanning for the channels selected in the ADANSB0/1 register restarts according to the conversion order of smaller channel number.
1	1	1	Group priority operation for two groups (groups A and B) • Single scanning for group B is continuously performed without a start trigger input. After A/D conversion for group B stopped, when A/D conversion for group A completes, single scanning for the channels selected in the ADANSB0/1 register restarts according to the conversion order of smaller channel number, beginning from the channel for which A/D conversion stopped.*1

Note: x: Don't care.
Note 1. When the self-diagnosis function is enabled (ADCER.DIAGM = 1), A/D conversion for the channel that has been stopped is started after self-diagnosis is performed.

(1) Group priority operation for two groups (when ADGSPCR.PGS = 1)

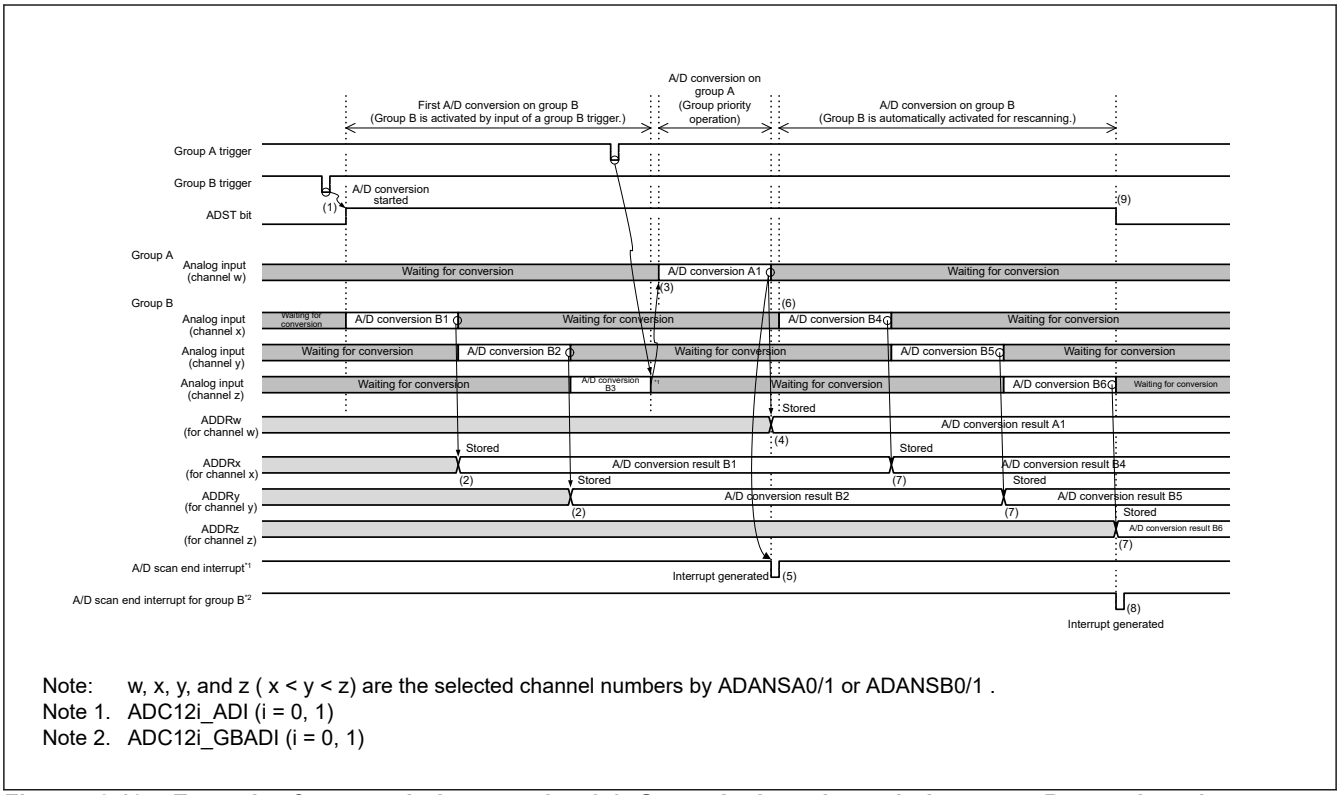
Operation examples 1-1 to 1-3 show group priority operations in group-scan mode (when ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 0, and ADGSPCR.LGRRS = 0).

Operation example 1-1: "Group A trigger input during group B scan" when rescanning is enabled

1. When input of a trigger for group B sets the ADCSR.ADST bit to 1 (starting A/D conversion), A/D conversion for the analog input channels selected in the ADANSB0 and ADANSB1 registers starts according to the conversion order from the channel with the smallest number n.
2. On completion of A/D conversion for each channel in group B, the result is stored in the corresponding A/D Data Register y (ADDRy).
3. When a trigger for group A is input during A/D conversion for group B, A/D conversion for group B stops while the ADCSR.ADST bit remains 1. Then A/D conversion for the group A analog input channels selected in the ADANSA0

and ADANSA1 registers starts according to the conversion order from the channel with the smallest number n. If A/D conversion stops before it is completed, the conversion result is not stored in the A/D Data Register y (ADDRy).

4. On completion of A/D conversion on the channels, the result is stored in the corresponding A/D Data Register y (ADDRy).
5. An ADC120_ADI interrupt request is generated.
6. If the setting of the ADGSPCR.GBRSCN bit is 1 (enabling rescanning of the group that was stopped in group priority operation), A/D conversion for the group B analog input channels selected in the ADANSB0 and ADANSB1 registers restarts according to the conversion order from the channel with the smallest number n while the ADCSR.ADST remains 1.
7. On completion of A/D conversion on the channels, the result is stored in the corresponding A/D Data Register y (ADDRy).
8. If the setting of the ADCSR.GBADIE bit is 1 (enabling interrupt generation on completion of group B scan), a group B scan end interrupt request is generated.
9. When A/D conversion for all the channels completes, the ADCSR.ADST bit is automatically cleared and the A/D converter enters a wait state.



Note: w, x, y, and z (x < y < z) are the selected channel numbers by ADANSA0/1 or ADANSB0/1 .
Note 1. ADC12i_ADI (i = 0, 1)
Note 2. ADC12i_GBADI (i = 0, 1)

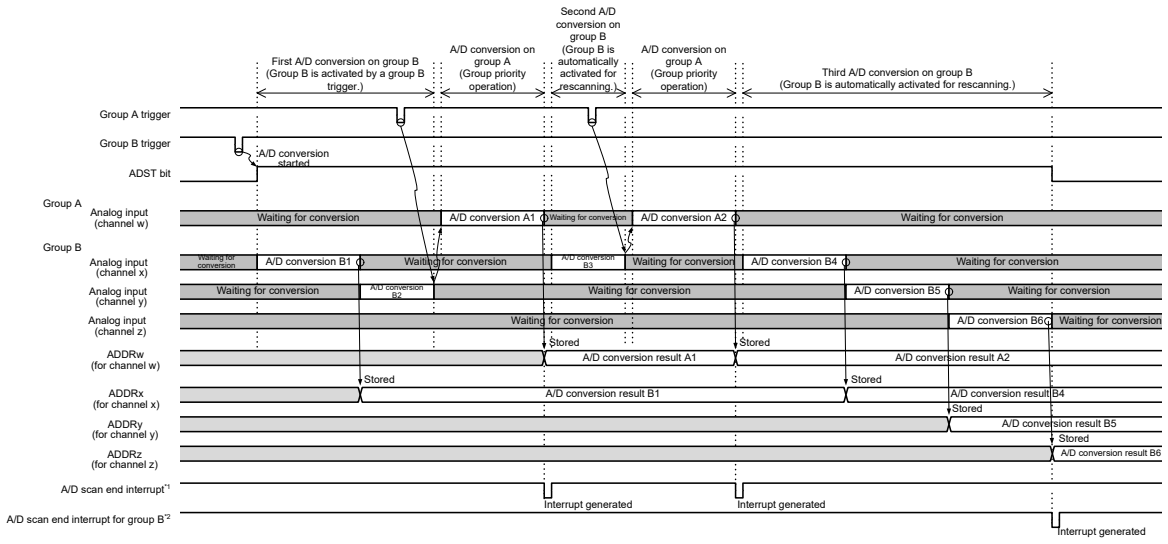
Figure 43.19 Example of group priority operation 1-1: Group A trigger input during group B scanning when rescanning is enabled (when ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 0, and ADGSPCR.LGRRS = 0)

Operation example 1-2: “Group A trigger input during rescanning of group B” when rescanning is enabled

Figure 43.20 shows the operation when a group A trigger is input during rescanning operation for group B.

Even during rescanning operation, when a trigger for group A is input, A/D conversion on group B stops and A/D conversion for group A starts. A/D conversion for group B starts after A/D conversion for group A completes.

Operations for setting the ADCSR.ADST bit, storing the A/D conversion result in the corresponding A/D Data Register y (ADDRy), and generating interrupt requests are the same as those in operation example 1-1.



Note: w, x, y, and z (x < y < z) are the selected channel numbers by ADANSA0/1 or ADANSB0/1.
Note 1. ADC12i_ADI (i = 0, 1)
Note 2. ADC12i_GBADI (i = 0, 1)

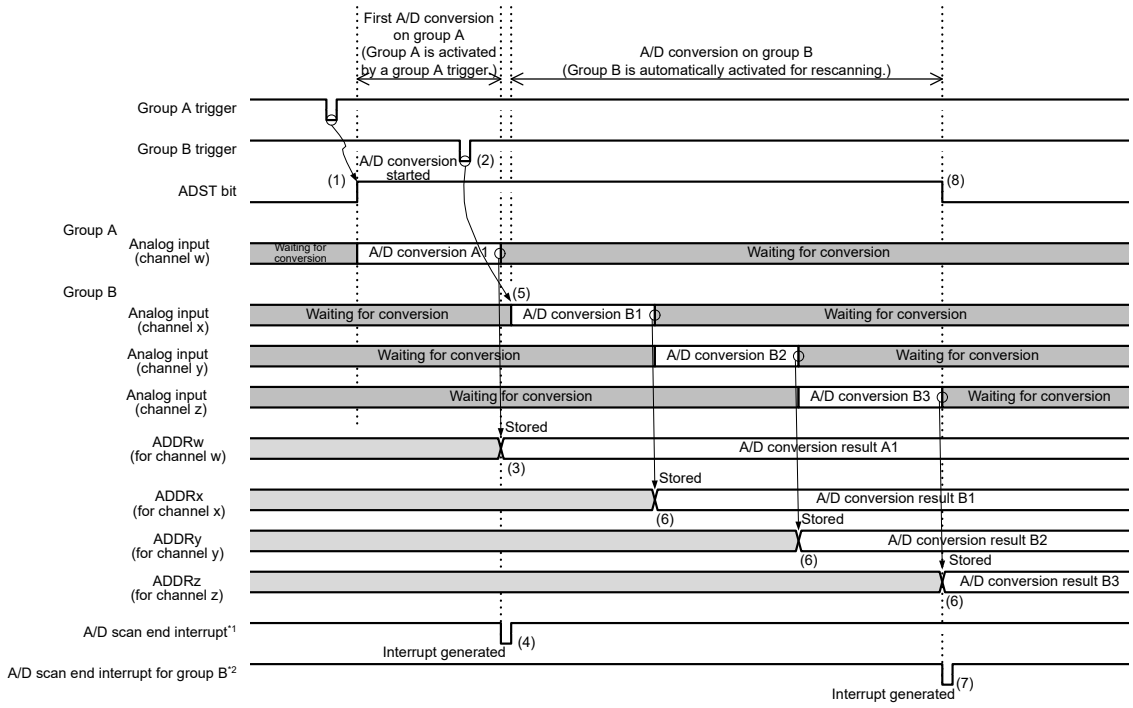
Figure 43.20 Example of group priority operation 1-2: Group A trigger input during rescanning of group B when rescanning is enabled (when ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 0, and ADGSPCR.LGRRS = 0)

Operation example 1-3: “Group B trigger input during group A scan” when rescanning is enabled

The following describes the operation when the setting of the ADGSPCR.GBRSCN bit is 1 (enabling rescanning of the group that was stopped in group priority operation) and a trigger for group B is input during scanning operation for group A.

If the setting of the ADGSPCR.GBRSCN bit is 0, any trigger for group B that is input during scanning operation for group A is invalid.

1. When input of a trigger for group A sets the ADCSR.ADST bit to 1 (starting A/D conversion), A/D conversion for the group A analog input channels selected in the ADANSA0 and ADANSA1 registers starts according to the conversion order from the channel with the smallest number n.
2. When a trigger for group B is input during A/D conversion for group A, group B is ready for A/D conversion.
3. On completion of A/D conversion for each channel in group A, the result is stored in the corresponding A/D Data Register y (ADDRy).
4. An ADC120_ADI interrupt request is generated.
5. When A/D conversion for group A completes, while the ADCSR.ADST bit remains 1, A/D conversion for the group B analog input channels selected in the ADANSB0 and ADANSB1 registers starts according to the conversion order from the channel with the smallest number n.
   (As with the case of operation example 1-1, if a trigger for group A is input during A/D conversion for group B, A/D conversion for group A starts. Then A/D conversion for group B starts upon completion of A/D conversion for group A.)
6. On completion of A/D conversion of a single channel, the result is stored in the corresponding A/D Data Register y (ADDRy).
7. Upon completion of A/D conversion for group B, a group B scan end interrupt request is generated if the setting of the ADCSR.GBADIE bit is 1 (enabling interrupt generation on completion of group B scan).
8. When A/D conversion for all the channels completes, the ADCSR.ADST bit is automatically cleared and the A/D converter enters a wait state.



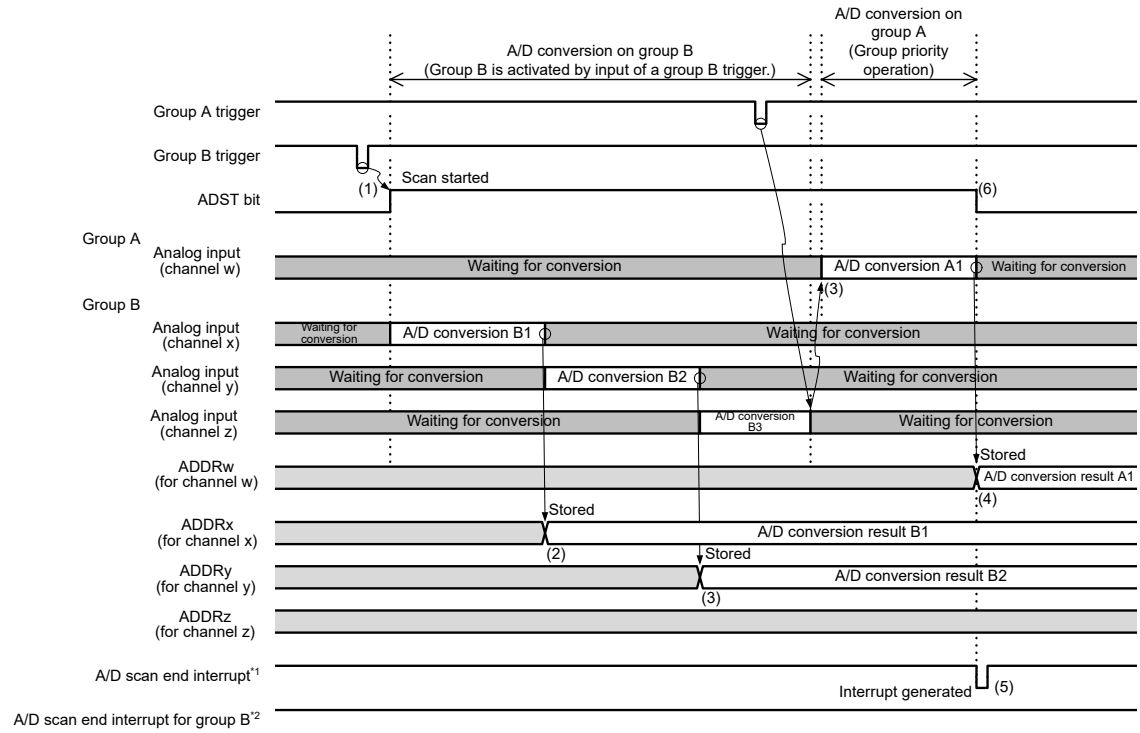
Note: w, x, y, and z (x < y < z) are the selected channel numbers by ADANSA0/1 or ADANSB0/1.
Note 1. ADC12i_ADI (i = 0, 1)
Note 2. ADC12i_GBADI (i = 0, 1)

Figure 43.21 Example of group priority operation 1-3: Group B trigger input during group A scan when rescanning is enabled (when ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 0, and ADGSPCR.LGRRS = 0)

Operation example 1-4 shows the group priority operation in group-scan mode (when ADGSPCR.GBRSCN = 0, ADGSPCR.GBRP = 0, and ADGSPCR.LGRRS = 0).

Operation example 1-4: “Group A trigger input during group B scan” when rescanning is disabled

1. When input of a trigger for group B sets the ADCSR.ADST bit to 1 (starting A/D conversion), A/D conversion for the analog input channels selected in the ADANSB0 and ADANSB1 registers starts according to the conversion order from the channel with the smallest number n.
2. On completion of A/D conversion for each channel in group B, the result is stored in the corresponding A/D Data Register y (ADDRy).
3. When a trigger for group A is input during A/D conversion for group B, A/D conversion for group B stops while the ADCSR.ADST bit remains 1, and then A/D conversion for the group A analog input channels selected in the ADANSA0 and ADANSA1 registers starts according to the conversion order from the channel with the smallest number n. If A/D conversion stops before it is completed, the conversion result is not stored in the A/D Data Register y (ADDRy).
4. On completion of A/D conversion of a single channel, the result is stored in the corresponding A/D Data Register y (ADDRy).
5. On completion of A/D conversion for group A, an ADC120_ADI interrupt request is generated.
6. When A/D conversion for group A completes, the ADCSR.ADST bit is automatically cleared and the A/D converter enters a wait state. A/D conversion for group B is not performed until a trigger for group B is input the next time.



Note: w, x, y, and z (x < y < z) are the selected channel numbers by ADANSA0/1 or ADANSB0/1.
Note 1. ADC12i_ADI (i = 0, 1)
Note 2. ADC12i_GBADI (i = 0, 1)

Figure 43.22 Group priority operation example 1-4: “Group A trigger is input during group B scan” when rescanning is disabled (when ADGSPCR.GBRSCN = 0, ADGSPCR.GBRP = 0, and ADGSPCR.LGRRS = 0)

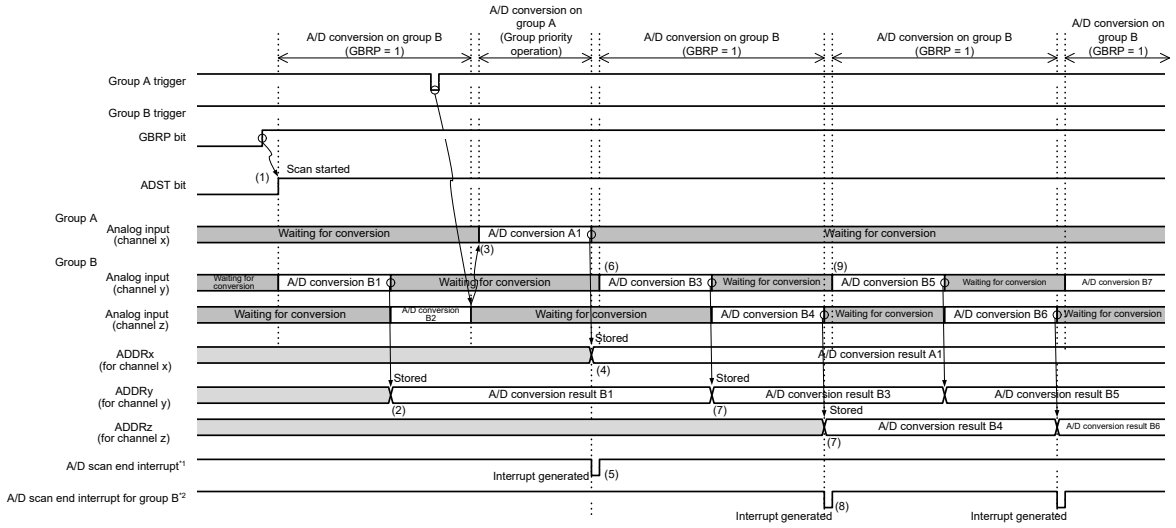
Operation example 1-5 shows the group priority operation in group-scan mode (when ADGSPCR.GBRP = 1, and ADGSPCR.LGRRS = 0).

Operation example 1-5: Continuously activating single-scan operation for group B

1. When ADGSPCR.GBRP = 1 is set, the ADCSR.ADST bit is set to 1 (starting A/D conversion) and A/D conversion for the analog input channels selected in the ADANSB0 and ADANSB1 registers starts according to the conversion order from the channel with the smallest number n.
2. On completion of A/D conversion for each channel in group B, the result is stored in the corresponding A/D Data Register y (ADDRy).
3. When a trigger for group A is input during A/D conversion for group B, A/D conversion for group B stops while the ADCSR.ADST bit remains 1, and then A/D conversion for group A analog input channels selected in the ADANSA0 and ADANSA1 registers starts according to the conversion order zfrom the channel with the smallest number n. If A/D conversion stops before it is completed, the conversion result is not stored in the A/D Data Register y (ADDRy).
4. On completion of A/D conversion of a single channel, the result is stored in the corresponding A/D Data Register y (ADDRy).
5. On completion of A/D conversion for group A, an ADC120_ADI interrupt request is generated.
6. If ADGSPCR.GBRP = 1 is set (performing single scan continuously), A/D conversion for the group B analog input channels selected in the ADANSB0 and ADANSB1 registers restarts according to the conversion order from the channel with the smallest number n while the ADCSR.ADST remains 1 (starting A/D conversion).
7. On completion of A/D conversion of a single channel, the result is stored in the corresponding A/D Data Register y (ADDRy).

8. If the setting of the ADCSR.GBADIE bit is 1 (enabling interrupt generation on completion of group B scan), a group B scan end interrupt request is generated.
9. If ADGSPCR.GBRP = 1 is set (performing single scan continuously), A/D conversion for the group B analog input channels selected in the ADANSB0 and ADANSB1 registers restarts according to the conversion order from the channel with the smallest number n while the ADCSR.ADST remains 1 (starting A/D conversion).

Steps 6 to 9 are repeated as long as the ADGSPCR.GBRP bit remains 1. Do not clear the ADCSR.ADST bit as long as the ADGSPCR.GBRP bit is 1. To forcibly stop A/D conversion while ADGSPCR.GBRP = 1, follow the procedure shown in Figure 43.38.



Note: x, y, and z (y < z) are the selected channel numbers by ADANSA0/1 or ADANSB0/1.
Note 1. ADC12i_ADI (i = 0, 1)
Note 2. ADC12i_GBADI (i = 0, 1)

Figure 43.23 Group priority operation example 1-5: Continuously activating single scan for group B (when ADGSPCR.GBRP = 1 , ADGSPCR.LGRRS = 0)

Note: To continuously activate single-scan operation for group B, disable group B trigger input.

43.3.5 Interleaved Operation

Interleaved operation is that two ADC units convert same one pin alternately in order to obtain the data faster. This function can be used with the channel AN000/AN100, AN001/AN101 or AN002/AN102 and can be used in single scan mode and continuous scan mode. Regarding trigger, synchronous trigger and external trigger are suitable to use. It is recommended to use synchronous trigger with AGT or GPT events in order to ensure AD conversion timing.

43.3.5.1 Trigger Input Timing

Trigger input timing for each ADC unit should be controlled not to overlap each sampling period as shown in Figure 43.24 and Table 43.26. For timing parameter (t_{SPL}, t_{SAM} and t_{SCAN}), see Table 43.27.

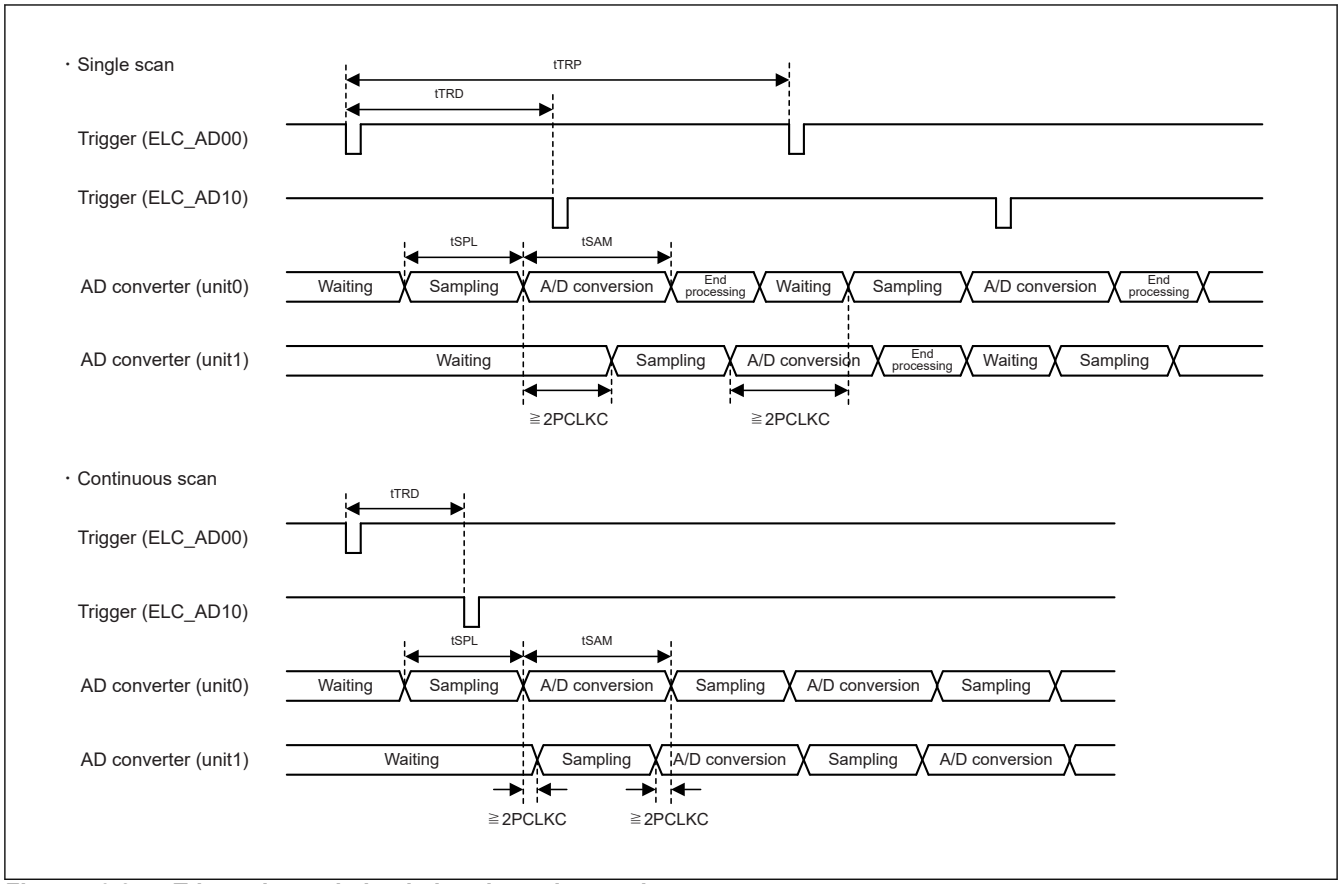


Figure 43.24 Trigger input timing in interleaved operation

Table 43.26 Setting for trigger input timing in interleaved operation

Parameter		Symbol	Min	Max
Trigger issuance delay period	Single scan	t_{TRD}	t_{SPL} + 2PCLKC	t_{TRP} - t_{SPL} - 2PCLKC
	Continuous scan	t_{TRD}	t_{SPL} + 2PCLKC	t_{SAM} - 2PCLKC
Trigger issuance period		t_{TRP}	tSCAN	—

43.3.5.2 Continuous Scan Mode

In this operation, assuming two ADC units are set to the same sampling period and conversion period.

The operation is as follows:

1. When the ADCSR.ADST bit of ADC0 is set to 1 by a synchronous trigger input (ELC) or asynchronous trigger input, A/D conversion of ADC0 is performed for the selected channel.
2. After certain period is elapsed after ADC0 starts (see section 43.3.5.1. Trigger Input Timing), when ADCSR.ADST bit of ADC1 is set to 1 by a synchronous trigger input (ELC) or asynchronous trigger input for the channel which is same analog input pin with ADC0, A/D conversion of ADC1 is performed for the selected channel.
3. A/D conversion of ADC0 completes prior to completion of ADC1. Then ADC120_ADI interrupt request is generated. ADC0 sequentially starts A/D conversion. A/D conversion is continued as long as ADCSR.ADST remains 1.
4. A/D conversion of ADC1 completes after completion of ADC0. Then ADC121_ADI interrupt request is generated. A/D conversion of ADC1 is continued as well as ADC0.

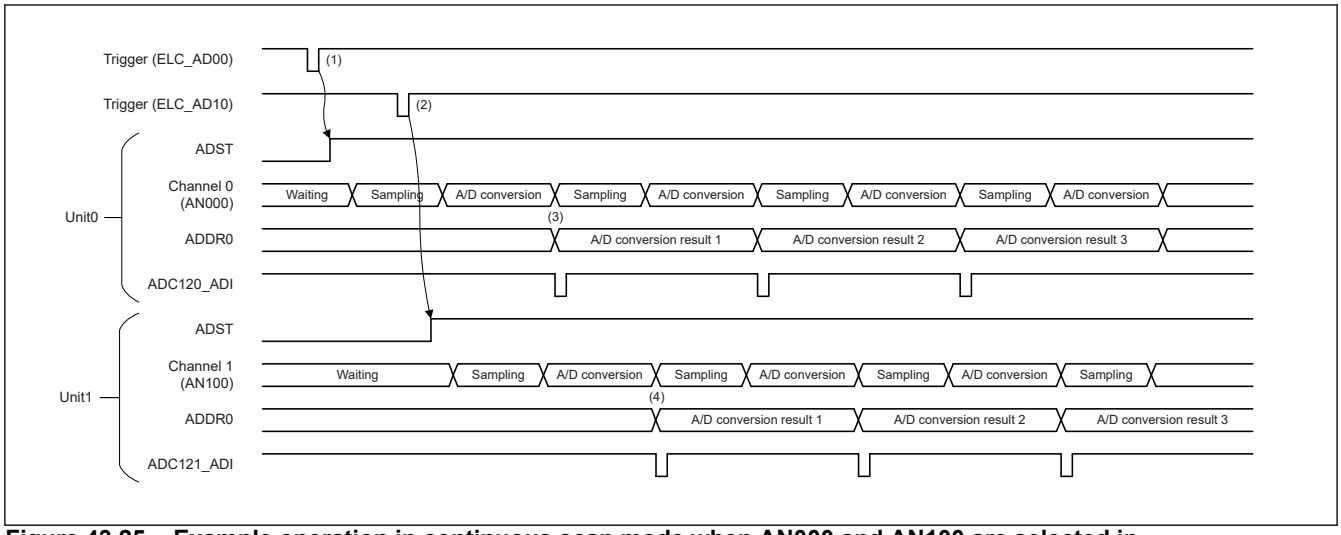

Figure 43.25 Example operation in continuous scan mode when AN000 and AN100 are selected in interleaved operation

43.3.5.3 Single Scan Mode

In this operation, assuming two ADC units are set to the same sampling period and conversion period.

The operation is as follows:

1. When the ADCSR.ADST bit of ADC0 is set to 1 by a synchronous trigger input (ELC) or asynchronous trigger input, A/D conversion of ADC0 is performed for the selected channel.
2. After certain period is elapsed after ADC0 starts (see section 43.3.5.1. Trigger Input Timing), when ADCSR.ADST bit of ADC1 is set to 1 by a synchronous trigger input (ELC) or asynchronous trigger input for the channel which is same analog input pin with ADC0, A/D conversion of ADC1 is performed for the selected channel.
3. A/D conversion of ADC0 completes prior to completion of ADC1. Then ADC120_ADI interrupt request is generated.
4. When A/D conversion of ADC0 completes, ADCSR.ADST bit is automatically cleared to 0. Then ADC120 enters a wait state.
5. Restart A/D conversion of ADC0. Let the sampling starts during conversion period of ADC1.
6. A/D conversion of ADC1 completes after the restart of ADC0. Then ADC121_ADI interrupt request is generated.
7. When A/D conversion of ADC1 completes, ADCSR.ADST bit is automatically cleared to 0. Then ADC121 enters a wait state.
8. Restart A/D conversion of ADC1. Let the sampling starts during conversion period of ADC0.

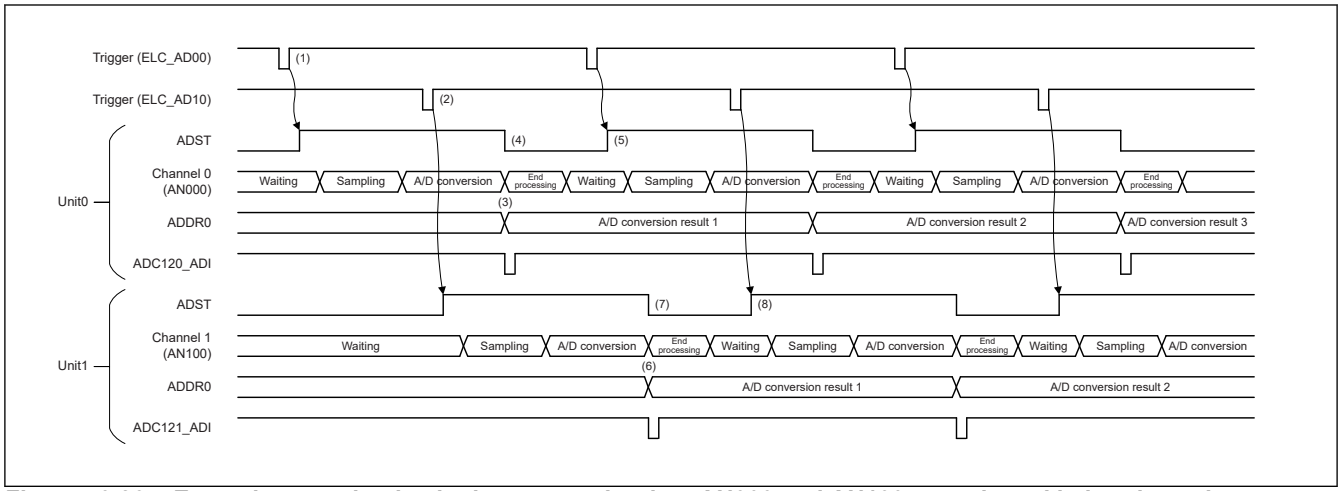

Figure 43.26 Example operation in single scan mode when AN000 and AN100 are selected in interleaved operation

43.3.5.4 Single Scan Mode with Extended Double-Trigger Mode

In this operation, assuming two ADC units are set to the same sampling period and conversion period.

For details of operation in extended double-trigger mode, see section 43.3.2.5. Extended Operations When Double-Trigger Mode Is Selected.

This operation can decimate period of interrupt generation and the conversion data can be read in consecutive address with ADDBLDRA and ADDBLDRB register.

The operation is as follows:

1. When the ADCSR.ADST bit of ADC0 is set to 1 by a synchronous trigger input (ELC_AD00), A/D conversion starts on the single channel selected in the ADCSR.DBLANS[4:0] bits.
2. After certain period is elapsed after ADC0 starts (see section 43.3.5.1. Trigger Input Timing), when ADCSR.ADST bit of ADC1 is set to 1 by a synchronous trigger input (ELC_AD10) for the channel which is same analog input pin with ADC0, A/D conversion of ADC1 starts for the selected channel.
3. A/D conversion of ADC0 completes prior to completion of ADC1. The A/D conversion result is stored in the ADC0's associated A/D Data Register y (ADDRy) and in A/D Data Duplexing Register A (ADDBLDRA).
4. The ADCSR.ADST bit is automatically cleared to 0 and the ADC120 enters a wait state. An ADC120_ADI interrupt request is not generated.
5. Restart A/D conversion of ADC0 by a synchronous trigger input (ELC_AD01). Let the sampling starts during conversion period of ADC1.
6. A/D conversion of ADC1 completes. The A/D conversion result is stored in the ADC1's associated A/D Data Register y (ADDRy) and in A/D Data Duplexing Register A (ADDBLDRA).
7. The ADCSR.ADST bit is automatically cleared to 0 and the ADC121 enters a wait state. An ADC121_ADI interrupt request is not generated.
8. Restart A/D conversion of ADC1 by a synchronous trigger input (ELC_AD11). Let the sampling starts during conversion period of ADC0.
9. A/D conversion of ADC0 completes. The A/D conversion result is stored in the ADC0's A/D Data Duplexing Register (ADDBLDR) and in A/D Data Duplexing Register B (ADDBLDRB).
10. The ADCSR.ADST bit is automatically cleared to 0 and the ADC120 enters a wait state. An ADC120_ADI interrupt request is generated.
11. Restart A/D conversion of ADC0 by a synchronous trigger input (ELC_AD00). Let the sampling starts during conversion period of ADC1.
12. A/D conversion of ADC1 completes. The A/D conversion result is stored in the ADC1's A/D Data Duplexing Register (ADDBLDR) and in A/D Data Duplexing Register B (ADDBLDRB).
13. The ADCSR.ADST bit is automatically cleared to 0 and the ADC121 enters a wait state. An ADC121_ADI interrupt request is generated.
14. Restart A/D conversion of ADC1 by a synchronous trigger input (ELC_AD10). Let the sampling starts during conversion period of ADC0.

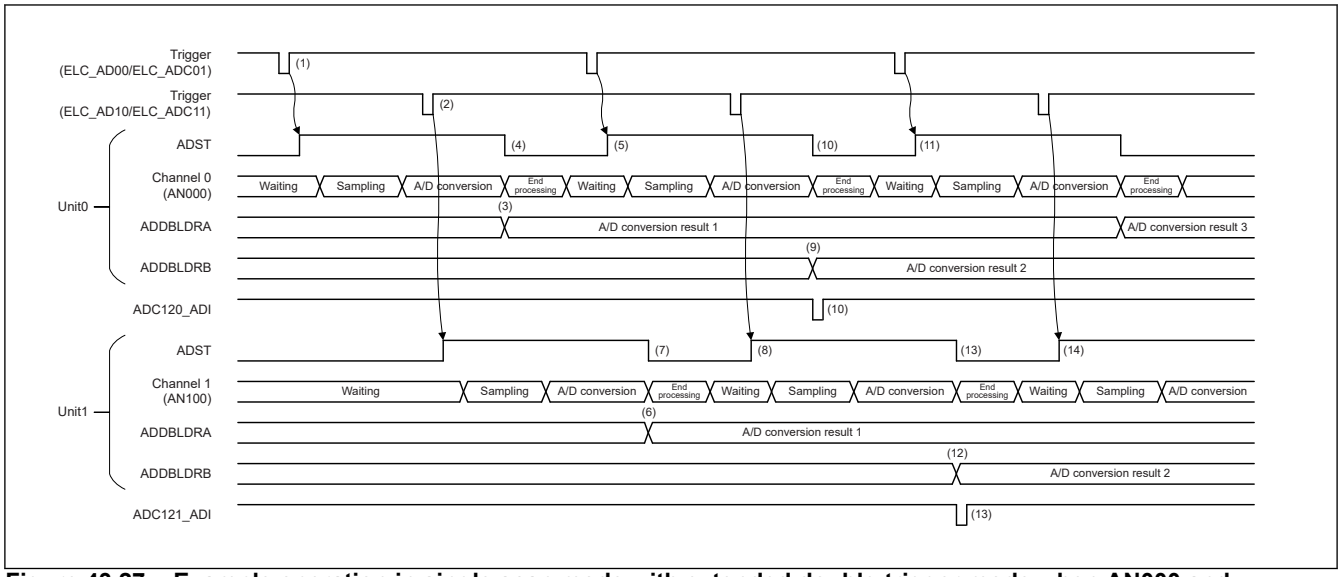

Figure 43.27 Example operation in single scan mode with extended double-trigger mode when AN000 and AN100 are selected in interleaved operation

43.3.6 Compare Function for Windows A and B

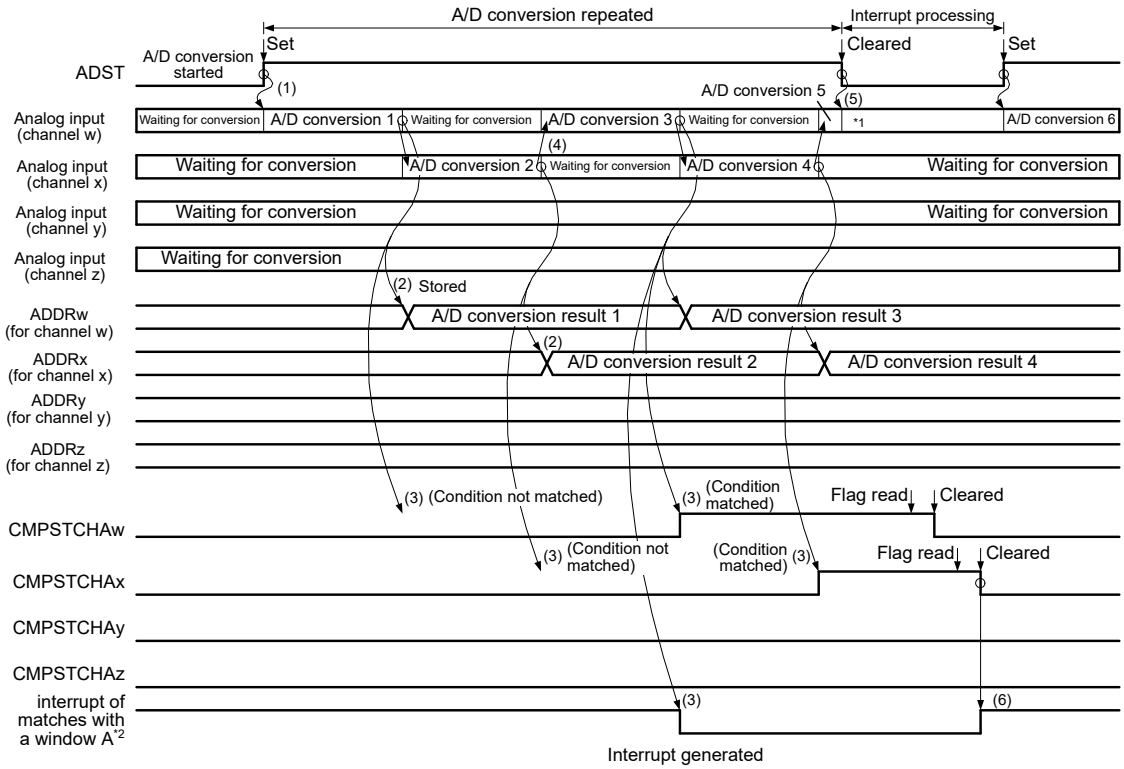
43.3.6.1 Compare Function Windows A and B

The compare function compares a reference value with the A/D conversion result. The reference value can be set for Window A and Window B independently. When the compare function is in use, the self-diagnosis function and double trigger mode cannot be used. The main differences between Window A and Window B are their different interrupt output signals and the constraint on Window B of only one selectable channel.

This section provides an example operation that combines continuous scan mode and the compare function.

The operation is as follows:

1. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by software, a synchronous trigger (ELC) or an asynchronous trigger, A/D conversion starts in the order of the selected channels , temperature sensor, and internal reference voltage.
2. On completion of A/D conversion, the A/D conversion result is stored in the associated A/D Data Register y (ADDRy, ADTSDR, or ADOCDR). When ADCMPCR.CMPAE = 1, if bits in the ADCMPANSRy register or the ADCMPANSER register are set for Window A, the A/D conversion result is compared with the set ADCMPDR0/1 register value. When ADCMPCR.CMPBE = 1, if bits in the ADCMPBNSR register are set for Window B, the A/D conversion result is compared with the ADWINULB/ADWINLLB register setting.
3. As a result of the comparison, when Window A meets the condition set in ADCMPLR0/1 or ADCMPLER, the Compare Window A Flag (ADCMPSR0.CMPSTCHAn, ADCMPSR1.CMPSTCHAn, ADCMPSER.CMPSTTSA or ADCMPSER.CMPSTOCA) sets 1. At this time, if the ADCMPCR.CMPAIE bit is 1, an ADC12i_CMPAI (i = 0, 1) interrupt request is generated. In the same way, when Window B meets the condition set in ADCMPBNSR.CMPLB, the Compare Window B Flag (ADCMPBSR.CMPSTB) sets to 1. At this time, if the ADCMPCR.CMPBIE bit is 1, an ADC12i_CMPBI (i = 0, 1) interrupt request is generated.
4. On completion of all selected A/D conversions and comparisons, scan restarts.
5. After the ADC12i_CMPAI (i = 0, 1) and ADC12i_CMPBI (i = 0, 1) interrupts are accepted, the ADCSR.ADST bit is set to 0 (A/D conversion stop) and processing is performed for channels for which the compare flag is set to 1.
6. When all compare flags of Window A are cleared, the ADC12i_CMPAI (i = 0, 1) interrupt request is canceled. In the same way, when all compare flags of Window B are cleared, the ADC12i_CMPBI (i = 0, 1) interrupt request is reset. To perform comparison again, restart the A/D conversion.



Note: w, x, y, and z (w < x < y < z) are the selected channel numbers by ADANSA0/1.
Note 1. Data on conversion is ignored.
Note 2. ADC12i_CMPAI (i = 0, 1)

Figure 43.28 Example of compare function operation, when the analog inputs (channel w to z) are compared

43.3.6.2 Event Output of Compare Function

The event output of the compare function specifies the upper-side reference voltage value and the lower-side reference voltage value for window A and window B, respectively. The output compares the A/D converted value of the selected channel with the upper and lower side reference voltage value and outputs events (ADC12i_WCMPM (i = 0, 1)/ ADC12i_WCMPUM (i = 0, 1)) based on event conditions (A or B, A and B, A xor B) and comparison result of window A and window B.

If more than one channel is selected for window A, and even when one channel in window A meets the comparison condition, the comparison result of window A is met. When using this function, perform A/D conversion in single scan mode.

Any channels from analog input, internal reference voltage, and temperature sensor output are selectable for window A.

One channel from analog input, internal reference voltage, and temperature sensor output is selectable for window B.

The following sequence is an example of how to set up and use the event output of the compare function:

1. Confirm that the value in the ADCSR.ADCS bits is 00b (single scan mode).
2. Select the channel for window A in the ADCMPANSR0/1 and ADCMPANSER registers. Set the window comparison conditions in the ADCMPLR0/1 and ADCMPLER registers. Set the upper-side and lower-side reference values in the ADCMPDR0/1 registers.
3. Select the channel and comparison conditions for Window B in the ADCMPBNSR register, and set the upper and lower reference values in the ADWINULB and ADWINLLB registers.
4. Set the composite conditions for window A/B, window A/B operation enable, and interrupt output enable in the ADCMPCR register.

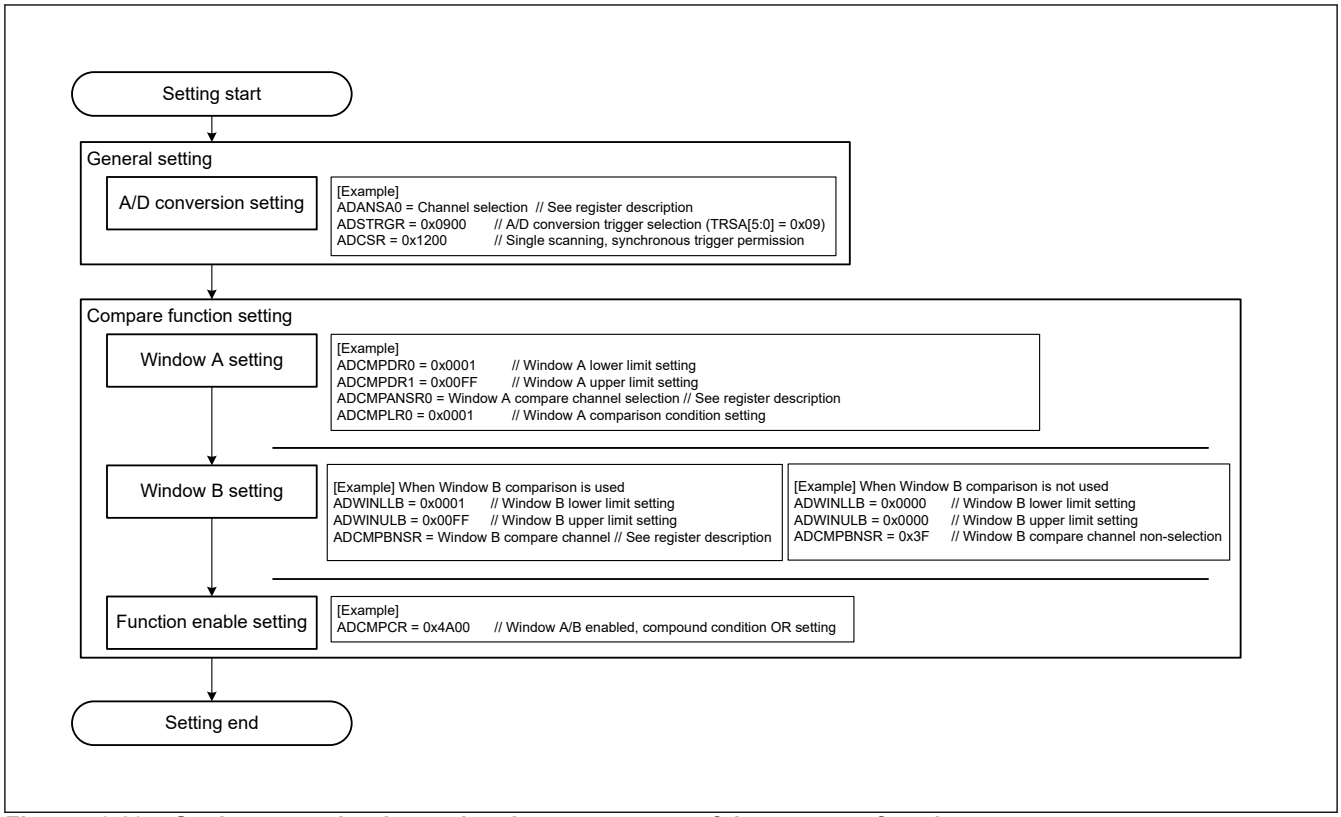


Figure 43.29 Setting example when using the event output of the compare function

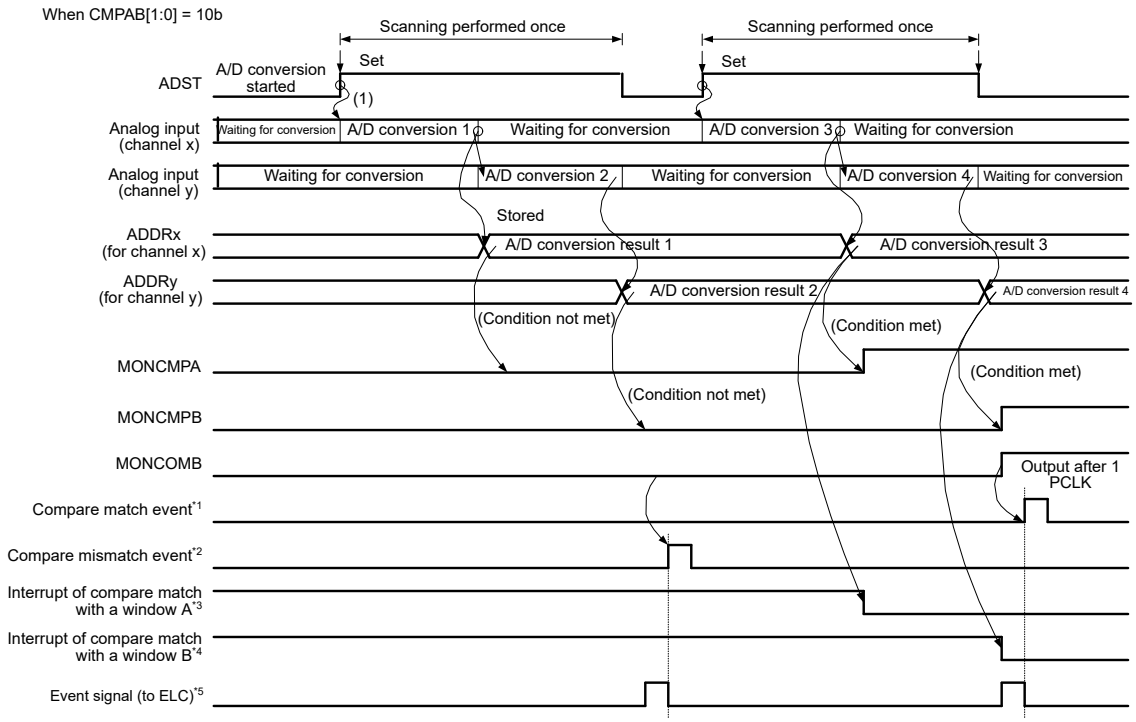
For event output usage when using only window A for the compare function, note the following:

- Enable both Window A and Window B (ADCMPCR.CMPAE = 1, ADCMPCR.CMPBE = 1)
- Set the compound condition of Window A and Window B to “OR condition” (ADCMPCR.CMPAB[1:0] = 00b)
- Set the compared channel of Window B to “No selection” (ADCMPBNSR.CMPCHB[5:0] = 0x3F)
- Set the compare condition of Window B to “0 < results < 0 always means mismatch”. (ADCMPCR.WCMPE = 1, ADWINLLB[15:0] = ADWINULB[15:0] = 0x0000, and ADCMPBNSR.CMPLB = 1)

Figure 43.30 shows the event output operation example of compare function.

A scan end event (ADC12i_ADI (i = 0, 1)) is output with the same timing as single scan completion. A match or mismatch event (ADC12i_WCMPM (i = 0, 1)/ADC12i_WCMPUM (i = 0, 1)) is output with 1 PCLKA cycle delay depending on the ADCMPCR.CMPAB[1:0] settings.

Note: The match and mismatch events are exclusive, so both events are never output simultaneously.



Note: x, and y (x < y) are the selected channel numbers by ADANSA0/1.
Note 1. ADC12i_WCMPM (i = 0, 1)
Note 2. ADC12i_WCMPUM (i = 0, 1)
Note 3. ADC12i_CMPAI (i = 0, 1)
Note 4. ADC12i_CMPBI (i = 0, 1)
Note 5. ADC12i_ADI (i = 0, 1)

Figure 43.30 Example operation of the compare function event output, when the analog inputs (channel x and y) are compared

Note: Event output of compare function outputs match/mismatch from the comparison results of Window A and Window B, based on the ADCMPCR.CMPAB[1:0] settings.

Note: The comparison result of Window A is the logical addition of the comparison results of the comparison target channels of Window A. The comparison results of Window A and Window B are updated by each A/D conversion, and are kept even when single scan ends. Set ADCMPCR.CMPAE and ADCMPCR.CMPBE to 0 to clear the comparison results to 0.

43.3.6.3 Restrictions on Compare Function

The following constraints apply for the compare function:

- The compare function cannot be used together with the self-diagnosis function or double-trigger mode. (The compare function is not available for ADRD, ADDBLDR, ADDBLDRA, and ADDBLDRB.)
- Specify single scan mode when using match/mismatch event outputs.
- When the temperature sensor output, internal reference voltage is selected for Window A, Window B operations are prohibited.
- When the temperature sensor output, internal reference voltage is selected for Window B, Window A operations are prohibited.
- Setting the same channel for Window A and Window B is prohibited.
- Set the reference voltage values so that the high-potential reference voltage value is equal to or larger than the low potential reference voltage value.

43.3.7 Analog Input Sampling and Scan Conversion Time

Scan conversion can be activated either by a software trigger, a synchronous trigger (ELC), or an asynchronous trigger (ADTRGn (n = 0, 1)). After the start-of-scanning-delay time (t_D) has elapsed, processing for disconnection detection assistance, and processing of conversion for self-diagnosis all proceed, followed by processing for A/D conversion.

Figure 43.31 shows the scan conversion timing, in which scan conversion is activated by a software trigger or a synchronous trigger (ELC). Figure 43.32 shows the scan conversion timing, in which scan conversion is activated by an asynchronous trigger (ADTRGn (n = 0, 1)). The scan conversion time (t_{SCAN}) includes the start-of-scanning-delay time (t_D), disconnection detection assistance processing time (t_{DIS})*1, self-diagnosis A/D conversion processing time (t_{DIAG} and t_{DSD})*2, A/D conversion processing time (t_{CONV}), and end-of-scanning-delay time (t_{ED}).

The A/D conversion processing time (t_{CONV}) consists of input sampling time (t_{SPL}) and time for conversion by successive approximation (t_{SAM}). The sampling time (t_{SPL}) is used to charge sample-and-hold circuits in the A/D converter. If there is not sufficient sampling time due to the high impedance of an analog input signal source, or if the A/ D conversion clock (ADCLK) is slow, sampling time can be adjusted using the ADSSTRn register.

The time for conversion by successive approximation (t_{SAM}) is the following

- 13 ADCLK states with 12-bit accuracy selected.
- 11 ADCLK states with 10-bit accuracy selected.
- 9 ADCLK states with 8-bit accuracy selected.

Table 43.27 shows the time for conversion by successive approximation (t_{SAM}).

The scan conversion time (t_{SCAN}) in single scan mode for which the number of selected channels is n can be determined as follows:

$$t_{SCAN} = t_D + (t_{DIS} \times n) + t_{DIAG} + t_{ED} + (t_{CONV} \times n)$$ *3

The scan conversion time for the first cycle in continuous scan mode is t_{SCAN} for single scan minus t_{ED} . The scan conversion time for the second and subsequent cycles in continuous scan mode is fixed in the following:

$$(t_{DIS} \times n) + t_{DIAG} + t_{DSD} + (t_{CONV} \times n)$$ *3

Note 1. When disconnection detection assistance is not selected, t_{DIS} = 0.

Only when the temperature sensor or internal reference voltage is A/D-converted, the auto-discharge period of 15 ADCLK states is inserted.

Note 2. When the self-diagnosis function is not used, t_{DIAG} = 0, t_{DSD} = 0.

Note 3. When input sampling times (t_{SPL}) of all selected channels are the same, this element equals t_{CONV} × n. If each channel has a different sampling time, this element equals that of t_{SPL} and t_{SAM} set to each selected channel.

Table 43.27 shows the times for conversion during scanning.

Table 43.27 Conversion times during scanning (in numbers of cycles of ADCLK and PCLKA)

Item			Symbol		Type/Conditions			Unit
					Synchronous trigger*4	Asynchronous trigger	Software trigger	
Scan start processing time*1 *2	A/D conversion on group A under group A priority control.	Group B is to be stopped (Group A is activated after group B is stopped by of an A/D conversion source from group A).	t_D		3 PCLKA + 6 ADCLK 5 PCLKA + 3 ADCLK*5	—	—	Cycles
		Group B is not to be stopped (activation by an A/D conversion source from group A).			2 PCLKA + 4 ADCLK	—	—	
	A/D conversion when self-diagnosis is enabled.	A/D conversion for self-diagnosis is to be started.			2 PCLKA + 6 ADCLK	4 PCLKA + 6 ADCLK	6 ADCLK	
	All other				2 PCLKA + 4 ADCLK	2 PCLKA + 4 ADCLK	4 ADCLK	
Disconnection detection assistance processing time			t_{DIS}		Setting in ADNDIS[3:0] (initial value = 0x0) × ADCLK			
Self-diagnosis conversion processing time*1	Sampling time		t_{DIAG}	t_{SPL}	Setting in ADSSTR00 (initial value = 0x0B) × ADCLK*3	—	—	
	Time for conversion by successive approximation	12-bit conversion accuracy		t_{SAM}	15 ADCLK	—	—	
		10-bit conversion accuracy			13 ADCLK	—	—	
		8-bit conversion accuracy			11 ADCLK	—	—	
	Wait time between self-diagnosis conversion end and analog channel sampling start.			t_{DED}	2 ADCLK			
	Wait time between last channel conversion end and self-diagnosis sampling start in continuous scan mode.		t_{DSD}		2 ADCLK			
A/D conversion processing time*1	Sampling time		t_{CONV}	t_{SPL}	Setting in ADSSTRn (n = 0 to 10, 12, 13(unit 0), 0 to 2(unit 1), L, T, O) (initial value = 0x0B) × ADCLK + 0.5 ADCLK			
	Time for conversion by successive approximation	12-bit conversion accuracy		t_{SAM}	13 ADCLK			
		10-bit conversion accuracy			11 ADCLK			
		8-bit conversion accuracy			9 ADCLK			
Scan end processing time*1			t_{ED}		1 PCLKA + 3 ADCLK 2 PCLKA + 3 ADCLK*5			

Note 1. See Figure 43.31 and Figure 43.32 for an illustration of times t_D, t_{SPLSH}, t_{DIAG}, t_{CONV}, and t_{ED}.
Note 2. This is the maximum time required from software writing or trigger input to A/D conversion start.
Note 3. The sampling time setting must satisfy the electrical characteristics.
Note 4. This does not include the time consumed in the path from timer output to trigger input.
Note 5. If ADCLK is faster than PCLKA (PCLKA to ADCLK frequency ratio = 1:2 or 1:4), the scan end processing time changes.

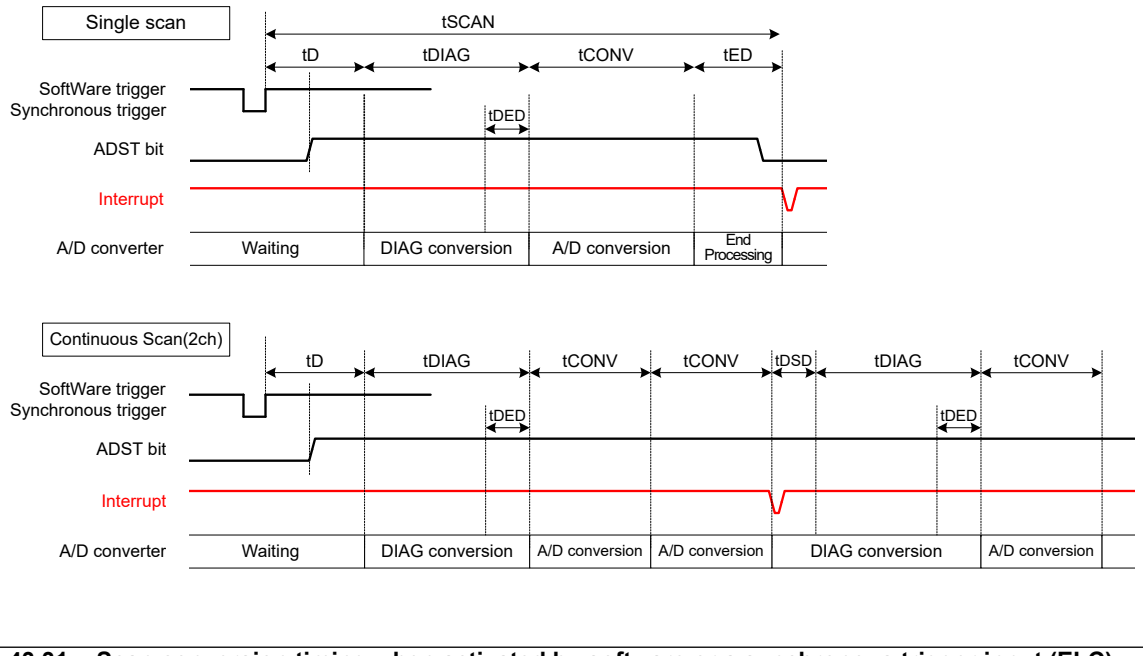


Figure 43.31 Scan conversion timing when activated by software or a synchronous trigger input (ELC)

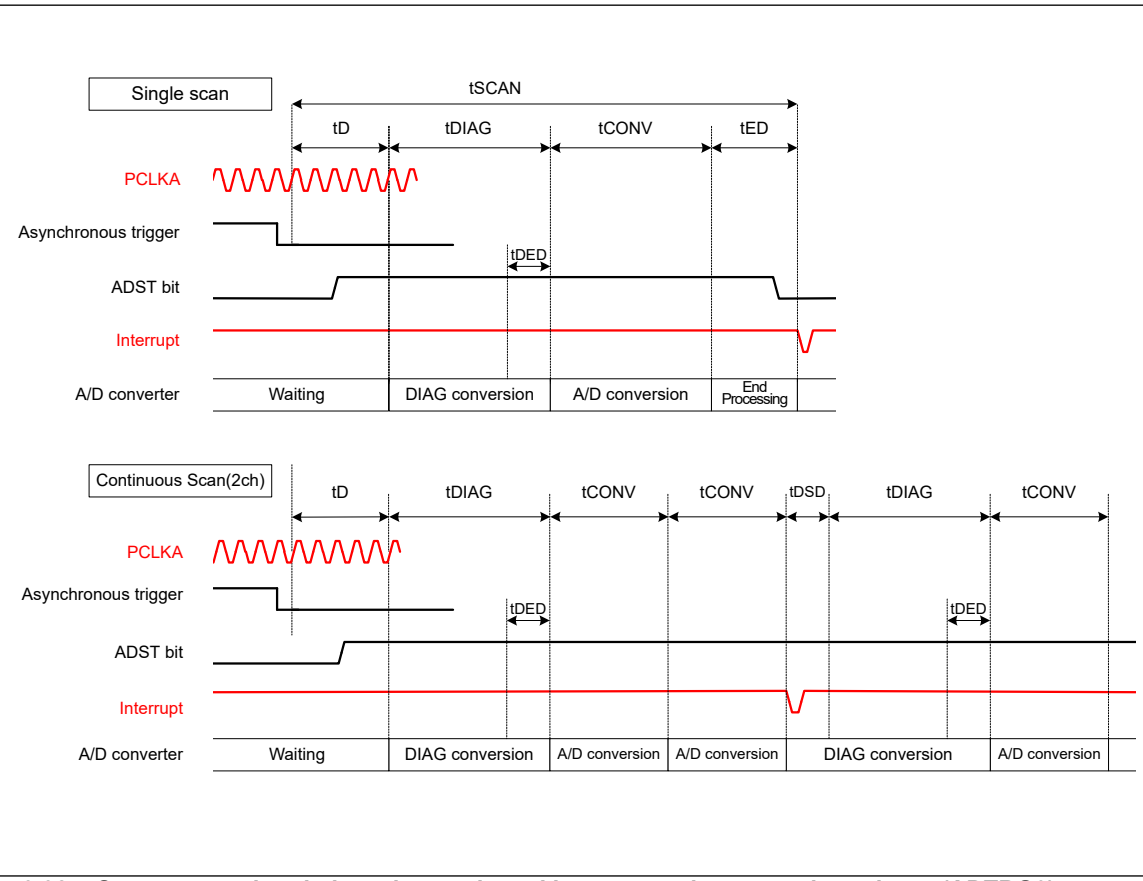

Figure 43.32 Scan conversion timing when activated by an asynchronous trigger input (ADTRG0)

43.3.8 Usage Example of A/D Data Register Automatic Clearing Function

Setting the ADCER.ACE bit to 1 automatically clears the A/D data registers (ADDRy, ADRD, ADDBLDR, ADDBLDRA, ADDBLDRB, ADTSDR, ADOCDR) to 0x0000 when the A/D data registers are read by the CPU or DTC or DMAC.

This function enables detection of update failures of the A/D data registers (ADDRy, ADRD, ADDBLDR, ADDBLDRA, ADDBLDRB, ADTSDR, ADOCDR). This section describes examples in which the function to automatically clear the ADDRy register is enabled and disabled.

- If the ADCER.ACE bit is 0 (automatic clearing is disabled) and for some reason, if the A/D conversion result (0x0222) is not written to the ADDRy register, the ADDRy value retains the old data (0x0111). In addition, if this ADDRy value is read into a general-purpose register using an A/D scan end interrupt, the old data (0x0111) can be saved in the general-purpose register. When checking whether there is an update failure, it is necessary to frequently save the old data in SRAM or in a general-purpose register.
- If the ADCER.ACE bit is 1 (automatic clearing is enabled), when ADDRy = 0x0111 is read by the CPU or DTC or DMAC, ADDRy is automatically set to 0x0000. Next, if the A/D conversion result of 0x0222 cannot be transferred to ADDRy for some reason, the cleared data (0x0000) remains as the ADDRy value. If this ADDRy value is read into a general-purpose register using an A/D scan end interrupt, 0x0000 is saved in the general-purpose register. Occurrence of an ADDRy update failure can be determined by checking that the read data value is 0x0000.

43.3.9 A/D-Converted Value Addition/Average Mode

A/D-converted value addition/average mode can be used when A/D conversion of the analog input of the selected channels, the temperature sensor output, the internal reference voltage is selected.

In A/D-converted value addition mode, the same channel is A/D-converted 1, 2, 3, 4, or 16 consecutive times, and the sum of the converted values is stored in the data register. The conversion count of the addition function can be set to 16 only when 12-bit accuracy is selected. In A/D-converted value average mode, the same channel is A/D-converted 2 or 4 consecutive times, and the mean of the converted values is stored in the data register. The use of the average of these results can improve the accuracy of A/D conversion, depending on the types of noise components that are present. This function, however, cannot always guarantee an improvement in A/D conversion accuracy.

The A/D-converted value addition/average function can be used when A/D conversion of the analog inputs of the selected channels or A/D conversion of the temperature sensor output or A/D conversion of the internal reference voltage is selected. The A/D-converted value addition/average function can also be used for channels for which the double-trigger function is selected.

The addition function for self-diagnosis is not provided.

43.3.10 Disconnection Detection Assist Function

The ADC12 incorporates a function to fix the charge for sampling capacitance to the specified state (VREFH0 or VREFL0 for unit 0, VREFH or VREFL for unit 1) before the start of A/D conversion. This function enables disconnection detection in wiring of analog inputs.

Figure 43.33 shows the A/D conversion operation when the disconnection detection assist function is used. Figure 43.34 shows an example of disconnection detection when precharge is selected. Figure 43.35 shows an example of disconnection detection when discharge is selected.

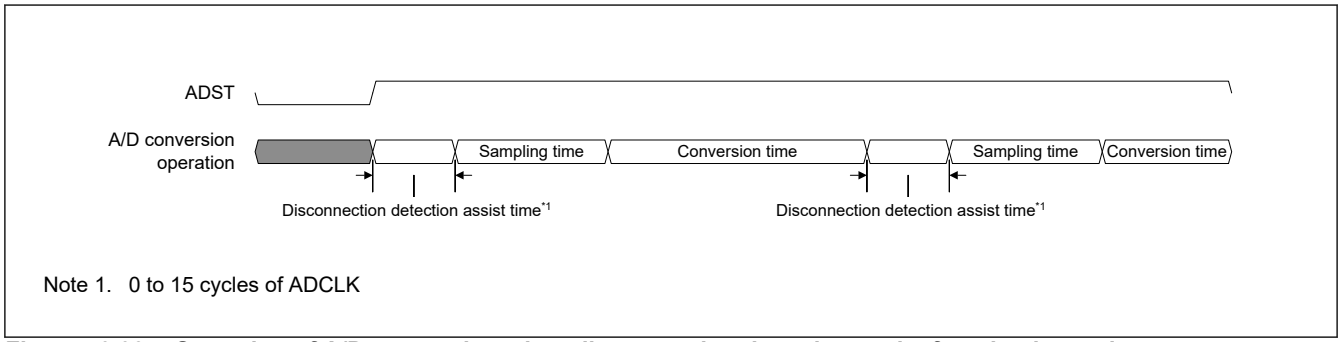

Figure 43.33 Operation of A/D conversion when disconnection detection assist function is used

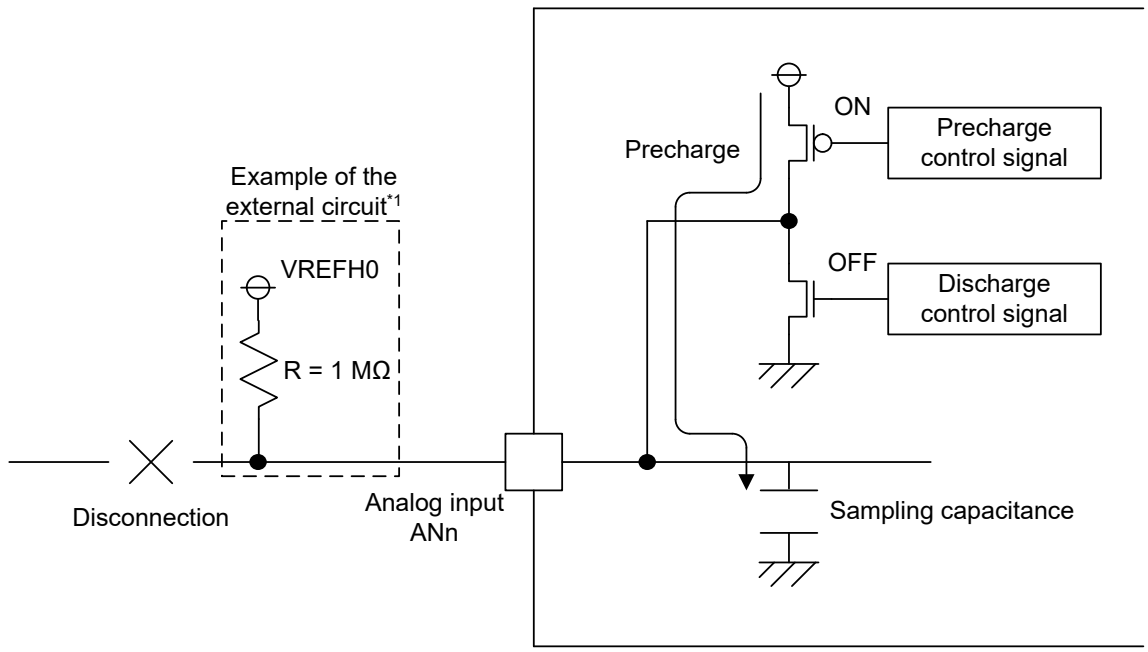
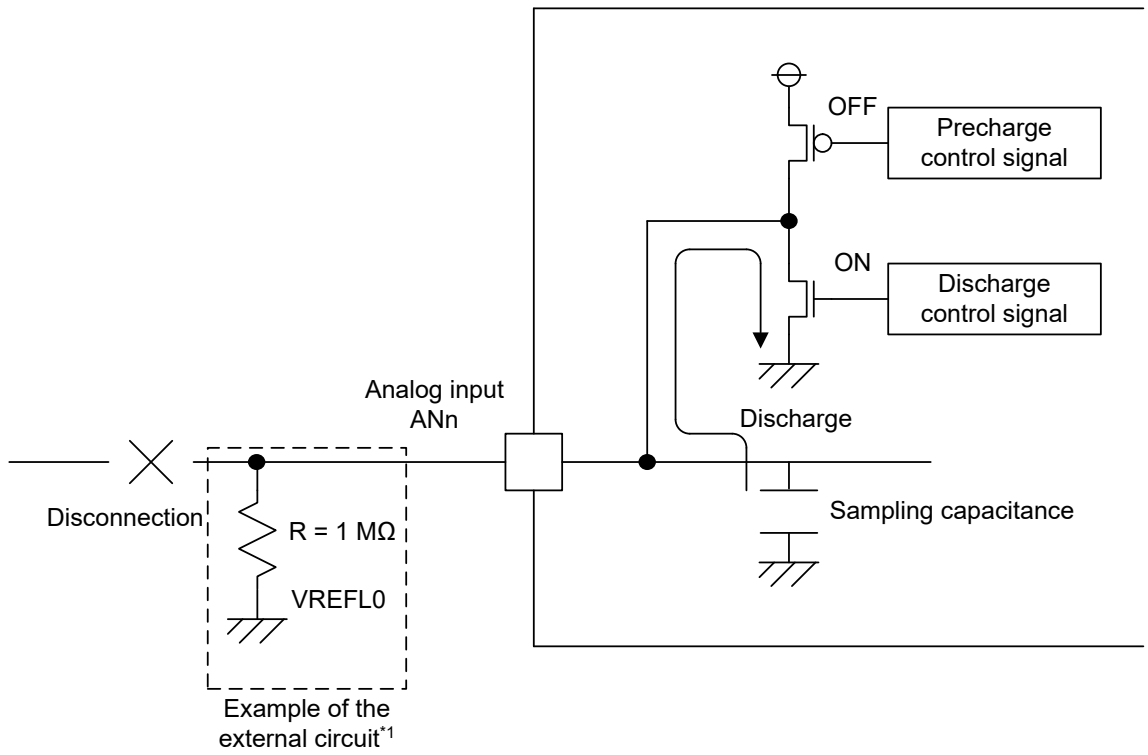


Note 1. The converted result should be used after it is fully evaluated because the result data when disconnection occurs varies depending on the external circuit.

Figure 43.34 Example of disconnection detection when precharge is selected



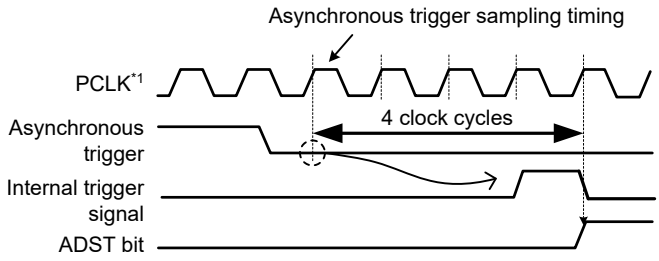
Note 1. The converted result should be used after it is fully evaluated because the result data when disconnection occurs varies depending on the external circuit.

Figure 43.35 Example of disconnection detection when discharge is selected

43.3.11 Starting A/D Conversion with an Asynchronous Trigger

A/D conversion can be started by the input of an asynchronous trigger. To start A/D conversion by an asynchronous trigger, set the pin function in the PmnPFS register, set the A/D Conversion Start Trigger Select bits (ADSTRGR.TRSA[5:0]) to 0x00, then input a high-level signal to the asynchronous trigger (ADTRGn (n = 0, 1) pin). Finally, set both the ADCSR.TRGE and ADCSR.EXTRG bits to 1. Figure 43.36 shows timing of the asynchronous trigger input.

An asynchronous trigger cannot be selected in the A/D conversion start trigger for group B used in group scan mode. For details on setting the pin function, see section 19, I/O Ports.



Note 1. PCLKA

Figure 43.36 Asynchronous trigger input timing

43.3.12 Starting A/D Conversion with a Synchronous Trigger from a Peripheral Module

A/D conversion can be started by a synchronous trigger (ELC). To do this, set the ADCSR.TRGE bit to 1 and the ADCSR.EXTRG bit to 0, and select the relevant sources in the ADSTRGR.TRSA[5:0] bits and ADSTRGR.TRSB[5:0] bits.

43.3.13 Using Data Buffers

This IP is provided with a ring buffer function consisting of 16 A/D data buffers. This function sequentially stores A/D conversion results other than self-diagnosis result (including addition/average results) in data buffers (ADBUFn, n = 0 to 15).

Each conversion result is stored at the timing when the A/D conversion result is stored in the data register, and most recent 16 conversion result data are retained.

The figure-below shows the schematic of data buffers, pointer, and overflow flag operations. When the BUFEN bit is set to 1, the A/D conversion result is transferred at each end of A/D conversion. The pointer indicates the number of data buffer to which the next transferred data is to be written. When data is written to up to buffer 15, the pointer is reset to 0000b and the overflow flag is set to 1. Subsequently transferred data overwrites the previously written data.

The overflow flag is reset to the initial value by writing 0x00 to the ADBUFPTR register.

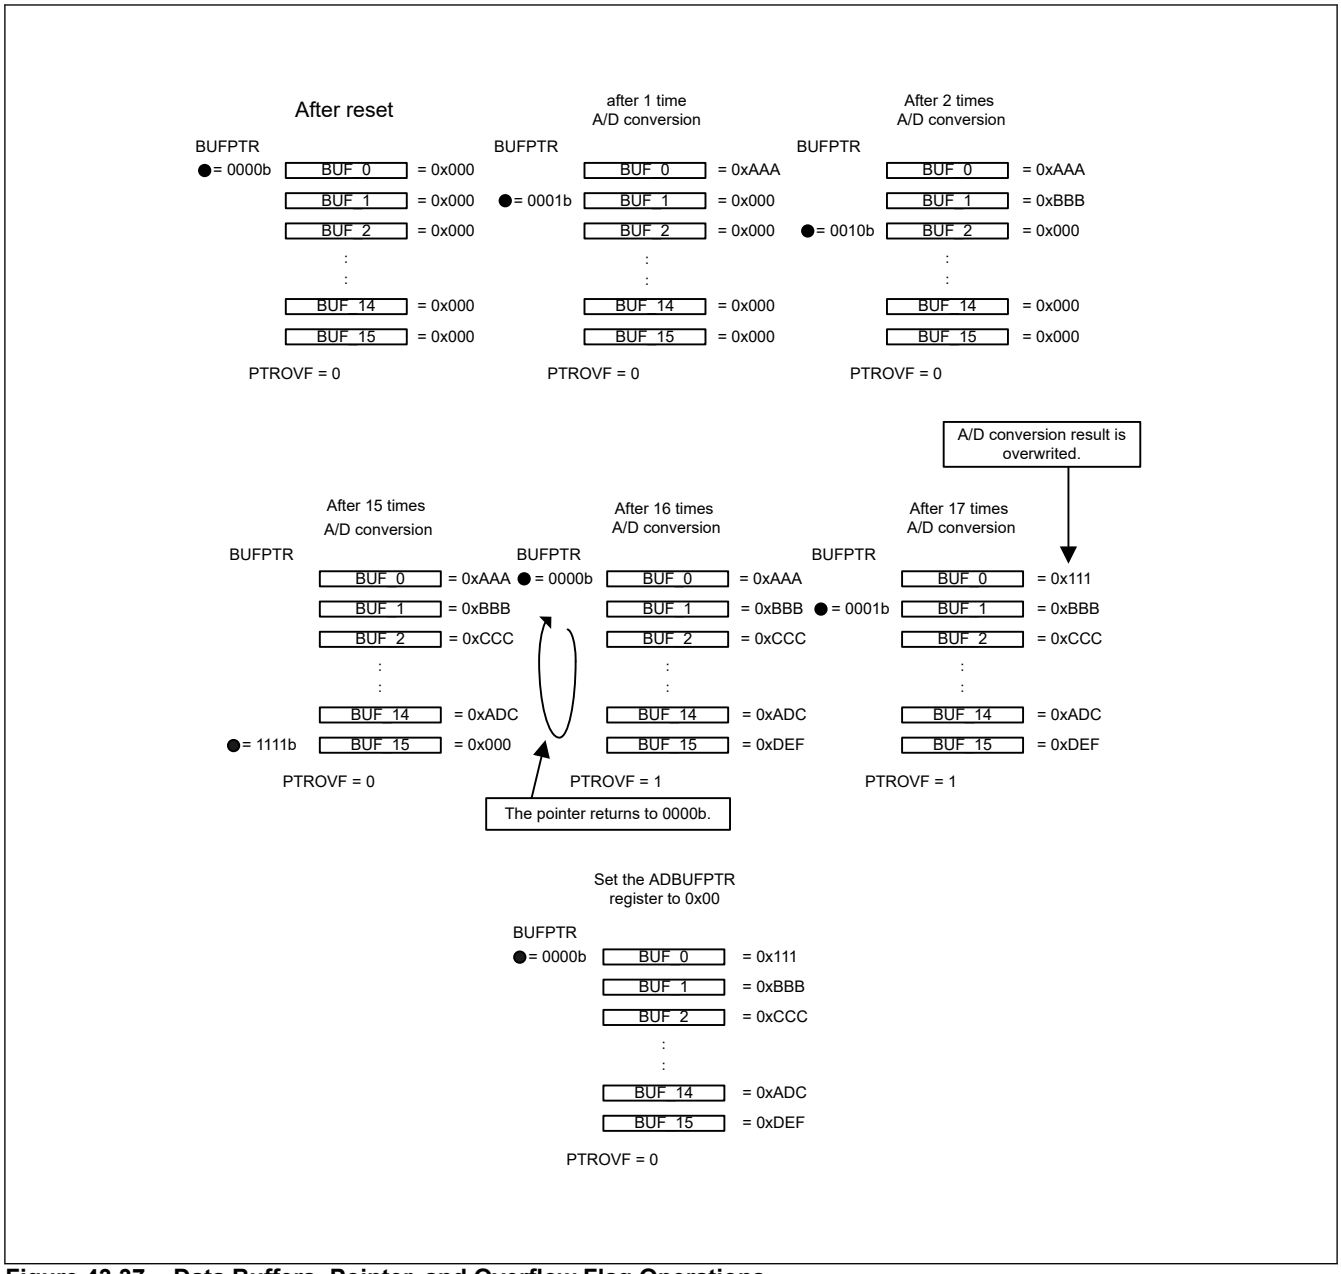


Figure 43.37 Data Buffers, Pointer, and Overflow Flag Operations

43.4 Interrupt Sources and DTC, DMAC Transfer Requests

43.4.1 Interrupt Requests

The ADC12 can send scan end interrupt requests ADC12i_ADI (i = 0, 1) and ADC12i_GBADI (i = 0, 1) to the CPU. The ADC12 also generates the ADC12i_CMPAI (i = 0, 1)/ADC12i_CMPBI (i = 0, 1) interrupt for the CPU in response to matches with a condition for comparison.

An ADC12i_ADI (i = 0, 1) interrupt is always generated. An ADC12i_GBADI (i = 0, 1) interrupt can be generated by setting the ADCSR.GBADIE bit to 1. Similarly, ADC12i_CMPAI (i = 0, 1) and ADC12i_CMPBI (i = 0, 1) interrupts can be generated by setting the ADCMPCR.CMPAIE and ADCMPCR.CMPBIE bit to 1.

In addition, the DTC or DMAC can be started when an ADC12i_ADI (i = 0, 1) or an ADC12i_GBADI (i = 0, 1) interrupt is generated. Using an ADC12i_ADI (i = 0, 1) or ADC12i_GBADI (i = 0, 1) interrupt to activate the DTC or DMAC to read the converted data enables continuous conversion without a burden on software.

Table 43.28 describes the interrupt sources and ELC events available for the ADC12.

Table 43.28 The interrupt source and ELC event of ADC12 (1 of 2)

Operation			Interrupt request or ELC event	Interrupt request	DTC or DMAC activation	ELC event request	Function
Scan mode	Double trigger mode	Compare function Window A/B					
Single scan mode	Deselected	Deselected	ADC12i_ADI (i = 0, 1)	✓	✓	✓	ADC12i_ADI (i = 0, 1) generated at the end of single scan
		Selected	ADC12i_ADI (i = 0, 1)	✓	✓	✓	ADC12i_ADI (i = 0, 1) generated at the end of single scan
			ADC12i_CMPAI (i = 0, 1)	✓	—	—	ADC12i_CMPAI (i = 0, 1) generated on a match comparison condition of Window A
			ADC12i_CMPBI (i = 0, 1)	✓	—	—	ADC12i_CMPBI (i = 0, 1) generated on a match comparison condition of Window B
			ADC12i_WCMPM (i = 0, 1)	—	✓	✓	ADC12i_WCMPM (i = 0, 1) generated on a match condition of the Window A/B compare function
			ADC12i_WCMPUM (i = 0, 1)	—	✓	✓	ADC12i_WCMPUM (i = 0, 1) generated on a mismatch condition of the Window A/B compare function
	Selected	Deselected	ADC12i_ADI (i = 0, 1)	✓	✓	✓	ADC12i_ADI (i = 0, 1) generated at the end of scans in the even numbered times
Continuous scan mode	Deselected	Deselected	ADC12i_ADI (i = 0, 1)	✓	✓	✓	ADC12i_ADI (i = 0, 1) generated at the end of scan of all selected channels
		Selected	ADC12i_CMPAI (i = 0, 1)	✓	—	—	ADC12i_CMPAI (i = 0, 1) generated on a match comparison condition of Window A
			ADC12i_CMPBI (i = 0, 1)	✓	—	—	ADC12i_CMPBI (i = 0, 1) generated on a match comparison condition of Window B

Table 43.28 The interrupt source and ELC event of ADC12 (2 of 2)

Operation			Interrupt request or ELC event	Interrupt request	DTC or DMAC activation	ELC event request	Function
Scan mode	Double trigger mode	Compare function Window A/B					
Group scan mode	Deselected	Deselected	ADC12i_ADI (i = 0, 1)	✓	✓	✓	ADC12i_ADI (i = 0, 1) generated at the end of group A scan
			ADC12i_GBADI (i = 0, 1)	✓	✓	—	ADC12i_GBADI (i = 0, 1) dedicated to group B generated at the end of group B scan
		Selected	ADC12i_ADI (i = 0, 1)	✓	✓	✓	ADC12i_ADI (i = 0, 1) generated at the end of group A scan
			ADC12i_GBADI (i = 0, 1)	✓	✓	—	ADC12i_GBADI (i = 0, 1) dedicated to group B generated at the end of group B scan

—: unavailable

For details on DTC settings, see section 17, Data Transfer Controller (DTC).

43.5 Event Link Function

43.5.1 Event Output to the ELC

The ELC uses the ADC12i_ADI (i = 0, 1) interrupt request signal as an event signal ADC12i_ADI (i = 0, 1), enabling link operation for the preset module. The ADC12i_GBADI (i = 0, 1) interrupt and ADC12i_CMPAI (i = 0, 1)/ADC12i_CMPBI (i = 0, 1) interrupts cannot be used as an event signal. For details, see Table 43.28.

An event signal can be output regardless of the settings of the corresponding interrupt request enable bits. For the scan end event(ADC12i_ADI (i = 0, 1)), a high-level pulse for one PCLKA cycle is output at the same output timing as the interrupt output (ADC12i_ADI (i = 0, 1)) shown in Table 43.28. For a compare function match (ADC12i_WCMPM (i = 0, 1)) and mismatch event (ADC12i_WCMPUM (i = 0, 1)) to the ELC, a high-level pulse for one PCLKA cycle is output at the timing delayed by one cycle (PCLKA) from the interrupt output (ADC12i_ADI (i = 0, 1)) shown in Table 43.28.

To use compare match (ADC12i_WCMPM (i = 0, 1)) or mismatch event (ADC12i_WCMPUM (i = 0, 1)) to the ELC, specify single-scan mode.

43.5.2 ADC12 Operation through an Event from the ELC

The ADC12 can start A/D conversion by the preset event specified in the ELSRn settings for the ELC as follows:

- Select the ELC_AD00 (unit 0) signal in the ELC.ELSR8 register
- Select the ELC_AD01 (unit 0) signal in the ELC.ELSR9 register

- Select the ELC_AD10 (unit 1) signal in the ELC.ELSR10 register
- Select the ELC_AD11 (unit 1) signal in the ELC.ELSR11 register.

If an ELC event occurs during A/D conversion, the event is disabled.

43.6 Usage Notes

43.6.1 Constraints on Setting the Registers

Set each register while the ADCSR.ADST bit is 0.

43.6.2 Constraints on Reading the Data Registers

The following registers must be read in halfword units:

- A/D Data Registers
- A/D Data Duplexing Register
- A/D Data Duplexing Register A
- A/D Data Duplexing Register B
- A/D Temperature Sensor Data Register
- A/D Internal Reference Voltage Register
- A/D Self-Diagnosis Data Register
- A/D Data Buffer Registers n (N = 0 to 15)

If a register is read twice in byte units, that is, the upper byte and lower byte are read separately, the A/D-converted value read initially might disagree with the A/D-converted value read subsequently. To prevent this, never read the data registers in byte units.

43.6.3 Constraints on Stopping A/D Conversion

(1) A/D Conversion Stop Procedure

To stop A/D conversion when an asynchronous trigger or a synchronous trigger is selected as the condition for starting A/D conversion, follow the procedure shown in Figure 43.38.

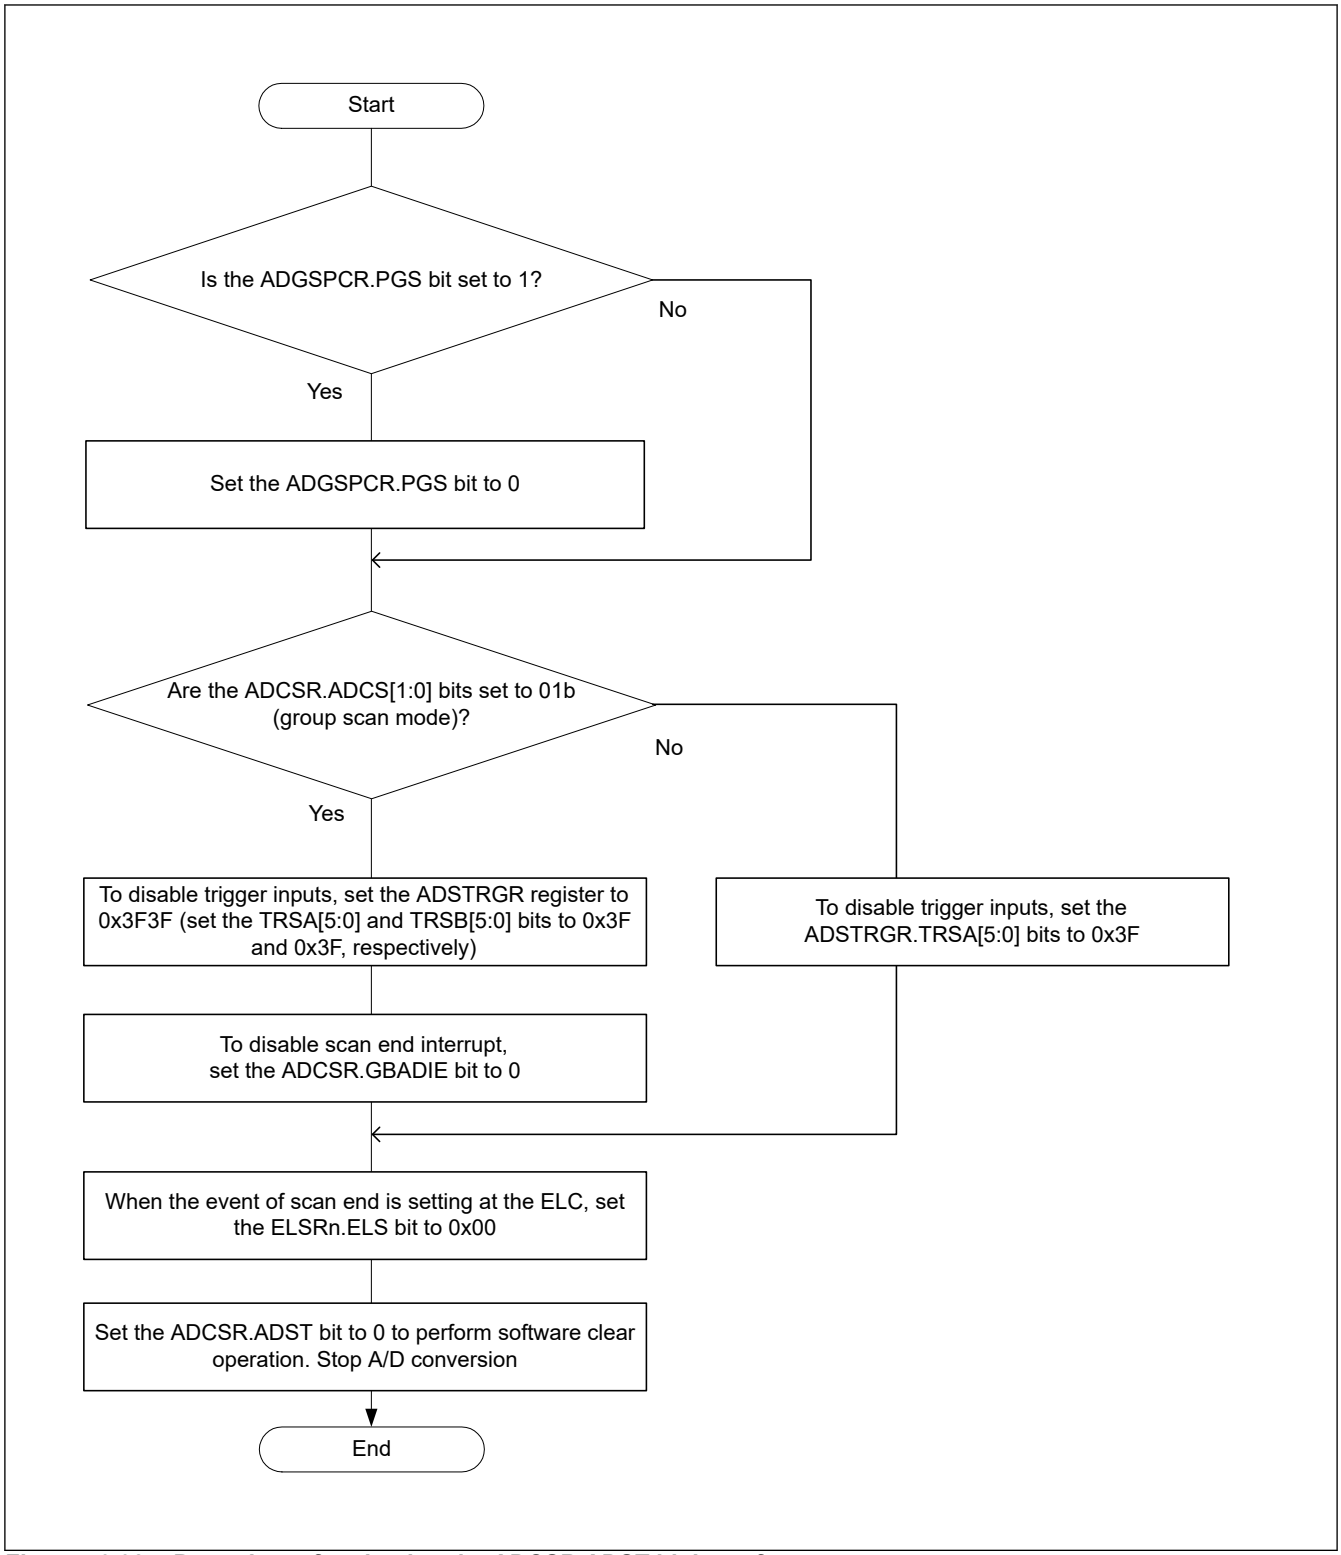

Figure 43.38 Procedures for clearing the ADCSR.ADST bit by software

To specify the following settings after performing the clear operation by software, provide a wait period for at least two ADCLK cycles.

- Enabling scan end interrupts
- Enabling scan end events for the event link controller
- Starting A/D conversion by software
- Enabling trigger input

(2) Notes on Modes and Status Bits

If necessary, individually initialize or set again the voltage status for self-diagnosis, the judgment of the even number or odd number specified for double-trigger mode, and the monitor flags of the compare function.

- To set again the voltage status for self-diagnosis, set the ADCER.DIAGLD bit to 1 and then set a desired value in the ADCER.DIAGVAL[1:0] bits.
- If the setting of the ADCSR.DBLE bit is changed from 0 to 1, the double-trigger mode operation starts from the first scanning.
- To initialize the monitor flags of the compare function (MONCMPA, MONCMPB, and MONCOMB), set the ADCMPCR.CMPAE and ADCMPCR.CMPBE bits to 0.

43.6.4 A/D Conversion Restart and Termination Timing

A maximum of 6 ADCLK cycles is required for the idle analog unit of the ADC12 to restart on setting the ADCSR.ADST bit to 1. A maximum of 2 ADCLK cycles is required for the operating analog unit of the ADC12 to terminate on setting the ADCSR.ADST bit to 0.

43.6.5 Constraints on Scan End Interrupt Handling

When scanning the same analog input twice using any trigger, the first A/D-converted data is overwritten with the second A/D-converted data. This occurs when the CPU does not complete the reading of the A/D-converted data by the time the A/D conversion of the first analog input for the second scan ends after the first scan end interrupt is generated.

43.6.6 Settings for the Module-Stop Function

The Module Stop Control Register can enable or disable ADC12 operation. The ADC12 is initially stopped after a reset. The registers become accessible on release from the module-stop state. After release from the module-stop state, wait for at least 1 µs before starting A/D conversion. For details, see section 10, Low Power Modes.

43.6.7 Notes on Entering the Low-Power States

Before entering the module-stop state or Software Standby mode, be sure to stop A/D conversion. Set the ADCSR.ADST bit in ADCSR to 0 and secure certain period until the analog unit of the ADC12 stops. Follow the procedure shown in Figure 43.38 to clear the ADCSR.ADST bit with software. Then, wait for 2 clock cycles of ADCLK before entering the module-stop state or Software Standby mode.

43.6.8 Error in Absolute Accuracy When Disconnection Detection Assistance Is in Use

Using disconnection detection assistance leads to an error in absolute accuracy of the ADC12. This error arises because an erroneous voltage is input to the analog input pins due to the resistive voltage division between the pull-up or pull- down resistor (Rp) and the resistance of the signal source (Rs). This error in absolute accuracy is calculated from the following formula:

$$\text{Maximum error in absolute accuracy (LSB)} = \left(2^{\text{Resolution}} - 1\right) \times \text{Rs} / \left(\text{Rs} + \text{Rp}\right)$$

Only use disconnection detection assistance after thorough evaluation.

43.6.9 Constraints on Operating Modes and Status Bits

Initialize or set again individually, if necessary, the voltage values in self-diagnosis, the value of the first scan or second scan in double trigger mode, the data buffer pointer, and status monitor in the compare function.

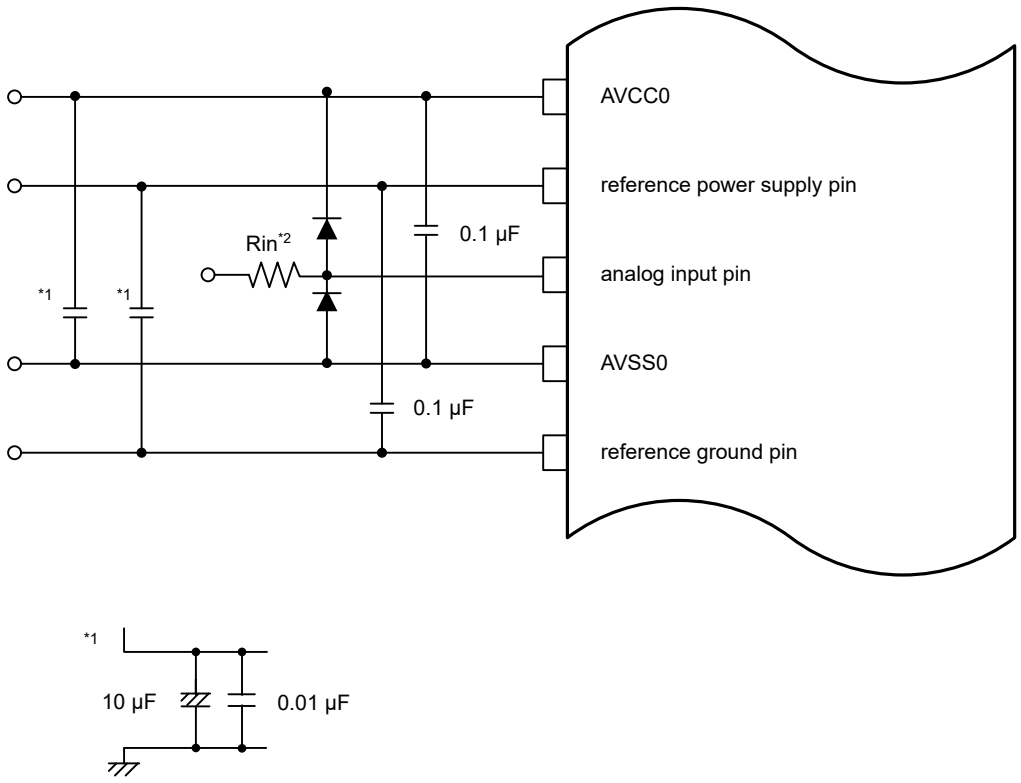
- Select the voltage values in self-diagnosis (ADCER.DIAGVAL[1:0]) after setting ADCER.DIAGLD to 1.
- Double-trigger mode operates as the first scan after setting ADCSR.DBLE from 0 to 1.
- The status monitor bits (MONCMPA, MONCMPB, MONCOMB) in the compare function are initialized after setting ADCMPCR.CMPAE and ADCMPCR.CMPBE to 0.

43.6.10 Notes on Board Design

The board should be designed so that digital circuits and analog circuits are separated from each other as far as possible. In addition, digital circuit signal lines and analog circuit signal lines should not intersect or be placed near each other. If these rules are not followed, noise can occur on analog signals and A/D conversion accuracy is affected. The analog input pins, reference power supply pin (VREFH0, VREFH), reference ground pin (VREFL0, VREFL), and analog power supply (AVCC0) should be separated from digital circuits using the analog ground (AVSS0). The analog ground (AVSS0) should be connected to a stable digital ground (VSS) on the board (single-point ground plane connection).

43.6.11 Constraints on Noise Prevention

To prevent the analog input pins from being destroyed by abnormal voltage such as excessive surge, insert a capacitor between AVCC0 and AVSS0 and between VREFH0 and VREFL0 and between VREFH and VREFL. Additionally, connect a protection circuit to protect the analog input pins as shown in Figure 43.39.



Note 1. The values shown here are reference values.
Note 2. Rin: Signal source impedance

Figure 43.39 Example protection circuit for analog inputs

43.6.12 Port Settings When Using the ADC12 Input

When using the high-precision channels, do not use PORT0 as general I/O. Renesas recommends that you do not use the digital output that is also used as the AD analog input if normal-precision channel is used. If the digital output that is also used as the AD analog input is used for output signals, perform A/D conversion several times, eliminate the maximum and minimum values, and obtain the average of the other results.

43.6.13 Notes on Canceling Software Standby Mode

After software standby mode is canceled, wait at least 1 µs after the stabilization time for the oscillator elapses and before starting A/D conversion. For details, see section 10, Low Power Modes

43.6.14 Calculation for Sampling Time

The sampling time can be easily estimated by the following figure and formula. This is the time to reach the voltage within 1/4 LSB.

$t_{SPL} = (R_{EXT} + R_{AD}) \times (C_{EXT} + C_{AD}) \times \ln (C_{AD} / (C_{EXT} + C_{AD}) \times 2^{N+2})$

R_{EXT} shows external signal source impedance
C_{EXT} shows external capacitance (pin capacitance*1 + PCB parasitic capacitance)
N = 12, 10 or 8 (conversion resolution)
C_{AD} = 5 pF (internal capacitance)
R_{AD} = 1.0 kΩ (internal resistance, case of high-speed channels)
R_{AD} = 2.0 kΩ (internal resistance, case of normal-speed channels)

Note 1. Typical value of analog input pin is 5 pF

For example, if R_{EXT} is 1 kΩ, C_{EXT} is 10 pF and N is 12 bits, t_{SPL} of high-speed channel is 258 ns.

This formula simplifies the general use case. This formula is not guaranteed and should be used only for estimation.

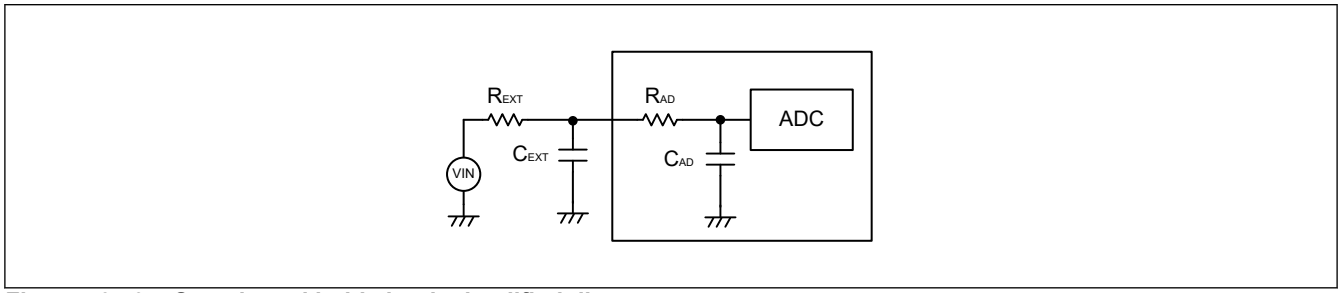


Figure 43.40 Sample and hold circuit simplified diagram

44. 12-Bit D/A Converter (DAC12)

44.1 Overview

The MCU provides a 12-bit D/A Converter (DAC12) with an output amplifier. Table 44.1 lists the DAC12 specifications, Figure 44.1 shows a block diagram, and Table 44.2 lists the I/O pins.

Table 44.1 DAC12 specifications

Parameter	Specifications
Resolution	12 bits
Output channels	2 channels
Interference reduction between analog modules	Methods provided to minimize interference between D/A and A/D conversion: • D/A converted data update timing is controlled by the synchronous D/A conversion enable input signal from the ADC12 (unit 1) • Degradation of A/D conversion accuracy caused by interference is reduced by controlling the DAC12 inrush current generation timing with the enable signal.
Module-stop function	Module-stop state can be set to reduce power consumption
Event link function (input)	The DA0 and DA1 conversion can be started on input of an event signal
D/A output amplifier control function	Controls whether the output amplifier (for both amplifier-through and amplifier-bias controls) is used
TrustZone Filter	Security attribution can be set

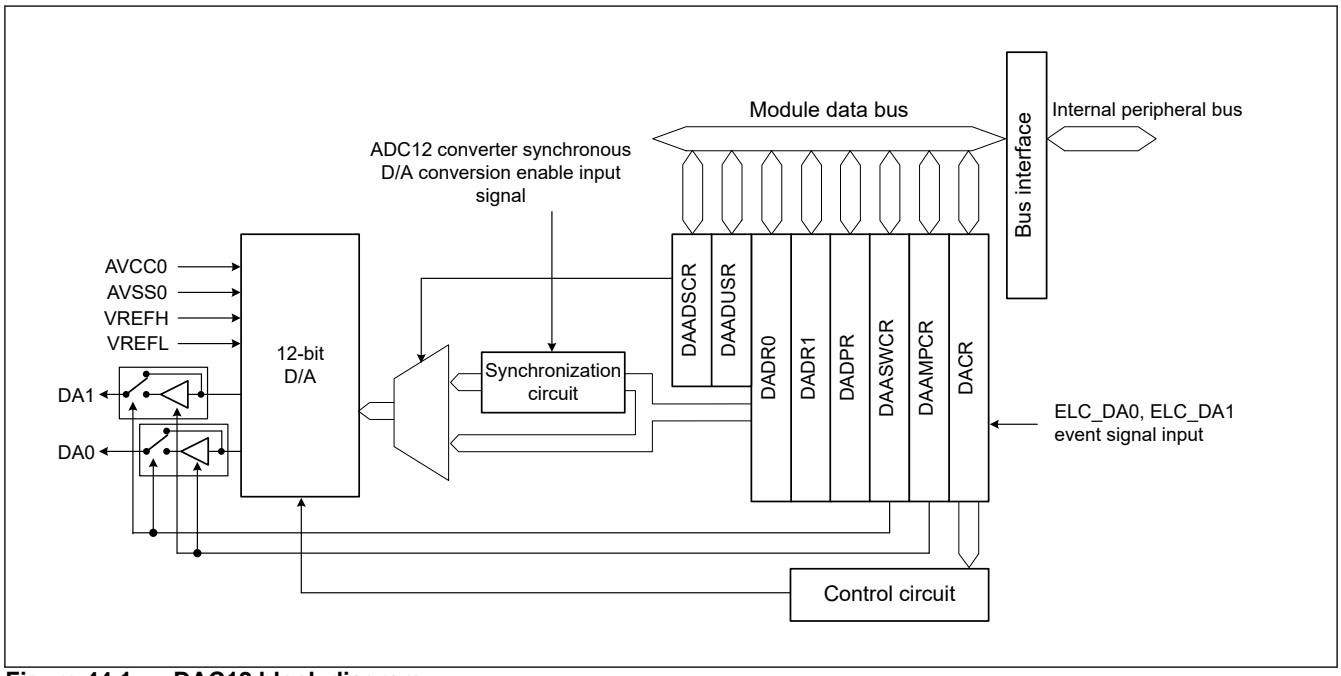

Figure 44.1 DAC12 block diagram

Table 44.2 lists the pin configuration of the DAC12.

Table 44.2 DAC12 I/O pins (1 of 2)

Pin name	I/O	Function
AVCC0	Input	• Analog power and analog reference top voltage supply pin for ADC12 and DAC12. • Connect to VCC when these modules are not used.
AVSS0	Input	• Analog ground and analog reference ground supply pin for ADC12 and DAC12. • Connect to VSS when these modules are not used.
VREFH	Input	Analog reference top voltage supply pin for the ADC12 (unit 1) and the DAC12
VREFL	Input	Analog reference ground pin for the ADC12 (unit 1) and the DAC12

Table 44.2 DAC12 I/O pins (2 of 2)

Pin name	I/O	Function
DA0	Output	Channel 0 output pin for the analog signals processed by the DAC12
DA1	Output	Channel 1 output pin for the analog signals processed by the DAC12

44.2 Register Descriptions

44.2.1 DADRn : D/A Data Register n (n = 0, 1)

Base address: DAC12 = 0x4017_1000

Offset address: 0x00 + 0x02 × n

Bit position:	15															0
Bit field:																
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DADRn register is 16-bit read/write registers that store data for D/A conversion. When an analog output is enabled, the values in DADRn are converted and output to the analog output pins.

12-bit data can be formatted as left- or right-justified in the DADPR.DPSEL bit setting. In right-justified format (DADPR.DPSEL = 0), the lower 12 bits, [11:0], are valid. In left-justified format (DADPR.DPSEL = 1), the upper 12 bits, [15:4], are valid.

44.2.2 DACR : D/A Control Register

Base address: DAC12 = 0x4017_1000

Offset address: 0x04

Bit position:	7	6	5	4	3	2	1	0
Bit field:	DAOE1	DAOE0	DAE	—	—	—	—	—
Value after reset:	0	0	0	1	1	1	1	1

Bit	Symbol	Function	R/W
4:0	—	These bits are read as 1. The write value should be 1.	R/W
5	DAE*1	D/A Enable 0: Control D/A conversion of channels 0 and 1 individually 1: Control D/A conversion of channels 0 and 1 collectively	R/W
6	DAOE0	D/A Output Enable 0 0: Disable analog output of channel 0 (DA0) 1: Enable D/A conversion of channel 0 (DA0)	R/W
7	DAOE1	D/A Output Enable 1 0: Disable analog output of channel 1 (DA1) 1: Enable D/A conversion of channel 1 (DA1)	R/W

Note 1. This bit controls D/A conversion in combination with the DAOEi bit (i = 0, 1), which controls the output of the conversion results. For details, see Table 44.3.

Table 44.3 D/A conversion controls

DAE	DAOE1	DAOE0	Description
0	0	0	Disable D/A conversion and analog output pins (DA0, DA1)*1
		1	• Enable D/A conversion of channel 0 and disable D/A conversion of channel 1 • Enable analog output of channel 0 (DA0) and disable analog output of channel 1 (DA1)*1
	1	0	• Disable D/A conversion of channel 0 and enable D/A conversion of channel 1 • Disable analog output of channel 0 (DA0)*1 and enable analog output of channel 1 (DA1)
		1	• Enable D/A conversion of channels 0 and 1 • Enable analog output of channels 0 and 1 (DA0, DA1)
1	x	x	• Enable D/A conversion of channels 0 and 1 • Collective enable analog output of channels 0 and 1 (DA0, DA1)

Note: x: Don't care
Note 1. When analog output is disabled, the analog output signal is placed in the Hi-Z state.

Only set this register while the ADC12 is halted when the DAADSCR.DAADST bit is 1 (interference reduction between D/A and A/D conversion is enabled). Only set DACR while the ADCSR.ADST bit is 0 and after selecting the software trigger, for the ADC12 trigger to securely stop the ADC12. This MCU only supports ADC12 (unit 1).

DAE bit (D/A Enable)

The DAE bit controls D/A conversion, amplifier operation, and analog output in combination with the DAOEi bit (i = 0, 1) and the DAAMPCR.DAAMPi bit (i = 0, 1). See Table 44.4.

When interference reduction between D/A and A/D conversions is enabled (DAADSCR.DAADST = 1), set the ADCSR.ADST bit of the ADC12 (unit 1) to 0. Then, select the software trigger for the ADC12 (unit 1) trigger to securely stop the ADC12 (unit 1).

DAOEi bit (D/A Output Enable i)

The DAOEi bit (i = 0, 1) controls D/A conversion, amplifier operation, and analog output in combination with the DAE bit and DAAMPCR.DAAMPi bit (i = 0, 1). See Table 44.4.

When both the DAOEi bit (i = 0, 1) and DAE bit are 0, D/A conversion of channel i (i = 0, 1) is not processed, and no conversion result is output.

When interference reduction between D/A and A/D conversions is enabled (DAADSCR.DAADST = 1), set the DAOEi bit while the ADCSR.ADST bit of the ADC12 (unit 1) is set to 0. Then, select the software trigger for the ADC12 (unit 1) trigger to securely stop the ADC12 (unit 1).

The event link function can be used to set the DAOEi bit to 1. The DAOE0 bit is set to 1 when the event specified in the ELSR12 register of the ELC (ELC_DA0 event) occurs, and output of the D/A conversion results starts. The DAOE1 bit is set to 1 when the event specified in the ELSR13 register of the ELC (ELC_DA1 event) occurs, and output of the D/A conversion results starts.

Table 44.4 D/A conversion and analog output control

DACR		DAAMPCR	Channel i operation	Amplifier operation of channel i	Analog output of channel i
DAE	DAOEi	DAAMPi			
0	0	0	Stop	Stop	Hi-Z
		1	Stop	Stop	Hi-Z
	1	0	Run	Stop	Amplifier-through
		1	Run	Run	Amplifier output
1	0	0	Run	Stop	Amplifier-through
		1	Run	Run	Amplifier output
	1	0	Run	Stop	Amplifier-through
		1	Run	Run	Amplifier output

Note: i = 0, 1

44.2.3 DADPR : DADRn Format Select Register

Base address: DAC12 = 0x4017_1000

Offset address: 0x05

Bit position:	7	6	5	4	3	2	1	0
Bit field:	DPSEL	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
6:0	—	These bits are read as 0. The write value should be 0.	R/W
7	DPSEL	DADRn Format Select 0: Right-justified format 1: Left-justified format	R/W

44.2.4 DAADSCR : D/A A/D Synchronous Start Control Register

Base address: DAC12 = 0x4017_1000

Offset address: 0x06

Bit position:	7	6	5	4	3	2	1	0
Bit field:	DAADST	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
6:0	—	These bits are read as 0. The write value should be 0.	R/W
7	DAADST	D/A A/D Synchronous Conversion 0: Do not synchronize DAC12 with ADC12 (unit 1) operation (disable interference reduction between D/A and A/D conversion). 1: Synchronize DAC12 with ADC12 (unit 1) operation (enable interference reduction between D/A and A/D conversion).	R/W

To minimize interference between D/A and A/D conversion, the DAADSCR register enables synchronization of the start timing of D/A conversion with the ADC12 synchronous D/A conversion enable input signal.

Only set this register while the ADC12 (unit 1) is halted, that is, while the ADCSR.ADST bit is 0 after selecting the software trigger as the ADC12 (unit 1) trigger.

Select unit 1 as the target ADC12 unit before setting the DAADST bit to 1. Set DAADUSR[1] bit to 1 to select unit 1. This MCU only supports ADC12 unit 1.

DAADST bit (D/A A/D Synchronous Conversion)

Setting the DAADST bit to 0 allows the DADRn register value to be converted into analog data at any time. Setting the DAADST bit to 1 allows synchronization of D/A conversion with the synchronous D/A conversion enable input signal from the ADC12 (unit 1). With this bit set, D/A conversion does not start until the ADC12 (unit 1) completes A/D conversion, even when the DADRn register is changed.

Set this bit while the ADCSR.ADST bit is set to 0. Then, select the software trigger for the ADC12 (unit 1) trigger to securely stop the ADC12 (unit 1). Set the DAADUSR.AMADSEL1 bit to 1 before setting the DAADST bit to 1.

The event link function cannot be used when the DAADST bit is set to 1. Stop the event link function by setting the ELSR12 and ELSR13 registers of the ELC. The setting of the DAADST bit is shared by channels 0 and 1 of the DAC12.

44.2.5 DAAMPCR : D/A Output Amplifier Control Register

Base address: DAC12 = 0x4017_1000

Offset address: 0x08

Bit position:	7	6	5	4	3	2	1	0
Bit field:	DAAMP1	DAAMP0	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	—	These bits are read as 0. The write value should be 0.	R/W
6	DAAMP0	Amplifier Control 0 0: Do not use channel 0 output amplifier 1: Use channel 0 output amplifier	R/W
7	DAAMP1	Amplifier Control 1 0: Do not use channel 1 output amplifier 1: Use channel 1 output amplifier	R/W

The DAAMPCR register selects D/A output with or without using the amplifier.

DAAMP0 bit (Amplifier Control 0)

When the DAAMP0 bit is 0, analog values are output for D/A output of channel 0 without using the amplifier. When the DAAMP0 bit is 1, analog values are output for D/A output of channel 0 through the amplifier.

When both the DACR.DAE and DACR.DAOE0 bits are 0, the amplifier is not used regardless of the setting of the DAAMP0 bit. See Table 44.4 for details.

DAAMP1 bit (Amplifier Control 1)

When the DAAMP1 bit is 0, analog values are output for D/A output of channel 1 without using the amplifier. When the DAAMP1 bit is 1, analog values are output for D/A output of channel 1 through the amplifier.

When both the DACR.DAE and DACR.DAOE1 bits are 0, the amplifier is not used regardless of the setting of the DAAMP1 bit. See Table 44.4 for details.

44.2.6 DAASWCR : D/A Amplifier Stabilization Wait Control Register

Base address: DAC12 = 0x4017_1000

Offset address: 0x1C

Bit position:	7	6	5	4	3	2	1	0
Bit field:	DAASW1	DAASW0	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	—	These bits are read as 0. The write value should be 0.	R/W
6	DAASW0	D/A Amplifier Stabilization Wait 0 0: Amplifier stabilization wait off (output) for channel 0 1: Amplifier stabilization wait on (high-Z) for channel 0	R/W
7	DAASW1	D/A Amplifier Stabilization Wait 1 0: Amplifier stabilization wait off (output) for channel 1 1: Amplifier stabilization wait on (high-Z) for channel 1	R/W

The DAASWCR register controls D/A output with the output amplifier. This register is used in the initialization procedure to wait for stabilization of the D/A output amplifier. Each bit in DAASWCR should be set to 1 when both the DACR.DAE bit and the DACR.DAOEi (i = 0, 1) bit are 0 . See section 44.6.5. Initialization Procedure with the Output Amplifier.

DAASW0 bit (D/A Amplifier Stabilization Wait 0)

Set the DAASW0 bit to 1 in the initialization procedure to wait for the stabilization of the D/A channel 0 output amplifier. When DAASW0 is set to 1, D/A conversion operates, but the conversion result of D/A is not output from channel 0. When the DAASW0 bit is 0, the stabilization wait time stops, and the D/A conversion result of channel 0 is output through the output amplifier.

DAASW1 bit (D/A Amplifier Stabilization Wait 1)

Set the DAASW1 bit to 1 in the initialization procedure to wait for the stabilization of the D/A channel 1 output amplifier. When DAASW1 is set to 1, D/A conversion operates, but the conversion result of D/A is not output from channel 1. When the DAASW1 bit is 0, the stabilization wait time stops, and the D/A conversion result of channel 1 is output through the output amplifier.

44.2.7 DAADUSR : D/A A/D Synchronous Unit Select Register

Base address: DAC12 = 0x4017_1000

Offset address: 0x10C0

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	AMADSEL1	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	—	This bit is read as 0. The write value should be 0.	R/W
1	AMADSEL1	A/D Unit 1 Select 0: Do not select unit 1 1: Select unit 1	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W

The DAADUSR register selects the target ADC12 unit for D/A and A/D synchronous conversions. Set the AMADSEL1 bit to 1 to select unit 1 as the target synchronous unit for the MCU. When setting the DAADSCR.DAADST bit to 1 for synchronous conversions, select the target unit in this register in advance.

Only set the DAADUSR register while the ADCSR.ADST bit of the ADC12 is set to 0 and the DAADSCR.DAADST bit is set to 0.

44.3 Operation

The DAC12 includes D/A conversion circuits for two channles, each of which can operate independently. When the DAOEn bit (n = 0, 1) in DACR is set to 1, DAC12 is enabled and the conversion result is output.

This following example shows D/A conversion on channel 0. Figure 44.2 shows the timing of this operation.

To process D/A conversion on channel 0:

1. Set the data for D/A conversion in the DADR0 register and the data format in the DADPR.DPSEL bit.
2. Set the DACR.DAOE0 bit to 1 to start D/A conversion. The conversion result is output from the analog output pin DA0 after the conversion time t_{DCONV} elapses. The conversion result continues to be output until DADR0 is written to again or the DAOE0 bit is set to 0. The output value (reference) is expressed by the following formula:

$$\frac{\text{Setting in DADR0}}{4096} \times \text{VREFH}$$

3. To start conversion again, write another value to DADR0. The conversion result is output after the conversion time t_{DCONV} elapses.
   When the DAADSCR.DAADST bit is 1 (interference reduction between D/A and A/D conversion is enabled), a maximum of one A/D conversion time is required for D/A conversion to start. When ADCLK is faster than the peripheral clock, a longer time might be required.
4. To disable analog output, set the DAOE0 bit to 0.

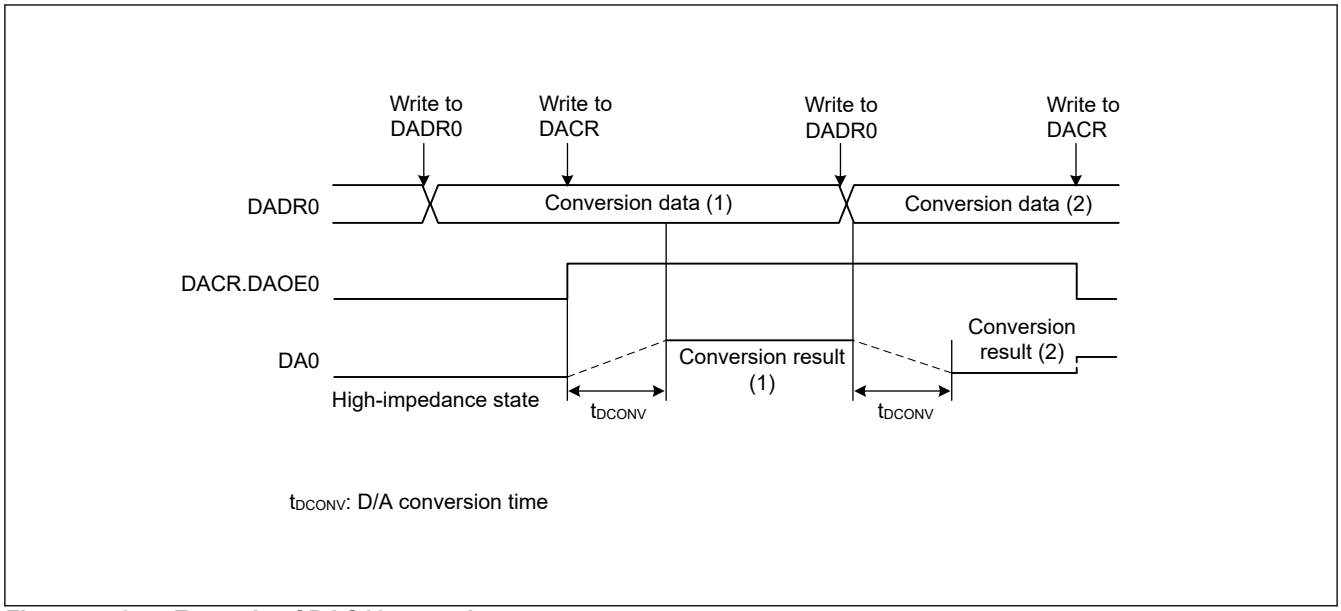

Figure 44.2 Example of DAC12 operation

44.3.1 Reducing Interference between D/A and A/D Conversion

When D/A conversion starts, the DAC12 generates inrush current. Because the DAC12 and ADC12 (unit 1) share the same analog power supply, the generated inrush current can interfere with ADC12 (unit 1) operation.

While the DAADSCR.DAADST bit is 1, D/A conversion does not start immediately on updating the DADRm register. Instead:

- If the DADRm register data is modified while the ADC12 is halted, D/A conversion starts in 1 PCLKA cycle.
- If the DADRm register data is modified while the ADC12 is performing a 12-bit A/D conversion, D/A conversion starts on A/D conversion completion. Therefore, it takes up to one A/D conversion time period for the DADRm register data update to be reflected as the D/A conversion circuit output. Until the D/A conversion completes, the DADRm register value does not correspond to the analog output value.

When the DAADSCR.DAADST bit is 1, it is not possible to check through software whether the DADRm register value was D/A-converted.

The following sequence provides an example of channel 0 D/A conversion, in which the DAC12 is synchronized with the ADC12 (unit 1). Figure 44.3 shows the timing of this operation.

To perform D/A conversion on channel 0 in synchronization with the ADC12 (unit 1):

1. Confirm that the ADC12 (unit 1) is halted and set the DAADUSR.AMADSEL1 bit to 1.
2. Confirm that the ADC12 (unit 1) is halted and set the DAADSCR.DAADST bit to 1.
3. Confirm that the ADC12 (unit 1) is halted and set the DACR.DAOE0 bit to 1.
4. Set the DADR0 register. If ADCLK is faster than the peripheral clock, D/A conversion might be delayed for longer than one A/D conversion time.
   - If the ADC12 (unit 1) is halted (ADCSR.ADST = 0) when the DADR0 register is modified, D/A conversion starts in 1 PCLKA cycle.
   - If the 12-bit A/D conversion is in progress (ADCSR.ADST = 1) when the DADR0 register is modified, D/A conversion starts on A/D conversion completion. If the DADR0 register is modified twice during A/D conversion, the first update might not be converted.

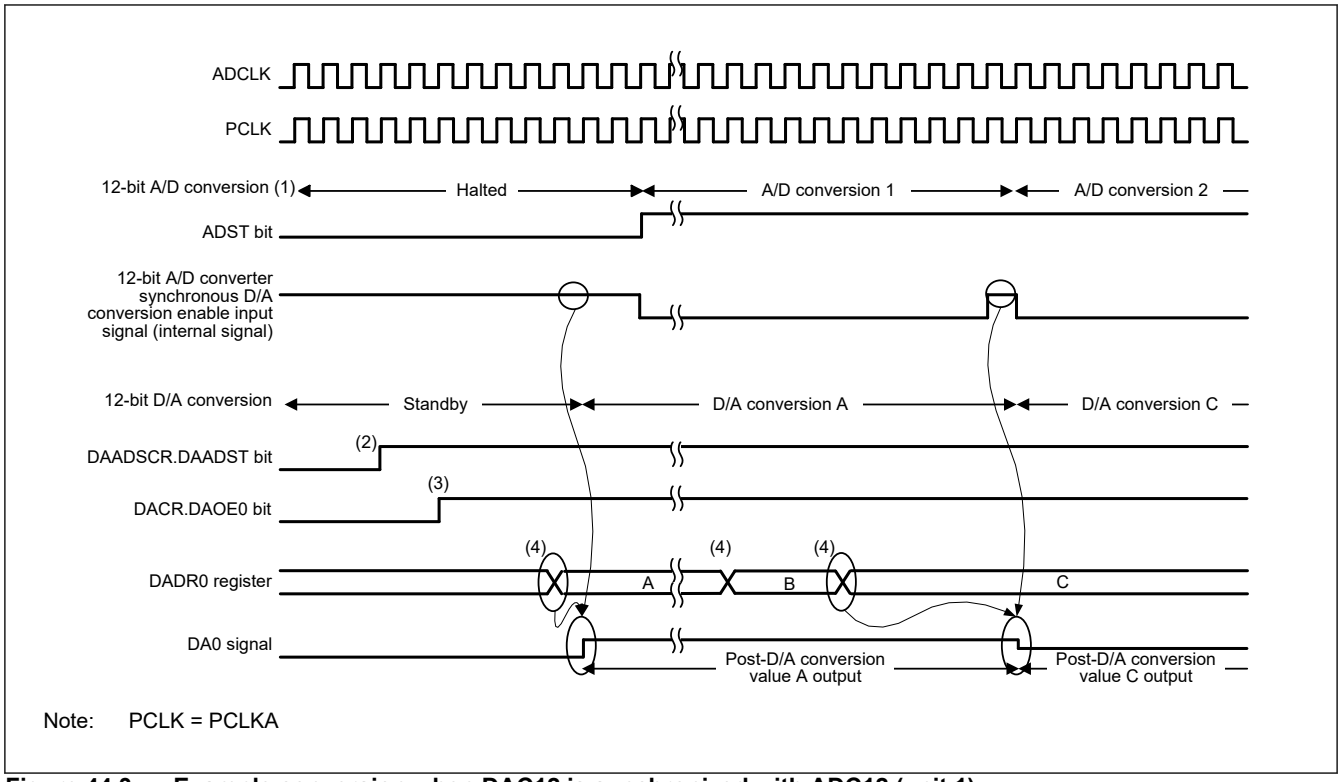

Figure 44.3 Example conversion when DAC12 is synchronized with ADC12 (unit 1)

When ADCLK is faster than PCLKA, the DAC12 might not be able to capture the synchronous D/A conversion enable input signal from the ADC12 (unit 1) during the 1 ADCLK cycle that is output between A/D conversion 1 and A/D conversion 2, as shown in Figure 44.4. In this case, post-D/A conversion value A is continuously output as the DA0 signal.

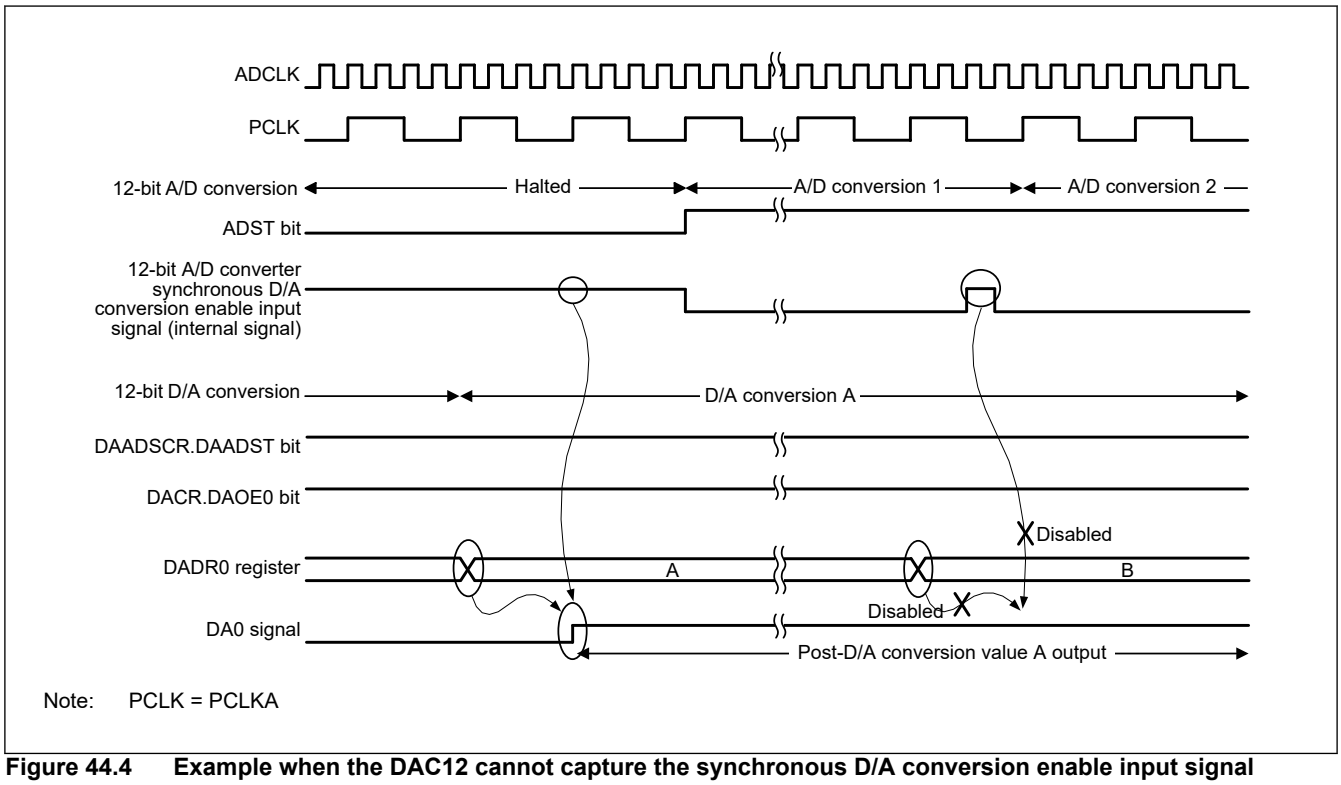

Figure 44.4 Example when the DAC12 cannot capture the synchronous D/A conversion enable input signal from the ADC12 (unit 1)

44.4 Event Link Operation Setting Procedure

This section describes the procedures used in event link operation.

44.4.1 DA0 Event Link Operation Setting Procedure

To set up DA0 event link operation:

1. Set the DADPR.DPSEL bit and the data for D/A conversion in the DADR0 register.
2. Set the ELC_DA0 event signal to be linked to each peripheral module in the ELSR12 register.
3. Set the ELCR.ELCON bit to 1. This enables event link operation for all modules with the event link function selected.
4. Set the event output source module to activate the event link. After the event is output from the module, the DACR.DAOE0 bit becomes 1, and D/A conversion starts on channel 0.
5. Set the ELSR12 register to 0x0000 to stop event link operation of DAC12 channel 0. All event link operation is stopped when the ELCR.ELCON bit is set to 0.

44.4.2 DA1 Event Link Operation Setting Procedure

To set up DA1 event link operation:

1. Set the DADPR.DPSEL bit and set the data for D/A conversion in the DADR1 register.
2. Set the ELC_DA1 event signal to be linked to each peripheral module in the ELSR13 register.
3. Set the ELCR.ELCON bit to 1. This enables the event link operation for all modules with the event link function selected.
4. Set the event output source module to activate the event link. After the event is output from the module, the DACR.DAOE1 bit is becomes 1, and D/A conversion starts on channel 1.
5. Set the ELSR13 register to 0x0000 to stop event link operation on DAC12 channel 1. All event link operation is stopped when the ELCR.ELCON bit is set to 0.

44.5 Usage Notes on Event Link Operation

- When the event link function is used, do not use the amplifier output function.
- When the event link function is used, set the DACR.DAE bit to 0.
- When the event specified for the ELC_DA0 event signal is generated while a write to the DACR.DAOE0 bit is performed, the write cycle is stopped, and the generated event takes precedence in setting the bit to 1.
- When the event specified for the ELC_DA1 event signal is generated while a write to the DACR.DAOE1 bit is performed, the write cycle is stopped, and the generated event takes precedence in setting the bit to 1.
- Use of the event link function is prohibited when the DAADSCR.DAADST bit is set to 1 to reduce interference between D/A and A/D conversions.

44.6 Usage Notes

44.6.1 Settings for the Module-Stop Function

DAC12 operation can be disabled or enabled using the Module Stop Control Register. The DAC12 is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

44.6.2 DAC12 Operation in the Module-Stop State

When the MCU enters the module-stop state with D/A conversion enabled, the D/A outputs are retained, and the analog power supply current is the same as during D/A conversion. If the analog power supply current must be reduced in the module-stop state, disable D/A conversion by setting the DACR.DAOE1, DAOE0, and DAE bits to 0.

44.6.3 DAC12 Operation in Software Standby Mode

When the MCU enters Software Standby mode with D/A conversion enabled, the D/A outputs are retained, and the analog power supply current is the same as during D/A conversion. If the analog power supply current must be reduced in Software Standby mode, disable D/A conversion by setting the DACR.DAOE1, DAOE0, and DAE bits to 0.

44.6.4 Constraint on Entering Deep Software Standby Mode

When the MCU enters Deep Software Standby mode with D/A conversion enabled, the outputs of the DAC12 are placed in a high impedance state.

44.6.5 Initialization Procedure with the Output Amplifier

Use the following initialization procedures with the output amplifier. The example shows the case for channel 0.

To initialize the DAC12 with the output amplifier:

1. Write 0x0000 to the DADR0 register.
2. Set the DAASWCR.DAASW0 bit to 1.
3. Set the DAAMPCR.DAAMP0 bit to 1.
4. Set the DACR.DAE bit or the DACR.DAOE0 bit to 1 to start operation of the amplifier.
5. Clear the DAASWCR.DAASW0 bit to 0 after waiting for the duration of D/A conversion time t_{DCONV}.
6. Write the value to be converted in the DADR0 register.

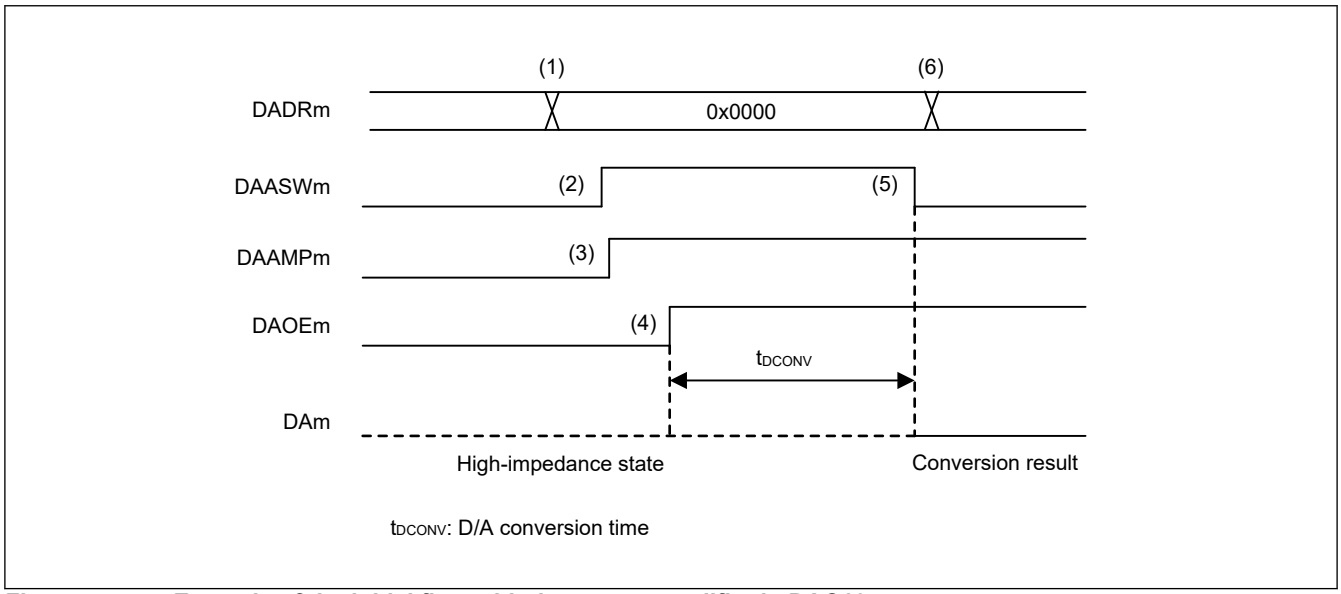

Figure 44.5 Example of the initial flow with the output amplifier in DAC12

While the amplifier is running, clearing the DACR.DAE and DACR.DAOE0 bits to 0 allows the amplifier to stop operation. To use the amplifier again, repeat steps 1 to 6.

44.6.6 Constraint on Usage When Interference Reduction between D/A and A/D Conversion Is Enabled

When the DAADSCR.DAADST bit is 1, enabling interference reduction between D/A and A/D conversion, do not place the ADC12 in the module-stop state. Doing so can halt D/A conversion in addition to A/D conversion.

45. Temperature Sensor (TSN)

45.1 Overview

The on-chip Temperature Sensor (TSN) determines and monitors the die temperature for reliable operation of the device. The sensor outputs a voltage directly proportional to the die temperature, and the relationship between the die temperature and the output voltage is fairly linear. The output voltage is provided to the ADC12 for conversion and can be further used by the end application.

Table 45.1 lists the TSN specifications, and Figure 45.1 shows a block diagram.

Table 45.1 TSN specifications

Item	Description
Temperature sensor voltage output	Temperature sensor outputs a voltage to the 12-bit A/D converter
Module-stop function	Module-stop state can be set to reduce power consumption
Temperature sensor calibration data	Reference data measured for each chip at factory shipment is stored in a register
TrustZone Filter	Security attribution can be set

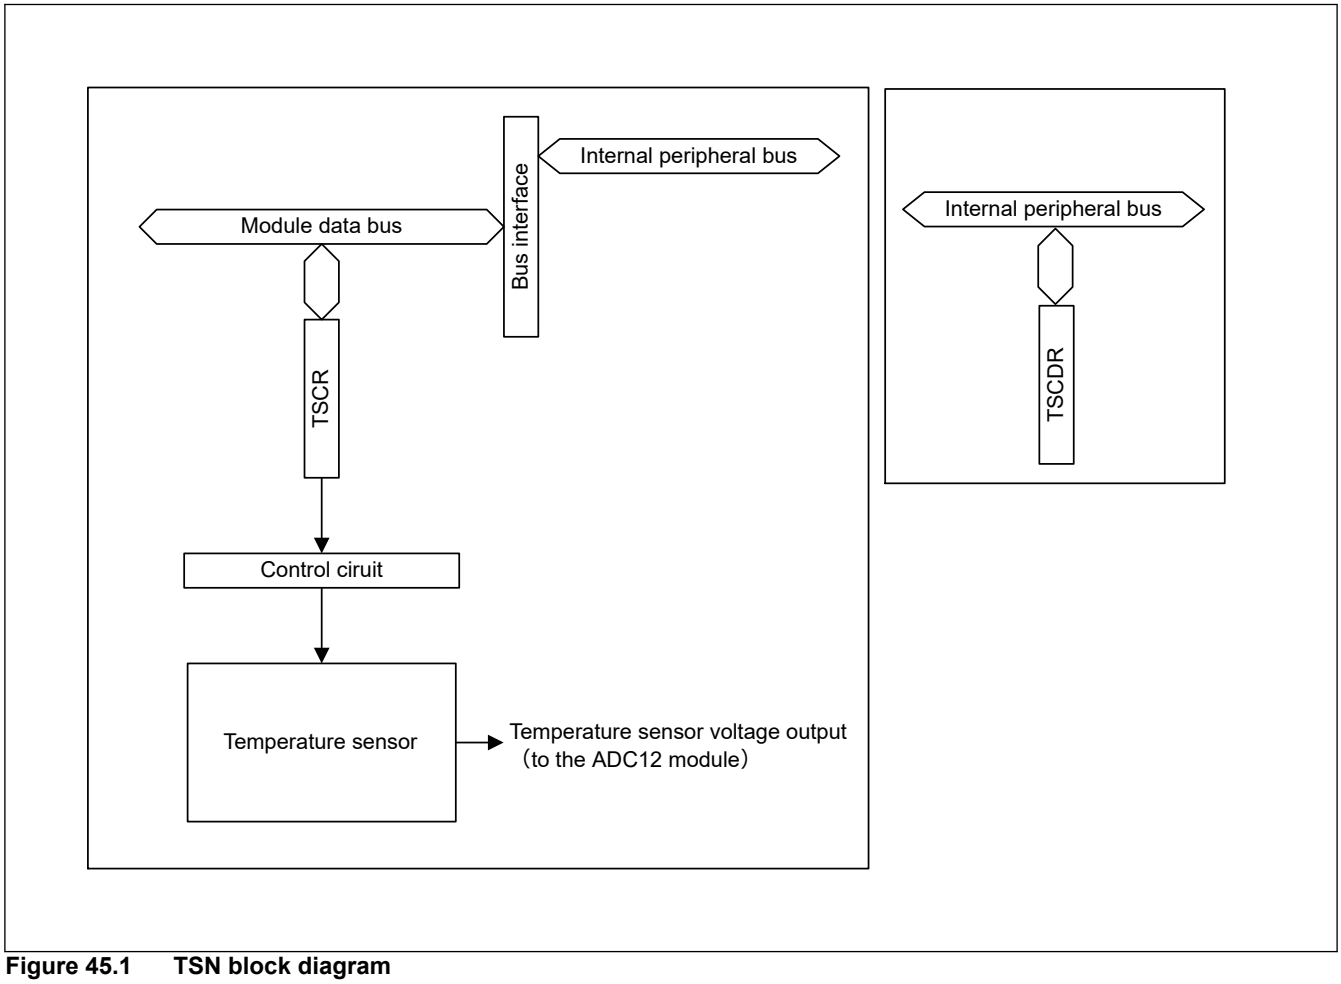

Figure 45.1 TSN block diagram

45.2 Register Descriptions

45.2.1 TSCR : Temperature Sensor Control Register

Base address: TSN = 0x400F_3000

Offset address: 0x00

Bit position:	7	6	5	4	3	2	1	0
Bit field:	TSEN	—	—	TSOE	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	—	These bits are read as 0. The write value should be 0.	R/W
4	TSOE	Temperature Sensor Output Enable 0: Disable output from the temperature sensor to the ADC12 1: Enable output from the temperature sensor to the ADC12	R/W
6:5	—	These bits are read as 0. The write value should be 0.	R/W
7	TSEN	Temperature Sensor Enable 0: Stop the temperature sensor 1: Start the temperature sensor.	R/W

The TSCR is a register which controls the temperature sensor. The timing constraints shown in Figure 45.3 apply to the settings of the TSCR register.

TSOE bit (Temperature Sensor Output Enable)

The TSOE bit enables or disables the temperature sensor output to ADC12.

TSEN bit (Temperature Sensor Enable)

The TSEN bit starts or stops the temperature sensor.

45.2.2 TSCDR : Temperature Sensor Calibration Data Register

Base address: TSD = 0x407F_B000

Offset Address: 0x017C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	TSCDR[15:0]															
Value after reset:	Chip-specific value															

Bit	Symbol	Function	R/W
15:0	TSCDR[15:0]	Temperature Sensor Calibration Data Chip-specific value	R
31:16	—	These bits are read as 0.	R

The TSCDR register stores temperature sensor calibration data measured for each chip at factory shipment.

Temperature sensor calibration data is the output voltage of the temperature sensor under the conditions Tj = 127°C and AVCC0 = VREFH0 = 3.3 V converted to a digital value by the 12-bit A/D converter.

The TSCDR register is a read-only 32-bit register. Read from this register in 32-bit units.

Temperature sensor calibration data is stored in the lower 12 bits of the TSCDR register.

45.3 Using the Temperature Sensor

The temperature sensor outputs a voltage that varies with the temperature. This voltage is converted to a digital value by the 12-bit A/D converter. To obtain the die temperature, convert this value into the temperature.

45.3.1 Preparation for Using the Temperature Sensor

The ambient temperature (T) is proportional to the temperature sensor voltage output (Vs), so ambient temperature is calculated with the following formula:

T = (Vs - V1) / slope + T1

- T: Ambient temperature of MCU as calculation result (°C)
- Vs: Voltage output by the temperature sensor on temperature measurement (V)
- T1: Temperature experimentally measured at one point (°C)
- V1: Voltage output by the temperature sensor on measurement of T1 (V)
- T2: Temperature experimentally measured at a second point (°C)
- V2: Voltage output by the temperature sensor on measurement of T2 (V)
- Slope: Temperature gradient of the temperature sensor (V / °C), slope = (V2 - V1) / (T2 -T1)

Characteristics vary between sensors, so Renesas recommends measuring two different sample temperatures as follows:

1. Use the 12-bit A/D converter to measure the voltage V1 output by the temperature sensor at temperature T1.
2. Again use the 12-bit A/D converter to measure the voltage V2 output by the temperature sensor at a different temperature T2.
3. Obtain the temperature gradient (slope = (V2 - V1) / (T2 - T1)) from these results.
4. Subsequently, obtain temperatures by substituting the slope into the formula for the temperature characteristic (T = (Vs - V1) / slope + T1).

If you are using the temperature gradient given in section 53, Electrical Characteristics, use the A/D converter to measure the voltage V1 output by the temperature sensor at temperature T1, then calculate the temperature characteristic using the following formula:

T = (Vs - V1) / slope + T1

Note: This method produces less accurate temperatures than measurement at two points.

In this MCU, the TSCDR register stores the temperature value (CAL127) of the temperature sensor measured under the condition Ta = Tj = 127°C and AVCC0 = VREFH0 = 3.3 V. If you use this value as the sample measurement result at the first point, you can omit the preparation before using the temperature sensor.

V1 is calculated from CAL127:

V1 = 3.3 × CAL127 / 4096 [V] (In case of 12 bit accuracy)

Using this value, the measured temperature can be calculated according to the following formula:

T = (Vs - V1) / slope + 127 [°C]

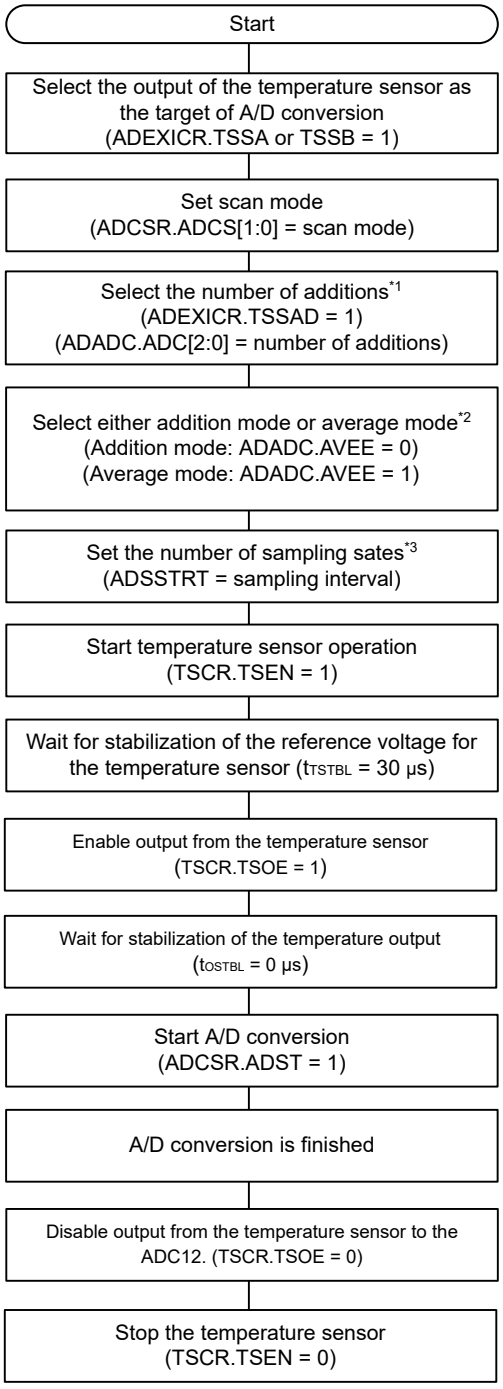
- T: Ambient temperature of MCU as calculation result (°C)
- Vs: Voltage output by the temperature sensor when the temperature is measured (V)
- V1: Voltage output by the temperature sensor when Ta = Tj = 127°C and AVCC0 = VREFH0 = 3.3 V (V)
- Slope: Temperature gradient of the temperature sensor*1 / 1000 (V/°C)

Note 1. See section 53, Electrical Characteristics

45.3.2 Procedures for Using the Temperature Sensor

Figure 45.2 shows the procedure for using the TSN.

For details, see section 43, 12-Bit A/D Converter (ADC12).



Note 1. This setting is not required if addition/average mode is not set.
Note 2. The ADADC.ADC[2:0] setting is limited to some values in additions/average mode. For details on the available ADADC.ADC[2:0] settings in additions/average mode, see section 43, 12-Bit A/D Converter (ADC12).
Note 3. Set the sampling time to more than the value described in section 53, Electrical Characteristics.

Figure 45.2 Procedure example for using the TSN

Figure 45.3 shows the timing from the start of temperature sensor operation until the completion of A/D conversion when the ADC12 is in single scan mode (the conversion target is the temperature sensor output only). The times shown in the figure are described in Table 45.2

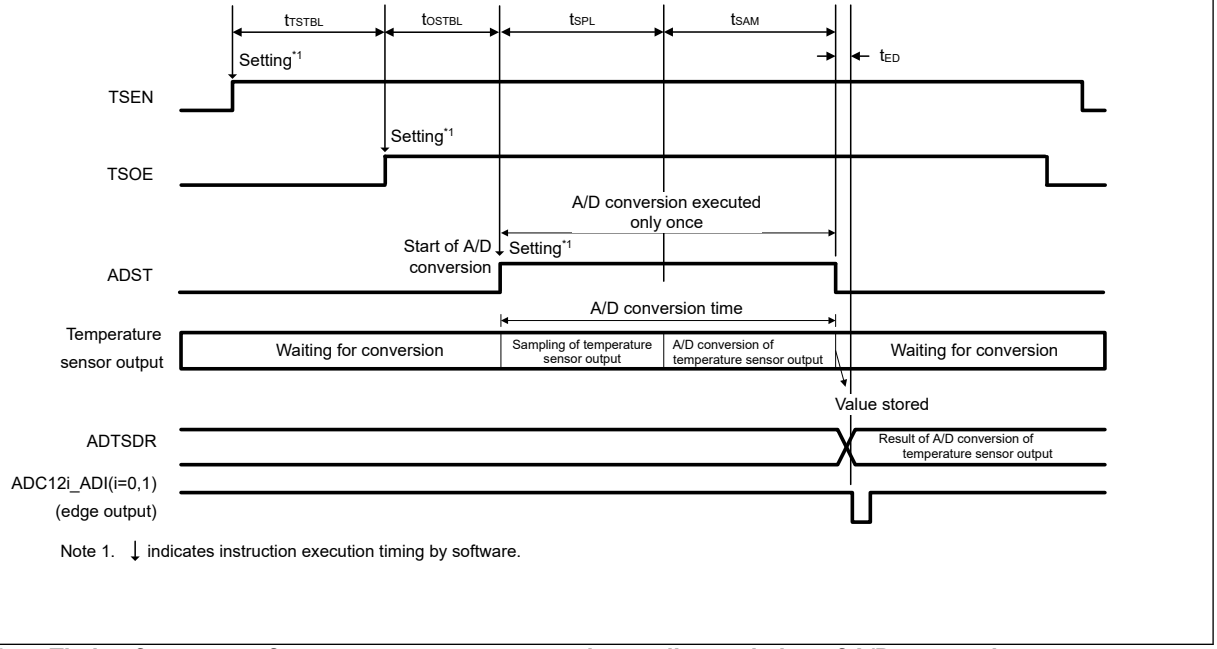


Figure 45.3 Timing from start of temperature sensor operation until completion of A/D conversion

Table 45.2 Time until completion of A/D conversion after start of temperature sensor operation

Parameter	Symbol	Time
Wait time for temperature sensor reference voltage stabilization	t_{TSTBL}	30 µs (min)
Wait time for temperature sensor output stabilization	t_{OSTBL}	0 µs (min)
A/D converter input sampling time	t_{SPL}	ADSSTRn setting × ADCLK cycles
A/D conversion time	t_{SAM}	See the table in section 43.3.7. Analog Input Sampling and Scan Conversion Time.
Scan conversion end delay	t_{ED}	

45.4 Usage Notes

45.4.1 Settings for the Module-Stop Function

TSN operation can be disabled or enabled using the associated bit in Module Stop Control Register D (MSTPCRD). The TSN is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

46. Capacitive Touch Sensing Unit (CTSU)

46.1 Overview

The Capacitive Touch Sensing Unit (CTSU) measures the electrostatic capacitance of the touch sensor. Changes in the electrostatic capacitance are determined by software that enables the CTSU to detect whether a finger is in contact with the touch sensor. The electrode surface of the touch sensor is usually enclosed with an electrical conductor so that a finger does not come into direct contact with the electrode.

As Figure 46.1 shows, electrostatic capacitance (parasitic capacitance) exists between the electrode and the surrounding conductors. Because the human body is an electrical conductor, when a finger is placed close to the electrode, the value of electrostatic capacitance increases.

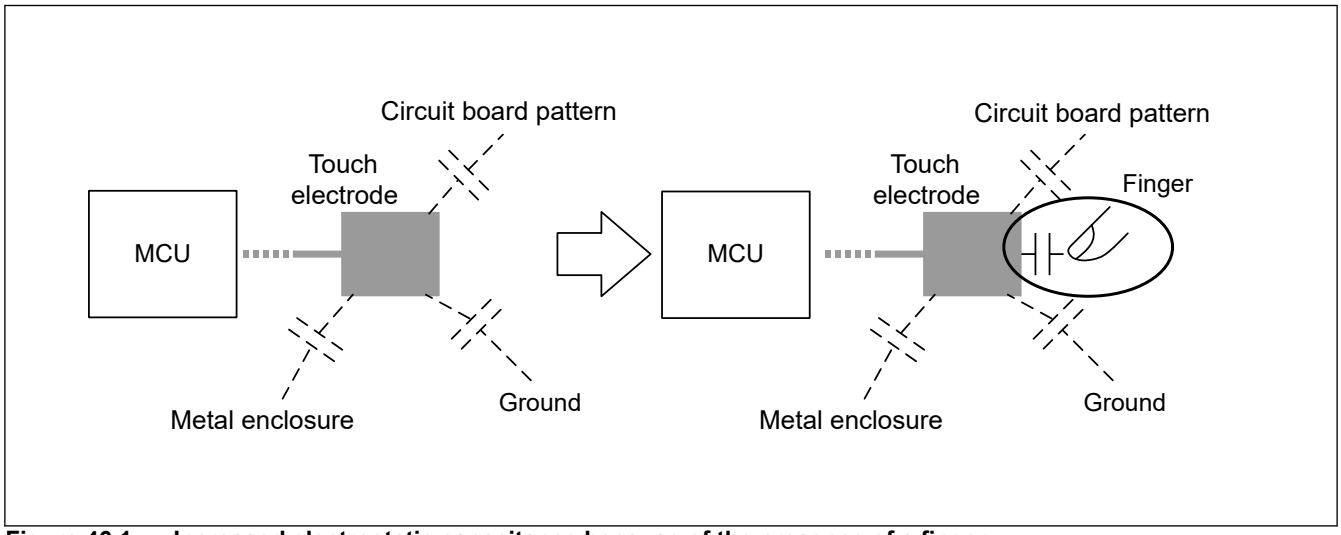

Figure 46.1 Increased electrostatic capacitance because of the presence of a finger

Electrostatic capacitance is detected by the self-capacitance and mutual capacitance methods. In the self-capacitance method, the CTSU detects electrostatic capacitance generated between a finger and a single electrode. In the mutual capacitance method, two electrodes are used one as a transmit electrode and the other as a receive electrode, and the CTSU detects the change in the electrostatic capacitance generated between the two when a finger is placed close to them.

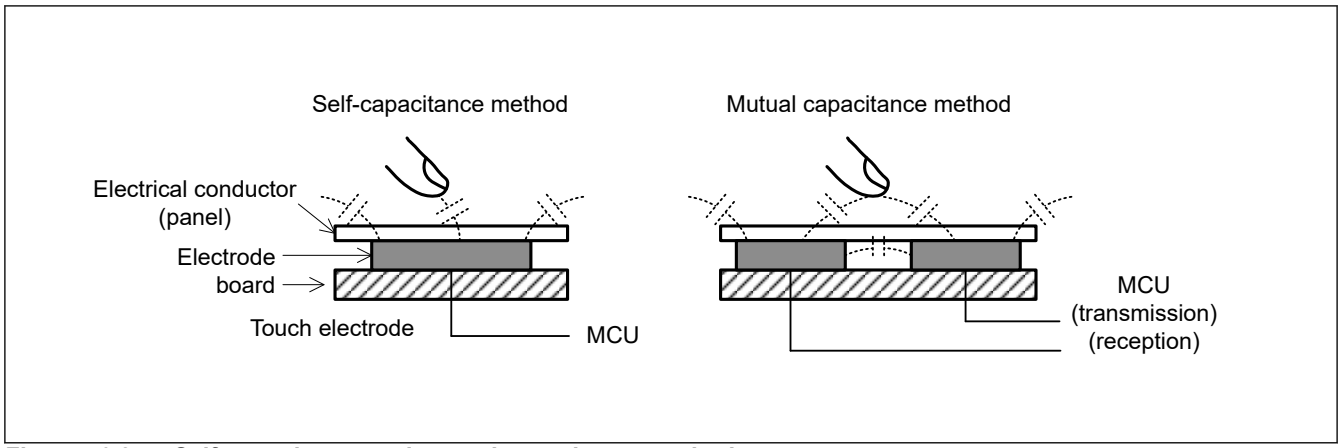

Figure 46.2 Self-capacitance and mutual capacitance methods

Electrostatic capacitance is measured by counting a clock signal whose frequency changes according to the amount of charged or discharged current, for a specified period. For details on the measurement principles of the CTSU, see section 46.3.1. Principles of Measurement Operation.

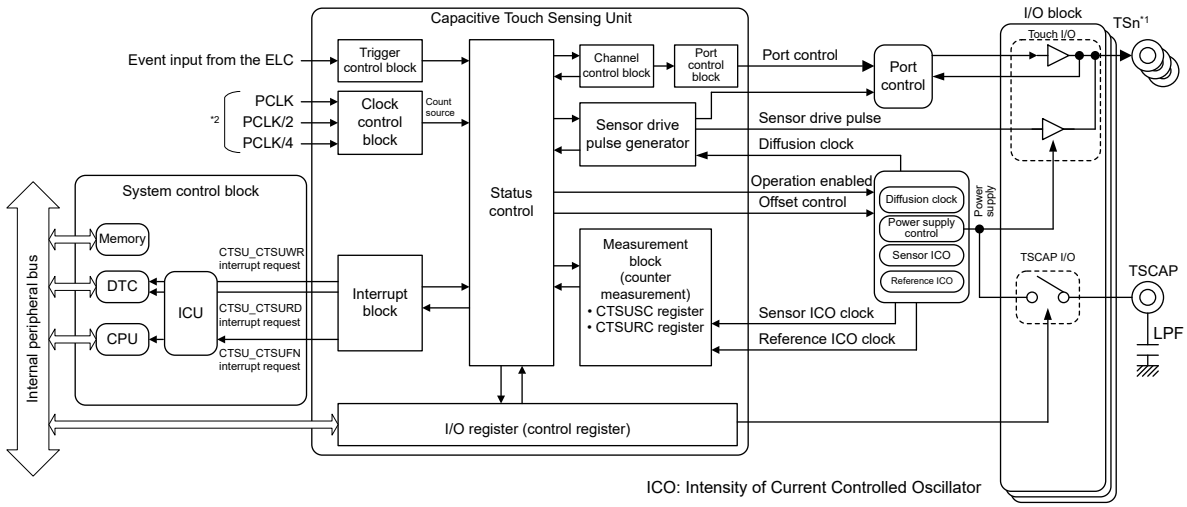
Table 46.1 lists the CTSU specifications and Figure 46.3 shows a block diagram.

Table 46.1 CTSU specifications

Parameter		Specifications
Operating clock		PCLKB, PCLKB/2, or PCLKB/4
Pins	Electrostatic capacitance measurement	20 channels
	TSCAP	Low Pass Filter (LPF) connection pin
Measurement modes	Self-capacitance single scan mode	Electrostatic capacitance is measured on one channel using the self-capacitance method.
	Self-capacitance multiscan mode	Electrostatic capacitance is measured successively on multiple channels using the self-capacitance method.
	Mutual capacitance full scan mode	Electrostatic capacitance is measured successively on multiple channels using the mutual capacitance method.
Calibration mode		Improvement of measured value accuracy by calibration of sensor ICO
Noise prevention		Synchronous noise prevention, high-pass noise prevention
Measurement start conditions		• Software trigger • External trigger (ELC_CTSU from the Event Link Controller (ELC))
TrustZone Filter		Security attribution can be set

As Figure 46.3 shows, the CTSU consists of the following components:

- Status control block
- Trigger control block
- Clock control block
- Channel control block
- Port control block
- Sensor drive pulse generator
- Measurement block
- Interrupt block
- I/O registers



Note 1. TSn = TS00 to TS19
Note 2. PCLK = PCLKB

Figure 46.3 CTSU block diagram

Table 46.2 CTSU I/O pins

Pin name	I/O	Function
TS00 to TS19	Input	Electrostatic capacitive measurement pins (touch pins)
TSCAP	—	LPF connection pin

46.2 Register Descriptions

46.2.1 CTSUCR0 : CTSU Control Register 0

Base address: CTSU = 0x400D_0000

Offset address: 0x00

Bit position:	7	6	5	4	3	2	1	0
Bit field:	CTSUTXVSEL	—	—	CTSUINIT	CTSUIOC	CTSUSNZ	CTSUCAP	CTSUSTRT
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CTSUSTRT	CTSU Measurement Operation Start 0: Stop measurement operation*1 1: Start measurement operation	R/W
1	CTSUCAP	CTSU Measurement Operation Start Trigger Select 0: Software trigger 1: External trigger	R/W
2	CTSUSNZ	CTSU Wait State Power-Saving Enable 0: Disable power-saving function during wait state 1: Enable power-saving function during wait state	R/W
3	CTSUIOC	CTSU Transmit Pin Control 0: The TS pins are driven low 1: The TS pins are driven high	R/W
4	CTSUINIT	CTSU Control Block Initialization Writing 1 to this bit initializes the CTSU control block and CTSUSC, CTSURC, CTSUMCH0, CTSUMCH1, and CTSUST registers. This bit is read as 0.	W
6:5	—	These bits are read as 0. The write value should be 0.	R/W
7	CTSUTXVSEL	CTSU Transmission Power Supply Select 0: TSCAP is selected as the power-supply voltage for the transmission pins. 1: VCL is selected as the power-supply voltage for the transmission pins.	R/W

Note 1. When the CTSU is not used, fix the value of this bit to 0.

Only set the CTSUCAP, CTSUSNZ, CTSUTXVSEL2 and CTSUTXVSEL bits when the CTSUSTRT bit is 0. These bits can be set at the same time that measurement operation starts.

CTSUSTRT bit (CTSU Measurement Operation Start)

The CTSUSTRT bit specifies whether CTSU operation starts or stops. When the CTSUSTRT bit is 0, measurement starts when the software writes 1 to the CTSUSTRT bit (software trigger) and stops when the hardware clears the CTSUSTRT bit to 0. When the CTSUSTRT bit is 1, the CTSU waits for an external trigger by writing 1 to the CTSUSTRT bit, and measurement starts on the rising edge of the external trigger. When measurement is stopped, the CTSU waits for the next external trigger and operation continues.

Table 46.3 lists the CTSU states.

Table 46.3 CTSU status (1 of 2)

CTSUSTRT bit	CTSUCAP bit	CTSU state
0	0	Stopped
0	1	Stopped

Table 46.3 CTSU status (2 of 2)

CTSUSTRT bit	CTSUCAP bit	CTSU state
1	0	Measurement in progress
1	1	Measurement in progress and waiting for an external trigger*1

Note 1. The state can be read from the CTSUST.CTSUSTC[2:0] flags as follows:
During measurement: CTSUST.CTSUSTC[2:0] flags ≠ 000b
While waiting for an external trigger: CTSUST.CTSUSTC[2:0] flags = 000b
When the CTSU is not used, fix the value of this bit to 0.

If the software sets the CTSUSTRT bit to 1 when the bit is already 1, the write is ignored and operation continues. To force operation to stop through the software when the CTSUSTRT bit is 1, set the CTSUSTRT bit to 0 and the CTSUINIT bit to 1 at the same time.

CTSUCAP bit (CTSU Measurement Operation Start Trigger Select)

The CTSUCAP bit specifies the measurement start condition. For details, see CTSUSTRT bit (CTSU Measurement Operation Start).

CTSUSNZ bit (CTSU Wait State Power-Saving Enable)

The CTSUSNZ bit enables or disables power-saving operation during a wait state. It can also suspend the CTSU power supply, which decreases power consumption during the wait state. In the suspended state, the CTSU power supply is turned off while the external TSCAP is still charged.

Table 46.4 shows the CTSU power supply state control.

Table 46.4 CTSU power supply state control

CTSUCR1.CTSUPON bit	CTSUSNZ bit	CTSUCAP bit	CTSUSTRT bit	CTSU power supply state
0	0	0	0	Stopped
1	0	—	—	Operating
1	1	0	0	Suspended

Note: Other settings are prohibited.

To start measurement from the suspended state, set the CTSUSNZ bit to 0, and then set the CTSUSTRT bit to 1. To suspend the module after measurement stops, set the CTSUSNZ bit to 1.

CTSUIOC bit (CTSU Transmit Pin Control)

The CTSUIOC bit selects the logic level of the TS pin when the CTSUERRS.CTSUTSOD bit is set to 1. This bit setting is ignored when the CTSUTSOD bit is 0.

CTSUINIT bit (CTSU Control Block Initialization)

Write 1 to the CTSUINIT bit to initialize the internal control registers. To force the current operation to stop, set the CTSUSTRT bit to 0 and the CTSUINIT bit to 1 at the same time. This stops the operation and initializes the internal control registers.

Do not write 1 to the CTSUINIT bit when the CTSUSTRT bit is 1.

CTSUTXVSEL bit (CTSU Transmission Power Supply Select)

The CTSUTXVSEL bit is used to switch the power supply for the transmit buffer in mutual capacitance full scan mode.

Set this bit to 0 for any other mode or when the VCC voltage is lower than 2.7 V. This bit switches the power supply for touch I/O, which is set for transmission by the CTSUCHTRCn registers. Table 46.5 lists the power supply for the TSm pin. When the VCC voltage fluctuates greatly due to switching of the output buffer, switching to the internal logic power supply can reduce the effect on the voltage fluctuation.

Table 46.5 Power supplied to the TSm pins

Setting of CTSUCHTRCn Register	CTSUTXVSEL bit	Power supply of TSm pins
0 (Reception)	*	VCC
1 (Transmission)	0 (VCC)	
	1 (Internal logic power supply)	Internal logic power supply

46.2.2 CTSUCR1 : CTSU Control Register 1

Base address: CTSU = 0x400D_0000

Offset address: 0x01

Bit position:	7	6	5	4	3	2	1	0
Bit field:	CTSUMD[1:0]		CTSUCLK[1:0]		CTSU ATUNE1	—	CTSU CSW	CTSU PON
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CTSUPON	CTSU Power Supply Enable 0: Power off the CTSU 1: Power on the CTSU	R/W
1	CTSUCSW	CTSU LPF Capacitance Charging Control This bit controls charging of the LPF capacitance connected to the TSCAP pin. 0: Turn off capacitance switch 1: Turn on capacitance switch	R/W
2	—	This bit is read as 0. The write value should be 0.	R/W
3	CTSUATUNE1	CTSU Power Supply Capacity Adjustment 0: Normal output 1: High-current output	R/W
5:4	CTSUCLK[1:0]	CTSU Operating Clock Select 0 0: PCLKB 0 1: PCLKB/2 (PCLKB divided by 2) 1 0: PCLKB/4 (PCLKB divided by 4) 1 1: Setting prohibited	R/W
7:6	CTSUMD[1:0]	CTSU Measurement Mode Select 0 0: Self-capacitance single scan mode 0 1: Self-capacitance multiscan mode 1 0: Setting prohibited 1 1: Mutual capacitance full scan mode	R/W

Only set the CTSUCR1 register when the CTSUCR0.CTSUSTRT bit is 0.

CTSUPON bit (CTSU Power Supply Enable)

The CTSUPON bit controls the power supply to the CTSU. Set the CTSUPON and CTSUCSW bits to the same value.

CTSUCSW bit (CTSU LPF Capacitance Charging Control)

The CTSUCSW bit controls charging of the LPF capacitor connected to the TSCAP pin by turning the capacitance switch on or off. After the capacitance switch is turned on, wait until the capacitance connected to the TSCAP pin is charged for the specified time before starting measurement by setting CTSUCR0.CTSUSTRT to 1. Before starting measurement, use an I/O port to output low to the TSCAP pin, and discharge the existing LPF capacitance. Set the CTSUPON and CTSUCSW bits to the same value.

CTSUATUNE1 bit (CTSU Power Supply Capacity Adjustment)

The CTSUATUNE1 bit sets the capacity of the CTSU power supply. Normally, set this bit to 0.

CTSUCLK[1:0] bits (CTSU Operating Clock Select)

The CTSUCLK[1:0] bits select the operating clock.

CTSUMD[1:0] bits (CTSU Measurement Mode Select)

The CTSUMD[1:0] bits set the measurement mode. For details, see section 46.3.2. Measurement Modes.

46.2.3 CTSUSDPRS : CTSU Synchronous Noise Reduction Setting Register

Base address: CTSU = 0x400D_0000

Offset address: 0x02

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	CTSUSOFF	CTSUPRMODE[1:0]		CTSUPRRATIO[3:0]			
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	CTSUPRRATIO[3:0]	CTSU Measurement Time and Pulse Count Adjustment These bits set the measurement time and the measurement pulse count setting. Recommended setting: 3 (0011b)	R/W
5:4	CTSUPRMODE[1:0]	CTSU Base Period and Pulse Count Setting These bits set the base pulse count. 0 0: 510 pulses 0 1: 126 pulses 1 0: 62 pulses (recommended setting) 1 1: Setting prohibited	R/W
6	CTSUSOFF	CTSU High-Pass Noise Reduction Function Off Setting This bit turns spectrum diffusion on or off to reduce high-pass noise. 0: Turn on 1: Turn off	R/W
7	—	This bit is read as 0. The write value should be 0.	R/W

Only set the CTSUSDPRS register when the CTSUCR0.CTSUSTRT bit is 0.

CTSUPRRATIO[3:0] bits (CTSU Measurement Time and Pulse Count Adjustment)

The CTSUPRRATIO[3:0] bits are used to determine the measurement time and the measurement pulse count. These values are calculated using the following formulas, where the base pulse count is determined by the CTSUPRMODE[1:0] setting:

$$\text{Measurement pulse count} = \text{base pulse count} \times (\text{CTSUPRRATIO[3:0] bits} + 1)$$

$$\text{Measurement time} = (\text{base pulse count} \times (\text{CTSUPRRATIO[3:0] bits} + 1) + (\text{base pulse count} - 2) \times 0.25) \times \text{base clock cycle}$$

Note: For details on the base clock cycle, see section 46.2.17. CTSUSO1 : CTSU Sensor Offset Register 1.

CTSUPRMODE[1:0] bits (CTSU Base Period and Pulse Count Setting)

The CTSUPRMODE[1:0] bits select the number of base pulses that occur during measurement.

CTSUSOFF bit (CTSU High-Pass Noise Reduction Function Off Setting)

The CTSUSOFF bit turns on or off the function for reducing high-pass noise. Set this bit to 1 to turn the function off.

46.2.4 CTSUSST : CTSU Sensor Stabilization Wait Control Register

Base address: CTSU = 0x400D_0000

Offset address: 0x03

Bit position:	7	6	5	4	3	2	1	0
Bit field:	CTSUSST[7:0]							
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	CTSUSST[7:0]	CTSU Sensor Stabilization Wait Control Fix the value of these bits to 00010000b.	R/W

Only set the CTSUSST register when the CTSUCR0.CTSUSTRT bit is 0.

CTSUSST[7:0] bits (CTSU Sensor Stabilization Wait Control)

The CTSUSST[7:0] bits set the stabilization wait time for the TSCAP pin voltage. Always fix these bits to 00010000b. If these bits are not set, the TSCAP voltage will be unstable at the start of measurement, and the CTSU will be unable to obtain correct touch measurement results.

46.2.5 CTSUMCH0 : CTSU Measurement Channel Register 0

Base address: CTSU = 0x400D_0000

Offset address: 0x04

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	CTSHMCH0[4:0]				
Value after reset:	0	0	0	1	1	1	1	1

Bit	Symbol	Function	R/W
4:0	CTSHMCH0[4:0]	CTSU Measurement Channel 0 In self-capacitance single scan mode, these bits set the channel to be measured. Other than when specified, starting measurement operation by setting CTSUCR0.CTSUSTRT to 1 is prohibited after these bits are set. In other measurement modes, these bits indicate the channel that is currently being measured. 0x00: TS00 0x01: TS01 ⋮ 0x12: TS18 0x13: TS19 0x1F: Measurement is being stopped. (Except in self-capacitance single scan mode)	R/W*1
7:5	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Writing to these bits is only enabled in self-capacitance single scan mode (CTSUCR1.CTSUMD[1:0] bits = 00b).

Only set the CTSUMCH0 register when the CTSUCR0.CTSUSTRT bit is 0.

CTSHMCH0[4:0] bits (CTSU Measurement Channel 0)

In self-capacitance single scan mode, the CTSHMCH0[4:0] bits set the channel to be measured. In this mode, only specify enabled channels (TS00 to TS19). In other modes, these indicate the receive channel that is being measured, and writing to these bits has no effect.

46.2.6 CTSUMCH1 : CTSU Measurement Channel Register 1

Base address: CTSU = 0x400D_0000

Offset address: 0x05

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	CTSUMCH1[4:0]				
Value after reset:	0	0	0	1	1	1	1	1

Bit	Symbol	Function	R/W
4:0	CTSUMCH1[4:0]	CTSU Measurement Channel 1 0x00: TS00 0x01: TS01 ⋮ 0x12: TS18 0x13: TS19 0x1F: Measurement is being stopped.	R
7:5	—	These bits are read as 0.	R

CTSUMCH1[4:0] bits (CTSU Measurement Channel 1)

In full scan mode, the CTSUMCH1[4:0] bits indicate the transmit channel that is being measured. They are always 0x1F when measurement is stopped, or in self-capacitance single scan and multi-scan modes.

46.2.7 CTSUCHAC0 : CTSU Channel Enable Control Register 0

Base address: CTSU = 0x400D_0000

Offset address: 0x06

Bit position:	7	6	5	4	3	2	1	0
Bit field:	CTSUCHAC0[7:0]							
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	CTSUCHAC0[7:0]	CTSU Channel Enable Control 0 These bits select whether the associated TS pin is measured. bit0 is associated with TS00 and bit7 with TS07. 0: Do not measure 1: Measure	R/W

Only set the CTSUCHAC0 register when the CTSUCR0.CTSUSTRT bit is 0.

CTSUCHAC0[7:0] bits (CTSU Channel Enable Control 0)

The CTSUCHAC0[7:0] bits select the receive and transmit pins whose electrostatic capacitance is to be measured.

46.2.8 CTSUCHAC1 : CTSU Channel Enable Control Register 1

Base address: CTSU = 0x400D_0000

Offset address: 0x07

Bit position:	7	6	5	4	3	2	1	0
Bit field:	CTSUCHAC1[7:0]							
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	CTSUCHAC1[7:0]	CTSU Channel Enable Control 1 These bits select whether the associated TS pin is measured. bit0 is associated with TS08 and bit7 with TS15. 0: Do not measure 1: Measure	R/W

Only set the CTSUCHAC1 register when the CTSUCR0.CTSUSTRT bit is 0.

CTSUCHAC1[7:0] bits (CTSU Channel Enable Control 1)

The CTSUCHAC1[7:0] bits select the receive and transmit pins whose electrostatic capacitance is to be measured.

46.2.9 CTSUCHAC2 : CTSU Channel Enable Control Register 2

Base address: CTSU = 0x400D_0000

Offset address: 0x08

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	CTSUCHAC2[3:0]			
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	CTSUCHAC2[3:0]	CTSU Channel Enable Control 2 These bits select whether the associated TS pin is measured. bit0 is associated with TS16 and bit3 with TS19. 0: Do not measure 1: Measure	R/W
7:4	—	These bits are read as 0. The write value should be 0.	R/W

Only set the CTSUCHAC2 register when the CTSUCR0.CTSUSTRT bit = 0.

CTSUCHAC2[3:0] bits (CTSU Channel Enable Control 2)

The CTSUCHAC2[3:0] bits select the receive and transmit pins whose electrostatic capacitance is to be measured.

46.2.10 CTSUCHTRC0 : CTSU Channel Transmit/Receive Control Register 0

Base address: CTSU = 0x400D_0000

Offset address: 0x0B

Bit position:	7	6	5	4	3	2	1	0
Bit field:	CTSUCHTRC0[7:0]							
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	CTSUCHTRC0[7:0]	CTSU Channel Transmit/Receive Control 0 bit0 is associated with TS00 and bit7 with TS07. 0: Reception 1: Transmission	R/W

Only set the CTSUCHTRC0 register when the CTSUCR0.CTSUSTRT bit is 0.

CTSUCHTRC0[7:0] bits (CTSU Channel Transmit/Receive Control 0)

In full scan mode, the CTSUCHTRC0[7:0] bits allocate reception or transmission to the associated TS pins. The setting is ignored in self-capacitance single scan and multi-scan modes.

46.2.11 CTSUCHTRC1 : CTSU Channel Transmit/Receive Control Register 1

Base address: CTSU = 0x400D_0000

Offset address: 0x0C

Bit position:	7	6	5	4	3	2	1	0
Bit field:	CTSUCHTRC1[7:0]							
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	CTSUCHTRC1[7:0]	CTSU Channel Transmit/Receive Control 1 bit0 is associated with TS08 and bit7 with TS15. 0: Reception 1: Transmission	R/W

Only set the CTSUCHTRC1 register when the CTSUCR0.CTSUSTRT bit is 0.

CTSUCHTRC1[7:0] bits (CTSU Channel Transmit/Receive Control 1)

In full scan mode, the CTSUCHTRC1[7:0] bits allocate reception or transmission to the associated TS pins. The setting is ignored in self-capacitance single scan and multiscan modes.

46.2.12 CTSUCHTRC2 : CTSU Channel Transmit/Receive Control Register 2

Base address: CTSU = 0x400D_0000

Offset address: 0x0D

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	CTSUCHTRC2[3:0]			
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	CTSUCHTRC2[3:0]	CTSU Channel Transmit/Receive Control 2 bit0 is associated with TS16 and bit3 with TS19. 0: Reception 1: Transmission	R/W
7:4	—	These bits are read as 0. The write value should be 0.	R/W

Only set the CTSUCHTRC2 register when the CTSUCR0.CTSUSTRT bit is 0.

CTSUCHTRC2[3:0] bits (CTSU Channel Transmit/Receive Control 2)

In full scan mode, the CTSUCHTRC2[3:0] bits allocate reception or transmission to the associated TS pins. The setting is ignored in self-capacitance single scan and multiscan modes.

46.2.13 CTSUDCLKC : CTSU High-Pass Noise Reduction Control Register

Base address: CTSU = 0x400D_0000

Offset address: 0x10

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	CTSUSSCNT[1:0]		—	—	CTSUSSMOD[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	CTSUSSMOD[1:0]	CTSU Diffusion Clock Mode Select Set these bits to 00b.	R/W
3:2	—	These bits are read as 0. The write value should be 0.	R/W
5:4	CTSUSSCNT[1:0]	CTSU Diffusion Clock Mode Control Set these bits to 11b.	R/W
7:6	—	These bits are read as 0. The write value should be 0.	R/W

Only set the CTSUDCLKC register when the CTSUCR0.CTSUSTRT bit is 0.

CTSUSSMOD[1:0] bits (CTSU Diffusion Clock Mode Select)

The CTSUSSMOD[1:0] bits set the mode of the spectrum diffusion clock for high-pass noise reduction. When using the high-pass function, always fix these bits to 00b. If these bits are not set, the CTSU will be unable to effectively reduce high-pass noise.

CTSUSSCNT[1:0] bits (CTSU Diffusion Clock Mode Control)

The CTSUSSCNT[1:0] bits adjust the amount of spectrum diffusion applied to reduce high-pass noise. When using the high-pass noise reduction function, always fix these bits to 11b. If these bits are not set, touch measurement might be performed incorrectly.

46.2.14 CTSUST : CTSU Status Register

Base address: CTSU = 0x400D_0000

Offset address: 0x11

Bit position:	7	6	5	4	3	2	1	0
Bit field:	CTSUPS	CTSUROVF	CTSUSOVF	CTSUDTSR	—	CTSUSTC[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	CTSUSTC[2:0]	CTSU Measurement Status Counter These counters indicate the current measurement status. 0 0 0: Status 0 0 0 1: Status 1 0 1 0: Status 2 0 1 1: Status 3 1 0 0: Status 4 1 0 1: Status 5	R
3	—	This bit is read as 0. The write value should be 0.	R/W
4	CTSUDTSR	CTSU Data Transfer Status Flag This flag indicates whether the measurement result stored in the sensor counter and the reference counter was read. 0: Read 1: Not read	R

Bit	Symbol	Function	R/W
5	CTSUSOVF	CTSU Sensor Counter Overflow Flag This flag indicates an overflow on the sensor counter. 0: No overflow occurred 1: Overflow occurred	R/W
6	CTSUROVF	CTSU Reference Counter Overflow Flag This flag indicates an overflow on the reference counter. 0: No overflow occurred 1: Overflow occurred	R/W
7	CTSUPS	CTSU Mutual Capacitance Status Flag This flag indicates the measurement status in mutual capacitance full scan mode. 0: First measurement 1: Second measurement	R

When using the CTSUCR0.CTSUINIT bit to clear an overflow flag, make sure that the CTSUCR0.CTSUSTRT bit is 0.

CTSUSTC[2:0] flags (CTSU Measurement Status Counter)

The CTSUSTC[2:0] flags are a counter indicating the current measurement status. For details on each status, see section 46.3.2.2. Status counter.

CTSUDTSR flag (CTSU Data Transfer Status Flag)

The CTSUDTSR flag indicates whether the measurement result stored in the sensor counter and the reference counter was read. The flag sets to 1 when measurement completes and 0 when the reference counter is read by software or the DTC. The flag can also be cleared using the CTSUCR0.CTSUINIT bit.

CTSUSOVF flag (CTSU Sensor Counter Overflow Flag)

The CTSUSOVF flag sets to 1 when the sensor counter, CTSUSC, overflows. On overflow, the counter value reads as 0xFFFF. Measurement processing continues for the specified period.

No interrupt occurs on an overflow. To determine the channel on which the overflow occurred, read the measurement result of each channel after measurement completes, signaled by a measurement end interrupt.

This flag is cleared when 0 is written after 1 is read by software. It can also be cleared using the CTSUCR0.CTSUINIT bit.

CTSUROVF flag (CTSU Reference Counter Overflow Flag)

The CTSUROVF flag sets to 1 when the reference counter, CTSURC, overflows. On overflow, the counter value reads as 0xFFFF. Measurement processing continues for the specified period.

No interrupt occurs on an overflow. To determine the channel on which the overflow occurred, read the measurement result of each channel after measurement completes, signaled by a measurement end interrupt.

This flag is cleared when 0 is written after 1 is read by software. It can also be cleared using the CTSUCR0.CTSUINIT bit.

CTSUPS flag (CTSU Mutual Capacitance Status Flag)

In mutual capacitance full scan mode, when CTSUCR1.CTSUMD[1:0] = 11b, the CTSUPS flag indicates whether the measurement is the first or second of two measurements for each channel. When measurement is stopped or in other measurement modes, this flag is always 0.

46.2.15 CTSUSSC : CTSU High-Pass Noise Reduction Spectrum Diffusion Control Register

Base address: CTSU = 0x400D_0000

Offset address: 0x12

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	CTSUSSDIV[3:0]				—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	—	These bits are read as 0. The write value should be 0.	R/W
11:8	CTSUSSDIV[3:0]	CTSU Spectrum Diffusion Frequency Division Setting These bits specify the spectrum diffusion frequency division setting based on the base clock frequency division setting.	R/W
15:12	—	These bits are read as 0. The write value should be 0.	R/W

CTSUSSDIV[3:0] bits (CTSU Spectrum Diffusion Frequency Division Setting)

The CTSUSSDIV[3:0] bits specify the spectrum diffusion frequency derived from the base clock frequency division setting. To calculate the correct setting for CTSUSSDIV[3:0], see the relationship between base clock frequencies and the settings in Table 46.6.

Table 46.6 Relationship between base clock frequencies and CTSUSSDIV[3:0] bits settings

Base clock frequency fb (MHz)	CTSUSSDIV[3:0] bit setting
4.00 ≤ fb	0000b
2.00 ≤ fb < 4.00	0001b
1.33 ≤ fb < 2.00	0010b
1.00 ≤ fb < 1.33	0011b
0.80 ≤ fb < 1.00	0100b
0.67 ≤ fb < 0.80	0101b
0.57 ≤ fb < 0.67	0110b
0.50 ≤ fb < 0.57	0111b
0.44 ≤ fb < 0.50	1000b
0.40 ≤ fb < 0.44	1001b
0.36 ≤ fb < 0.40	1010b
0.33 ≤ fb < 0.36	1011b
0.31 ≤ fb < 0.33	1100b
0.29 ≤ fb < 0.31	1101b
0.27 ≤ fb < 0.29	1110b
fb < 0.27	1111b

46.2.16 CTSUSO0 : CTSU Sensor Offset Register 0

Base address: CTSU = 0x400D_0000

Offset address: 0x14

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CTSUSNUM[5:0]						CTSUSO[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
9:0	CTSUSO[9:0]	CTSU Sensor Offset Adjustment These bits adjust the electronic capacitance when the electrode is not being touched. 0x000: Current offset is 0. 0x001: Current offset is 1. 0x002: Current offset is 2. ⋮ ⋮ 0x3FE: Current offset is 1022. 0x3FF: Current offset is maximum.	R/W

Bit	Symbol	Function	R/W
15:10	CTSUSNUM[5:0]	CTSU Measurement Count Setting These bits set the number of measurements.	R/W

CTSUSO[9:0] bits (CTSU Sensor Offset Adjustment)

The CTSUSO[9:0] bits offset the sensor ICO input current generated from electrostatic capacitance during touch measurement when the electrode is not being touched. This prevents the CTSU sensor counter from overflowing. Set the TS pin that is to be measured next after a CTSU_CTSUWR interrupt occurs.

CTSUSNUM[5:0] bits (CTSU Measurement Count Setting)

The CTSUSNUM[5:0] bits specify how many times the measurement pulse count specified in the CTSUSDPRS.CTSUPRRATIO[3:0] and CTSUSDPRS.CTSUPRMODE[1:0] bits is repeated during the measurement time. The measurement pulse count is repeated (CTSUSNUM[5:0] bits + 1) times. Set the TS pin that is to be measured next after a CTSU_CTSUWR interrupt is generated.

46.2.17 CTSUSO1 : CTSU Sensor Offset Register 1

Base address: CTSU = 0x400D_0000

Offset address: 0x16

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	CTSUICOG[1:0]		CTSUSDPA[4:0]					CTSURICOA[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	CTSURICOA[7:0]	CTSU Reference ICO Current Adjustment These bits adjust the input current of the reference ICO. 0x00: Current offset is 0 0x01: Current offset is 1 0x02: Current offset is 2 ⋮ 0xFE: Current offset is 254 0xFF: Current offset is maximum.	R/W

Bit	Symbol	Function	R/W
12:8	CTSUSDPA[4:0]	CTSU Base Clock Setting These bits are used to generate the base clock. 0x00: Operating clock divided by 2*1 0x01: Operating clock divided by 4 0x02: Operating clock divided by 6 0x03: Operating clock divided by 8 0x04: Operating clock divided by 10 0x05: Operating clock divided by 12 0x06: Operating clock divided by 14 0x07: Operating clock divided by 16 0x08: Operating clock divided by 18 0x09: Operating clock divided by 20 0x0A: Operating clock divided by 22 0x0B: Operating clock divided by 24 0x0C: Operating clock divided by 26 0x0D: Operating clock divided by 28 0x0E: Operating clock divided by 30 0x0F: Operating clock divided by 32 0x10: Operating clock divided by 34 0x11: Operating clock divided by 36 0x12: Operating clock divided by 38 0x13: Operating clock divided by 40 0x14: Operating clock divided by 42 0x15: Operating clock divided by 44 0x16: Operating clock divided by 46 0x17: Operating clock divided by 48 0x18: Operating clock divided by 50 0x19: Operating clock divided by 52 0x1A: Operating clock divided by 54 0x1B: Operating clock divided by 56 0x1C: Operating clock divided by 58 0x1D: Operating clock divided by 60 0x1E: Operating clock divided by 62 0x1F: Operating clock divided by 64	R/W
14:13	CTSUICOG[1:0]	CTSU ICO Gain Adjustment These bits adjust the output frequency gain of the sensor ICO and the reference ICO. 0 0: 100% gain 0 1: 66% gain 1 0: 50% gain 1 1: 40% gain	R/W
15	—	This bit is read as 0. The write value should be 0.	R/W

Note 1. Do not set the CTSUSDPA[4:0] bits set to 00000b while the high-pass noise reduction function is turned off (CTSUSDPRS.CTSUSOFF bit = 1) in mutual capacitance full scan mode (CTSUCR1.CTSUMD[1:0] bits = 11b).

After a CTSU_CTSUWR interrupt occurs, write first to the CTSUSSC register, next to the CTSUSO0 register, and then to the CTSUSO1 register. The write to the CTSUSO1 register causes a transition to Status 3. (See Table 46.7 and Table 46.8.) Set all of the bits in a single operation when writing to the CTSUSO1 register.

CTSURICOA[7:0] bits (CTSU Reference ICO Current Adjustment)

The CTSURICOA[7:0] bits adjust the oscillation frequency using the input current of the reference ICO.

CTSUSDPA[4:0] bits (CTSU Base Clock Setting)

The CTSUSDPA[4:0] bits select the base clock used as the source for the sensor drive pulse by dividing the operating clock. For details on the setting procedure, see section 46.3.2.1. Initial settings flow.

CTSUICOG[1:0] bits (CTSU ICO Gain Adjustment)

The CTSUICOG[1:0] bits adjust the output frequency gain of the sensor ICO and the reference ICO. Normally, set these bits to 00b for the maximum gain. If changes in the capacitance between when the electrode is touched and when it is not touched greatly exceed the dynamic range of the sensor ICO, adjust the gain appropriately with this setting.

46.2.18 CTSUSC : CTSU Sensor Counter

Base address: CTSU = 0x400D_0000

Offset address: 0x18

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CTSUSC[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	CTSUSC[15:0]	CTSU Sensor Counter These bits indicate the measurement result of the sensor ICO. They read 0xFFFF when an overflow occurs.	R

After a CTSU_CTSURD interrupt occurs, read first from the CTSUSC counter and then from the CTSURC counter.

CTSUSC[15:0] bits (CTSU Sensor Counter)

The CTSUSC[15:0] bits are configured as an increment counter for the sensor ICO clock. Read these bits after a CTSU_CTSURD interrupt occurs. After the CTSURC counter is read, these bits are cleared immediately before the CTSU measurement status counter value changes to Status 4 (the CTSUST.CTSUSTC[2:0] flags changes to 100b) in the next measurement. They can also be cleared using the CTSUCR0.CTSUINIT bit.

46.2.19 CTSURC : CTSU Reference Counter

Base address: CTSU = 0x400D_0000

Offset address: 0x1A

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CTSURC[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	CTSURC[15:0]	CTSU Reference Counter These bits indicate the measurement result of the reference ICO. They read 0xFFFF when an overflow occurs.	R

After a CTSU_CTSURD interrupt occurs, read first from the CTSUSC counter and then from the CTSURC counter.

Status 3 continues until the CTSURC counter is read, even if the stabilization time specified for Status 3 elapses.

CTSURC[15:0] bits (CTSU Reference Counter)

The CTSURC[15:0] bits are configured as an increment counter for the reference ICO clock. The reference ICO optimizes touch measurement performed by the sensor ICO. There is some deviation depending on the internal sensor ICO and the reference ICO in the CTSU, but both ICOs have almost the same characteristics, including the dynamic range and the current-to-frequency characteristics. The range of current amount that can be set in the reference ICO current adjustment bits is about the same as the dynamic range of both ICOs, and the current amount input to the sensor ICO must be within this dynamic range. To ensure this, use the reference ICO to check the differences between the ICOs and measure the current-to-oscillation frequency characteristics. Because the reference ICO oscillation frequency can be obtained from the reference ICO counter, the ICO oscillation frequency (counter value/measurement time) for the input current amount can be measured by setting the value in the reference ICO current adjustment bits and measuring the reference ICO counter. The reference ICO counter value measured using the maximum value in the reference ICO current adjustment bits is the maximum value of the ICO dynamic range. The current to the sensor ICO must be offset in the offset adjustment bits so that the sensor ICO counter value does not exceed this value.

Read the CTSURC[15:0] bits after a CTSU_CTSURD interrupt occurs. After these bits are read, they are cleared immediately before the CTSU measurement status counter value changes to Status 4 (the CTSUST.CTSUSTC[2:0] flags changes to 100b) in the next measurement. They can also be cleared using the CTSUCR0.CTSUINIT bit.

46.2.20 CTSUERRS : CTSU Error Status Register

Base address: CTSU = 0x400D_0000

Offset address: 0x1C

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CTSUICOMP	—	—	—	—	—	—	—	CTSUTSOC	CTSUCLKSEL1	—	—	CTSUDRV	CTSUTSOD	CTSUSPMD[1:0]	
Value after reset:	x	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	CTSUSPMD[1:0]	Calibration Mode 0 0: Capacitance measurement mode 1 0: Calibration mode Others: Seting prohibited	R/W
2	CTSUTSOD	TS Pin Fixed Output 0: Capacitance measurement mode 1: TS pins are forced to be high or low	R/W
3	CTSUDRV	Calibration Setting 1 0: Capacitance measurement mode 1: Calibration setting 1	R/W
5:4	—	These bits are read as 0. The write value should be 0.	R/W
6	CTSUCLKSEL1	Calibration Setting 3 0: Capacitance measurement mode 1: Calibration setting 3	R/W
7	CTSUTSOC	Calibration Setting 2 0: Capacitance measurement mode 1: Calibration setting 2	R/W
14:8	—	These bits are read as 0. The write value should be 0.	R/W
15	CTSUICOMP	TSCAP Voltage Error Monitor 0: Normal TSCAP voltage 1: Abnormal TSCAP voltage*1	R

Note 1. When the CTSUCR1.CTSUPON bit is 0, this bit is set to 1.

CTSUSPMD[1:0] bits (Calibration Mode)

The CTSUSPMD[1:0] bits are used to calibrate the CTSU. When measuring the capacitance, set these bits to 00b.

CTSUTSOD bit (TS Pin Fixed Output)

The CTSUTSOD bit is used to calibrate the CTSU. When setting this bit to 1, the TS pins are forced to the logic level specified by the CTSUCR0.CTSUIOC bit. When measuring the capacitance, set this bit to 0.

CTSUDRV bit (Calibration Setting 1)

The CTSUDRV bit is used to calibrate the CTSU. When measuring the capacitance, set this bit to 0.

CTSUCLKSEL1 bit (Calibration Setting 3)

The CTSUCLKSEL1 bit is used to calibrate the CTSU. When measuring the capacitance, set this bit to 0.

CTSUTSOC bit (Calibration Setting 2)

The CTSUTSOC bit is used to calibrate the CTSU. When measuring capacitance, set this bit to 0.

CTSUICOMP bit (TSCAP Voltage Error Monitor)

The CTSUICOMP bit monitors the TSCAP voltage and this bit is set to 1 if the voltage becomes abnormal.

If the offset current specified in the CTSUSO0 register exceeds the sensor ICO input current during touch measurement, the TSCAP voltage becomes abnormal and touch measurement cannot be performed correctly.

If the TSCAP voltage becomes abnormal, the sensor ICO counter value becomes undefined, but touch measurement completes normally, so it is difficult to detect an abnormality by reading the sensor ICO counter value. If the CTSU reference ICO current adjustment bits (CTSURICOA[7:0]) in the CTSUSO1 register are set to any value other than 0, always check this bit when touch measurement completes.

This bit is cleared by writing 0 to the CTSUCR1.CTSUPON bit and turning off the power supply.

46.2.21 CTSUTRMR : CTSU Reference Current Calibration Register

Base address: CTSU = 0x400D_0000

Offset address: 0x20

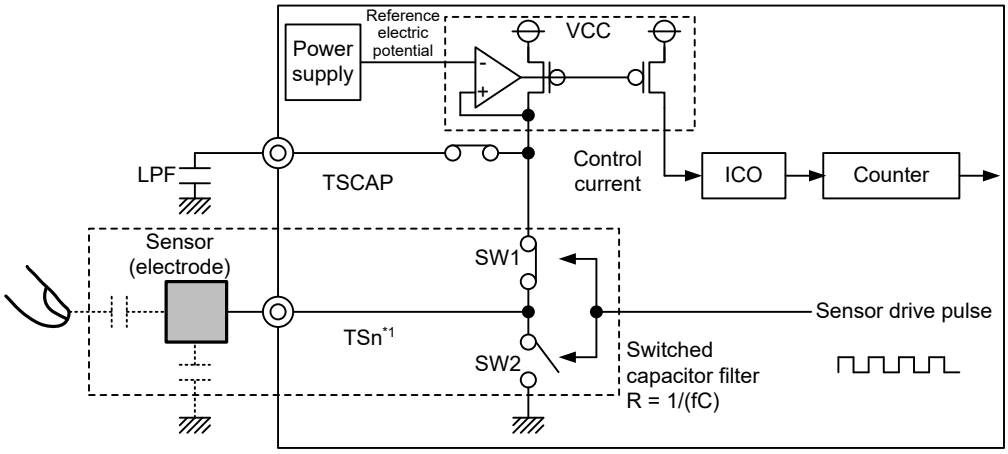
Bit position:	7	6	5	4	3	2	1	0
Bit field:								
Value after reset:	Unique value for each chip							

The CTSUTRMR resister stores a reference current value calibrated under the specified condition for each chip at factory shipment. When rewriting this register, set the CTSUERRS.CTSUSPMD[1:0] bits to 10b (calibration mode). When resetting the MCU, the values returns to the factory setting value. Do not rewrite this register when the CTSUSPMD[1:0] bits are 00b (capacitance measurement mode).

46.3 Operation

46.3.1 Principles of Measurement Operation

Figure 46.4 shows the measurement circuit.



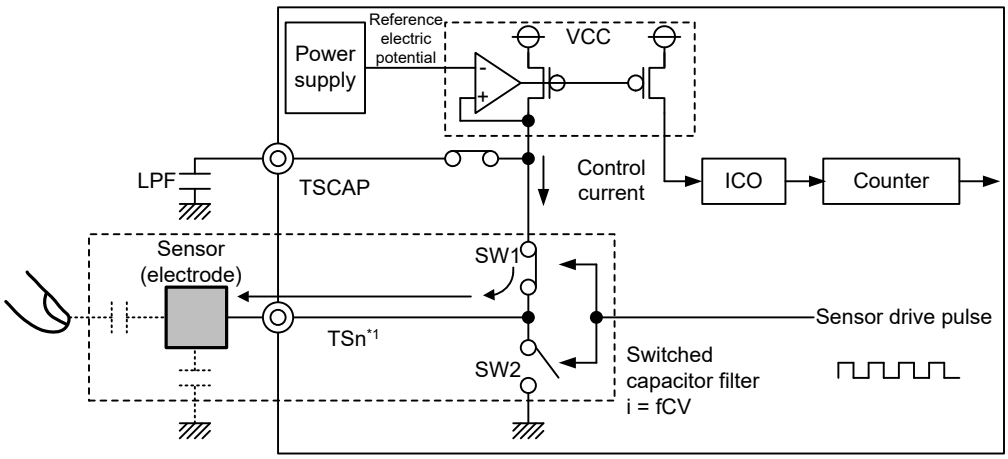
Note 1. TSn = TS00 to TS19

Figure 46.4 Measurement circuit

Figure 46.5 to Figure 46.7 explain the electrostatic capacitance measurement operation principles of the CTSU current frequency conversion. The operation is as follows:

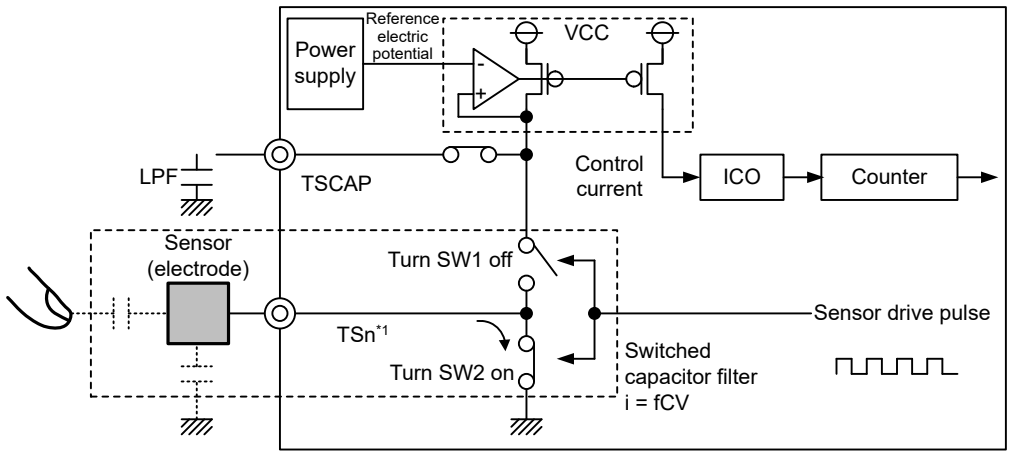
1. The electrostatic capacitance of the electrode is charged by turning SW1 on and SW2 off (Figure 46.5).

2. The charged capacitance is discharged by turning SW1 off and SW2 on (Figure 46.6).
3. Current flows to the switched capacitor filter by switching between charging and discharging. At this point, if a finger is in close proximity, the capacitance and the flowing current change. A clock is generated by supplying the control current, which is proportional to the amount of current flowing through the switched capacitor filter, from the circuit that generates the TSCAP power supply to the ICO. The counter measures the clock frequency that changes depending on whether a finger is in close proximity. The software uses the value read from the counter to determine contact with a finger (Figure 46.7).



Note 1. TSn = TS00 to TS19

Figure 46.5 Charging operation



Note 1. TSn = TS00 to TS19

Figure 46.6 Discharging operation

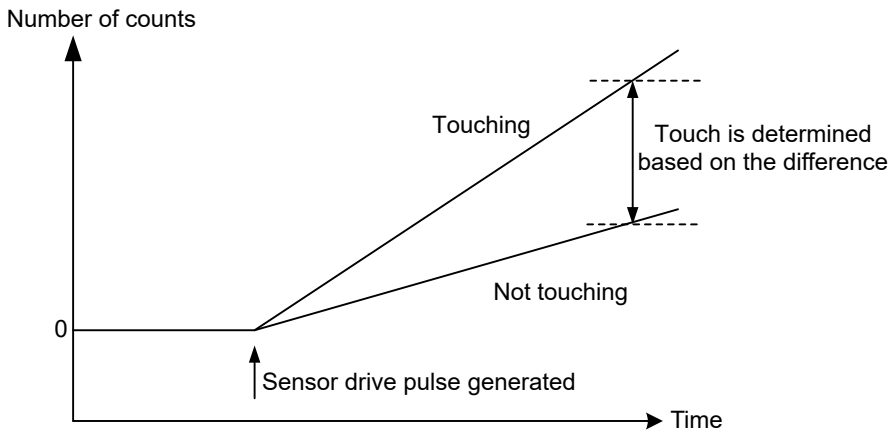


Figure 46.7 Change in measured value when finger is touching and not touching

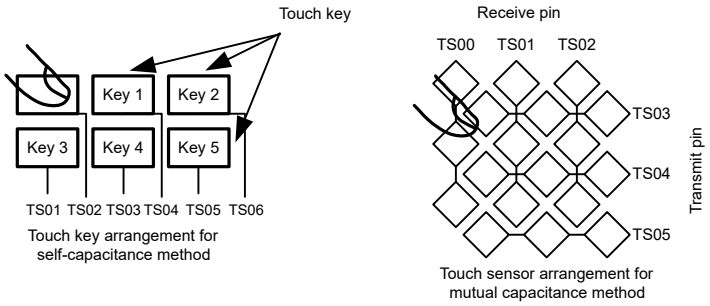
46.3.2 Measurement Modes

The CTSU supports self-capacitance and mutual capacitance methods. Figure 46.8 illustrates these methods.



Note: This figure indicates a usage example. About available pins, see Table 46.2

Figure 46.8 Overview of self-capacitance method and mutual capacitance method

In the self-capacitance method, a single touch pin is allocated to a single touch key to measure individual electrostatic capacitance when a finger is in close proximity. In this method, capacitance can be measured in both single scan and multiscan modes.

In the mutual capacitance method, the capacitance between two opposing electrodes (transmit and receive pins) is measured.

46.3.2.1 Initial settings flow

Figure 46.9 shows the flow for the CTSU initial settings.

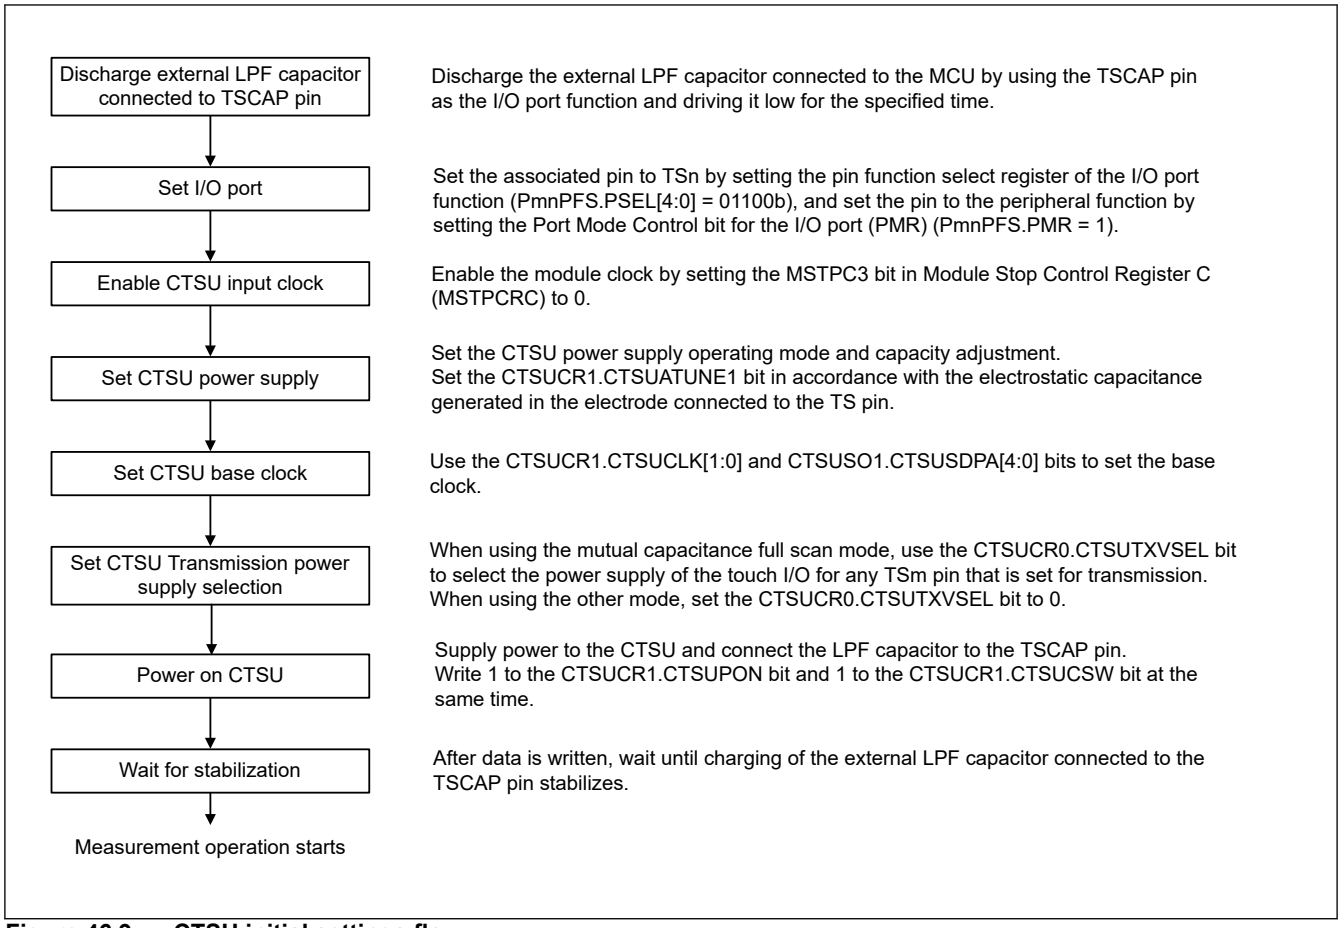


Figure 46.9 CTSU initial settings flow

Figure 46.10 shows the flow for stopping CTSU operation and invoking the standby state.

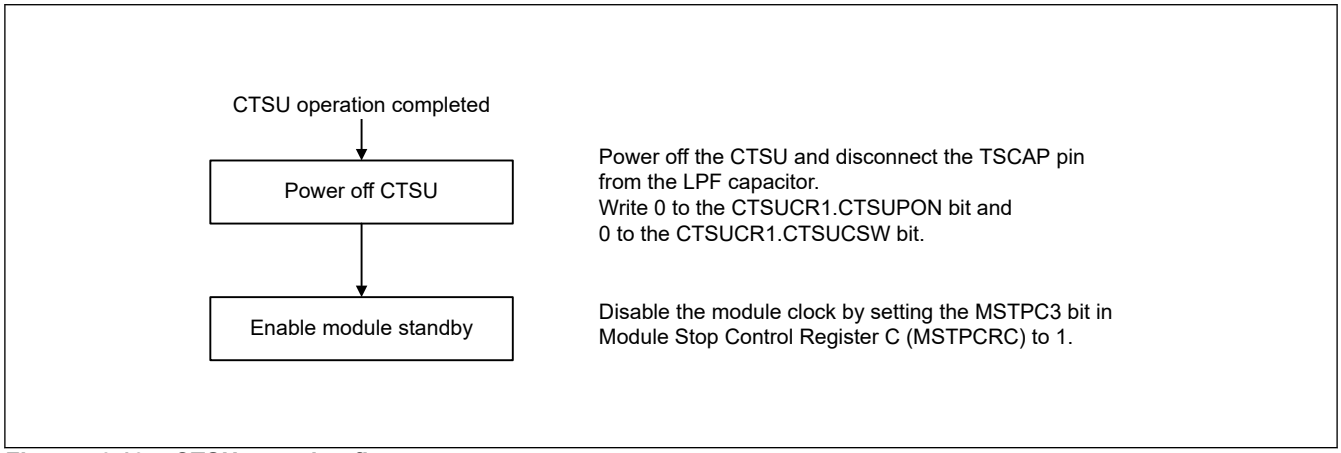

Figure 46.10 CTSU stopping flow

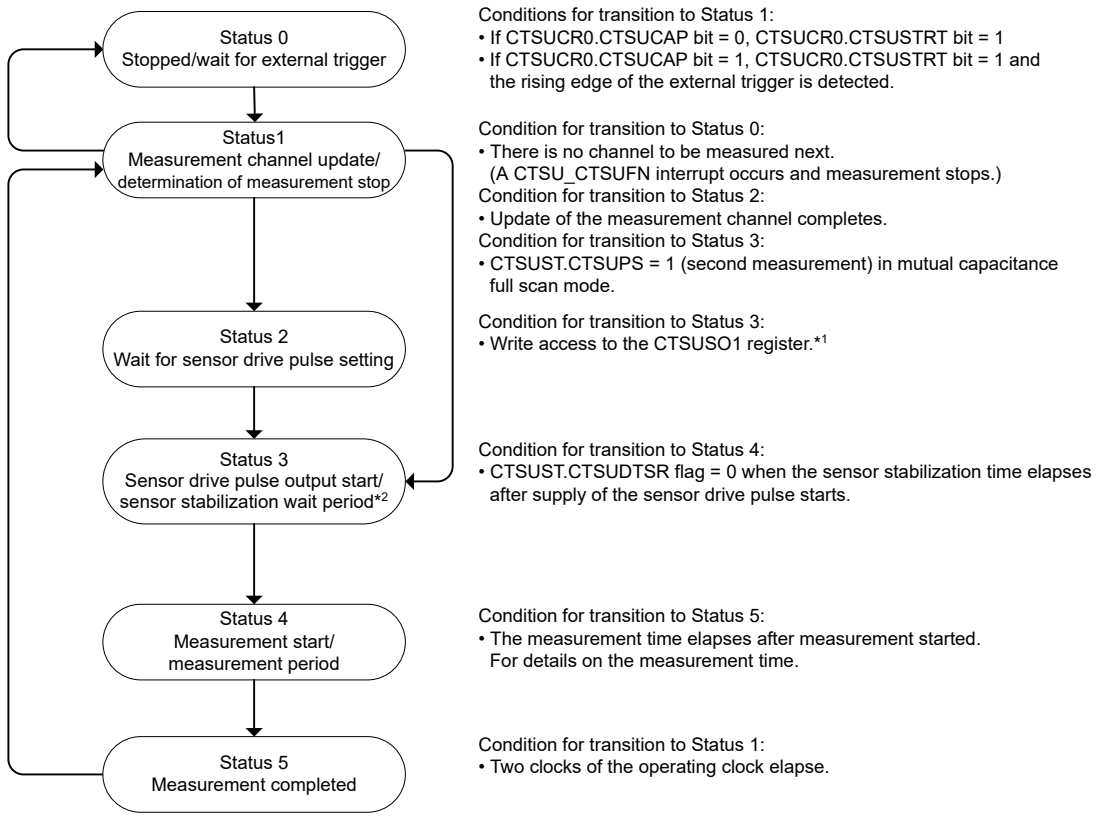
When restarting operation after it stops, follow the initial settings flow shown in Figure 46.9.

46.3.2.2 Status counter

The measurement status counter of the CTSU Status Register (CTSUST) indicates the current measurement status. The measurement status is shared by all three modes. Figure 46.11 shows the status operation transitions.



Note 1. When using the DTC or ICU to set the registers during CTSU_CTSUWR interrupt handling, write to the CTSUSO1 register last.
Note 2. If the CTSUST.CTSUDTSR flag = 1, wait until the previous measurement result is transferred.

Figure 46.11 Status operation transitions

The status counter transitions to Status 0 when all of the specified measurement channels are measured.

The CTSUCR0.CTSUSTRT bit is set to 0 by hardware when a software trigger is used. When an external trigger is used, the value of 1 is retained, and the CTSU waits for the next trigger.

When operation is forced to stop during measurement or the trigger wait state, by a simultaneous 0 write to the CTSUCR0.CTSUSTRT bit and a 1 write to the CTSUCR0.CTSUINIT bit, the status transitions to Status 0 and measurement stops.

If the channel to be measured is not set in the CTSUCHAC0 to CTSUCHAC2 or CTSUCHTRC0 to CTSUCHTRC2 registers, a CTSU_CTSUFN interrupt occurs immediately after a transition to Status 1, and then the status transitions to Status 0.

In the following situations, there is no channel to be measured:

- No measurement target channel is specified in the CTSUCHAC0 to CTSUCHAC2 registers.
- In self-capacitance single scan mode, the channel specified in the CTSUMCH0 register is not a measurement target in the CTSUCHAC0 to CTSUCHAC2 registers.
- In full scan modes, there is no transmit channel or receive channel to be measured based on the combined settings of the CTSUCHAC0 to CTSUCHAC2 and CTSUCHTRC0 to CTSUCHTRC2 registers.

If there is no channel to be measured based on these settings, a CTSU_CTSUFN interrupt occurs immediately after a transition to Status 1, and the counter transitions to Status 0.

46.3.2.3 Self-capacitance single scan mode operation

In self-capacitance single scan mode, electrostatic capacitance on one channel is measured. Figure 46.12 shows the software flow and an operation example, and Figure 46.13 shows the timing.

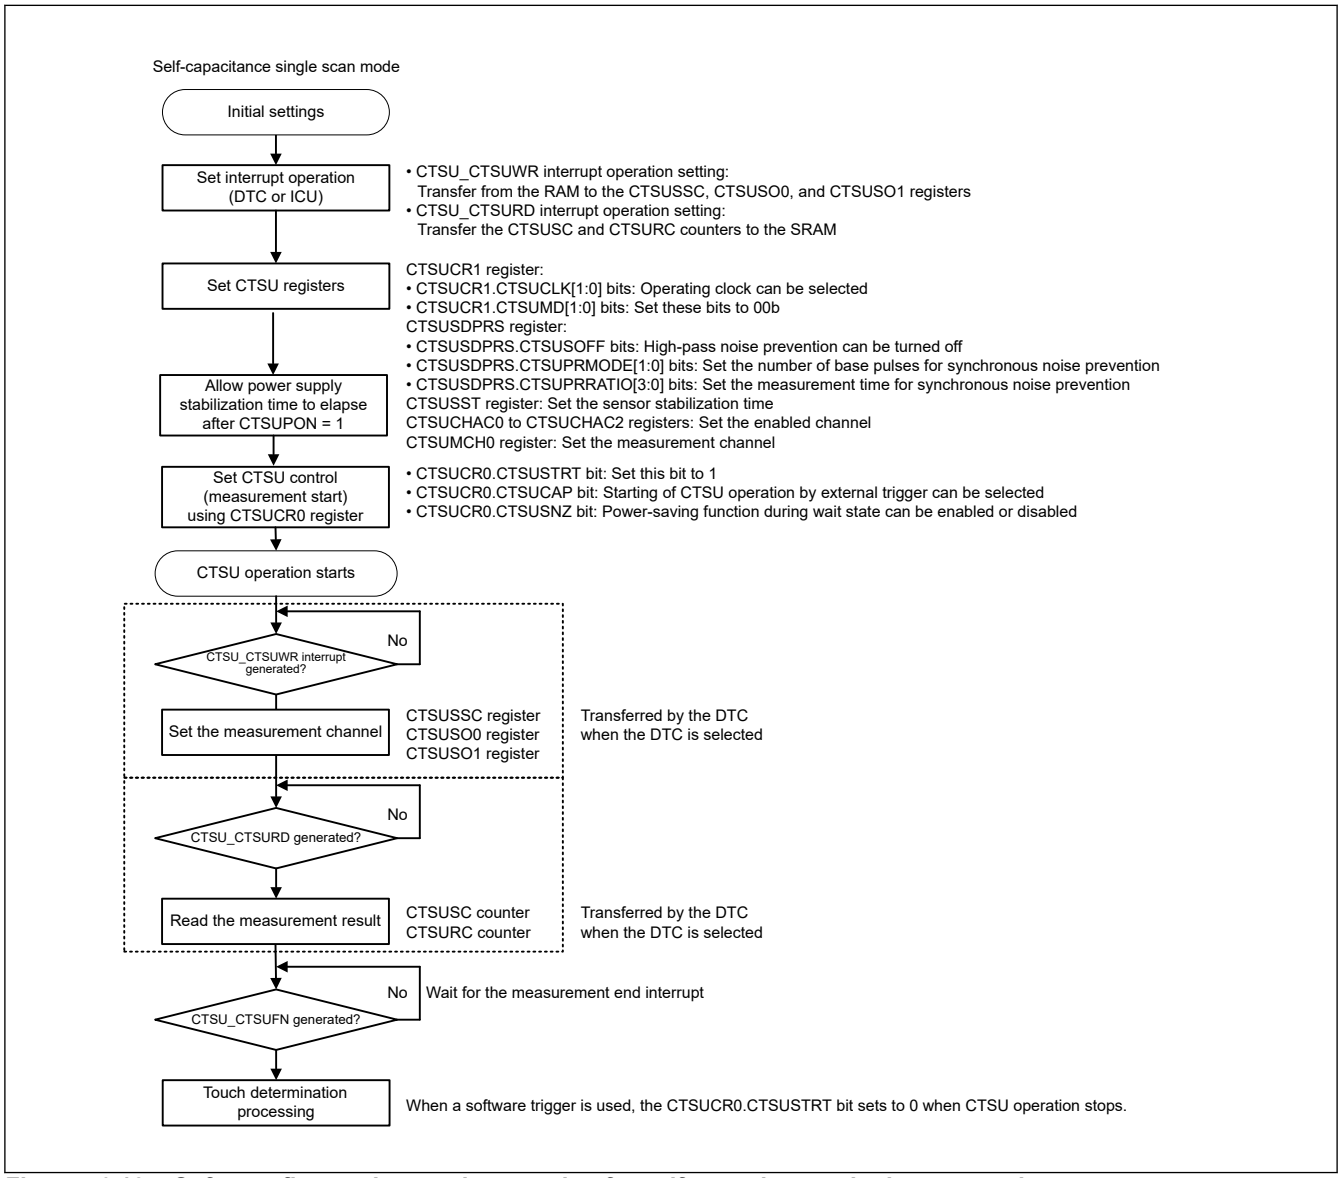


Figure 46.12 Software flow and example operation for self-capacitance single scan mode

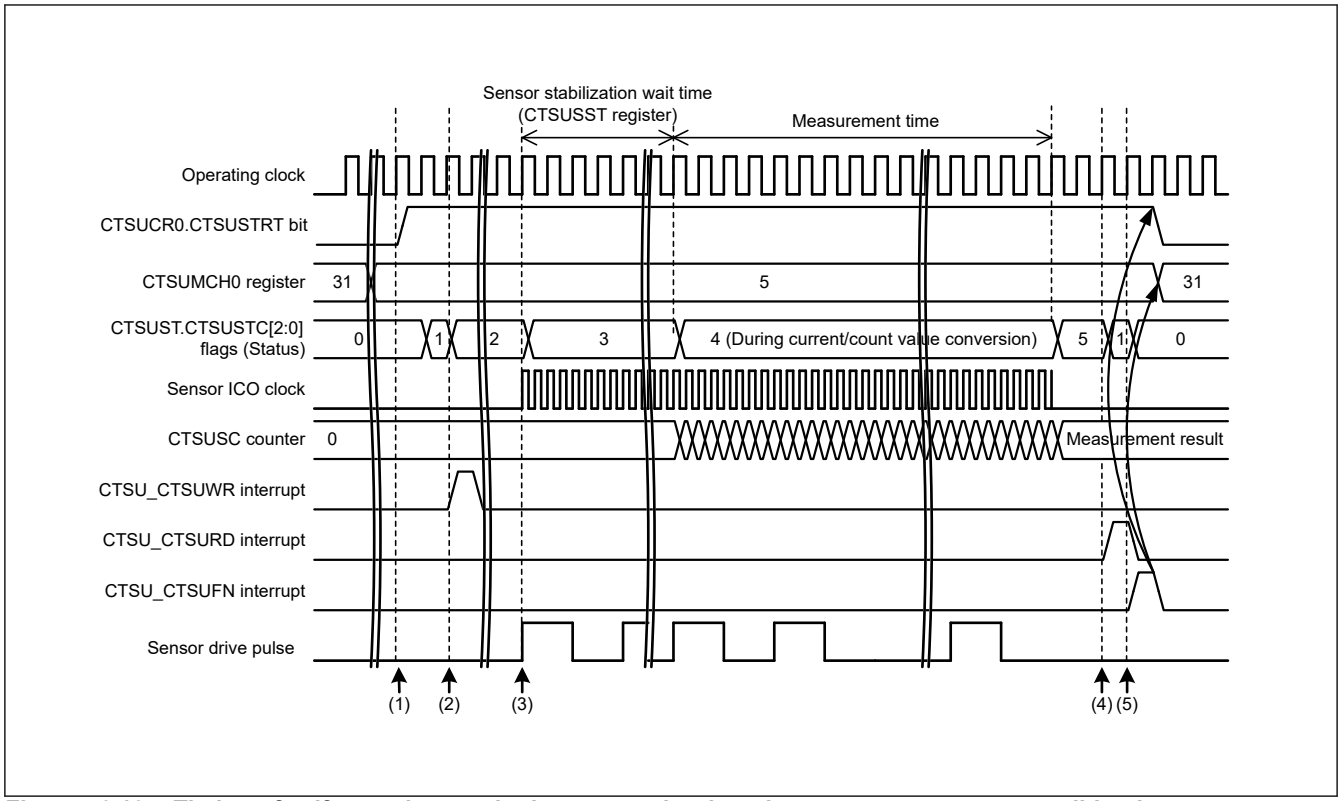

Figure 46.13 Timing of self-capacitance single scan mode when the measurement start condition is a software trigger

The following describes the operation shown in Figure 46.13.

1. After initial settings are made, operation is started by writing 1 to the CTSUCR0.CTSUSTRT bit.
2. After the channel to be measured is determined in accordance with the preset conditions, a request for setting the channel (CTSU_CTSUWR) is output.
3. On completion of writing the measurement channel settings (CTSUSSC, CTSUSO0, and CTSUSO1 registers), the sensor drive pulse is output and the sensor ICO clock and reference ICO clock operate.
4. After the sensor stabilization wait time and the measurement time elapse, and measurement stops, a measurement result read request (CTSU_CTSURD) is output.
5. A measurement end interrupt (CTSU_CTSUFN) is output and measurement stops (transition to Status 0).

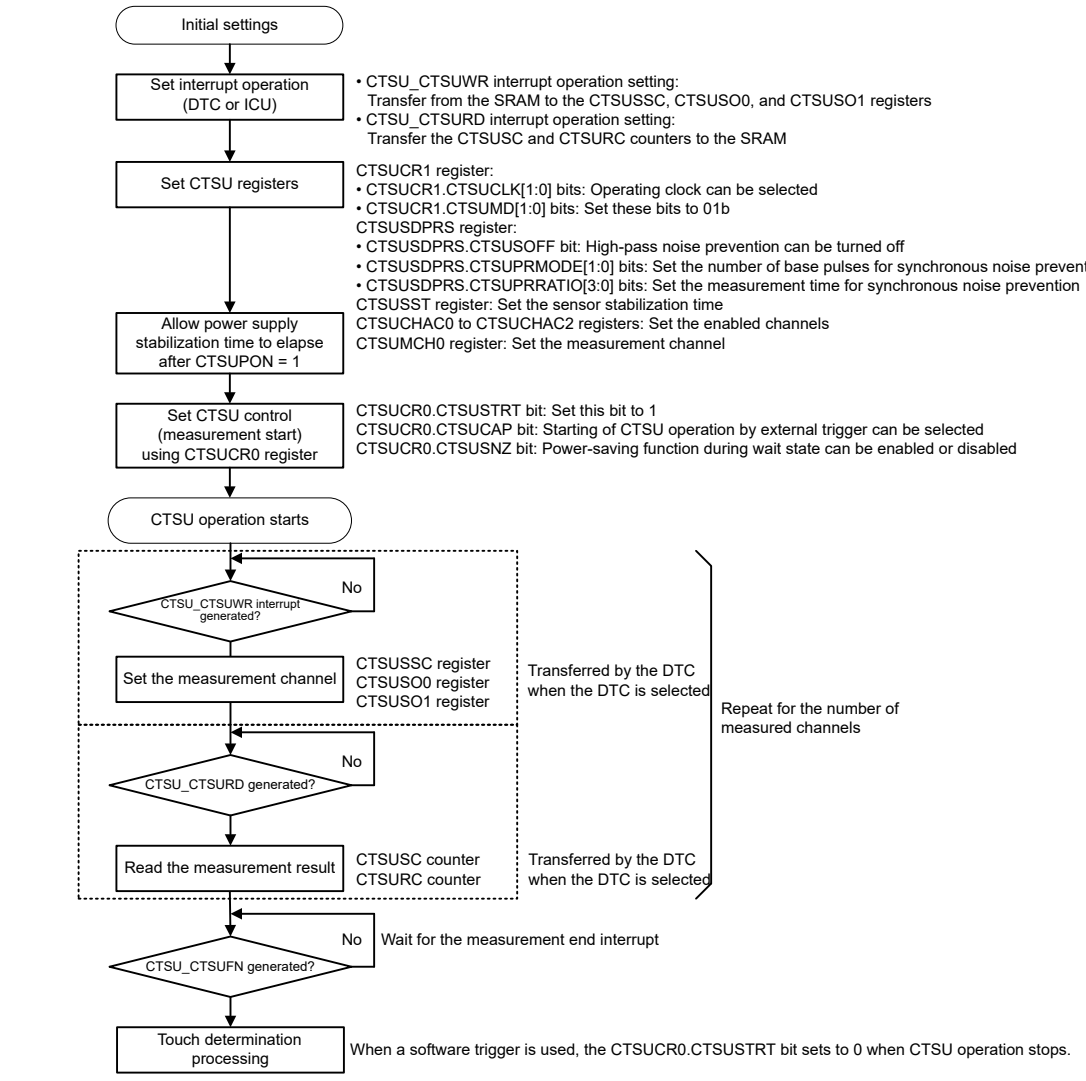
Table 46.7 lists the touch pin states in self-capacitance single scan mode.

Table 46.7 Touch pin states in self-capacitance single scan mode

Status	Touch pin	
	Measured channel	Non-measured channel
0	Low	Low
1	Low	Low
2	Low	Low
3	Pulse	Low
4	Pulse	Low
5	Low	Low

46.3.2.4 Self-capacitance multi-scan mode operation

In self-capacitance multi-scan mode, electrostatic capacitance on all channels that are specified as measurement targets in the CTSUCHAC0 to CTSUCHAC2 registers is measured sequentially in ascending order. Figure 46.14 shows the software flow and an operation example, and Figure 46.15 shows the timing.



Channel measurement sequence in self-capacitance multiscan mode

Settings:
• Select self-capacitance multiscan mode (CTSUCR1.CTSUMD[1:0] bits = 01b)
• Set channels 0, 2, 5, and 6 to enabled channels (CTSUCHAC0.CTSUCHAC0[7:0] bits = 01100101b)

Receive Channels							
Channel 7	Channel 6	Channel 5	Channel 4	—	Channel 2	—	Channel 0
	(4)	(3)			(2)		(1)

Figure 46.14 Software flow and example operation for self-capacitance multi-scan mode

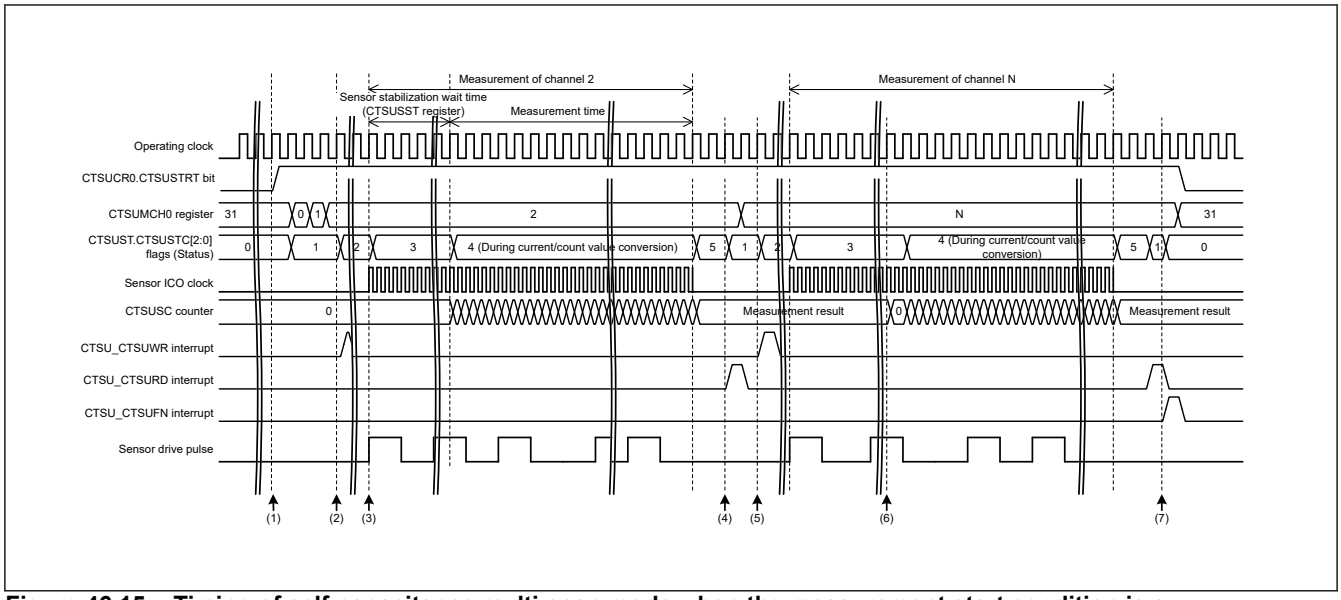


Figure 46.15 Timing of self-capacitance multi-scan mode when the measurement start condition is a software trigger

The following describes the operation shown in Figure 46.15:

1. After initial settings are made, operation is started by writing 1 to the CTSUCR0.CTSUSTRT bit.
2. After the channel to be measured is determined in accordance with the preset conditions, a request for setting the channel (CTSU_CTSUWR) is output.
3. On completion of writing the measurement channel settings (CTSUSSC, CTSUSO0, and CTSUSO1 registers), the sensor drive pulse is output and the sensor ICO clock and the reference ICO clock operate.
4. After the sensor stabilization wait time and the measurement time elapse, and measurement stops, a measurement result read request (CTSU_CTSURD) is output.
5. After the channel to be measured next is determined, a measurement channel setting request (CTSU_CTSUWR) is output.
6. After the stabilization wait time elapses and when the previous measurement is read, the result is cleared and measurement starts.
7. On completion of all measurement channels, a measurement end interrupt (CTSU_CTSUFN) is output and measurement is stopped (transition to Status 0).

Table 46.8 lists the touch pin states in self-capacitance multi-scan mode.

Table 46.8 Touch pin states in self-capacitance multi-scan mode

Status	Touch pin	
	Measured channel	Non-measured channel
0	Low	Low
1	Low	Low
2	Low	Low
3	Pulse	Low
4	Pulse	Low
5	Low	Low

46.3.2.5 Mutual capacitance full scan mode operation

In mutual capacitance full scan mode, measurement is performed during the high-level period of the sensor drive pulse on the receive channel by applying the edge to the target transmit channel to be measured. A single measurement target is measured twice, on the rising and falling edges. The difference between the data of these two measurements determines whether or not the electrode was touched, which results in a higher touch sensitivity.

Electrostatic capacitance is measured sequentially on channels set to transmission or reception in the CTSUCHTRC0 to CTSUCHTRC2 registers, and specified as measurement targets in the CTSUCHAC0 to CTSUCHAC2 registers. The capacitance is measured by combining these signals. Figure 46.16 shows the software flow and an operation example, and Figure 46.17 shows the timing.

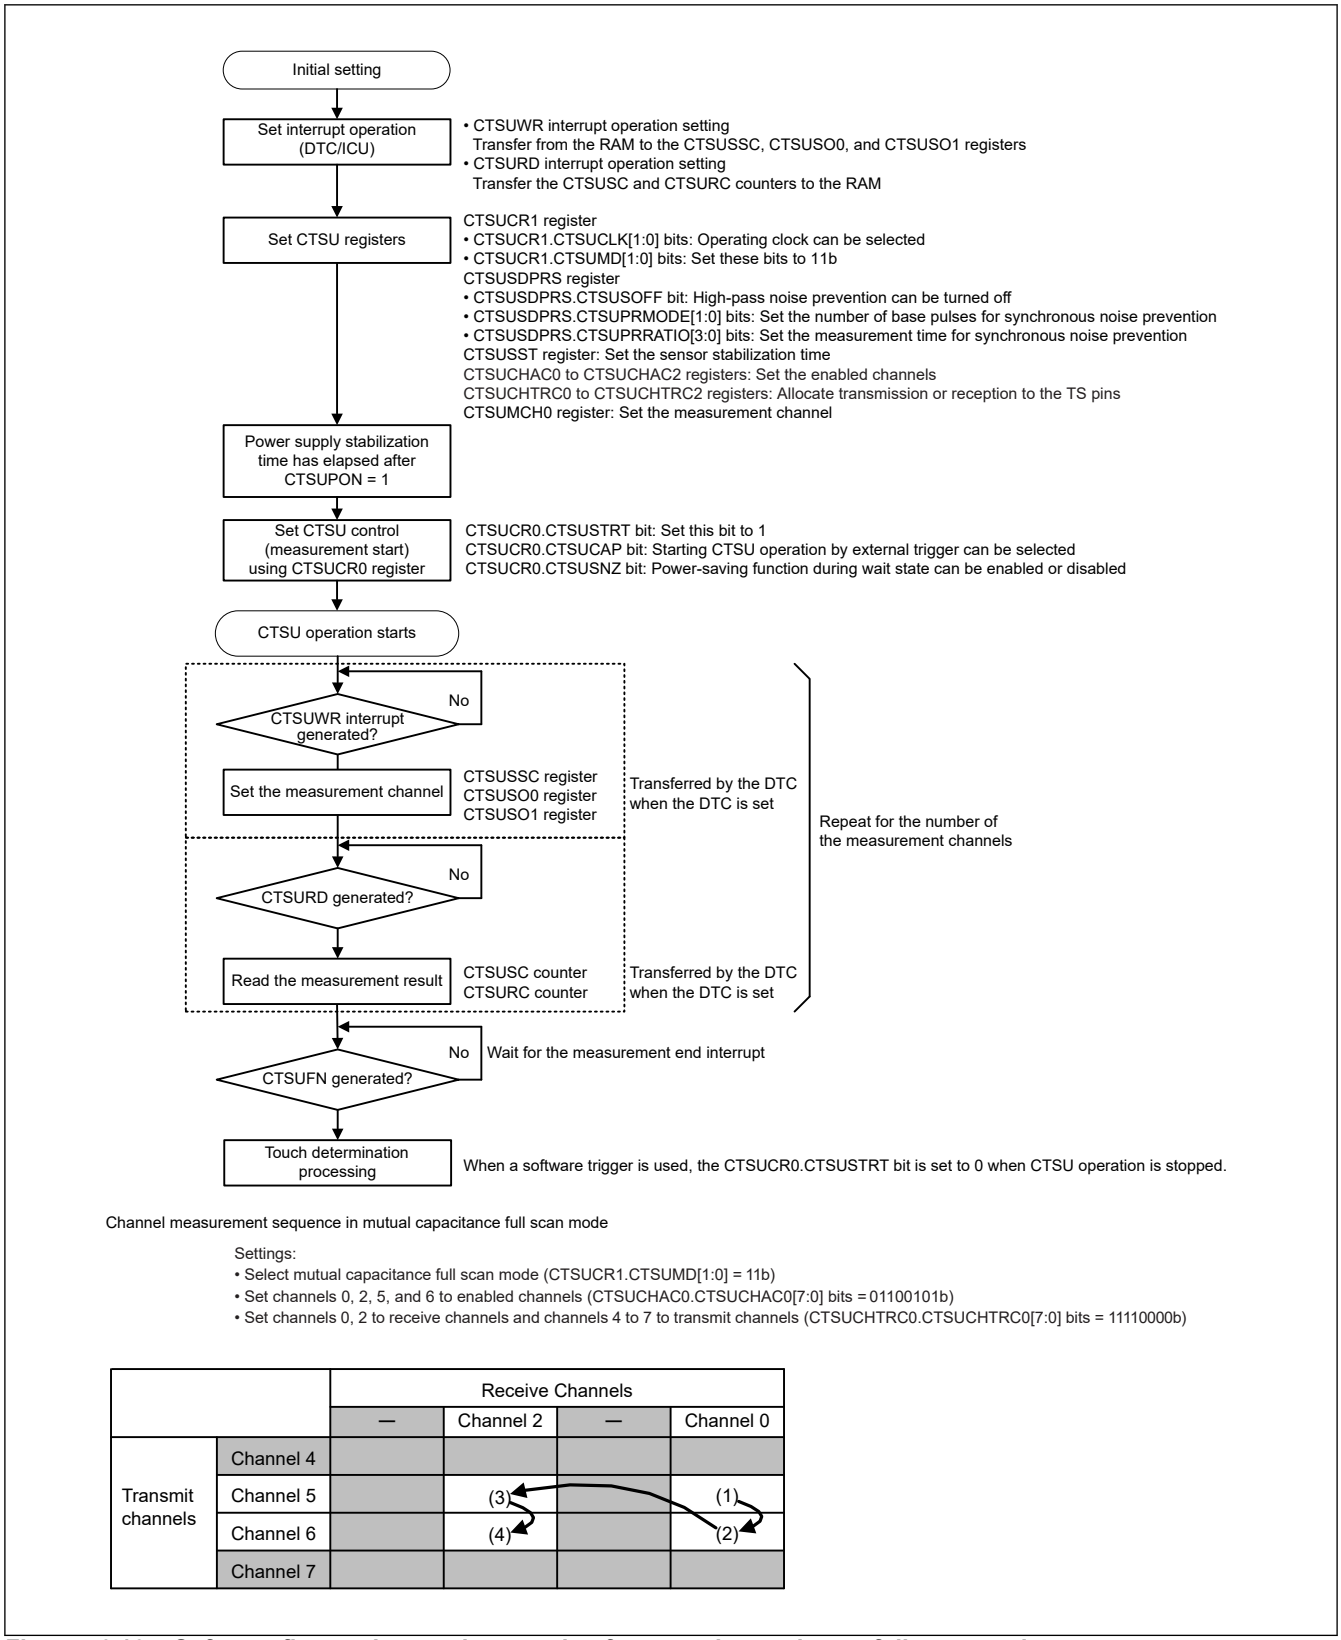

Figure 46.16 Software flow and example operation for mutual capacitance full scan mode

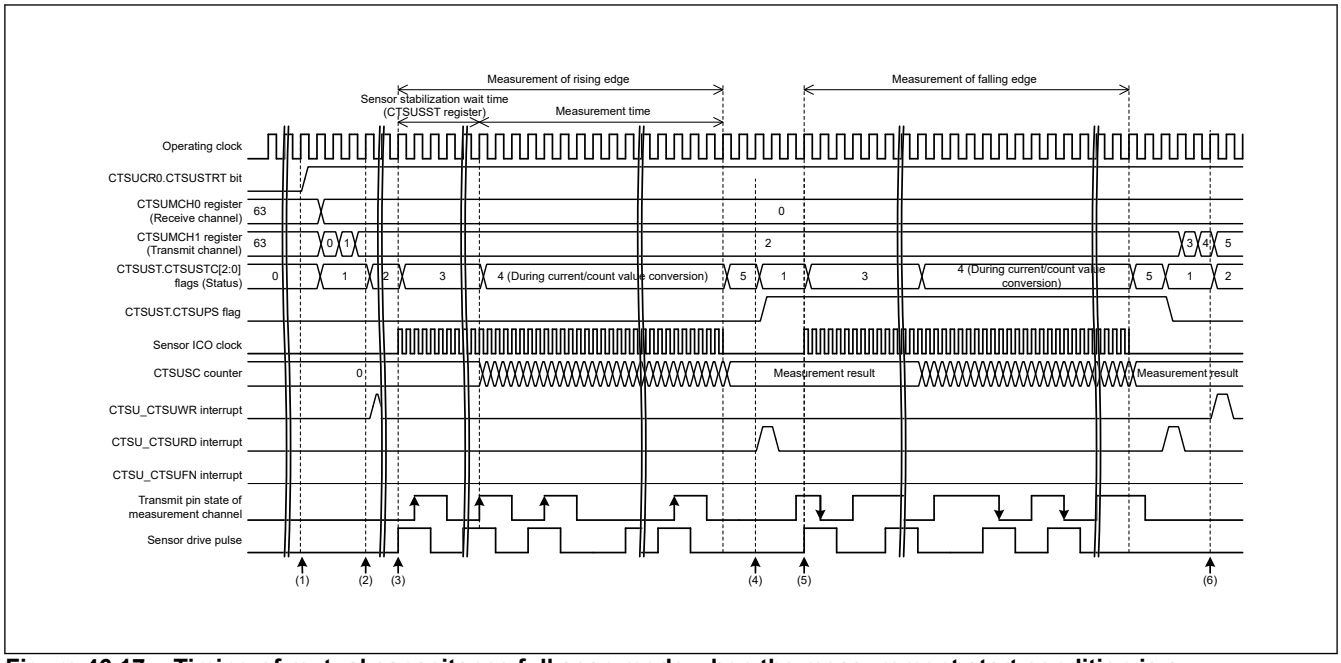

Figure 46.17 Timing of mutual capacitance full scan mode when the measurement start condition is a software trigger

The following describes the operation shown in Figure 46.17

1. After initial settings are made, operation is started by writing 1 to the CTSUCR0.CTSUSTRT bit.
2. After the channel to be measured is determined in accordance with the preset conditions, a request for setting the channel (CTSU_CTSUWR) is output.
3. On completion of writing the measurement channel settings (CTSUSSC, CTSUSO0, and CTSUSO1 registers), the sensor drive pulse is output and the sensor ICO clock and the reference ICO clock operate. At the same time, a pulse detected on the rising edge is output to the transmit pin on the measurement channel during the high-level period of the sensor drive pulse.
4. After the sensor stabilization wait time and the measurement time elapsed and measurement stops, a measurement result read request (CTSU_CTSURD) is output.
5. The same channel is measured by outputting a pulse detected on the falling edge during the high-level period of the sensor drive pulse.
6. After the same channel is measured twice, the channel to be measured next is determined and measured in the same way.
7. On completion of all measurement channels, a measurement end interrupt (CTSU_CTSUFN) is output and measurement stops (transition to Status 0).

The mutual capacitance measurement status flag (CTSUST.CTSUPS bit) changes when Status 5 transitions to Status 1. Table 46.9 lists the touch pin states in mutual capacitance full scan mode.

Table 46.9 Touch pin states in mutual capacitance full scan mode (1 of 2)

Status	Touch pins for receive channels		Touch pins for transmit channels		Remarks
	Measured channel	Non-measured channel	Measured channel	Non-measured channel	
0	Low	Low	Low	Low	—
1	Low	Low	Low/high	Low	—
2	Low	Low	Low	Low	—
3	Pulse	Low	Pulse	Low	The phase pulse is the same as that of the receive channel on the first measurement and opposite on the second measurement.
4	Pulse	Low	Pulse	Low	—

Table 46.9 Touch pin states in mutual capacitance full scan mode (2 of 2)

Status	Touch pins for receive channels		Touch pins for transmit channels		Remarks
	Measured channel	Non-measured channel	Measured channel	Non-measured channel	
5	Low	Low	Low	Low	—

46.3.3 Parameters Common to Multiple Modes

46.3.3.1 Sensor stabilization wait time and measurement time

Figure 46.18 shows the timing of the sensor stabilization wait and measurement.

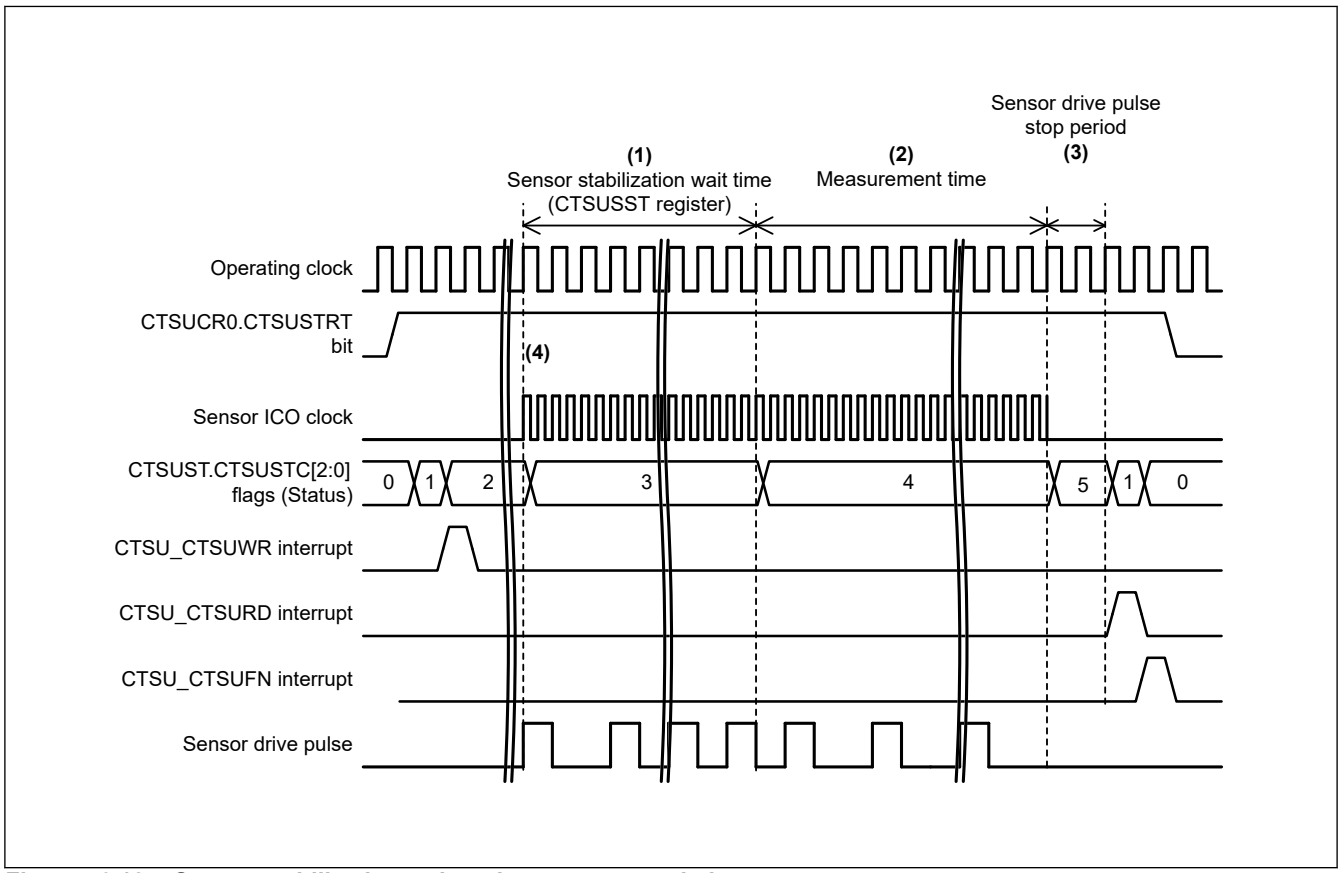

Figure 46.18 Sensor stabilization wait and measurement timing

The following describes the operation shown in Figure 46.18:

1. In response to the CTSU_CTSUWR interrupt request, output of the sensor drive pulse is started by a write access to the CTSUSO1 register. The CTSU waits for the stabilization time set in the CTSUSST register.
2. When the sensor stabilization time elapses and the CTSUST.CTSUDTSR flag clears to 0, measurement starts on transition to Status 4. The measurement time is determined by the base clock cycle setting and the CTSUSDPRS.CTSUPRMODE[1:0], CTSUPRRATIO[3:0], and CTSUSO0.CTSUSNUM[5:0] bits. When the measurement time elapses, measurement of the channel stops.
3. After the measurement time elapses, the status transitions to Status 1 after two operating clock cycles, and a CTSU_CTSURD interrupt occurs. Read the data from the CTSUSC and CTSURC counters. At this time, the sensor drive pulse is output at the low level. When measurement of all specified channels is completed, the CTSUCR0.CTSUSTRT bit clears to 0.
4. The sensor ICO clock oscillates while the CTSUST.CTSUSTC[2:0] flags = 011b (Status 3) or 100b (Status 4).

46.3.3.2 Interrupts

The CTSU supports the following interrupts:

- Write request interrupt for setting registers for each channel (CTSU_CTSUWR)
- Measurement data transfer request interrupt (CTSU_CTSURD)
- Measurement end interrupt (CTSU_CTSUFN)

(1) Write request interrupt for setting registers for each channel (CTSU_CTSUWR)

Store the settings for each measurement channel in the SRAM, and set up the DTC or ICU transfer associated with the CTSU_CTSUWR interrupt in advance. The CTSU_CTSUWR interrupt is output when Status 1 transitions to Status 2. Write the settings for the selected channel from the SRAM to the CTSUSSC, CTSUSO0, and CTSUSO1 registers (Figure 46.19). Because write access to the CTSUSO1 register controls the transition to the next status, you must set this register last.

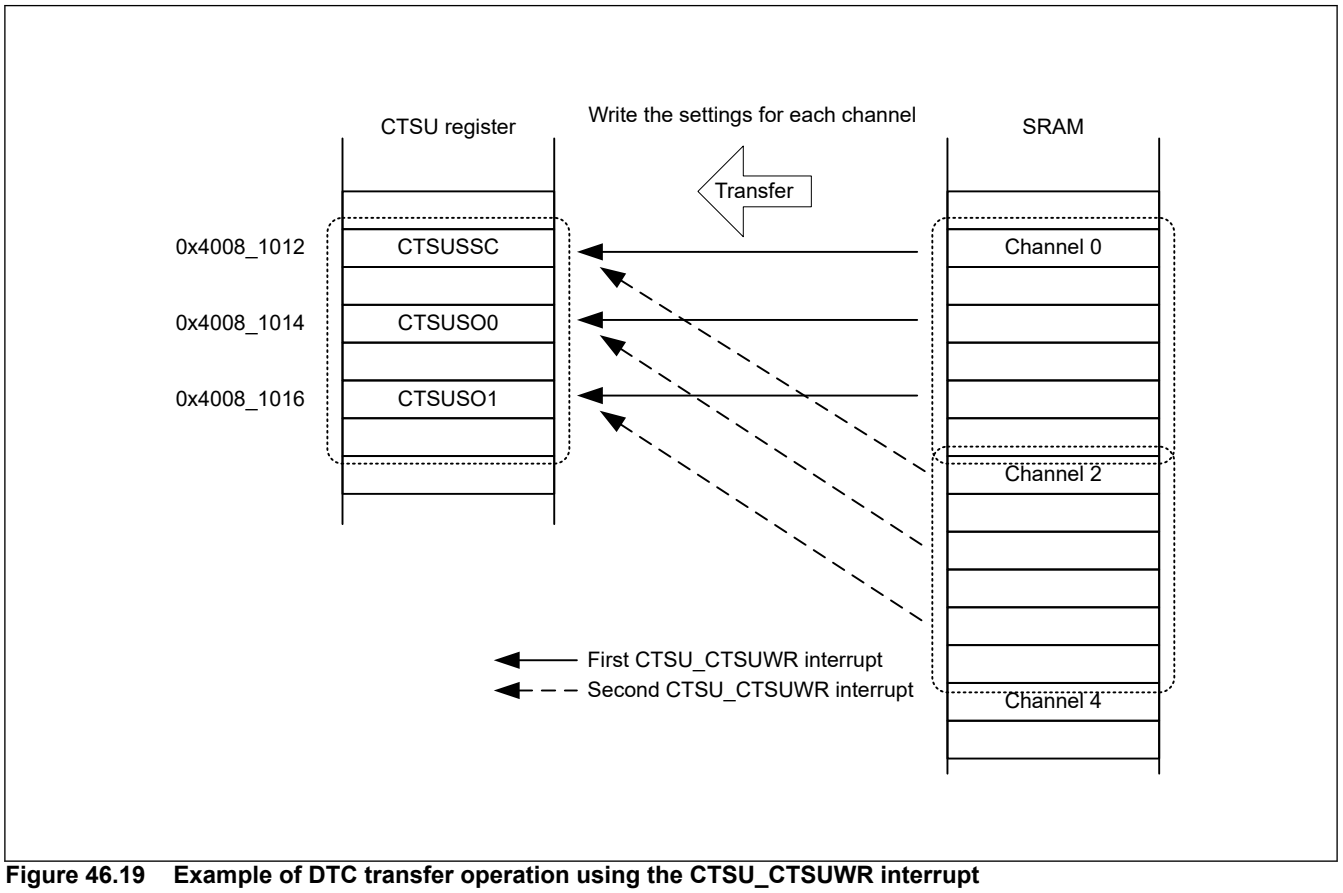

Figure 46.19 Example of DTC transfer operation using the CTSU_CTSUWR interrupt

The registers to be set (CTSUSSC, CTSUSO0, and CTSUSO1) are allocated at sequential addresses. On CTSU_CTSUWR interrupt generation, set up the operation as follows:

- Transfer destination address: CTSUSSC register address
- Handling at the transfer destination address: Transfer 2-byte data three times with a single interrupt. The address of the start byte is fixed.
- Transfer source address: CTSUSSC register data storage address for the lowest number channel in the settings stored in the SRAM
- Handling at the transfer source address: Transfer 2-byte data three times with a single interrupt. The address of the first byte is continued from the previous interrupt handling.
- Number of transfers per interrupt: Specify the number of measurements.

(2) Measurement data transfer request interrupt (CTSU_CTSURD)

Set up the DTC or ICU transfer associated with the CTSU_CTSURD interrupt in advance. The CTSU_CTSURD interrupt is output when Status 5 transitions to Status 1. Read the measurement result from the CTSUSC and CTSURC counters (Figure 46.20).

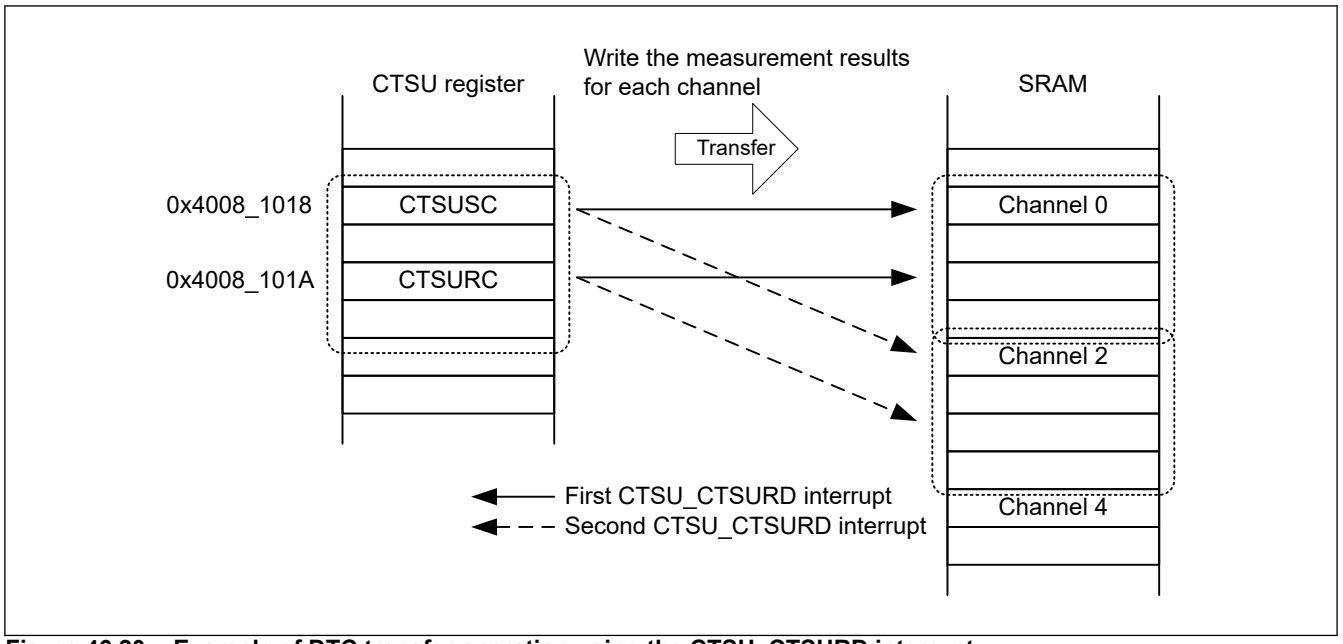

Figure 46.20 Example of DTC transfer operation using the CTSU_CTSURD interrupt

The measurement result registers (CTSUSC and CTSURC counters) used as transfer sources are allocated at sequential addresses. On CTSU_CTSURD interrupt generation, set up the operation as follows:

- Transfer source address: CTSUSC counter address
- Handling at the transfer source address: Transfer 2-byte data twice with a single interrupt. The start address is fixed.
- Transfer destination address: CTSUSC counter data storage address for the lowest number channel in the settings stored in the SRAM
- Handling at the transfer destination address: Transfer 2-byte data twice with a single interrupt. The start address is continued from the previous interrupt handling.
- Number of transfers per interrupt: Specify the number of measurements.

(3) Measurement end interrupt (CTSU_CTSUFN)

When all channels are measured, an interrupt occurs when Status 1 transitions to Status 0. In the software, check the overflow flags (CTSUST.CTSUSOVF and CTSUROVF) and read the measurement results to determine whether or not the electrode was touched. Interrupt requests are accepted or disabled in the interrupt control block.

46.4 Usage Notes

46.4.1 Measurement Result Data (CTSUSC and CTSURC Counters)

Read access during measurement is prohibited. If the measurement result data is accessed, an incorrect value might be read because of asynchronous operation.

46.4.2 Constraint on Software Trigger

When 10b (PCLKB/4) is selected in the CTSUCR1.CTSUCLK[1:0] bits, to restart measurement by writing 1 to the CTSUR0.CTSUSTRT bit after measurement is complete, wait for at least 3 cycles to elapse after an interrupt occurs, and then write to the CTSUCR0.CTSUSTRT bit.

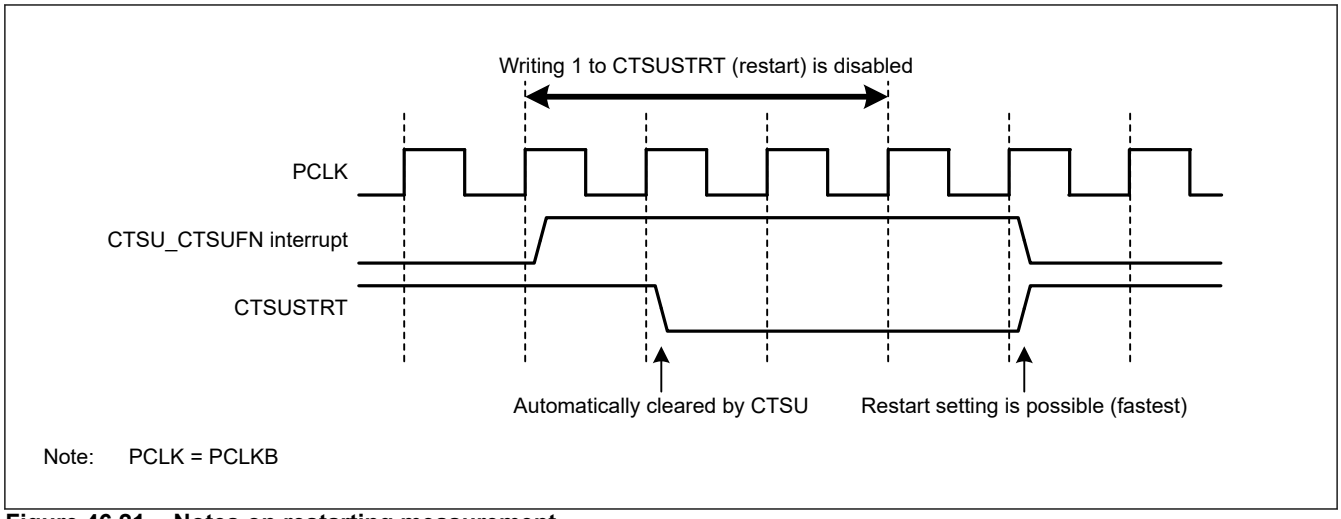

Figure 46.21 Notes on restarting measurement

46.4.3 Constraints on External Triggers

- If an external trigger is input during the measurement time, measurement does not start. The next external event is enabled after 1 cycle of the operating clock when a CTSU_CTSUFN interrupt occurs.
- To stop external trigger mode, write 0 to the CTSUCR0.CTSUSTRT bit and 0 to the CTSUCR0.CTSUINIT bit at the same time (forced stop).

46.4.4 Constraints on Forced Stops

To force the current operation to stop, write 0 to the CTSUCR0.CTSUSTRT bit and 1 to the CTSUCR0.CTSUINIT bit at the same time. After this setting, the operation is stopped and the internal control registers are initialized.

When the CTSUCR0.CTSUINIT bit is used for initialization, the following registers are initialized in addition to the initialization of the internal measurement state.

- CTSUMCH0 register
- CTSUMCH1 register
- CTSUST register
- CTSUSC counter
- CTSURC counter

If operation is forced to stop, an interrupt request might be generated depending on the internal state. After a forced stop, also perform the processing for stopping and disabling the DTC or ICU. If a DTC transfer is stopped in an installed system for some reason, also perform the processing for forcing stop to and initializing the CTSU.

46.4.5 TSCAP Pin

The TSCAP pin requires an external decoupling capacitor to stabilize CTSU internal voltage. The traces between the TSCAP pin and the capacitor, and the capacitor and ground should be as short and wide as physically possible.

The capacitor connected to the TSCAP pin should be fully discharged using I/O port control to output a low level, before turning on the switch (CTSUCR1.CTSUCSW bit = 1) to establish a connection.

46.4.6 Constraints on Measurement Operation (CTSUCR0.CTSUSTRT Bit = 1)

During measurement (CTSUCR0.CTSUSTRT bit = 1), do not use the settings for stopping the peripheral clock or changing the port settings related to the touch pins (TSn and TSCAP pins) and Transmission power supply selection (CTSUCR0.CTSUTXVSEL) in the higher layers of the system.

If control settings non-compliant with these constraints are made, operation is forced to stop (CTSUCR0.CTSUSTRT bit = 0 and CTSUCR0.CTSUINIT bit = 1), write 0 to the CTSUCR1.CTSUPON bit and 0 to the CTSUCR1.CTSUCSW bit at the same time, and set the CTSUCR0.CTSUSNZ bit to 0. Next, restart from the initial settings flow shown in Figure 46.9.

47. Data Operation Circuit (DOC)

47.1 Overview

The Data Operation Circuit (DOC) compares, adds, and subtracts 16-bit data. When a selected condition applies, 16-bit data is compared and an interrupt can be generated. Table 47.1 lists the DOC specifications and Figure 47.1 shows a block diagram.

Table 47.1 DOC specifications

Item	Description
Data operation function	16-bit data comparison, addition, and subtraction
Module-stop function	The module-stop state can be set to reduce power consumption.
Interrupts and event link function (DOC_DOPCI)	An interrupt occurs on the following conditions: • The compared values either match or mismatch • The result of data addition is greater than 0xFFFF • The result of data subtraction is less than 0x0000
TrustZone Filter	Security attribution can be set

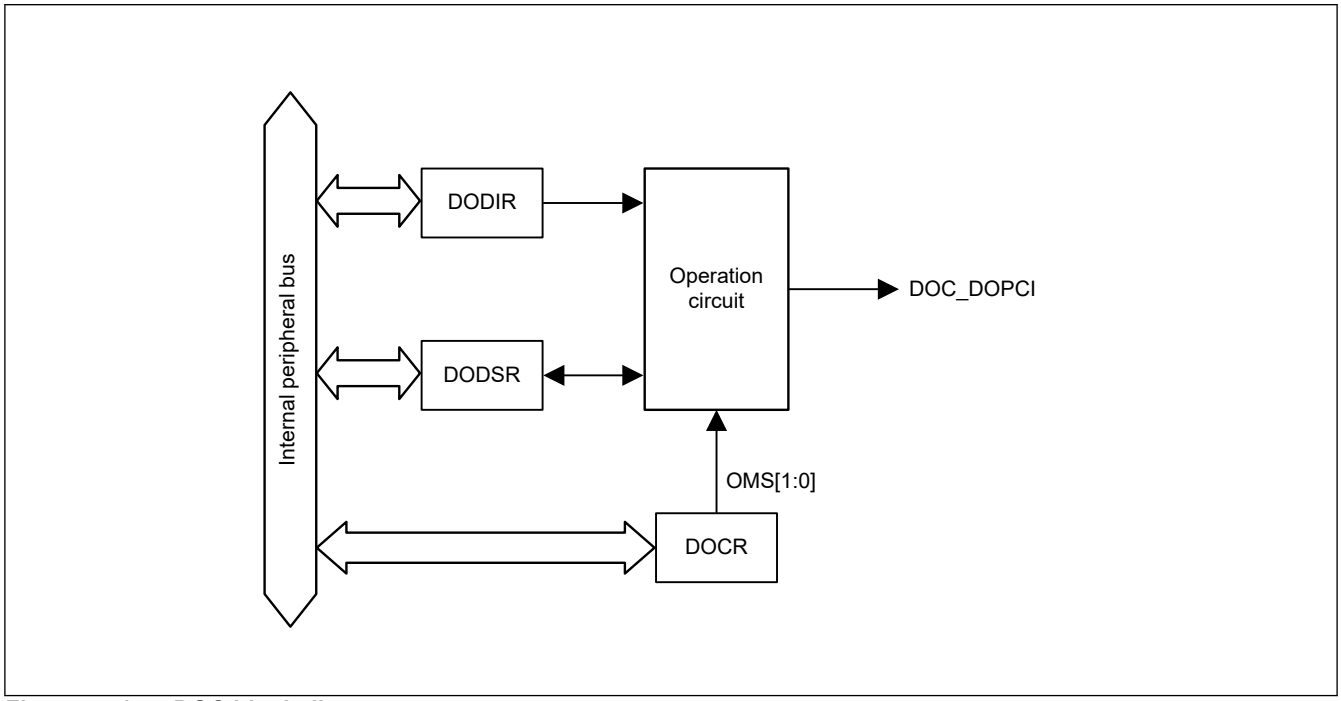

Figure 47.1 DOC block diagram

47.2 DOC Register Descriptions

47.2.1 DOCR : DOC Control Register

Base address: DOC = 0x4010_9000

Offset address: 0x00

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	DOPCFCL	DOPCF	—	—	DCSEL	OMS[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	OMS[1:0]	Operating Mode Select 0 0: Data comparison mode 0 1: Data addition mode 1 0: Data subtraction mode 1 1: Setting prohibited	R/W
2	DCSEL*1	Detection Condition Select 0: Set DOPCF flag when data mismatch is detected 1: Set DOPCF flag when data match is detected	R/W
4:3	—	These bits are read as 0. The write value should be 0.	R/W
5	DOPCF	DOC Flag Indicates the result of an operation.	R
6	DOPCFCL	DOPCF Clear 0: Retain DOPCF flag state 1: Clear DOPCF flag	R/W
7	—	These bits are read as 0. The write value should be 0.	R/W

Note 1. Only valid when data comparison mode is selected.

OMS[1:0] bits (Operating Mode Select)

The OMS[1:0] bits select the operating mode of the DOC.

DCSEL bit (Detection Condition Select)

The DCSEL bit selects the detection condition in data comparison mode. This bit is only valid when data comparison mode is selected.

DOPCF flag (DOC Flag)

The DOPCF flag indicates the result of an operation.

[Setting conditions]

- The result of data comparison matches the condition selected in the DCSEL bit
- A data addition result is greater than 0xFFFF
- A data subtraction result is less than 0x0000

[Clearing condition]

- Writing 1 to the DOPCFCL bit

DOPCFCL bit (DOPCF Clear)

Setting the DOPCFCL bit to 1 clears the DOPCF flag. This bit is read as 0.

47.2.2 DODIR : DOC Data Input Register

Base address: DOC = 0x4010_9000

Offset address: 0x02

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:																
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	n/a	It stores 16-bit data used in the operations.	R/W

47.2.3 DODSR : DOC Data Setting Register

Base address: DOC = 0x4010_9000

Offset address: 0x04

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:																
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	n/a	It stores 16-bit data used as a reference in data comparison mode. This register also stores the results of operations in data addition and subtraction modes.	R/W

47.3 Operation

47.3.1 Data Comparison Mode

Figure 47.2 shows an example operation in data comparison mode operation by the DOC. The following sequence is an example operation when DCSEL is set to 0 (data mismatch is detected as a result of data comparison):

1. Write 00b to the DOCR.OMS[1:0] bits to select data comparison mode.
2. Set 16-bit reference data in DODSR.
3. Write the 16-bit data for comparison to DODIR.
4. Continue writing the 16-bit data until all data for comparison is written to DODIR.
5. If a value written to DODIR does not match that in DODSR, the DOCR.DOPCF flag is set to 1.

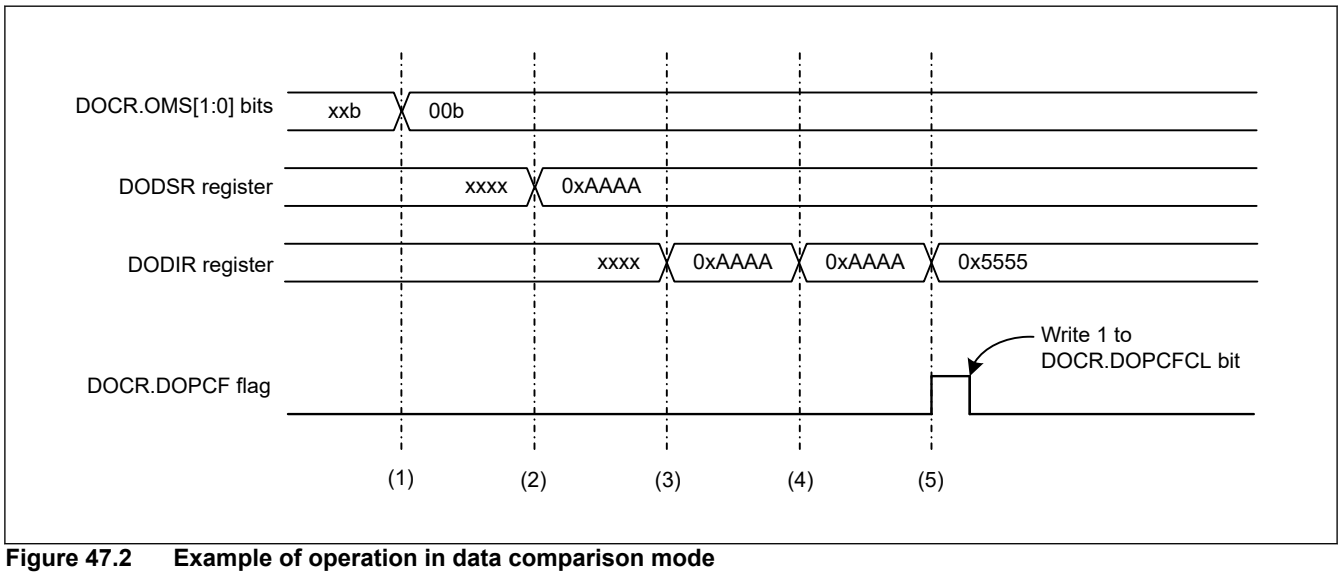

Figure 47.2 Example of operation in data comparison mode

47.3.2 Data Addition Mode

Figure 47.3 shows an example operation in data addition mode. The steps are as follows:

1. Write 01b to the DOCR.OMS[1:0] bits to select data addition mode.
2. Set 16-bit data as the initial value in the DODSR register.
3. Write the 16-bit data to be added to the DODIR register. The result of the operation is stored in the DODSR register.
4. Continue writing the 16-bit data until all data to be added is written to the DODIR.
5. If the result of an operation is greater than 0xFFFF, the DOCR.DOPCF flag is set to 1.

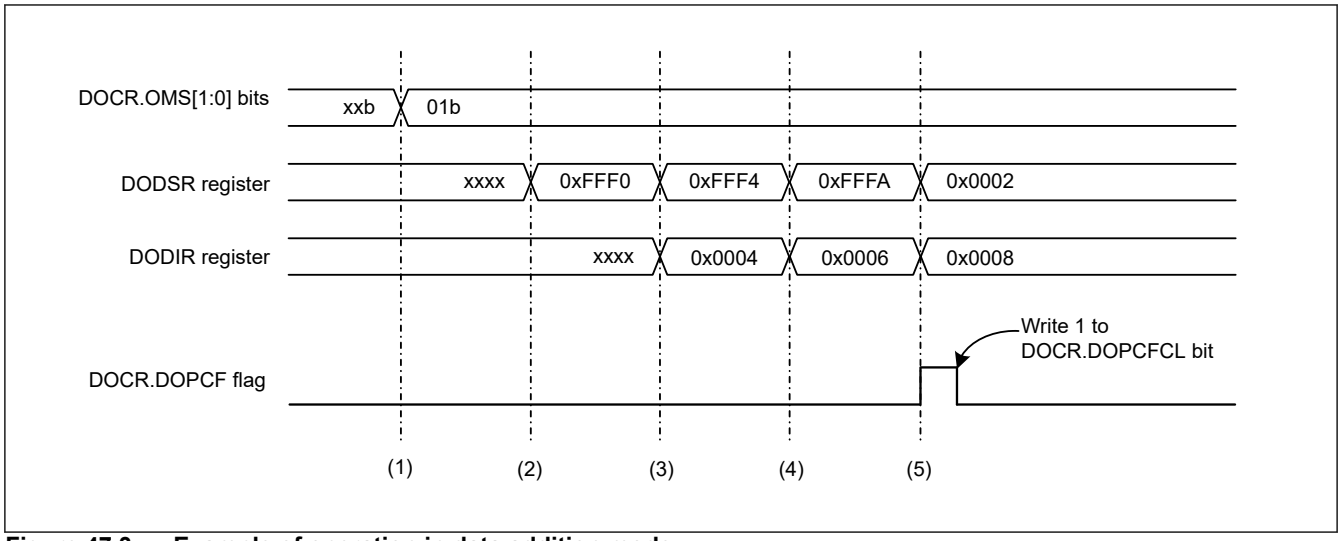

Figure 47.3 Example of operation in data addition mode

47.3.3 Data Subtraction Mode

Figure 47.4 shows an example operation in data subtraction mode. The steps are as follows:

1. Write 10b to the DOCR.OMS[1:0] bits to select data subtraction mode.
2. Set 16-bit data as the initial value in the DODSR register.
3. Write the 16-bit data to be subtracted to the DODIR register. The result of the operation is stored in DODSR.
4. Continue writing the 16-bit data to the DODIR register until all data to be subtracted is written.
5. If the result of an operation is less than 0x0000, the DOCR.DOPCF flag is set to 1.

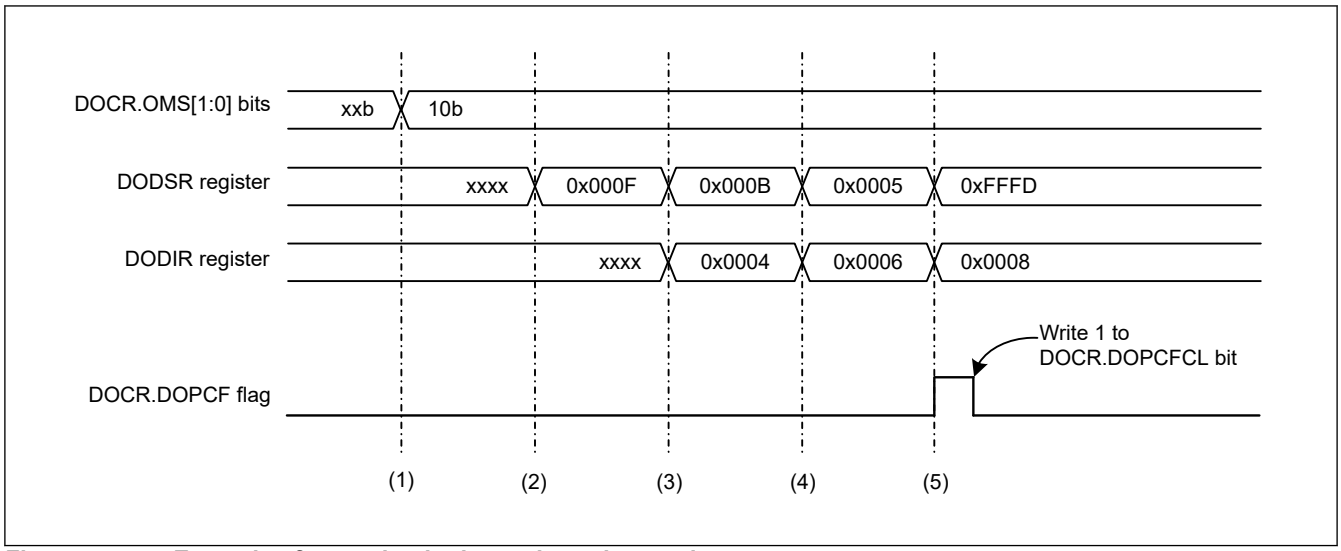

Figure 47.4 Example of operation in data subtraction mode

47.4 Interrupt Source

The DOC generates the DOC interrupt (DOC_DOPCI) as an interrupt request. Table 47.2 describes the DOC interrupt request.

Table 47.2 Interrupt request from DOC

Interrupt request	Status flag	Interrupt source
DOC interrupt	DOPCF	• The result of data comparison matches the condition selected in the DOCR.DCSEL bit. • The result of data addition is greater than 0xFFFF. • The result of data subtraction is less than 0x0000.

47.5 Output of an Event Signal to the Event Link Controller (ELC)

The DOC outputs an event signal for the ELC under the following conditions:

- The compared values either match or mismatch
- The data addition result is greater than 0xFFFF
- The data subtraction result is less than 0x0000

This signal can be used to initiate operations by other modules selected in advance and can also be used as an interrupt request. When an event signal is generated, the DOC Flag (DOCR.DOPCF) is set to 1.

47.6 Usage Notes

47.6.1 Settings for the Module-Stop State

The module Stop Control Register C (MSTPCRC) can enable or disable DOC operation. The DOC is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see section 10, Low Power Modes.

48. SRAM

48.1 Overview

The MCU provides an on-chip, high-density SRAM module with either parity-bit checking or Error Correction Code (ECC). The first 64 KB area of the SRAM0 is the ECC. Parity check is performed on the other areas.

Table 48.1 lists the SRAM specifications.

Table 48.1 SRAM specifications

Parameter	Without ECC	With ECC
SRAM capacity	SRAM0: 448 KB	SRAM0: 64 KB
SRAM address	SRAM0: 0x2001_0000 to 0x2007_FFFF	SRAM0: 0x2000_0000 to 0x2000_FFFF
Access	Wait states are inserted into the read cycle by default. If the ICLK frequency is faster than 100 MHz, wait state is required. If the ICLK frequency is 100 MHz or less, a wait state is not required. For details, see section 48.3.9. Access Cycle	
Data retention function	Not available in Deep Software Standby mode	
Module-stop function	Module-stop state can be set to reduce power consumption	
Parity	Even parity with 8-bit data and 1-bit parity	No parity
Error checking	even-parity（Date:8bit, parity:1bit）	SEC-DED (Single-Error Correction and Double-Error Detection Code)
Security	TrustZone Filter is integrated for memory access and SFR access. Access to the memory space is controlled by setting the memory Security Attribution (SA). And, access to I/O space (SFR) space is controlled by setting the register SA. See section 48.3.6. TrustZone Filter function.	

48.2 Register Descriptions

48.2.1 SRAMSAR : SRAM Security Attribution Register

Base address: CPSCU = 0x4000_8000

Offset address: 0x10

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	SRAMSA2	SRAMSA1	SRAMSA0
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
0	SRAMSA0	Security attributes of registers for SRAM Protection 0: Secure 1: Non-Secure	R/W
1	SRAMSA1	Security attributes of registers for SRAM Protection 2 0: Secure 1: Non-Secure	R/W
2	SRAMSA2	Security attributes of registers for ECC Relation 0: Secure 1: Non-Secure	R/W
31:3	—	These bits are read as 1. The write value should be 1.	R/W

Note: Only secure access can write to this register. Both secure access and Non-secure read access are allowed but Non-secure write access is not allowed and TrustZone access error is not generated.

Note: This register is write-protected by PRCR register.

SRAMSA0 bit (Security attributes of registers for SRAM Protection)

Security attributes of registers for SRAM Protection. The target registers are as follow.

- PARIOAD
- SRAMPRCR

SRAMSA1 bit (Security attributes of registers for SRAM Protection 2)

Security attributes of registers for SRAM Protection 2. The target registers are as follow.

- SRAMWTSC
- SRAMPRCR2

SRAMSA2 bit (Security attributes of registers for ECC Relation)

Security attributes of registers for ECC Relation. The target registers are as follow.

- ECCMODE
- ECC2STS
- ECC1STSEN
- ECC1STS
- ECCPRCR
- ECCPRCR2
- ECCETST
- ECCOAD

48.2.2 PARIOAD : SRAM Parity Error Operation After Detection Register

Base address: SRAM = 0x4000_2000

Offset address: 0x00

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	OAD
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	OAD	Operation After Detection 0: Non-maskable interrupt 1: Reset	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: If the security attribution is configured as secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

The PARIOAD register controls the operation on detection of a parity error. The SRAM Protection Register (SRAMPRCR) protects this register against writes. Always set the SRAMPRCR bit in SRAMPRCR to 1 before writing to this bit. Do not write to the PARIOAD register while accessing the SRAM.

OAD bit (Operation After Detection)

The OAD bit specifies the generation of either a reset or non-maskable interrupt when a parity error is detected. The OAD bit is commonly used for SRAM0 (without ECC)/Standby SRAM.

48.2.3 SRAMPRCR : SRAM Protection Register

Base address: SRAM = 0x4000_2000

Offset address: 0x04

Bit position:	7						1	0
Bit field:	KW[6:0]							SRAMPRCR
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SRAMPRCR	Register Write Control 0: Disable writes to protected registers 1: Enable writes to protected registers	R/W
7:1	KW[6:0]	Write Key Code These bits enable or disable writes to the SRAMPRCR bit	W

Note: If the security attribution is configured as secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

SRAMPRCR bit (Register Write Control)

The SRAMPRCR bit controls the write mode of the PARIOAD register. Setting the bit to 1 enables writes to the PARIOAD register. When you write to this bit, always write 0x78 to KW[6:0] bits simultaneously.

KW[6:0] bits (Write Key Code)

The KW[6:0] bits enable or disable writes to the SRAMPRCR bit. When you write to the SRAMPRCR bit, always write 0x78 to these bits simultaneously. When a value other than 0x78 is written to KW[6:0], the SRAMPRCR bit is not updated. The KW[6:0] bits are always read as 0x00.

48.2.4 SRAMWTSC : SRAM Wait State Control Register

Base address: SRAM = 0x4000_2000

Offset address: 0x08

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	SRAM0WTEN
Value after reset:	0	0	0	0	0	0	0	1

Bit	Symbol	Function	R/W
0	SRAM0WTEN	SRAM0 wait enable 0: No wait 1: Add wait state in read access cycle to SRAM0	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: If the security attribution is configured as secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

This register can be rewritten only when the SRAMPRCR2 bit in the SRAMPRCR2 register is 1.

The protection register (SRAMPRCR2) protects this register against writing. Change the effective bit in the protection register (SRAMPRCR2) to write in this register.

Do not write to SRAMWTSC while access to SRAM is in progress.

SRAM0WTEN bit (SRAM0 wait enable)

This bit sets the wait cycle to the operation region in SRAM0 (Both parity and ECC areas). When it is set 1 in the SRAM0WTEN bit, 1 wait cycle is inserted into the read cycle of operation region in SRAM0. And 1 wait cycle is also inserted between the “write to read/write” sequential cycle in the same region of SRAM0. When read access frequency is more than 100 MHz, it is necessary to set 1 wait cycle in SRAM0WTEN bit.

48.2.5 SRAMPRCR2 : SRAM Protection Register 2

Base address: SRAM = 0x4000_2000

Offset address: 0x0C

Bit position:	7	6	5	4	3	2	1	0
Bit field:	KW[6:0]							SRAMPRCR2
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SRAMPRCR2	Register Write Control 0: Disable writes to the protectedregisters 1: Enable writes to the protected registers	R/W
7:1	KW[6:0]	Write Key Code These bits enable or disable writes to the SRAMPRCR2 bit	W

Note: If the security attribution is configured as secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

SRAMPRCR2 bit (Register Write Control)

The SRAMPRCR2 bit controls the write mode of the SRAMWTSC register. Setting the bit to 1 enables writes to the SRAMWTSC register. When you write to this bit, always write 0x78 to KW[6:0] at the same time.

KW[6:0] bits (Write Key Code)

The KW[6:0] bits enable or disable writes to the SRAMPRCR2 bit. When you write to SRAMPRCR2 bit, always write 0x78 to these bits at the same time. When a value other than 0x78 is written to KW[6:0], the SRAMPRCR2 bit is not updated. The KW[6:0] bits are always read as 0x00.

48.2.6 ECCMODE : ECC Operating Mode Control Register

Base address: SRAM = 0x4000_2000

Offset address: 0xC0

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	ECCMOD[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	ECCMOD[1:0]	ECC Operating Mode Select 0 0: Disable ECC function 0 1: Setting prohibited 1 0: Enable ECC function without error checking 1 1: Enable ECC function with error checking	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W

Note: If the security attribution is configured as secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

The ECCMODE register specifies the ECC operating mode. The ECC Protection Register (ECCPRCR) protects this register against writes. Before writing to this register, set the ECCPRCR bit in the ECCPRCR register to 1 (write protection disabled). Do not write to the ECCMODE register while accessing the SRAM.

ECCMOD[1:0] bits (ECC Operating Mode Select)

The ECCMOD[1:0] bits set the access mode to the ECC area in SRAM0.

48.2.7 ECC2STS : ECC 2-Bit Error Status Register

Base address: SRAM = 0x4000_2000

Offset address: 0xC1

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	ECC2ERR
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	ECC2ERR	ECC 2-Bit Error Status 0: No 2-bit ECC error occurred 1: 2-bit ECC error occurred	R/W*1
7:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: If the security attribution is configured as secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note 1. Only 0 can be written to clear the bit.

ECC2ERR bit (ECC 2-Bit Error Status)

The ECC2ERR bit indicates whether a 2-bit ECC error occurred in the ECC area of SRAM0. When a 2-bit error is detected while ECC operations are enabled and error checking is selected, theECC2ERR bit is set to 1. The SRAM error signal is also asserted at this time. The 2-bit ECC error can be cleared by writing 0 to the ECC2ERR bit.

The SRAM error can be specified as a non-maskable interrupt or a reset in the ECCOAD register. Do not access the ECC area in SRAM0 while writing 0 to this register.

48.2.8 ECC1STSEN : ECC 1-Bit Error Information Update Enable Register

Base address: SRAM = 0x4000_2000

Offset address: 0xC2

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	E1STSEN
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	E1STSEN	ECC 1-Bit Error Information Update Enable 0: Disable updating of 1-bit ECC error information 1: Enable updating of 1-bit ECC error information	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: If the security attribution is configured as secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:

- Secure and Non-secure access are allowed.

The ECC1STSEN register enables or disables updating of the ECC 1-bit Error Status Register (ECC1STS) in response to a 1-bit error ECC error in the SRAM0 (ECC area).

The ECC Protection Register (ECCPRCR) protects this register against writes. Before writing to this bit, set the ECCPRCR bit in the ECCPRCR register to 1 (write protection disabled).

E1STSEN bit (ECC 1-Bit Error Information Update Enable)

The E1STSEN bit enables or disables updating of the SRAM (ECC area) 1-Bit Error Status Register (ECC1STS) in response to a 1-bit error in the ECC area of SRAM0. This register also functions as an interrupt or a reset mask.

48.2.9 ECC1STS : ECC 1-Bit Error Status Register

Base address: SRAM = 0x4000_2000

Offset address: 0xC3

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	ECC1ERR
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	ECC1ERR	ECC 1-Bit Error Status 0: No 1-bit ECC error occurred 1: 1-bit ECC error occurred	R/(W)*1
7:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: If the security attribution is configured as secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

Note 1. Only 0 can be written to clear the bit.

ECC1ERR bit (ECC 1-Bit Error Status)

The ECC1ERR bit indicates whether a 1-bit ECC error occurred in the ECC area of SRAM0. When a 1-bit error is detected while ECC operations are enabled and error checking is selected, theECC1ERR bit is set to 1. The SRAM error signal is also asserted at this time. The 1-bit ECC error can be cleared by writing 0 to the ECC1ERR bit.

The SRAM error can be specified as a non-maskable interrupt or a reset in the ECCOAD register. Do not access the ECC area in SRAM0 while writing 0 to this register.

48.2.10 ECCPRCR : ECC Protection Register

Base address: SRAM = 0x4000_2000

Offset address: 0xC4

Bit position:	7	6	5	4	3	2	1	0
Bit field:	KW[6:0]							ECCPRCR
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	ECCPRCR	Register Write Control 0: Disable writes to the protected registers 1: Enable writes to the protected registers	R/W
7:1	KW[6:0]	Write Key Code 0x78: Enable write to the ECCPRCR bit Others: Disable write to the ECCPRCR bit	W

Note: If the security attribution is configured as secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

ECCPRCR bit (Register Write Control)

The ECCPRCR bit controls the write of the ECCMODE, ECC1STSEN, and ECCOAD registers. When this bit is set to 1, writing to the ECCMODE, ECC1STSEN, and ECCOAD registers is enabled. When writing to this bit, write 0x78 to the KW[6:0] bits at the same time.

KW[6:0] bits (Write Key Code)

The KW[6:0] bits enable or disable writes to the ECCPRCR bit. When writing toECCPRCR bit, write 0x78 to the KW[6:0] bits at the same time. When a value other than 0x78 is written to theKW[6:0] bits, the ECCPRCR bit is not updated. The KW[6:0] bits are always read as 0x00.

48.2.11 ECCPRCR2 : ECC Protection Register 2

Base address: SRAM = 0x4000_2000

Offset address: 0xD0

Bit position:	7	6	5	4	3	2	1	0
Bit field:	KW2[6:0]							ECCPRCR2
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	ECCPRCR2	Register Write Control 0: Disable writes to the protected registers 1: Enable writes to the protected registers	R/W
7:1	KW2[6:0]	Write Key Code 0x78: Enable write to the ECCPRCR2 bit Others: Disable write to the ECCPRCR2 bit	W

Note: If the security attribution is configured as secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

ECCPRCR2 bit (Register Write Control)

The ECCPRCR2 bit controls the write mode of the ECCETST register. When the ECCPRCR2 bit is set to 1, writes to the ECCETST register is enabled. When writing to this bit, write 0x78 to the KW2[6:0] bits at the same time.

KW2[6:0] bits (Write Key Code)

The KW2[6:0] bits enable or disable writes to the ECCPRCR2 bit. When writing to ECCPRCR2 bit, write 0x78 to the KW2[6:0] bits at the same time. When a value other than 0x78 is written to the KW2[6:0] bits, the ECCPRCR2 bit is not updated. The KW2[6:0] bits are always read as 0x00.

48.2.12 ECCETST : ECC Test Control Register

Base address: SRAM = 0x4000_2000

Offset address: 0xD4

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	TSTBYP
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TSTBYP	ECC Bypass Select 0: Disable ECC bypass 1: Enable ECC bypass	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: If the security attribution is configured as secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

The ECC Protection Register 2 (ECCPRCR2) protects this register against writes. Before writing to this bit, set the ECCPRCR2 bit in the ECCPRCR2 register to 1 (write protection disabled). Do not write to the ECCETST register while accessing the SRAM.

TSTBYP bit (ECC Bypass Select)

The TSTBYP bit enables direct access to the ECC code by bypassing the ECC function. When the ECC bypass function is used, the ECCMOD[1:0] bits in the ECCMODE register are set to 00b. The ECC must be accessed in 32 bits using the same address for 32-bit data. The ECC code is assigned to the lower 7 bits of the 32-bit data. When writing the ECC code, the upper 25 bits are ignored. When reading the ECC code, the upper 25 bits are undefined.

Note: For details of ECC test, see section 48.3.4. ECC Decoder Testing.

48.2.13 ECCOAD : SRAM ECC Error Operation After Detection Register

Base address: SRAM = 0x4000_2000

Offset address: 0xD8

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	OAD
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	OAD	Operation After Detection 0: Non-maskable interrupt 1: Reset	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: If the security attribution is configured as secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

The ECC Protection Register (ECCPRCR) protects this register against writes. Before writing to this bit, set the ECCPRCR bit in the ECCPRCR register to 1 (write protection disabled). Do not write to the ECCOAD register while accessing the SRAM.

OAD bit (Operation After Detection)

The OAD bit selects whether to generate a reset or a non-maskable interrupt when an ECC error is detected. The OAD bit in the ECCOAD register is used for SRAM0 (ECC area).

48.3 Operation

48.3.1 Module Stop Function

Power consumption can be reduced by setting module stop control register A (MSTPCRA) to stop supply of the clock signal to SRAM.

SRAM0 is controlled by SRAM0 bit in MSTPCRA register and, in the case of 1, SRAM0 becomes the clock stop state.

The SRAM is thus placed in the module-stop state by stopping supply of the clock signals. The SRAM operates after a reset.

SRAM is not accessible if it is in the module-stop state. A transition to the module-stop state should not be made while access to SRAM is in progress.

Access to the SRAM in the module-stop state is prohibited. If access is attempted, correct operation is not guaranteed.

For details on the MSTPCRA register, see section 10, Low Power Modes.

48.3.2 Correction of ECC errors

Enabling and disabling of ECC error correction can be selected through ECCMODE register setting. In the initial state, ECC error correction is disabled. The ECC check type is SEC-DED (Single-Error Correction and Double-Error Detection Code).

When ECC function is enabled, 7-bit check bits are appended to 32-bit data for writing. For reading, 39-bit (data: 32 bits, check bits: 7 bits) data is read out from the SRAM (ECC area).

When ECC function is enabled and error checking is selected by setting ECCMOD[1:0] in the ECCMODE register to 00b, error correction is done if a 1-bit error occurs and the ECC1ERR bit in the ECC1STS register is set to 1 if the E1STSEN bit in the ECC1STSEN register is 1. If a 2-bit error occurs, error detection is done and the ECC2ERR bit in the ECC2STS register is set to 1, though error correction is not performed.

When ECC function is enabled and the error checking is disable, error correction is done if a 1-bit error occurs but ECC1ERR bit in the ECC1STS register is not updated although E1STSEN bit in the ECC1STSEN register is 1. If a 2-bit error occurs, this error is detected but the ECC2ERR bit in the ECC2STS register is not updated, and error correction is not performed.

When ECC function is disable, neither error correction nor error detection is done although 1-bit or 2-bit error occur.

So ECC1ERR bit and ECC2ERR bit are not updated.

There is no way to confirm the location where the error was found. Therefore, when after the occurrence of an error, update all the data.

When updating all the data after the occurrence of an error, the 32-bit data writing is only supported.

Since the SRAM data is undefined after power on and release from Deep Software Standby mode, accessing the SRAM when ECC function is enabled and error checking is selected causes an ECC error to occur. Therefore, before using ECC function, initial writing with 32-bit data size to the area to be used in the SRAM should be done.

When a read access is executed in a row after a write access, read access is executed with priority. Therefore, during initialization, do not perform the read access in a row after the write access.

48.3.3 ECC Error Interrupt Function

When ECC function is enabled and error checking is applied to the SRAM (ECC area), an ECC error occurs when either the ECC2ERR bit in the ECC2STS register or the ECC1ERR bit in the ECC1STS register becomes 1 to indicate that ECC checking revealed a 2-bit error or a 1-bit error, respectively.

An ECC erroris output with a pulse width of ICLK.When the ECC 1-bit error is to be masked, set the ECC1STSEN.E1STSEN bit to 0 to disable updating of the ECC1ERR bit. An ECC error will not be generated while ECC function is disabled or when ECC function is enabled but error checking is not selected.

ECC error can choose non maskable interrupt or reset by ECCOAD register. When set 1 in the OAD bit of the ECCOAD register, ECC error is output to the Reset function. When set 0 in the OAD bit of the ECCOAD register, ECC Error interrupt is output to the ICU as non-maskable interrupt.

48.3.4 ECC Decoder Testing

Figure 48.1 shows the ECC decoder testing.

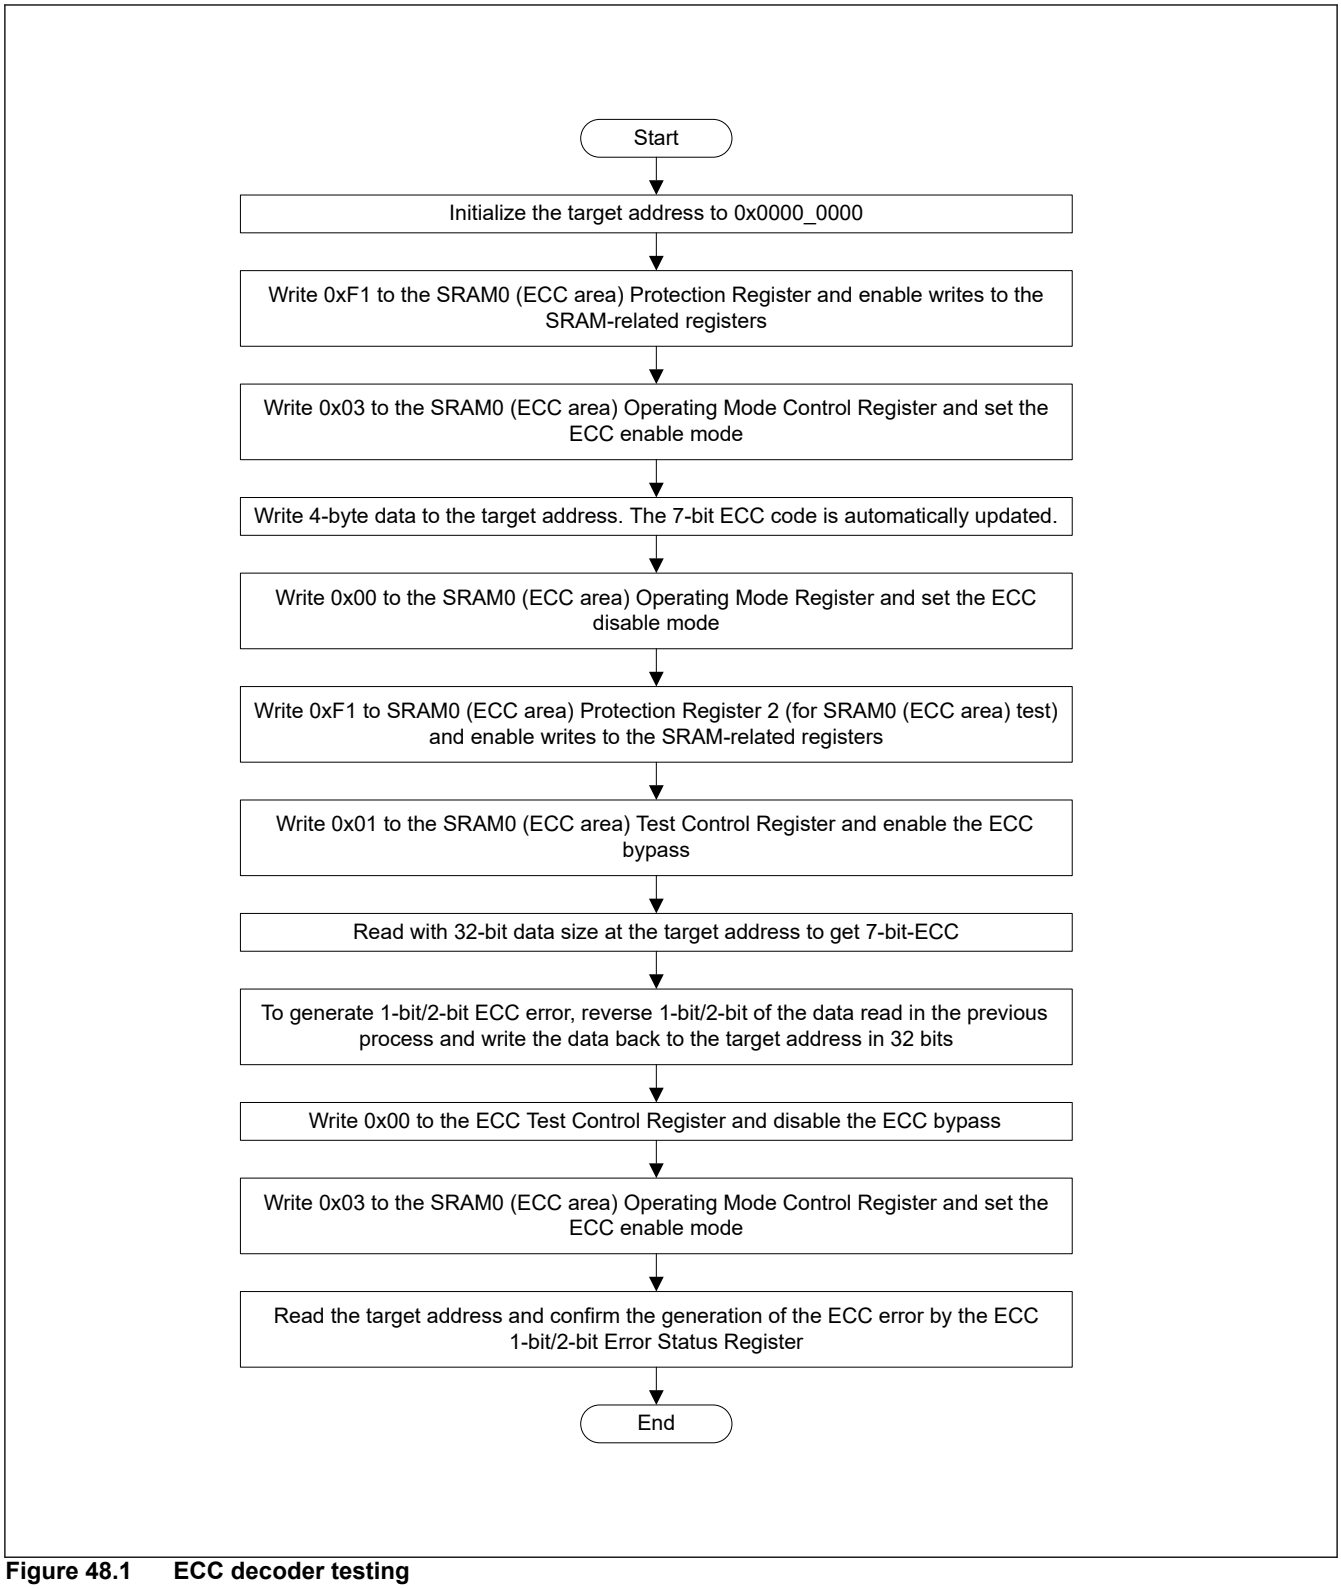

Figure 48.1 ECC decoder testing

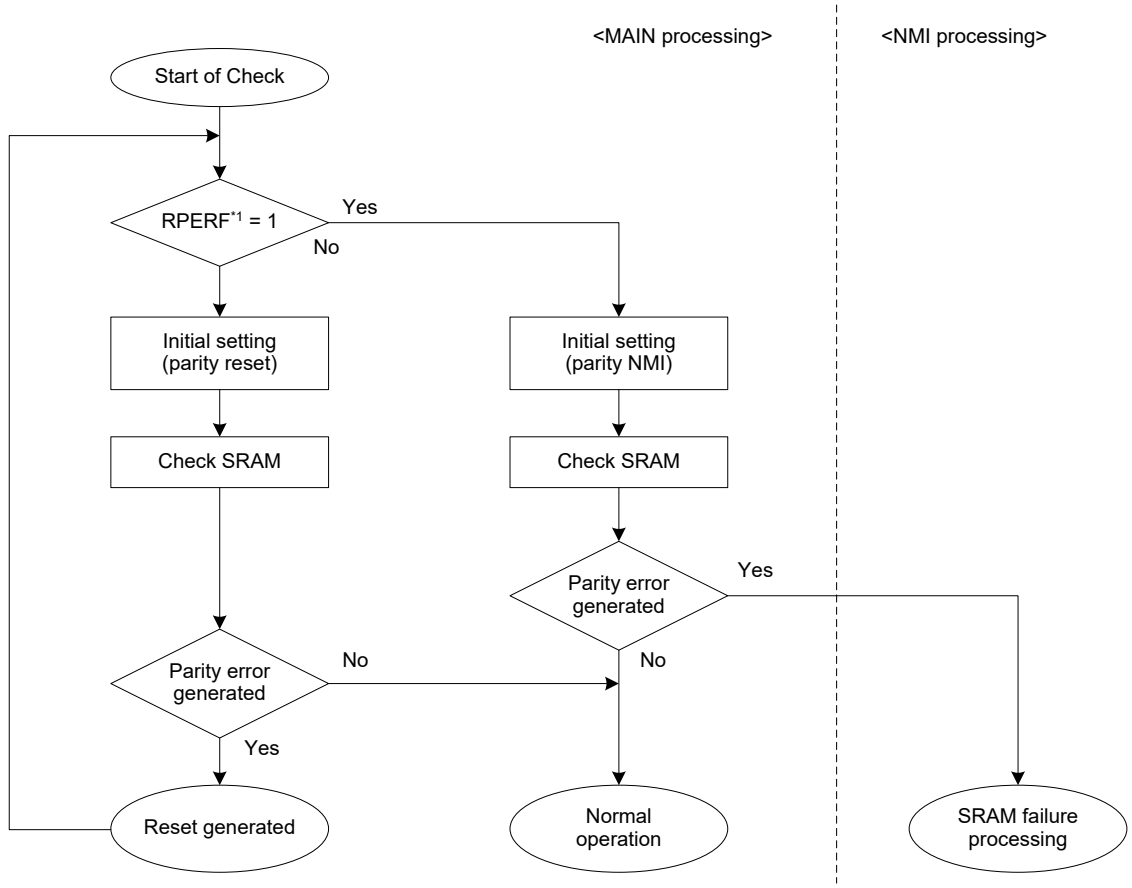
48.3.5 Parity Calculation Function

The IEC60730 standard requires the checking of SRAM data. When data is written, a parity bit is added to every 8-bit data in the SRAM which has 32-bit data width, and when data is read, the parity is checked. When a parity error occurs, a parity-error notification is generated. This function can also be used to trigger a reset.

The parity-error notification can be specified as a non-maskable interrupt or a reset in the OAD bit of the PARIOAD register. When the OAD bit is set to 1, a parity error is output to the reset function. When the OAD bit is set to 0, a parity error is output to the ICU as a non-maskable interrupt.

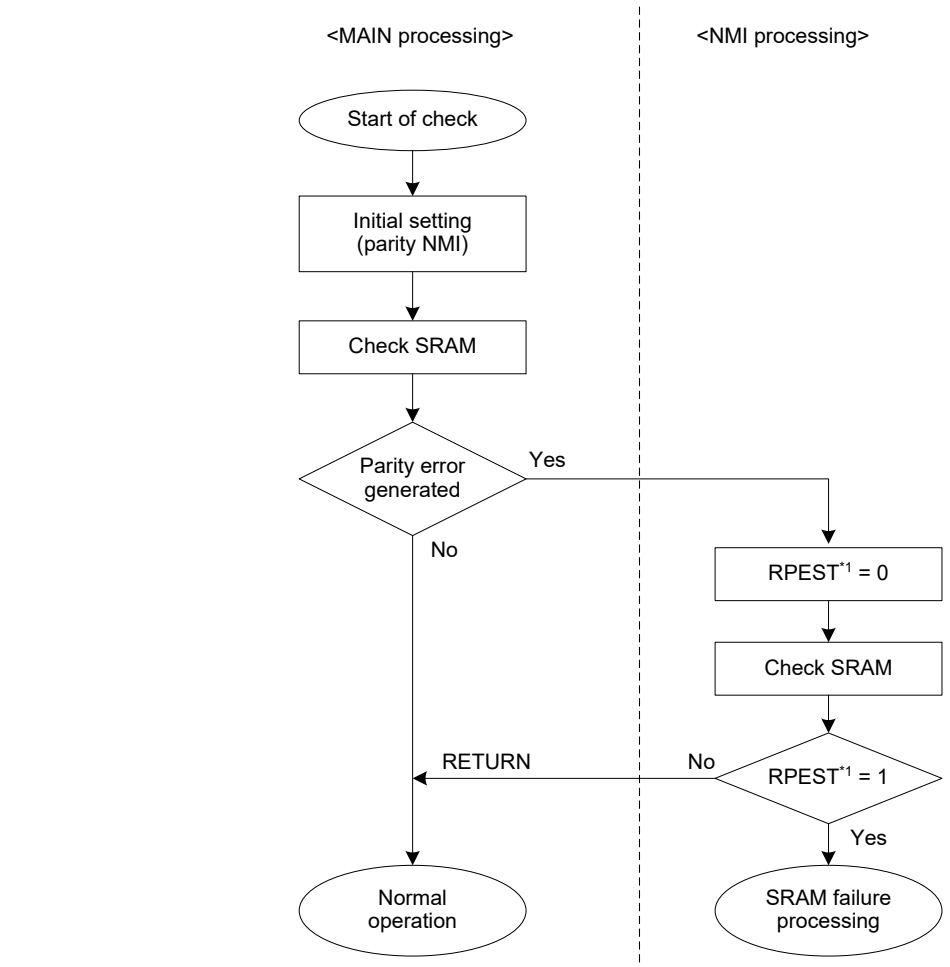
Parity errors can be occasionally caused by noise. To confirm whether the cause of the parity error is noise or corruption, follow the parity check flows shown in Figure 48.2 and Figure 48.3.

When a read access is executed in a row after a write access, read access is executed with priority. Therefore, during initialization, do not perform the read access in a row after the write access.



Note 1. RPERF: SRAM Parity Error Reset Detect Flag (RSTSR1.RPERF bit)

Figure 48.2 Flow of SRAM parity check when SRAM parity reset is enabled



Note 1. RPEST: SRAM Parity Error Interrupt Status Flag (NMISR.RPEST bit)

Figure 48.3 Flow of SRAM parity check when SRAM parity interrupt is enabled

48.3.6 TrustZone Filter function

There are two types of TrustZone Filter function for SRAM.

- TrustZone Filter for SRAM register protection
- TrustZone Filter for SRAM memory protection

48.3.6.1 TrustZone Filter for SRAM register protection

SRAM registers can be protected with a Security Attribution (SA) from Non-secure access. When SA indicates that SRAM registers are secure status, non-secure access cannot overwrite them because TrustZone Filter detects finds an error and protects the write access. SA for SRAM registers is just one to be used commonly among SRAM registers.

Table 48.2 Register protection (1 of 2)

SA	Access status	Write access	Read access
Secure	Secure	Permit	Permit
	Non-secure	TrustZone Filter error Protected	Permit

Table 48.2 Register protection (2 of 2)

SA	Access status	Write access	Read access
Non-secure	Secure	Permit	Permit
	Non-secure	Permit	Permit

When TrustZone Filter error for SRAM register access occurs, no error notification and no error response occurs.

48.3.6.2 TrustZone Filter for SRAM memory protection

SRAM memory, e.g. SRAM0 include ECC region and Parity can be divided into Secure/Non secure callable/Non secure status with Memory Security Attribution (MSA) and can be protected from Non-secure access. When MSA indicates that SRAM memory region are Secure or Non secure callable status, Non-secure access can't overwrite them.

Table 48.3 Memory protection

SA	Access status	Write access	Read access
Secure / Non secure callable	Secure	Permit	Permit
	Non-secure	TrustZone Filter error • Protected • Error response occurs	TrustZone Filter error • Read data is 0 • Error response occurs
Non-secure	Secure	Permit	Permit
	Non-secure	Permit	Permit

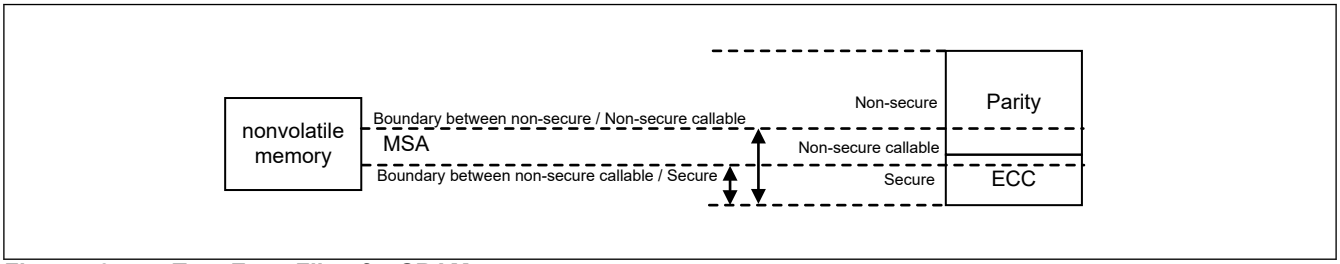


Figure 48.4 TrustZone Filter for SRAM memory

When TrustZone Filter error for SRAM memory access occurs, an error notification which become Reset request or NMI request occurs. See section 52.2. Arm TrustZone Security .

48.3.7 Interrupt Source

The SRAM interrupt source includes an ECC error, Parity error and TrustZone filter error. ECC error and Parity error can choose non-maskable interrupt or reset by OAD bit. When the debugger is connected, reset and non-maskable interrupt are maskable. Also, if these masks are set by the debugger, each status register is not set even if an ECC error occurs. For details on the debug mode, see section 2, CPU.

Table 48.4 SRAM Interrupt Source

Name	Interrupt Source	DTC Activation	DMAC Activation
ECCERR	ECC error (ECC operation region in SRAM0)	Not possible	Not possible
PARITYERR	Parity error	Not possible	Not possible
TZFLT	TrustZone filter error	Not possible	Not possible

48.3.8 Wait state

When ICLK frequencies is SRAM0 = 200 MHz to 100 MHz, if you want to access to the SRAM0, do not set 0x00 in wait enable bit for each RAM of the SRAMWTSC register, in order to insert a wait cycle. When the wait is not inserted, we cannot guarantee the operation.

Depending on the operating frequency of ICLK, the WAIT setting for SRAM access has the following conditions.

[ICLK frequency] (SRAM0):

- 200 MHz ≥ ICLK > 100 MHz = 1 wait
- 100 MHz ≥ ICLK = No-wait

48.3.9 Access Cycle

■ Number of cycles from the CPU

- When the cache is hit, access is one cycle.
- For cache off or non cacheable

Table 48.5 SRAM0 (ECC Area)

Register Setting		Read (cycles)		Write (cycles)	
		Word access	Half-word/Byte access	Word access	Half-word/Byte access
ECC Off ECCMOD[1] = 0	SRAM0WTEN = 0	3		2*1	
	SRAM0WTEN = 1	4		2*1	
ECC On ECCMOD[1] = 1	SRAM0WTEN = 0	3		2*1	4
	SRAM0WTEN = 1	4		2*1	4

Note 1. For efficiency of the access, when read access occurs to the same memory after write, memory write by the precedent write command delays it until for the next idle cycle or the next write access. When read continues, it is given priority to read.

Table 48.6 SRAM0 (Parity Area)

Register Setting	Read (cycles)		Write (cycles)	
	Word access	Half-word/Byte access	Word access	Half-word/Byte access
SRAM0WTEN = 0	3		2*1	
SRAM0WTEN = 1	4		2*1	

Note 1. For efficiency of the access, when read access occurs to the same memory after write, memory write by the precedent write command delays it until for the next idle cycle or the next write access. When read continues, it is given priority to read.

- For cache on and cacheble (When the cache miss hit)

Table 48.7 SRAM0 (ECC Area)

Register Setting		Read (cycles)		Write (cycles)	
		Word access	Half-word/Byte access	Word access	Half-word/Byte access
ECC Off ECCMOD[1] = 0	SRAM0WTEN = 0	3		1*1	
	SRAM0WTEN = 1	4		1*1	
ECC On ECCMOD[1] = 1	SRAM0WTEN = 0	3		1*1	
	SRAM0WTEN = 1	4		1*1	

Note 1. For efficiency of the access, when read access occurs to the same memory after write, memory write by the precedent write command delays it until for the next idle cycle or the next write access. When read continues, it is given priority to read.

Table 48.8 SRAM0 (Parity Area)

Register Setting	Read (cycles)		Write (cycles)	
	Word access	Half-word/Byte access	Word access	Half-word/Byte access
SRAM0WTEN = 0	3		1*1	
SRAM0WTEN = 1	4		1*1	

Note 1. For efficiency of the access, when read access occurs to the same memory after write, memory write by the precedent write command delays it until for the next idle cycle or the next write access. When read continues, it is given priority to read.

48.3.10 ECC encode specification

The following table shows ECC encoding specifications. Add the ECC cord (eout [6:0]) formed by the following calculating formula to higher 7 bits (din [38:32]) of write data and write in it at SRAM.

Table 48.9 ECC encode

ECC code	calculation formula
eout[6]	(din[13] ^ din[12] ^ din[11] ^ din[10] ^ din[9] ^ din[8] ^ din[7] ^ din[6] ^ din[5] ^ din[4] ^ din[3] ^ din[2] ^ din[1] ^ din[0])
eout[5]	(din[23] ^ din[22] ^ din[21] ^ din[20] ^ din[19] ^ din[18] ^ din[17] ^ din[16] ^ din[15] ^ din[14] ^ din[3] ^ din[2] ^ din[1] ^ din[0])
eout[4]	(din[29] ^ din[28] ^ din[27] ^ din[26] ^ din[25] ^ din[24] ^ din[17] ^ din[16] ^ din[15] ^ din[14] ^ din[7] ^ din[6] ^ din[5] ^ din[4])
eout[3]	(din[31] ^ din[30] ^ din[26] ^ din[25] ^ din[24] ^ din[20] ^ din[19] ^ din[18] ^ din[14] ^ din[10] ^ din[9] ^ din[8] ^ din[4] ^ din[0])
eout[2]	(din[31] ^ din[30] ^ din[28] ^ din[27] ^ din[24] ^ din[22] ^ din[21] ^ din[18] ^ din[15] ^ din[12] ^ din[11] ^ din[8] ^ din[5] ^ din[1])
eout[1]	~(din[30] ^ din[29] ^ din[27] ^ din[25] ^ din[23] ^ din[21] ^ din[19] ^ din[16] ^ din[13] ^ din[11] ^ din[9] ^ din[6] ^ din[2] ^ din[0])
eout[0]	~(din[31] ^ din[29] ^ din[28] ^ din[26] ^ din[23] ^ din[22] ^ din[20] ^ din[17] ^ din[13] ^ din[12] ^ din[10] ^ din[7] ^ din[3] ^ din[0])

Note: eout[6:0] = ECC code, din[31:0] = write data

49. Standby SRAM

49.1 Overview

An on-chip SRAM is provided to retain data in Deep Software Standby mode. Table 49.1 lists the Standby SRAM specifications.

Table 49.1 Standby SRAM specifications

Item	Description
SRAM capacity	1 KB
SRAM address	0x2800_0000 to 0x2800_03FF
Access	Standby SRAM clock is the same clock as the PCLKB. See section 49.3.5. Access Cycle for details.
Data retention function	Data can be retained in Deep Software Standby mode. See section 49.3.1. Data Retention for details.
parity	Even parity (data: 8 bits, parity: 1 bit)
Module-stop function	Module-stop state can be set to reduce power consumption. See section 49.3.2. Setting for the Module-stop Function for details.
Security	Permits the read and write operations to Standby RAM following TrustZone Filter function. See section 49.3.4. TrustZone Filter function for details.

49.2 Register Descriptions

49.2.1 STBRAMSAR : Standby RAM memory Security Attribution Register

Base address: CPSCU = 0x4000_8000

Offset address: 0x014

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	NSBSTBR[3:0]			
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	0	0	0	0

Bit	Symbol	Function	R/W
3:0	NSBSTBR[3:0]	Security attributes of each region for Standby RAM 0x0: Region7-0 are all Secure. 0x1: Region7 is Non-secure. Region6-0 are Secure 0x2: Region7-6 are Non-secure. Region5-0 are Secure. 0x3: Region7-5 are Non-secure. Region4-0 are Secure. 0x4: Region7-4 are Non-secure. Region 3-0 are Secure. 0x5: Region7-3 are Non-secure. Region 2-0 are Secure. 0x6: Region7-2 are Non-secure. Region 1-0 are Secure. 0x7: Region7-1 are Non-Secure. Region0 is Secure. Others: Region7-0 are all Non-Secure.	R/W
31:4	—	This bit is read as 1.	R

Note: Only secure access can write to this register. Both secure access and Non-secure read access are allowed but Non-secure write access is not allowed and TrustZone access error is not generated.

Note: This register is write-protected by PRCR register.

NSBSTBR[3:0] bit (Security attributes of each region for Standby RAM)

Standby RAM is divided into 8 regions. Each region can be set as Secure or Non-secure state with NSBSTBR[3:0]

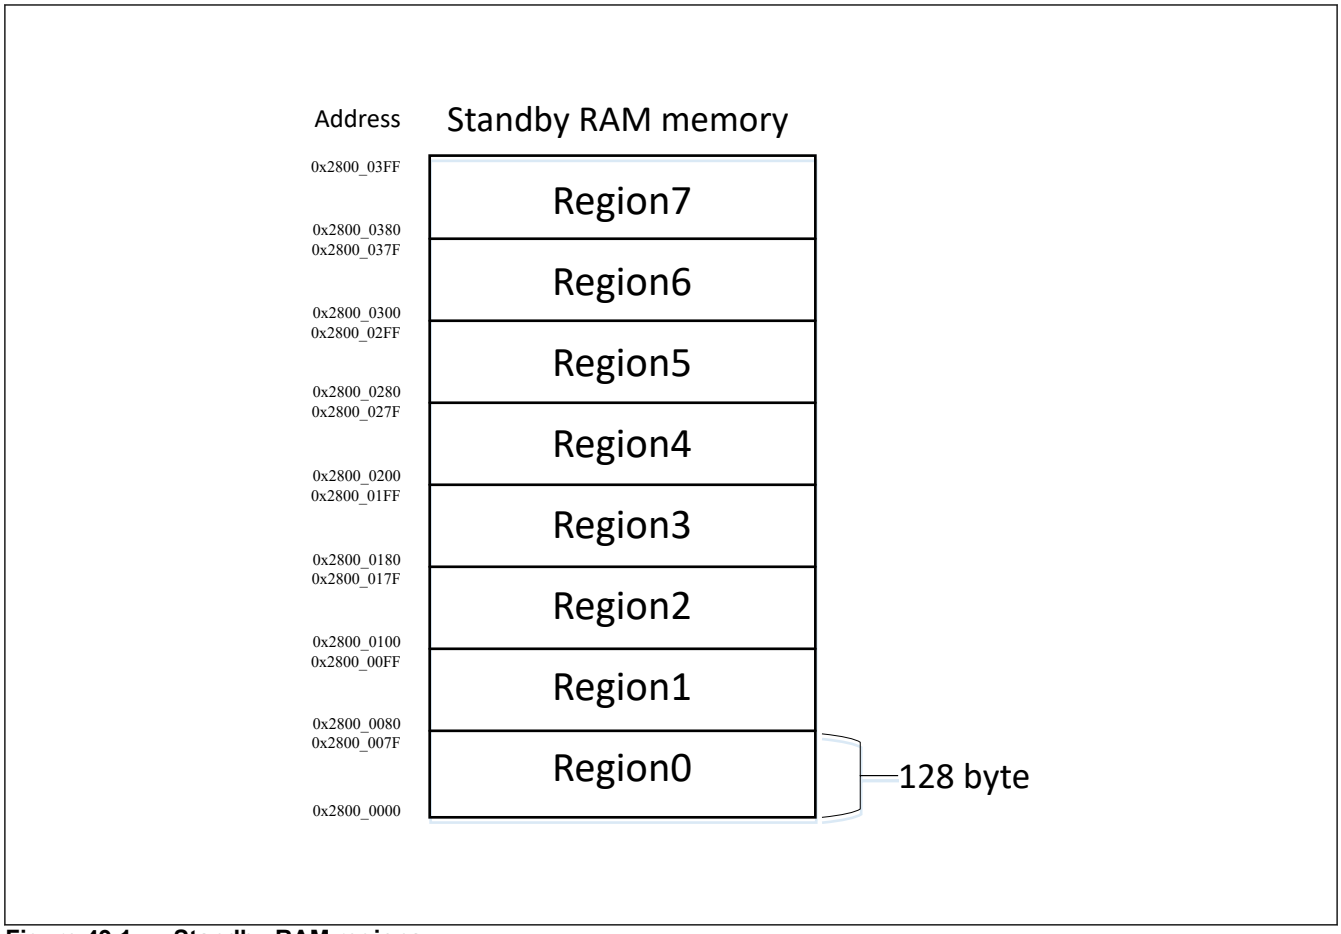

Figure 49.1 Standby RAM regions

49.3 Operation

49.3.1 Data Retention

The power supply to the Standby SRAM in Deep Software Standby mode is enabled by the DPSBYCR.DEEPCUT[1:0] bits. If the DPSBYCR.DEEPCUT[1:0] bits are set to 00b, data in the Standby SRAM is retained in Deep Software Standby mode. For details on the DPSBYCR.DEEPCUT[1:0] bits, see section 10, Low Power Modes.

49.3.2 Setting for the Module-stop Function

Power consumption can be reduced by setting module stop control register A (MSTPCRA) to stop supply of the clock signal to SRAM.

If the Standby SRAM bit in MSTPCRA is set to 1, supply of the clock signal to the Standby SRAM is stopped.

The Standby SRAM is thus placed in the module-stop state by stopping supply of the clock signals. The Standby SRAM operates after a reset.

The Standby SRAM is not accessible if it is in the module-stop state. A transition to the module-stop state should not be made while access to the standby SRAM is in progress.

For details on the MSTPCRA register, see section 10, Low Power Modes.

49.3.3 Parity Calculation Function

The parity calculation Function for Standby SRAM is as same as SRAM without ECC.

See section 48.3.5. Parity Calculation Function and section 48.3.7. Interrupt Source.

OAD bit in PARIOAD register is commonly used for SRAM0 (without ECC) / Standby SRAM.

49.3.4 TrustZone Filter function

There is only one type of TrustZone Filter function for Standby SRAM and that is, TrustZone Filter for SRAM memory protection

49.3.4.1 TrustZone Filter for Standby SRAM Memory Protection

Standby SRAM memory can be divided into 8 regions, 128 bytes each with a Security Attribution (SA) to be protected from Non-secure access. When SA indicates that the region in Standby SRAM is secure status, non-secure access cannot overwrite them because TrustZone Filter detects finds an error and protects the write access.

Table 49.2 Security Attribution and Access status

SA	Access status	Write access	Read access
Secure	Secure	Permit	Permit
	Non-secure	TrustZone Filter error - Protected	TrustZone Filter error - Read data is 0
Non-secure	Secure	Permit	Permit
	Non-secure	Permit	Permit

When TrustZone Filter error for Standby SRAM access occurs, no error notification and no error response occurs.

49.3.5 Access Cycle

Number of cycles from the CPU.

For Standby SRAM, cache always has non-cacheable access.

Table 49.3 Standby SRAM (parity area 0x2800_0000 to 0x2800_03FF)

	Read cycle		Write cycle	
	Word access	Halfword/Byte access	Word access	Halfword/Byte access
ICLK ≥ PCLKB	Min.: 2 ICLK + 2 PCLKB Max.: (n + 1) ICLK + 2 PCLKB		Min.: 1 ICLK + 1 PCLKB Max.: n ICLK + 1 PCLKB	

Note: When the frequency ratio of ICLK : PCLKB is n : 1.

49.4 Usage Notes

49.4.1 Instruction Fetch from the Standby SRAM Area

When using Standby SRAM to operate a program, initialize the Standby SRAM area so that the CPU can correctly prefetch data. A parity error might occur if the CPU prefetches from an area that is not initialized. Initialize the additional 12-byte area from the end address of the program with the 4-byte boundary. Renesas recommends using the NOP instruction for data initialization.

50. Flash Memory

This MCU incorporates code flash memory, data flash memory, and option-setting memory. The code flash memory stores instructions and operands, and the data flash memory stores data. For option-setting memory, see section 6, Option-Setting Memory.

50.1 Overview

Table 50.1 lists the specifications of the flash memory, and Figure 50.1 is block diagrams of the flash memory related modules.

The I/O pins used in boot mode, see Table 50.33.

The FCU (flash control unit) controls programming and erasure of the flash memory. The FACI (flash application command interface) controls the FCU according to the specified FACI commands.

Regarding the configuration of the code flash memory, see Figure 50.2 to Figure 50.3, and for the configuration of the data flash memory, see Figure 50.4.

Table 50.1 Specifications of flash memory (1 of 2)

Item	Code flash memory	Data flash memory
Memory capacity	User area: 2 Mbytes max	Data area: 8 Kbytes
Read cycle	See section 50.16.3. Access Cycle	See section 50.16.3. Access Cycle
Value after erasure	0xFF	Undefined
Programming/erasing method	• Programming and erasing the code flash memory and data flash memory, and programming the option-setting memory are handled by the FACI commands specified in the FACI command issuing area (0x407E_0000) (self-programming). • Programming/erasure through transfer by a serial-programmer via a serial interface (serial programming)	
Protection	Protects against erroneous rewriting of the flash memory	
Dual bank function	The dual-bank structure makes a safe update possible in cases where programming is suspended. • Linear mode: the code flash memory is used as one area. • Dual mode: the code flash memory is divided into two areas.	Not available
Block swap function	The block swap structure makes a safe update for a part of non-secure application possible in case where programming is suspended.	Not available
Background operations (BGOs)*1	• The code flash memory can be read while the code flash memory is being programmed or erased.*1 • The data flash memory can be read while the code flash memory is being programmed or erased. • The code flash memory can be read while the data flash memory is being programmed or erased.	
Units of programming and erasure	• Units of programming for the user area: 128 bytes • Units of erasure for the user area: Block units	• Unit of programming for the data area:4/8/16 bytes • Unit of erasure for the data area:64/128/256 bytes
Other functions	Interrupts can be accepted during self-programming. In the initial settings of this MCU, an expansion area of the option-setting memory can be set.	
On-board programming (four types)	Programming/erasure in boot mode (for the SCI interface) • The asynchronous serial interface (SCI9) is used. • The transfer rate is adjusted automatically. Programming/erasure in boot mode (for the USB interface) • USBFS is used. • Dedicated hardware is not required, so direct connection to a PC is possible. Programming/erasure in On-chip debug mode • JTAG or SWD interface is used Programming and erasure by self-programming • This allows code flash memory programming/erasure without resetting the system.	

Table 50.1 Specifications of flash memory (2 of 2)

Item	Code flash memory	Data flash memory
Unique ID	A 16-byte ID code provided for each MCU	
FACI command	Program : 128 bytes Block erase: 1 block (8 KB or 32 KB) P/E suspend P/E resume Forced Stop Status Clear Configuration set (16 bytes)	Program: 4/8/16 bytes Block Erase: 1 block (64 bytes) Multi Block Erase: 64/128/256 bytes P/E suspend P/E resume Forced Stop Blank Check: 4 bytes to data flash memory capacity Status Clear
Security function	Protects against illicit tampering with or reading out of data in flash memory Startup area select setting protection ● BTFLG and FSUACR registers are protected by the FSPR bit. Permanent block protect setting protection ● Code flash memory is permanently protected from programming/erasure operation by the permanent block protect function. Flash memory protection for TrustZone ● Protection for flash memory area (P/E) ● Protection for flash memory area (read) ● Protection for register ● Protection during FACI command operation. ● Code flash P/E mode entry protection	
Safety function	Software protection ● FACI command protection by FENTRYR register. ● Flash memory is protected by FWEPROR register ● The user area is protected by the block protect setting Error protection ● Error is detected when unintended commands or prohibited settings occur. The FACI command is not accepted after an error detection. Boot area protection ● The start-up area select function allows customer to safely update the boot firmware. The size of the start-up area is 8 KB.	
Interrupt request	● FRDYI (flash sequencer ready (processing end)) : Enabled by FRDYIE bit. ● FIFERR (flash sequencer error) : Enabled by CFAEIE/CMDLKIE/DFAEIE bits	
Address conversion	Start-up area select function is supported in linear mode Dual mode and Linear mode ● Bank swap function is supported in dual mode ● Block swap function is supported in linear mode	

Note 1. Limitations apply to the combinations of the address ranges for programming/erasure process and reading process: see Table 50.35.

Figure 50.1 shows how modules related to flash memory can be configured. The flash sequencer is configured with the FCU and FACI. The FCU executes basic control for rewriting of the flash memory. The FACI receives FACI commands using peripheral bus, and controls FCU operations accordingly.

In response to a reset, the FACI transfers data from the flash memory to the option byte storage registers.

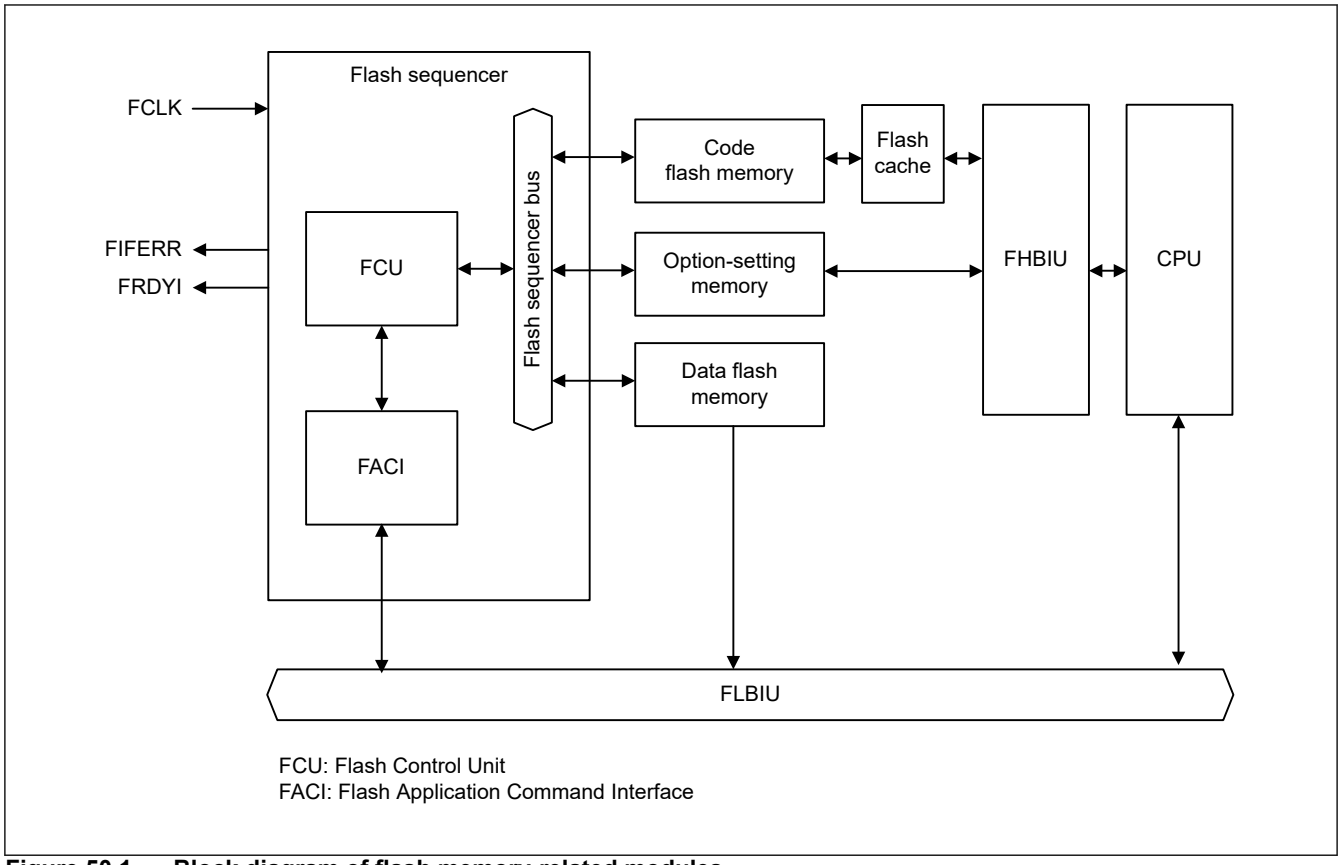

Figure 50.1 Block diagram of flash memory-related modules

50.2 Structure of Memory

Figure 50.2 shows the memory map of code flash memory in linear mode. Figure 50.3 shows the memory map of code flash memory in dual mode. This MCU can use the code flash memory as 2 bank areas by using the dual bank function. This dual-bank structure allows a safe update of a program while a user program is running.

The user area of the code flash memory in this MCU is divided into 8- and 32-Kbyte blocks, which serve as the units of erasure.

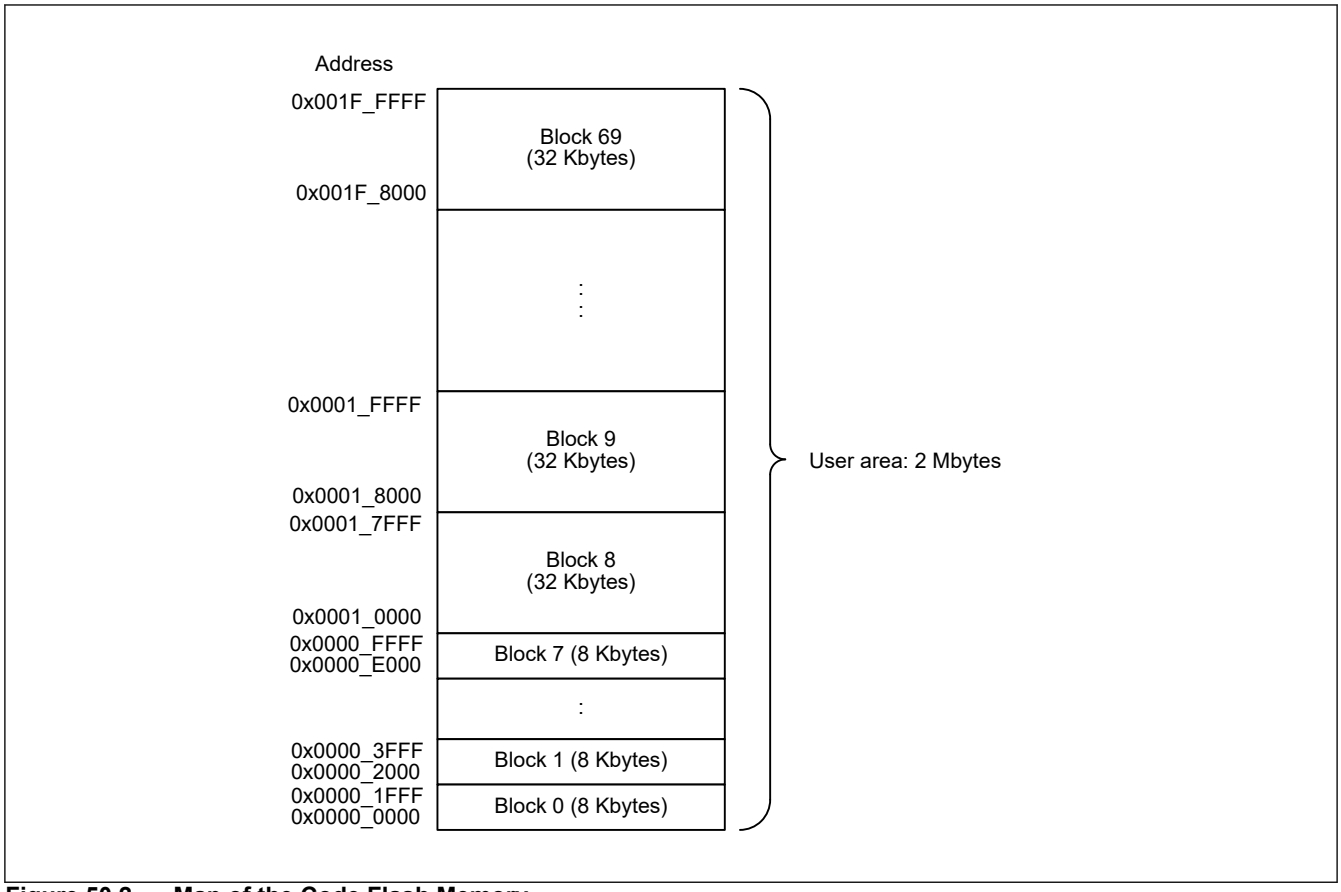

Figure 50.2 Map of the Code Flash Memory

Table 50.2 Read and programming/erasure address by product for the code flash memory

Product	Address	Number of blocks
2 Mbytes product	0x0000_0000 to 0x001F_FFFF	0 to 69
1.5 Mbytes product	0x0000_0000 to 0x0017_FFFF	0 to 53
1 Mbytes product	0x0000_0000 to 0x000F_FFFF	0 to 37

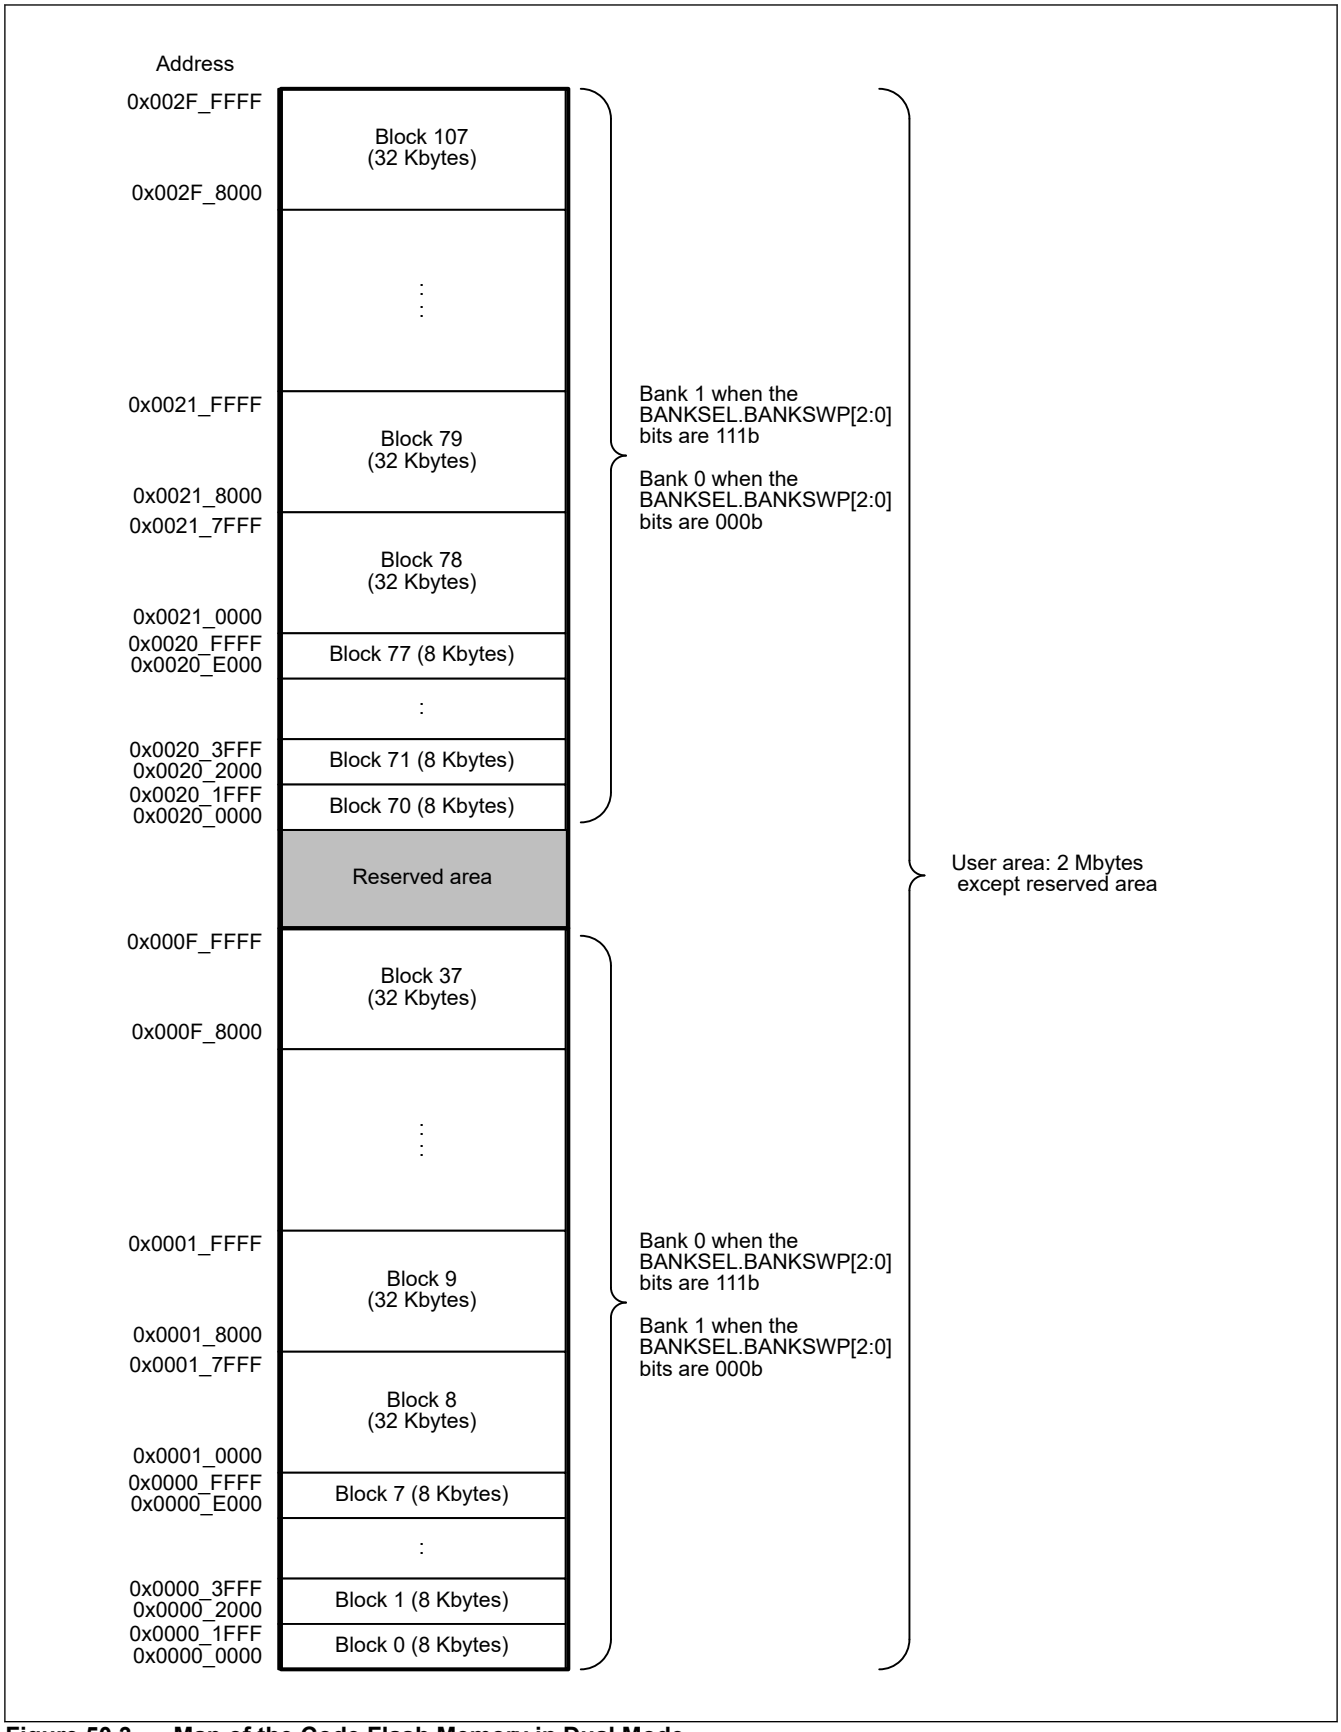

Figure 50.3 Map of the Code Flash Memory in Dual Mode

Table 50.3 Read and programming/erasure address by product for the code flash memory

Product	Address	Number of blocks
2 Mbytes product, lower side bank	0x0000_0000 to 0x000F_FFFF	0 to 37
2 Mbytes product, upper side bank	0x0020_0000 to 0x002F_FFFF	70 to 107
1.5 Mbytes product, lower side bank	0x0000_0000 to 0x000B_FFFF	0 to 29
1.5 Mbytes product, upper side bank	0x0020_0000 to 0x002B_FFFF	70 to 99
1 Mbytes product, lower side bank	0x0000_0000 to 0x0007_FFFF	0 to 21
1 Mbytes product, upper side bank	0x0020_0000 to 0x0027_FFFF	70 to 91

The data area of the data flash memory in this MCU is divided into 64-byte blocks, with each being a unit for erasure. Figure 50.4 shows the mapping of the data flash memory.

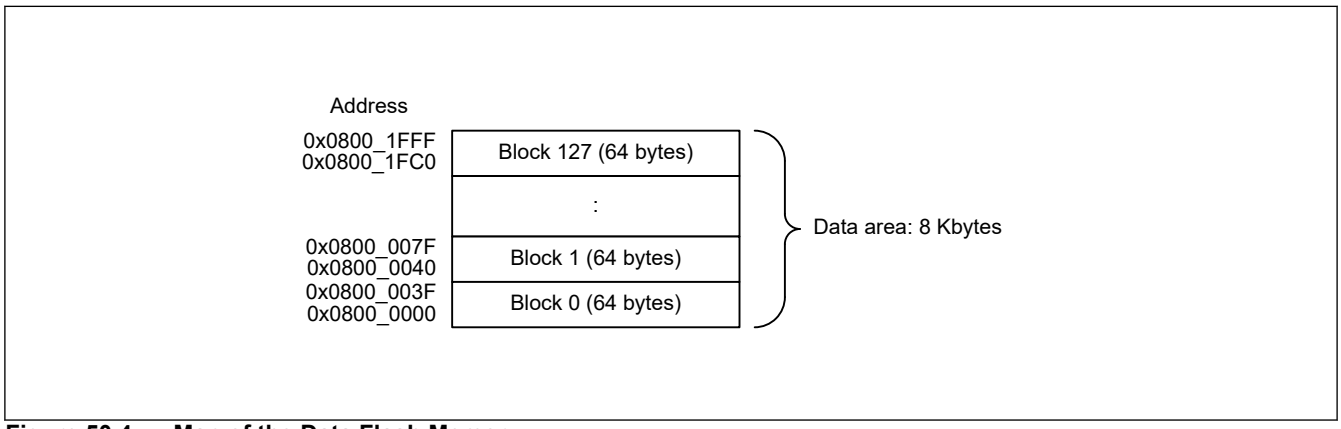

Figure 50.4 Map of the Data Flash Memory

50.3 Address Space

Using the hardware interface with flash memory requires access to all registers of the hardware, which is for issuing FACI commands. Table 50.4 provides information about the hardware interface.

Table 50.4 Information on the hardware interface area

Area	Address	Capacity
Area containing various registers of the hardware	See section 50.4. Register Descriptions.	See section 50.4. Register Descriptions.
FACI command-issuing area	0x407E_0000	4 bytes

For the address information of the flash memory, see Figure 50.2.

50.4 Register Descriptions

50.4.1 FCACHEE : Flash Cache Enable Register

Base address: FCACHE = 0x4001_C100

Offset address: 0x000

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	FCACHEEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	FCACHEEN	Flash Cache Enable 0: FCACHE is disabled 1: FCACHE is enabled	R/W
15:1	—	These bits are read as 0. The write value should be 0.	R/W

This register is not controlled by any security attribute register.

FCACHEEN bit (Flash Cache Enable)

FCACHEE.FCACHEEN bit enable and disables the function of Flash Cache of FCACHE1, FCACHE2 and FLPF.

FCACHEE.FCACHEEN bit dose not influence for FCACHEIV.FCACHEIV.

When FCACHE is enabled, it works for accesses marked as cacheable.

It is prohibited to disable FCACHE after enabling.

50.4.2 FCACHEIV : Flash Cache Invalidate Register

Base address: FCACHE = 0x4001_C100

Offset address: 0x004

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	FCACHEIV
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	FCACHEIV	Flash Cache Invalidate 0: Read: Do not invalidate. Write: The setting is ignored. 1: Invalidate FCACHE is invalidated.	R/W
15:1	—	These bits are read as 0. The write value should be 0.	R/W

This register is not controlled by any security attribute register.

FCACHEIV bit (Flash Cache Invalidate)

When 1 is written to FCACHEIV.FCACHEIV bit, the Flash cache data of FCACHE1, FCACHE2 and FLPF is invalidated.

Invalidate FCACHE with keeping FCACHE enabled after programming or erasing the code flash or the option setting memory.

50.4.3 FLWT : Flash Wait Cycle Register

Base address: FCACHE = 0x4001_C100

Offset address: 0x01C

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	FLWT[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	FLWT[2:0]	Flash Wait Cycle 0 0 0: 0 wait (ICLK ≤ 50 MHz) 0 0 1: 1 wait (50 MHz < ICLK ≤ 100 MHz) 0 1 0: 2 wait (100 MHz < ICLK ≤ 150 MHz)	R/W

Bit	Symbol	Function	R/W
		0 1 1: 3 wait (ICLK > 150 MHz) Others: Setting prohibited	
7:3	—	These bits are read as 0. The write value should be 0.	R/W

Note: If the security attribution is configured as secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

FLWT[2:0] bits (Flash Wait Cycle)

The Flash Wait Cycle Register (FLWT) sets the access wait count for the flash memory.

For faster clock frequencies, set FLWT.FLWT before changing the clock frequency. For slower clock frequencies, set FLWT.FLWT after changing the clock frequency.

For information on the frequency setting, see section 8, Clock Generation Circuit.

50.4.4 FSAR : Flash Security Attribution Register

Base address: FCACHE = 0x4001_C100

Offset address: 0x040

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	FCKMHZSA	—	—	—	—	—	—	—	FLWTSA
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
0	FLWTSA	FLWT Security Attribution Target register : FLWT 0: Secure 1: Non-Secure	R/W
7:1	—	These bits are read as 1. The write value should be 1.	R/W
8	FCKMHZSA	FCKMHZ Security Attribution Target register : FCKMHZ 0: Secure 1: Non-Secure	R/W
15:9	—	These bits are read as 1. The write value should be 1.	R/W

Note: Only secure access can write to this register. Both secure access and Non-secure read access are allowed but Non-secure write access is not allowed and TrustZone access error is not generated.

Note: This register is write-protected by PRCR register.

Write access is invalid when PRCR.PRC4 bit is 0. See section 12, Register Write Protection.

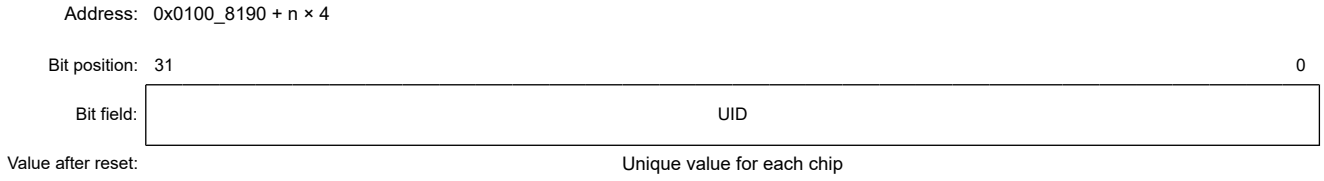
FLWTSA bit (FLWT Security Attribution)

This bit sets the security attribute of FLWT.

FCKMHZSA bit (FCKMHZ Security Attribution)

This bit sets the security attribute of FCKMHZ.

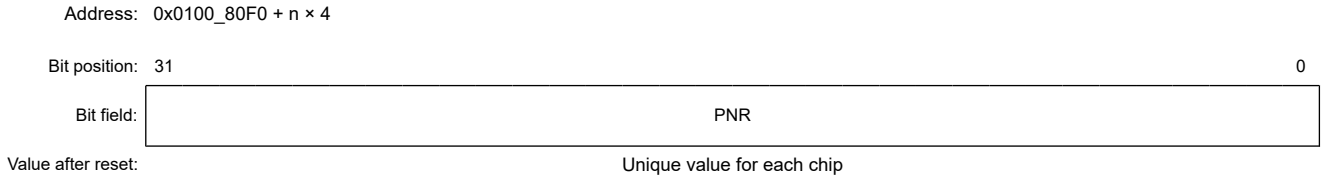
50.4.5 UIDRn : Unique ID Registers n (n = 0 to 3)



Bit	Symbol	Function	R/W
31:0	UID	Unique ID	R

The UIDRn is a read-only register that stores a 16-byte ID code (unique ID) for identifying the individual MCU. The UIDRn register should be read in 32-bit units. When reading by the signature request command of the serial programming interface, the data is read in order from the data with the large address. That is, the data in 0x0100_819F is read first, and in 0x0100_8190 is read last.

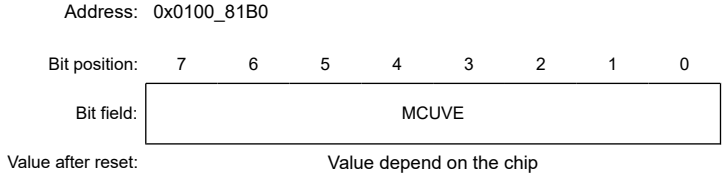
50.4.6 PNRn : Part Numbering Register n (n = 0 to 3)



Bit	Symbol	Function	R/W
31:0	PNR	Part Number	R

The PNRn is a read-only register that stores a 16-byte part numbering. The PNRn register should be read in 32-bit units. Each byte corresponds to the ASCII code representation of the product part number as detailed in Table 1.14. The first character ("R", 0x52 in ASCII code) of the part number is stored in the byte with the smallest address (0x0100_80F0). When reading by the signature request command of the serial programming interface, the data is read in order from the data with the small address. That is, the data in 0x0100_80F0 is read first, and in 0x0100_80FF is read last.

50.4.7 MCUVER : MCU Version Register



Bit	Symbol	Function	R/W
7:0	MCUVE	MCU Version	R

The MCUVER is a read-only register that stores a MCU version. The MCUVER register should be read in 8-bit units.

50.4.8 FWEPROR : Flash P/E Protect Register

Base address: SYSC = 0x4001_E000

Offset address: 0x416

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	FLWE[1:0]	
Value after reset:	0	0	0	0	0	0	1	0

Bit	Symbol	Function	R/W
1:0	FLWE[1:0]	Flash Programming and Erasure 0 0: Prohibits Program, Block Erase, Multi Block Erase, Blank Check, and Configuration set command processing. 0 1: Permits Program, Block Erase, Multi Block Erase, Blank Check, and Configuration set command processing. 1 0: Prohibits Program, Block Erase, Multi Block Erase, Blank Check, and Configuration set command processing. 1 1: Prohibits Program, Block Erase, Multi Block Erase, Blank Check, and Configuration set command processing.	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W

It is possible that Program, Block Erase, Multi Block Erase, Blank Check, and Configuration set command processing are prohibited by software.

The FWEPROR register is initialized by a reset from the following:

- All reset source
- Transition to Deep Software Standby mode
- Transition to Software Standby mode.

FLWE[1:0] bits (Flash Programming and Erasure)

The FLWE[1:0] bits are used to set the flash P/E protection. The value after reset is 10b.

If these bits are set to other than 01b that does not allow programming and erasure of the flash memory, the following commands cannot be executed. Issuing any of the following commands leads to setting of the FLWEERR bit in the FSTATR register to 1.

Program / Block Erase / Multi Block Erase / Blank Check / Configuration set command

50.4.9 FASTAT : Flash Access Status Register

Base address: FACI = 0x407F_E000

Offset address: 0x10

Bit position:	7	6	5	4	3	2	1	0
Bit field:	CFAE	—	—	CMDLK	DFAE	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	—	These bits are read as 0. The write value should be 0.	R/W
3	DFAE	Data Flash Memory Access Violation Flag 0: No data flash memory access violation has occurred 1: A data flash memory access violation has occurred.	R/W*1
4	CMDLK	Command Lock Flag 0: The flash sequencer is not in the command-locked state 1: The flash sequencer is in the command-locked state.	R

Bit	Symbol	Function	R/W
6:5	—	These bits are read as 0. The write value should be 0.	R/W
7	CFAE	Code Flash Memory Access Violation Flag 0: No code flash memory access violation has occurred 1: A code flash memory access violation has occurred.	R/W*1

Note 1. Only 0 can be written to clear the flag after 1 is read.

The FASTAT register indicates whether a code flash or data flash memory access violation has occurred. If any of the CFAE, CMDLK, and DFAE bits is set to 1, the flash sequencer enters the command-locked state (see section 50.11.2. Error Protection). To release it from the command-locked state, issue a status clear command or Forced Stop command to the flash sequencer.

DFAE bit (Data Flash Memory Access Violation Flag)

The DFAE bit indicates whether a data flash memory access violation occurred. When this bit is set to 1, the ILGLERR bit in the FSTATR register is set to 1, placing the flash sequencer in the command-locked state.

[Setting conditions]

FACI commands issued in the data flash P/E mode are as follows:

- The setting of the FSADDR or FEADDR register is the reserved portion of the data area
- FACI commands of non-secure access are issued while the setting of the FSADDR or FEADDR register is the secure region address.

[Clearing conditions]

- When this bit is written as 0 after it is set to 1
- When the flash sequencer starts to process the Status Clear or Forced Stop command.

CMDLK bit (Command Lock Flag)

The CMDLK bit indicates that the flash sequencer is in the command-locked state.

[Setting conditions]

- The flash sequencer detects an error and enters the command-locked state.

[Clearing conditions]

- When the flash sequencer starts to process the Status Clear or Forced Stop command.

CFAE bit (Code Flash Memory Access Violation Flag)

The CFAE bit indicates whether a code flash memory access violation has occurred. When this bit is set to 1, the ILGLERR bit in the FSTATR register is set to 1, placing the flash sequencer in the command-locked state.

[Setting conditions]

FACI commands issued in the code flash P/E mode are as follows:

- The setting of the FSADDR register is the reserved portion of the user area
- The Configuration set command is issued while the setting of the FSADDR register is from 0x0000A100 to 0x0000A2F0 in self-programming mode
- FACI commands of non-secure access are issued while the setting of the FSADDR register is the secure region address.

[Clearing conditions]

- When this bit is written as 0 after it is set to 1
- When the flash sequencer starts to process the Status Clear or Forced Stop command.

50.4.10 FAEINT : Flash Access Error Interrupt Enable Register

Base address: FACI = 0x407F_E000

Offset address: 0x14

Bit position:	7	6	5	4	3	2	1	0
Bit field:	CFAEIE	—	—	CMDLKIE	DFAEIE	—	—	—
Value after reset:	1	0	0	1	1	0	0	0

Bit	Symbol	Function	R/W
2:0	—	These bits are read as 0. The write value should be 0.	R/W
3	DFAEIE	Data Flash Memory Access Violation Interrupt Enable 0: Generation of an FIFERR interrupt request is disabled when FASTAT.DFAE is set to 1 1: Generation of an FIFERR interrupt request is enabled when FASTAT.DFAE is set to 1.	R/W
4	CMDLKIE	Command Lock Interrupt Enable 0: Generation of an FIFERR interrupt request is disabled when FASTAT.CMDLK is set to 1 1: Generation of an FIFERR interrupt request is enabled when FASTAT.CMDLK is set to 1.	R/W
6:5	—	These bits are read as 0. The write value should be 0.	R/W
7	CFAEIE	Code Flash Memory Access Violation Interrupt Enable 0: Generation of an FIFERR interrupt request is disabled when FASTAT.CFAE is set to 1 1: Generation of an FIFERR interrupt request is enabled when FASTAT.CFAE is set to 1.	R/W

The FAEINT register enables or disables generation of a flash access error (FIFERR) interrupt request.

DFAEIE bit (Data Flash Memory Access Violation Interrupt Enable)

The DFAEIE bit enables or disables generation of an FIFERR interrupt request when a data flash memory access violation occurs, setting the DFAE bit in the FASTAT register to 1.

CMDLKIE bit (Command Lock Interrupt Enable)

The CMDLKIE bit enables or disables generation of an FIFERR interrupt request when the flash sequencer enters the command-locked state, setting the CMDLK bit in the FASTAT register to 1.

CFAEIE bit (Code Flash Memory Access Violation Interrupt Enable)

The CFAEIE bit enables or disables generation of an FIFERR interrupt request when a code flash memory access violation occur, setting the CFAE bit in the FASTAT register to 1.

50.4.11 FRDYIE : Flash Ready Interrupt Enable Register

Base address: FACI = 0x407F_E000

Offset address: 0x18

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	FRDYIE
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	FRDYIE	Flash Ready Interrupt Enable 0: Generation of an FRDY interrupt request is disabled 1: Generation of an FRDY interrupt request is enabled.	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W

The FRDYIE register enables or disables generation of a flash ready (FRDY) interrupt request.

FRDYIE bit (Flash Ready Interrupt Enable)

The FRDYIE bit enables or disables generation of an FRDY interrupt request when the FRDY bit in the FSTATR register is changed from 0 to 1 on completion of processing by the flash sequencer of the Program, Block Erase, Multi Block Erase, Blank Check, and Configuration set command.

50.4.12 FSADDR : FACI Command Start Address Register

Base address: FACI = 0x407F_E000

Offset address: 0x30

Bit position:	31																												0
Bit field:	FSADDR[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	FSADDR[31:0]	Start Address for FACI Command Processing	R/W*1

Note 1. These bits can be written when the FRDY bit in the FSTATR register is 1. Writing to these bits are ignored when the FRDY bit is 0. Note that b0 and b1 are read-only.

Table 50.5 FACI command addres boundary

Command	Address Boundary
Program (code flash memory)	128-byte
Program (data flash memory)	4, 8, 16 -byte
Block Erase (code flash memory)	8-KB or 32-KB
Block Erase (data flash memory)	64-byte
Multi Block Erase (data flash memory)	64-byte
Blank Check (data flash memory)	4-byte
Configuration set	16-byte

The FSADDR register specifies the address where the target area for command processing starts when the FACI command for Program, Block Erase, Multi Block Erase, Blank Check, or Configuration set is issued.

The FSADDR value is initialized when the SUINIT bit in the FSUINITR register is set to 1. It is also initialized by a reset.

FSADDR[31:0] bits (Start Address for FACI Command Processing)

The FSADDR[31:0] bits specify the start address for FACI command processing. Bits [31:24] are ignored in FACI command processing for the code flash memory. Bits [31:17] are ignored in FACI command processing for the data flash memory. Bits associated with the address bits of lower order than the address boundary listed in Table 50.5 are also ignored.

For information on the addresses of the code flash memory and the data flash memory, see section 50.2. Structure of Memory.

For information on the addresses of the configuration setting, see section 50.9.3.15. Configuration Set Command.

50.4.13 FEADDR : FACI Command End Address Register

Base address: FACI = 0x407F_E000

Offset address: 0x34

Bit position:	31																												0
Bit field:	FEADDR[31:0]																												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	FEADDR[31:0]	End Address for FACI Command Processing	R/W*1

Note 1. These bits can be written when the FRDY bit in the FSTATR register is 1. Writing to these bits are ignored when the FRDY bit is 0. Note that bit [0] and bit [1] are read-only.

The FEADDR register specifies the end address of the target area for Multi Block Erase and Blank Check command processing. When incremental mode is selected as the addressing mode for Blank Checking (when FBCCNT.BCDIR = 0), the address specified in the FSADDR register should be equal to or smaller than the address in the FEADDR register. Conversely, the address in the FSADDR register should be equal to or larger than the address in the FEADDR register when decremental mode is selected as the addressing mode for Blank Check (i.e. when FBCCNT.BCDIR = 1). If the BCDIR, FSADDR, and FEADDR bit settings are inconsistent with the specified rules, the flash sequencer enters the command-locked state (see section 50.11.2. Error Protection).

The FEADDR value is initialized when the SUINIT bit in the FSUINITR register is set to 1. It is also initialized by a reset.

FEADDR[31:0] bits (End Address for FACI Command Processing)

The FEADDR[31:0] bits specify the end address for Multi Block Erase and Blank Check command processing. In command processing, bits 31 to 17 and any bits that do not reach the address boundaries listed in the section 50.4.12. FSADDR : FACI Command Start Address Register are ignored.

For information on the addresses of the flash memory, see section 50.2. Structure of Memory.

50.4.14 FMEPROT : Flash P/E Mode Entry Protection Register

Base address: FACI = 0x407F_E000

Offset address: 0x44

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	KEY[7:0]								—	—	—	—	—	—	—	CEPROT
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Function	R/W
0	CEPROT	Code Flash P/E Mode Entry Protection 0: FENTRYC bit is not protected 1: FENTRYC bit is protected.	R/W*1 *2 *4
7:1	—	These bits are read as 0. The write value should be 0.	R/W
15:8	KEY[7:0]	Key Code	W*3

Note 1. Writing to this bit is only possible when the FRDY bit in the FSTATR register is 1. Writing to this bit while the FRDY bit = 0 is ignored.
Note 2. Writing to this bit is only possible when 16 bits are written and the value written to the KEY bits is 0xD9.
Note 3. Written values are not retained by these bits (always read as 0x00).
Note 4. Only secure access can write to this register. Both secure access and non-secure read access are allowed. Non-secure write access is denied, but TrustZone access error is not generated.

CEPROT bit (Code Flash P/E Mode Entry Protection)

The CEPROT bit specifies the protection setting of the FRNTRYC bit in the FENTRYR register.

[Setting condition]

- 1 being written to the CEPROT bit while writing to FMEPROT is enabled.

[Clearing condition]

- 0 being written to the CEPROT bit while writing to FMEPROT is enabled.

50.4.15 FBPROT0 : Flash Block Protection Register

Base address: FACI = 0x407F_E000

Offset address: 0x78

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	KEY[7:0]								—	—	—	—	—	—	—	BPCN0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	BPCN0	Block Protection for Non-secure Cancel 0: Block protection is enabled 1: Block protection is disabled.	R/W*1 *2
7:1	—	These bits are read as 0. The write value should be 0.	R/W
15:8	KEY[7:0]	Key Code	W*3

Note 1. This bit can be written when the FRDY bit in the FSTATR register is 1. Writing to this bit is ignored when the FRDY bit is 0.
Note 2. Writing to this bit is only possible when 16 bits are written and the value written to the KEY[7:0] bits is 0x78.
Note 3. Written values are not retained by these bits (always read as 0x00).

The FBPROT0 register is used to disable the block protect function for non-secure. When the block protect setting is locked by the permanent block setting, it cannot be disabled by this register.

The FBPROT0 value is initialized when the SUINIT bit in the FSUINITR is set to 1, because the FENTRYR value is initialized to 0x0000. It is also initialized by a reset.

BPCN0 bit (Block Protection for Non-secure Cancel)

The BPCN0 bit disables the block protect setting for non-secure function.

[Setting condition]

- When the write-enabling conditions are satisfied and the FENTRYR is not 0x0000, write 1 to this bit.

[Clearing conditions]

- 8 bits being written to FBPROT0 while the FRDY bit is 1.
- A value other than 0x78 specified in the KEY bits and 16 bits are written to FBPROT0 while the FRDY bit is 1.
- 0 being written to the BPCN0 bit while writing to FBPROT0 is enabled.
- The FENTRYR register value is 0x0000.

50.4.16 FBPROT1 : Flash Block Protection for Secure Register

Base address: FACI = 0x407F_E000

Offset address: 0x7C

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	KEY[7:0]								—	—	—	—	—	—	—	BPCN1
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	BPCN1	Block Protection for Secure Cancel 0: Block protection is enabled 1: Block protection is disabled.	R/W*1 *2
7:1	—	These bits are read as 0. The write value should be 0.	R/W
15:8	KEY[7:0]	Key Code	W*3

Note 1. Writing to this bit is only possible when the FRDY bit in the FSTATR register is 1. Writing to this bit while FRDY bit = 0 is ignored.
Note 2. Writing to this bit is only possible when 16 bits are written and the value written to the KEY[7:0] bits is 0xB1.
Note 3. Written values are not retained by these bits (always read as 0x00).

The FBPROT1 register is used to disable the block protect function for secure developer. When the block protect setting is locked by the permanent block setting, it cannot be disabled by this register.

The FBPROT1 value is initialized when the SUINIT bit in the FSUINITR is set to 1, because the FENTRYR value is initialized to 0x0000. It is also initialized by a reset.

BPCN1 bit (Block Protection for Secure Cancel)

The BPCN1 bit disables the block protect setting for secure function.

[Setting condition]

- When the write-enabling conditions are satisfied and the FENTRYR is not 0x0000, write 1 to BPCN1.

[Clearing conditions]

- 8 bits being written to FBPROT1 while the FRDY bit is 1.
- A value other than 0xB1 specified in the KEY bits and 16 bits are written to FBPROT1 while the FRDY bit is 1.
- 0 being written to the BPCN1 bit while writing to FBPROT1 is enabled.
- The FENTRYR register value is 0x0000.

50.4.17 FSTATR : Flash Status Register

Base address: FACI = 0x407F_E000

Offset address: 0x80

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	ILGCOMERR	FESETERR	SECERR	OTERR	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	FRDY	ILGLERR	ERSERR	PRGERR	SUSRDY	DBFULL	ERSSPD	PRGSPD	—	FLWEERR	—	—	—	—	—	—
Value after reset:	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	—	These bits are read as 0. The write value should be 0.	R/W
6	FLWEERR	Flash Write/Erase Protect Error Flag 0: An error has not occurred 1: An error has occurred.	R
7	—	These bits are read as 0. The write value should be 0.	R/W
8	PRGSPD	Programming Suspend Status Flag 0: The flash sequencer is not in the programming suspension processing state or programming suspended state 1: The flash sequencer is in the programming suspension processing state or programming suspended state.	R

Bit	Symbol	Function	R/W
9	ERSSPD	Erasure Suspend Status Flag 0: The flash sequencer is not in the erasure suspension processing state or the erasure suspended state 1: The flash sequencer is in the erasure suspension processing state or the erasure suspended state.	R
10	DBFULL	Data Buffer Full Flag 0: The data buffer is empty 1: The data buffer is full.	R
11	SUSRDY	Suspend Ready Flag 0: The flash sequencer cannot receive P/E suspend commands 1: The flash sequencer can receive P/E suspend commands.	R
12	PRGERR	Programming Error Flag 0: Programming has completed successfully 1: An error has occurred during programming.	R
13	ERSERR	Erasure Error Flag 0: Erasure has completed successfully 1: An error has occurred during erasure.	R
14	ILGLERR	Illegal Command Error Flag 0: The flash sequencer has not detected an illegal FACI command or illegal flash memory access 1: The flash sequencer has detected an illegal FACI command or illegal flash memory access.	R
15	FRDY	Flash Ready Flag 0: Program, Block Erase, Multi Block Erase, P/E suspend, P/E resume, Forced Stop, Blank Check, or Configuration set command processing is in progress 1: None of the above is in progress.	R
19:16	—	These bits are read as 0. The write value should be 0.	R/W
20	OTERR	Other Error 0: A status clear or forced stop command processing is complete 1: An error has occurred.	R
21	SECERR	Security Error 0: A status clear or forced stop command processing is complete 1: An error has occurred.	R
22	FESETERR	FENTRY Setting Error 0: A status clear or forced stop command processing is complete 1: An error has occurred.	R
23	ILGCOMERR	Illegal Command Error 0: A status clear or forced stop command processing is complete 1: An error has occurred.	R
31:24	—	These bits are read as 0. The write value should be 0.	R/W

The FSTATR register indicates the state of the flash sequencer.

FLWEERR flag (Flash Write/Erase Protect Error Flag)

The FLWEERR flag indicates a violation of the flash memory overwrite protection setting in the FWEPROR register. When this flag is 1, the flash sequencer is in the command-locked state.

[Setting condition]

- An error has occurred.

[Clearing condition]

- The flash sequencer starts processing the Forced Stop command.

PRGSPD flag (Programming Suspend Status Flag)

The PRGSPD flag indicates that the flash sequencer is in the programming suspension processing state or programming suspended state.

[Setting condition]

- The flash sequencer starts processing in response to the programming suspend command.

[Clearing conditions]

- Reception of the P/E resume command by the flash sequencer (after write access to the FACI command-issuing area is complete)
- The flash sequencer starts processing the Forced Stop command.

ERSSPD flag (Erasure Suspend Status Flag)

The ERSSPD flag indicates that the flash sequencer is in the erasure suspension processing state or erasure suspended state.

[Setting condition]

- The flash sequencer starts processing in response to an erasure suspend command.

[Clearing condition]

- Reception of the P/E resume command by the flash sequencer (after write access to the FACI command-issuing area is complete)
- The flash sequencer starts processing of the Forced Stop command.

DBFULL flag (Data Buffer Full Flag)

The DBFULL flag indicates the state of the data buffer when the program command is issued. The flash sequencer incorporates a buffer for write data (data buffer). When data for writing to the flash memory are written to the FACI command-issuing area while the data buffer is full, the flash sequencer inserts a wait cycle in the peripheral bus.

[Setting condition]

- The data buffer becomes full while program commands are issued.

[Clearing condition]

- The data buffer becomes empty.

SUSRDY flag (Suspend Ready Flag)

The SUSRDY flag indicates whether the flash sequencer can receive a P/E suspend command.

[Setting condition]

- After starting programming/erasure processing, the flash sequencer enters a state in which P/E suspend commands can be received.

[Clearing conditions]

- Reception of the P/E suspend command or Forced Stop command by the flash sequencer (after write access to the FACI command-issuing area is complete)
- During programming or erasure, the flash sequencer enters the command-locked state
- Programming or erasure has completed.

PRGERR flag (Programming Error Flag)

The PRGERR flag indicates the result of programming of the flash memory. When this flag is 1, the flash sequencer is in the command-locked state.

[Setting condition]

- An error has occurred during programming.

[Clearing condition]

- The flash sequencer starts processing of the Status Clear or Forced Stop command.

ERSERR flag (Erasure Error Flag)

The ERSERR flag indicates the result of erasure of the flash memory. When this flag is 1, the flash sequencer is in the command-locked state.

[Setting condition]

- An error has occurred during erasure.

[Clearing condition]

- The flash sequencer starts processing of the Status Clear or Forced Stop command.

ILGLERR flag (Illegal Command Error Flag)

The ILGLERR flag indicates that the flash sequencer has detected an illegal FACI command or flash memory access. If this flag is 1, the flash sequencer is in the command-locked state.

[Setting conditions]

- See section 50.11.2. Error Protection.

[Clearing condition]

- The flash sequencer starts processing of the Status Clear or Forced Stop command.

FRDY flag (Flash Ready Flag)

The FRDY flag indicates the command processing state of the flash sequencer.

[Setting conditions]

- The flash sequencer completes command processing
- The flash sequencer receives a P/E suspend command and suspends programming of the flash memory
- The flash sequencer received the Forced Stop command and ended command processing.

[Clearing conditions]

- The flash sequencer received an FACI command
- For Program and Configuration setting, the first write access to the FACI command-issuing area
- For other commands, the last write access to the FACI command-issuing area.

OTERR flag (Other Error)

See Table 50.26. When this flag is 1, the flash sequencer is in the command-lock state.

[Setting condition]

- An error has occurred.

[Clearing condition]

- The status clear or forced stop command processing is complete.

SECERR flag (Security Error)

See Table 50.26. When this flag is 1, the flash sequencer is in the command-lock state.

[Setting condition]

- An error has occurred.

[Clearing condition]

- The status clear or forced stop command processing is complete.

FESETERR flag (FENTRY Setting Error)

See Table 50.26. When this flag is 1, the flash sequencer is in the command-lock state.

[Setting condition]

- An error has occurred.

[Clearing condition]

- The status clear or forced stop command processing is complete.

ILGCOMERR flag (Illegal Command Error)

See Table 50.26. When this flag is 1, the flash sequencer is in the command-lock state.

[Setting condition]

- An error has occurred.

[Clearing condition]

- The status clear or forced stop command processing is complete.

50.4.18 FENTRYR : Flash P/E Mode Entry Register

Base address: FACI = 0x407F_E000

Offset address: 0x84

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	KEY[7:0]								FENTRYD	—	—	—	—	—	—	FENTRYC
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	FENTRYC	Code Flash P/E Mode Entry 0: Code flash is in read mode 1: Code flash is in P/E mode.	R/W*1*2
6:1	—	These bits are read as 0. The write value should be 0.	R/W
7	FENTRYD	Data Flash P/E Mode Entry 0: Data flash is in read mode 1: Data flash is in P/E mode.	R/W*1*2
15:8	KEY[7:0]	Key Code	W*3

Note 1. These bits can be written when the FRDY bit in the FSTATR register is 1. Writing to these bits are ignored when the FRDY bit is 0.
Note 2. Writing to these bits is only possible when 16 bits are written and the value written to the KEY[7:0] bits is 0xAA.
Note 3. Written values are not retained by these bits (always read 0x00).

FENTRYR is used to specify code flash P/E mode or data flash P/E mode. To specify the code flash P/E mode or data flash P/E mode so that the flash sequencer can receive FACI commands, set either the FENTRYD or FENTRYC bit to 1 to place the flash sequencer in P/E mode.

FENTRYR is initialized when the SUINIT bit in FSUINITR is set to 1. It is also initialized by a reset.

Note: Writing a value of 0XAA81 to this register causes the ILGLERR bit in the FSTATR register to be set to 1, resulting in the flash sequencer being placed in the command-locked state.

FENTRYC bit (Code Flash P/E Mode Entry)

The FENTRYC bit specifies P/E mode for the code flash memory.

[Setting condition]

- Write 1 to the FENTRYC bit while writing to FENTRYR is enabled and FENTRYR is 0x0000.

[Clearing conditions]

- Write 8 bits to FENTRYR while the FRDY bit is 1
- A value other than 0xAA is specified in the KEY[7:0] bits and 16 bits are written to FENTRYR while the FRDY bit is 1
- Write 0 to the FENTRYC bit while writing to FENTRYR is enabled
- Write to FENTRYR while writing is enabled and its value is other than 0x0000

- The protection of FMEPROT register is enabled.

FENTRYD bit (Data Flash P/E Mode Entry)

The FENTRYD bit specifies P/E mode for the data flash memory.

[Setting condition]

- Write 1 to the FENTRYD bit while writing to FENTRYR is enabled and FENTRYR is 0x0000.

[Clearing conditions]

- Write 8 bits to FENTRYR while the FRDY bit is 1
- Writing of 16 bits to FENTRYR with a value other than 0xAA specified for the KEY[7:0] bits while the FRDY bit is 1
- Write 0 to the FENTRYD bit while writing to FENTRYR is enabled
- Write to FENTRYR while writing is enabled and its value is other than 0x0000.

KEY[7:0] bits (Key Code)

The KEY[7:0] bits control writing permission to the FENTRYD or FENTRYC bits.

50.4.19 FSUINITR : Flash Sequencer Setup Initialization Register

Base address: FACI = 0x407F_E000

Offset address: 0x8C

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	KEY[7:0]								—	—	—	—	—	—	—	SUINIT
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SUINIT	Set-Up Initialization 0: The FSADDR, FEADDR, FBPROT0, FBPROT1, FENTRYR, FBCCNT, and FCPSR flash sequencer setup registers keep their current values 1: The FSADDR, FEADDR, FBPROT0, FBRPOT1, FENTRYR, FBCCNT, and FCPSR flash sequencer setup registers are initialized.	R/W*1*2
7:1	—	These bits are read as 0. The write value should be 0.	R/W
15:8	KEY[7:0]	Key Code	W*3

Note 1. This bit can be written when the FRDY bit in the FSTATR register is 1. Writing to this bit is ignored when the FRDY bit is 0.
Note 2. Writing to these bits is only possible when 16 bits are written and the value written to the KEY[7:0] bits is 0x2D.
Note 3. Written values are not retained by these bits (always read 0x00).

FSUINITR is used for initialization of the flash sequencer setup.

SUINIT bit (Set-Up Initialization)

The SUINIT bit initializes the following flash sequencer setup registers:

- FSADDR
- FEADDR
- FBPROT0
- FBPROT1
- FENTRYR
- FBCCNT
- FCPSR.

KEY[7:0] bits (Key Code)

The KEY[7:0] bits control writing permission to the SUINIT bit.

50.4.20 FCMDR : FACI Command Register

Base address: FACI = 0x407F_E000

Offset address: 0xA0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CMDR[7:0]								PCMDR[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	PCMDR[7:0]	Pre-command Flag The command just before the latest command is stored.	R
15:8	CMDR[7:0]	Command Flag The latest command is stored.	R

FCMDR records the two most recent commands accepted by the flash sequencer.

PCMDR[7:0] bits (Pre-command Flag)

The PCMDR[7:0] bits indicate the command received immediately before the latest command received by the flash sequencer.

CMDR[7:0] bits (Command Flag)

The CMDR[7:0] bits indicate the latest command received by the flash sequencer.

Table 50.6 States of FCMDR after receiving commands

Command	CMDR	PCMDR
Program	0xE8	Previous command
Block erase	0xD0	0x20
Multi block erase	0xD0	0x21
P/E suspend	0xB0	Previous command
P/E resume	0xD0	Previous command
Status Clear	0x50	Previous command
Forced Stop	0xB3	Previous command
Blank Check	0xD0	0x71
Configuration set	0x40	Previous command

50.4.21 FBCCNT : Blank Check Control Register

Base address: FACI = 0x407F_E000

Offset address: 0xD0

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	BCDIR
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	BCDIR	Blank Check Direction 0: Blank checking is executed from the lower addresses to the higher addresses (incremental mode) 1: Blank checking is executed from the higher addresses to the lower addresses (decremental mode).	R/W

Bit	Symbol	Function	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W

FBCCNT specifies the addressing mode in processing the Blank Check command. FBCCNT is initialized when the SUINIT bit in FSUINITR is set to 1. It is also initialized by a reset.

BCDIR bit (Blank Check Direction)

The BCDIR bit specifies the addressing mode for Blank Check.

50.4.22 FBCSTAT : Blank Check Status Register

Base address: FACI = 0x407F_E000

Offset address: 0xD4

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	BCST
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	BCST	Blank Check Status Flag 0: The target area is in the non-programmed state, that is, the area has been erased but has not yet been reprogrammed 1: The target area has been programmed with 0s or 1s.	R
7:1	—	These bits are read as 0. The write value should be 0.	R/W

FBCSTAT stores the results of checking in response to the Blank Check command.

BCST flag (Blank Check Status Flag)

The BCST flag indicates the results of checking in response to the Blank Check command.

50.4.23 FPSADDR : Data Flash Programming Start Address Register

Base address: FACI = 0x407F_E000

Offset address: 0xD8

Bit position:	31	17	16	0
Bit field:	—	—	—	PSADR[16:0]
Value after reset:	0	0	0	0

Bit	Symbol	Function	R/W
16:0	PSADR[16:0]	Programmed Area Start Address The address of the first programmed area	R
31:17	—	These bits are read as 0. The write value should be 0.	R/W

FPSADDR indicates the address of the first programmed area found in processing of the Blank Check command.

PSADR[16:0] bits (Programmed Area Start Address)

The PSADR[16:0] bits indicate the address of the first programmed area found in processing of the Blank Check command. The address is an offset from the address where the data flash memory starts. The setting of these bits is only valid if the BCST bit in the FBCSTAT register is 1 and while the FRDY bit in the FSTATR register is 1. When the BCST bit in the FBCSTAT register is 0, the PSADR[16:0] bits hold the address produced by the previous check.

50.4.24 FSUASMON : Flash Startup Area Select Monitor Register

Base address: FACI = 0x407F_E000

Offset address: 0xDC

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	BTFLG	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0/1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	FSPR	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0/1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
14:0	—	These bits are read as 0. The write value should be 0.	R
15	FSPR	Protection Programming Flag to set Boot Flag and Startup Area Control 0: Protected state 1: Non-protected state.	R
30:16	—	These bits are read as 0. The write value should be 0.	R
31	BTFLG	Flag of Startup Area Select for Boot Swap 0: The startup area is the alternate block (block 1) 1: The startup area is the default block (block 0).	R

FSPR bit (Protection Programming Flag to set Boot Flag and Startup Area Control)

The FSPR bit indicates the protection state against the configuration set command for the BTFLG bit, and FSUACR Register.

In response to a reset or configuration set command, the FACI transfers data from flash memory to this register.

BTFLG bit (Flag of Startup Area Select for Boot Swap)

The BTFLG bit indicates whether the address of the startup area is exchanged for the boot swap function or not.

In response to a reset or configuration set command, the FACI transfers data from flash memory to this register.

50.4.25 FCPSR : Flash Sequencer Processing Switching Register

Base address: FACI = 0x407F_E000

Offset address: 0xE0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ESUSPMD
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	ESUSPMD	Erasure Suspend Mode 0: Suspension priority mode 1: Erasure priority mode.	R/W
15:1	—	These bits are read as 0. The write value should be 0.	R/W

FCPSR selects the erasure suspension mode. FCPSR is initialized when the SUINIT bit in FSUINITR is set to 1. It is also initialized by a reset.

ESUSPMD bit (Erasure Suspend Mode)

The ESUSPMD bit selects the erasure suspension mode when a P/E suspend command is issued while the flash sequencer is executing erasure processing (see section 50.9.3.10. P/E Suspend Command). This bit should be set before issuing Block Erase or Multi Block Erase command.

50.4.26 FPCKAR : Flash Sequencer Processing Clock Notification Register

Base address: FACI = 0x407F_E000

Offset address: 0xE4

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	KEY[7:0]								PCKA[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	1	1	0	0	1	0

Bit	Symbol	Function	R/W
7:0	PCKA[7:0]	Flash Sequencer Operating Clock Notification These bits are used to set the operating frequency of the flash sequencer while processing FACI commands.	R/W*1*2
15:8	KEY[7:0]	Key Code	W*3

Note 1. This bit can be written when the FRDY bit in the FSTATR register is 1. Writing to this bit is ignored when the FRDY bit is 0.
Note 2. Writing to these bits is only possible when 16 bits are written and the value written to the KEY[7:0] bits is 0x1E.
Note 3. Written values are not retained by these bits (always read 0x00).

FPCKAR specifies the operating frequency of the flash sequencer while processing FACI commands. The highest operating frequency for the given product is set as the initial value.

PCKA[7:0] bits (Flash Sequencer Operating Clock Notification)

The PCKA[7:0] bits specify the operating frequency of the flash sequencer while processing FACI commands. Set the desired frequency for these bits before issuing an FACI command. Specifically, convert the frequency in MHz to a binary number and set it for these bits.

Example:

Frequency is 35.9 MHz (PCKA = 0x24)

Round up the first decimal place of 35.9 MHz to a whole number (= 36) and convert it into a binary number.

If the value set in these bits is smaller than the actual operating frequency of the flash sequencer, the flash memory programming/erasure characteristics cannot be guaranteed. If the value set in these bits is greater than the actual operating frequency of the flash sequencer, the flash memory programming/erasure characteristics can be guaranteed but the FACI command processing time such as the time programming/erasure takes will increase. The minimum FACI command processing time is obtained when the operating frequency of the flash sequencer is the same as the PCKA value.

KEY[7:0] bits (Key Code)

The KEY[7:0] bits control writing permission to the PCKA bit.

50.4.27 FSUACR : Flash Startup Area Control Register

Base address: FACI = 0x407F_E000

Offset address: 0xE8

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	KEY[7:0]								—	—	—	—	—	—	SAS[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	SAS[1:0]	Startup Area Select 0 0: Startup area is selected by BTFLG bit 0 1: Startup area is selected by BTFLG bit 1 0: Startup area is temporarily switched to the default area (block 0) 1 1: Startup area is temporarily switched to the alternate area (block 1).	R/W*1 *3
7:2	—	These bits are read as 0. The write value should be 0.	R/W
15:8	KEY[7:0]	Key Code	W*2

Note 1. Following described the write condition of thisese bits (these conditions are required at the same time).
1. Access size to this register is 16 bits
2. The value of KEY[7:0] is 0x66
3. The FSPR bit is 1.

Note 2. Written values are not retained by these bits (always read 0x00).

Note 3. Only secure access can write to this register. Both secure access and non-secure read access are allowed. Non-secure write access is denied, but TrustZone access error is not generated.

FSUACR sets the startup area for the boot swap function. Do not use this register in dual mode (the DUALSEL.BANKMD[2:0] bits are 000b). In dual mode, starting up proceeds from startup area 0.

SAS[1:0] bits (Startup Area Select)

The SAS[1:0] bits select the startup area. Three methods are available for changing the startup area.

KEY[7:0] bits (Key Code)

The KEY[7:0] bits control writing permission to the SAS [1:0] bits.

50.4.28 FCKMHZ : Data Flash Access Frequency Register

Base address: FLAD = 0x407F_C000

Offset address: 0x40

Bit position:	7	6	5	4	3	2	1	0
Bit field:	FCKMHZ[7:0]							
Value after reset:	0	0	1	1	1	1	0	0

Bit	Symbol	Function	R/W
7:0	FCKMHZ[7:0]	Data Flash Access Frequency Register These bits optimize the speed of reading the data flash memory.	R/W

Note: If the security attribution is configured as secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

This register optimizes the speed of reading the data flash memory.

Set the frequency of the peripheral module clock (FCLK) of internal peripheral bus which is the clock for access to the data flash memory, in MHz units. For example, 35.9 MHz should be rounded up and set the frequency to 36. Number of cycles required for access to the data flash memory are inserted according to the frequency. When changing the frequency of the FCLK, follow the procedure below to modify the value of the data flash access frequency register (FCKMHZ) in either of the following ways according to whether operation is at a lower frequency before or after the change.

- When changing the speed from low to high: Modify FCKMHZ. After confirming the change by reading FCKMHZ, change the frequency.
- When changing the speed from high to low: Change the frequency. After the frequency is changed, modify FCKMHZ.

50.5 Flash Cache

50.5.1 Feature of flash cache

The FCACHE (Flash Cache) speeds up read access from bus master to the flash memory. The FCACHE includes:

- FCACHE1, for CPU instruction fetches
- FCACHE2, for CPU operand access and access from EDMAC
- FLPF, for the prefetch access in CPU instruction fetches

Table 50.7 Flash Cache 1 (FCACHE1) overview

Cache Target Region	0x0000_0000 - 0x007F_FFFF
Target Bus Master	CPU instruction Fetch
Capacity	256 Bytes
Associativity	8WAY set associative
	128 bits/entry (128 bit aligned data), 2 entries/way
Access Cycle	Cache Hit : 0 wait Cache Miss : wait number of Flash Wait Cycle Register

Table 50.8 Flash Cache 2 (FCACHE2) overview

Cache Target Region	0x0000_0000 - 0x007F_FFFF
Target Bus Master	CPU Operand Access and Access from EDMAC
Capacity	16 Bytes
Associativity	Full Associative
	128 bits/entry (128 bit aligned data), 1 entry
Access Cycle	Cache Hit : 0 wait Cache Miss : wait number of Flash Wait Cycle Register

Table 50.9 Prefetch Buffer (FLPF) overview

Cache Target Region	0x0000_0000 - 0x007F_FFFF
Capacity	32 Bytes
Associativity	Full Associative
	128 bits/entry (128 bit aligned data), 2 entries
Request Address	Next address of previous CPU Instruction
Access Cycle	Cache Hit : 0 wait Cache Miss : wait number of Flash Wait Cycle Register

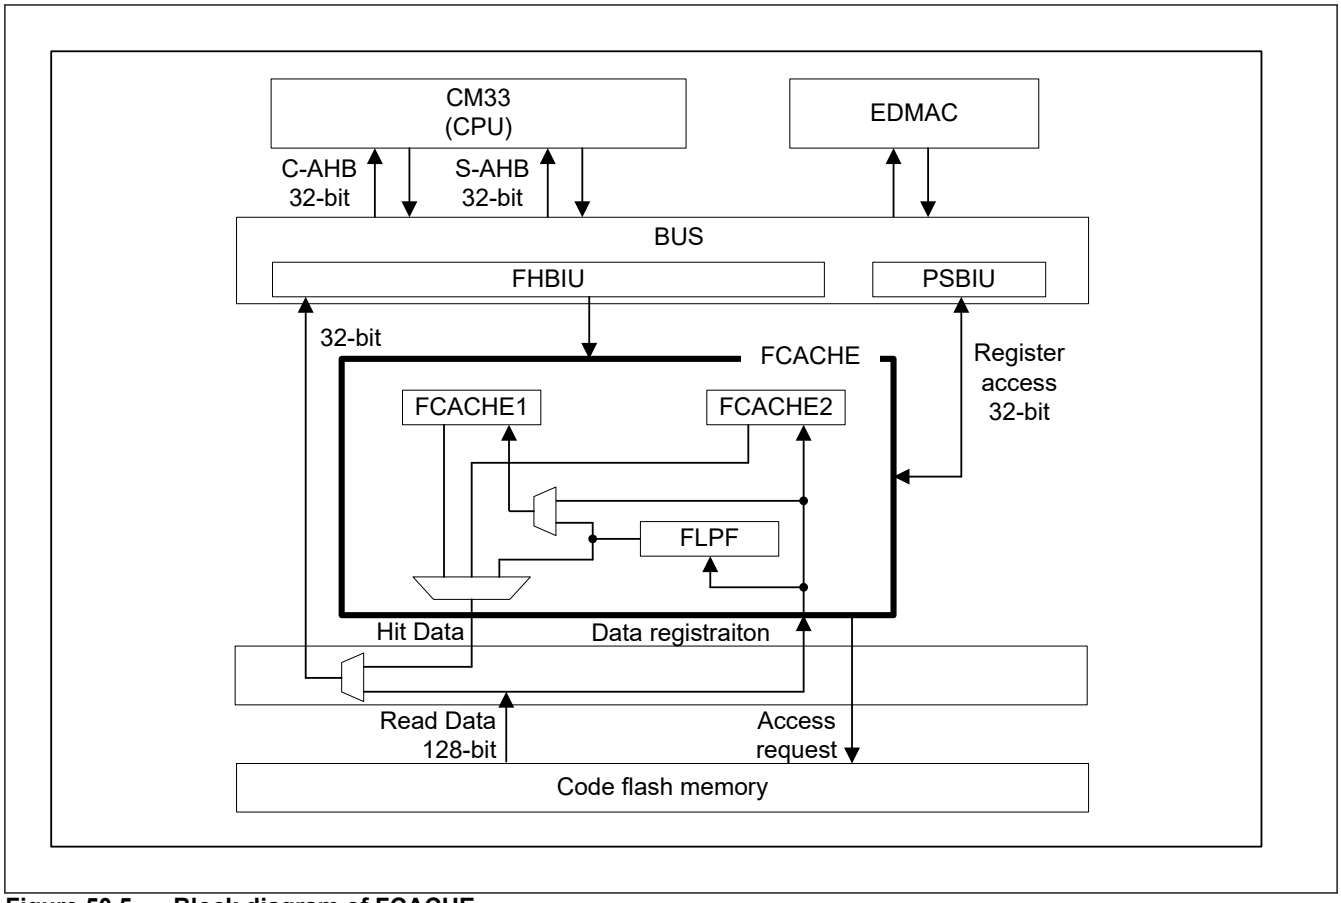


Figure 50.5 Block diagram of FCACHE

50.6 Operating Modes Associated with Flash Memory

Figure 50.6 is a diagram of the mode transitions associated with the flash memory. For the procedures for setting the modes, see section 6, Option-Setting Memory.

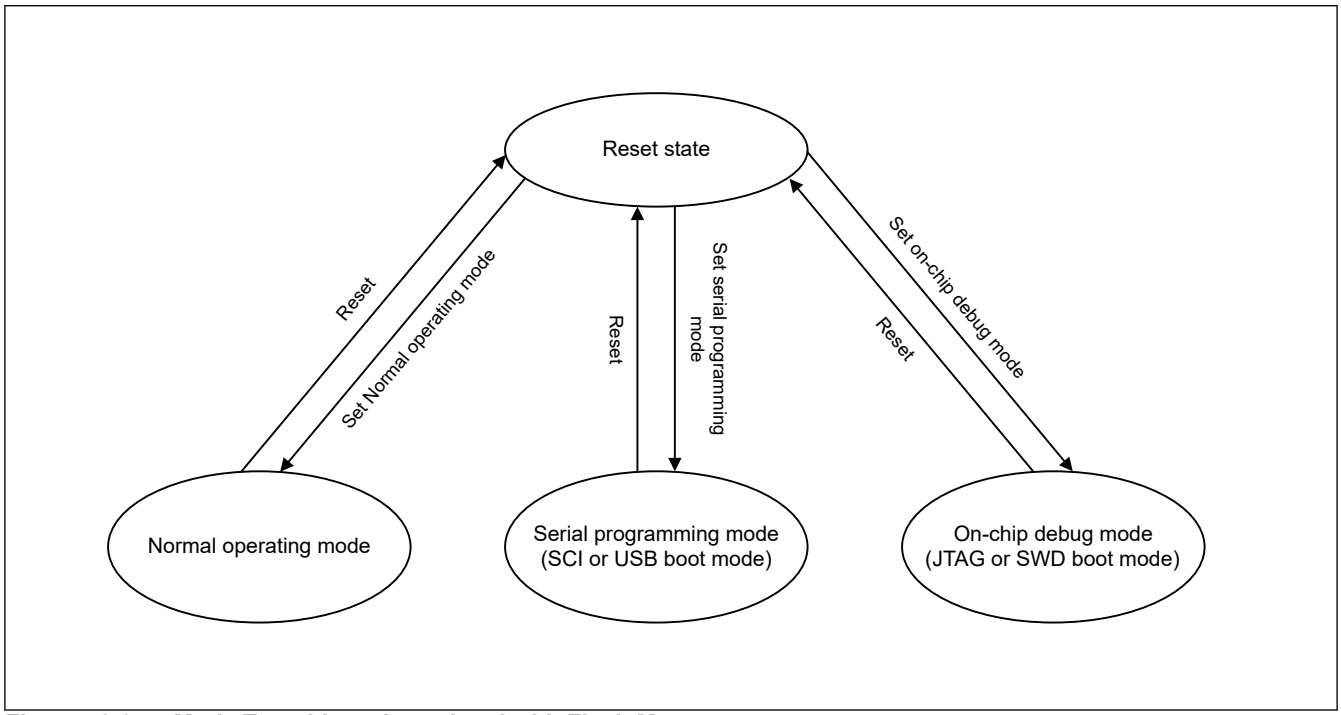

Figure 50.6 Mode Transitions Associated with Flash Memory

The flash memory area where programming and erasure are permitted and the boot program after a reset are different according to each mode. The differences between modes are listed in Table 50.10.

Table 50.10 Differences between Modes

Parameter	Normal operating mode	Serial programming mode (SCI or USB boot mode)	On-chip debug mode (JTAG or SWD boot mode)
Programmable and erasable areas	• Code flash memory • Data flash memory • Option setting memory (programming only)	• Code flash memory • Data flash memory • Option-setting memory (programming only)	• Code flash memory • Data flash memory • Option setting memory (programming only)
Erasure in block units	Possible	Possible	Possible
Boot program at a reset	User area program	Embedded program for serial programming	Depends on debug command

50.7 Overview of Functions

By using a dedicated flash-memory programmer to program the flash memory through a serial interface (serial programming) or JTAG/SWD interface (on-chip debug mode), the device can be rewritten regardless of whether this is before or after it is mounted on the target system.

Furthermore, security functions to prohibit rewriting or reading of the user program written to the flash memory are incorporated, and this can prevent falsification and illicit reading of the programs by third parties.

Programming by the user program (self-programming) is available to suit applications where the application on the target system may require updating after manufacturing or shipment. Protection features for the safe rewriting of the flash memory are also incorporated. Furthermore, interrupt processing during self-programming is supported, so programming can proceed at the same time as processing for external communications, etc., and this is the case in various situations. Table 50.11 lists the overview of the methods of programming and the corresponding operating modes.

Table 50.11 Programming methods

Programming method	Functional overview	Operating mode
Serial programming	A dedicated flash-memory programmer through the SCI or USBFS interface enables on-board programming of the flash memory after the device is mounted on the target system.	Serial programming mode
	A dedicated flash-memory programmer through the SCI or USBFS interface and a dedicated programming adapter board allow off-board programming of the flash memory, for example, programming of the device before it is mounted on the target system.	
Self-programming	A user program written to memory in advance of serial programming execution can also program the flash memory. The background operation capability makes it possible to fetch instructions or otherwise read data from the code flash memory while the data flash memory is programmed. As a result, a program resident in the code flash memory is able to program the data flash memory. For background operations that are not possible, instructions in the code flash memory cannot be fetched and data cannot be accessed while the code flash memory is being programmed by self-programming. In such cases, a program for programming from the internal SRAM or external memory must be transferred in advance and executed.	Normal operating mode
JTAG or SWD programming	A dedicated flash-memory programmer or an on-chip debugger through JTAG or SWD enables on-board programming of the flash memory after the device is mounted on the target system. A dedicated flash-memory programmer or an on-chip debugger through JTAG or SWD and a dedicated programming adapter board allow off-board programming of the flash memory, for example, programming of the device before it is mounted on the target system.	On-chip debug mode

Table 50.12 lists the functions of the flash memory. Serial programmer commands realize each function of serial programming, while reading of the flash memory by an FACI command or the user program realizes each function of self-programming.

Table 50.12 Basic Functions

Function	Functional overview	Availability	
		Serial programming	Self-programming
Blank check	Checks a specified block to ensure that writing to it has not already proceeded. Results of reading from data flash memory to which nothing is written after erasure are not guaranteed, so use blank checking to confirm that writing to memory has not proceeded after erasure.	Not supported	Supported (data flash programming only)
Block erasure	Erases the memory contents in the specified block	Supported	Supported
Programming	Writes to the specified address	Supported	Supported
CRC	Calculates the CRC in the specified range of the flash memory and transfers it to the flash programmer	Supported	Non supported
Read	Reads data programmed in the flash memory	Supported	Not supported (read by user program is possible)
Start-up program protection functions	Configures the start-up program protection functions	Supported	Supported
Option function selection	Selects the option function, and modifies the initial setting of this MCU	Supported	Supported
Dual bank function	Switches different modes (linear or dual)	Supported	Supported
Block swap function	Setting block swap functions	Supported	Supported
Block protection	Setting block protection	Supported	Supported
Device lifecycle transition	Transitions the device lifecycle	Supported	Not supported
Memory security attribution	Setting the memory security attribution	Supported	Not supported
Key	Injects key	Supported	Supported (except the key related to device lifecycle transition)
All erasure	Erase the flash memory to the state after shipment	Supported	Not supported

The flash memory supports various security functions.

Table 50.13 lists the security functions supported by the flash memory.

Table 50.13 Lists of Security Functions

Function	Description
Security flag for Start-up area select	Start-up area selection can be protected by setting of security flag (FSPR).
Permanently block protection	Programming or erasure of each block of code flash memory can be protected permanently.
Protection for TrustZone	Programming or erasure area, readable area, register access, and FACI command operation are protected by ARM TrustZone security.
Programming or erasure mode protection	Only secure developer can enter the programming or erasure mode for code flash.

50.8 Operating Modes of the Flash Sequencer

The flash sequencer has three operating modes as shown in Figure 50.7. Transitions between modes are initiated by changing the value of the FENTRYR register.

When the value of the FENTRYR register is 0x0000, the flash sequencer is in read mode. In this mode, it does not receive FACI commands. The code flash memory and data flash memory are both readable.

When the value of the FENTRYR register is 0x0001, the flash sequencer is in code flash P/E mode where the code flash memory can be programmed or erased by FACI commands. In this mode, the data flash memory is readable. In addition, the code flash memory is not readable if background operation (BGO) is disabled. If BGO is enabled, the code flash memory that is not selected by FSADDR register is readable when the FRDY bit in the FSTATR register is 0. As for the condition for enabling BGO, see section 50.15.2. Background Operation.

When the value of the FENTRYR register is 0x0080, the flash sequencer is in data flash P/E mode where the data flash memory can be programmed or erased by FACI commands. In this mode, the data flash memory is not readable. However, the code flash memory is readable.

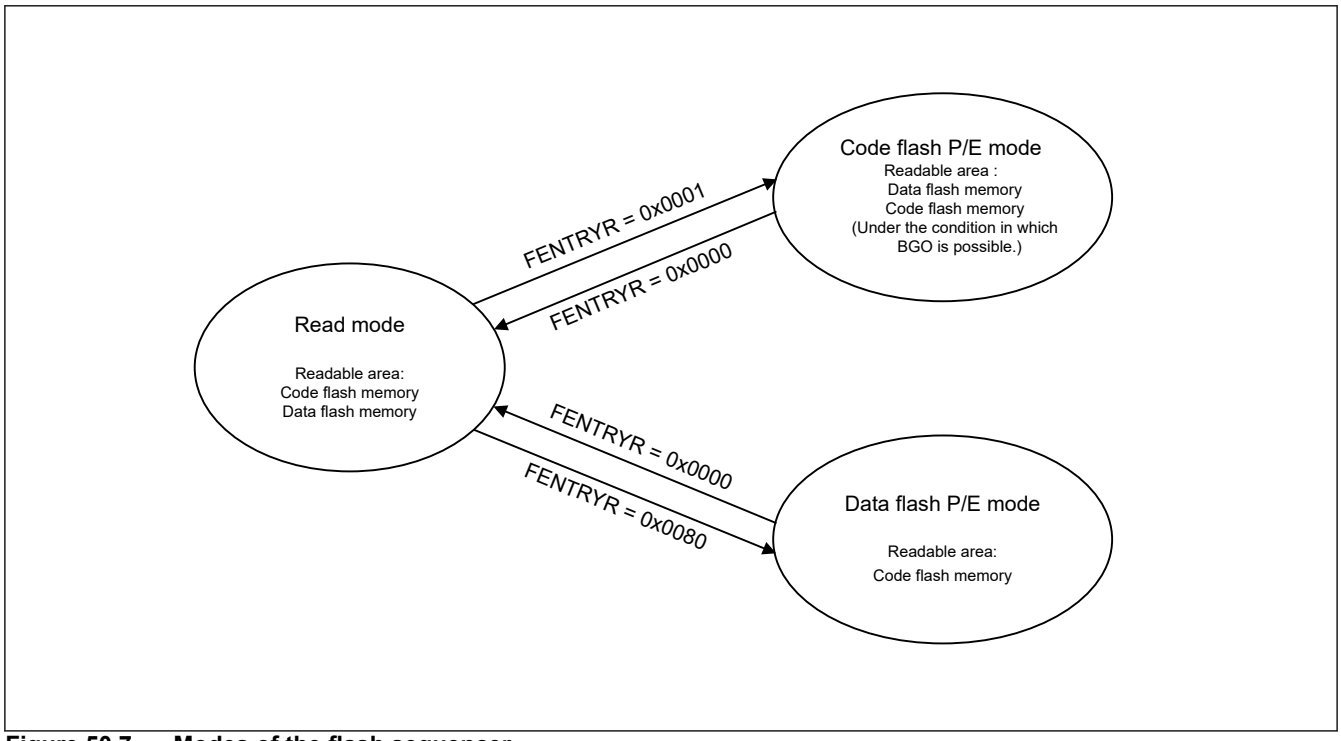

Figure 50.7 Modes of the flash sequencer

50.9 FACI Commands

50.9.1 List of FACI Commands

The FACI controls the FCU according to the specified FACI commands.

This section describes information about the FACI commands and Table 50.14 lists the FACI commands.

Table 50.14 FACI commands (1 of 2)

FACI command	Function
Program	Programs the user area and data area. Units of programming are 128 bytes for the user area and 4, 8, or 16 bytes for the data area.
Block erase	Erases user area and data area. The erase unit is 8 KB or 32 KB for user area, and 64 bytes for data flash.
Multi block erase	Erases data area. The erase unit is 64, 128, 256 bytes for data flash.
P/E suspend	Suspends programming or erasure processing.
P/E resume	Resumes suspended programming or erasure processing.
Status clear	Initializes the ILGLERR, ERSERR, PRGERR, ILGCOMERR, FESETERR, SECERR, and OTERR bits in the FSTATR register and the CMDLK, CFAE, and DFAE bits in the FASTAT register, and the flash sequencer released from command-locked state.
Forced stop	Forcibly stops processing of FACI commands and initializes the FSTATR and FASTAT registers.

Table 50.14 FACI commands (2 of 2)

FACI command	Function
Blank check	Checks if data areas are blank. Units of Blank Check: 4 bytes to data flash memory capacity (specified in 4-byte units).
Configuration set	Sets the option-setting memory. Units of setting: 16 bytes.

The FACI commands are issued by writing to the FACI command-issuing area (see Table 50.4). When write access as shown in Table 50.15 proceeds in the specified state, the flash sequencer executes the processing associated with the given command (see section 50.9.2. Relationship between the Flash Sequencer State and FACI Commands).

Table 50.15 FACI command formats

FACI commands	Number of write access	Write data to the FACI command-issuing area			
		1st access	2nd access	3rd to (N+2)th access	(N+3)th access
Program (user area) N = 64	67	0xE8	0x40 (=N)	WD1 to WD64	0xD0
Program (data area) 4-byte programming: N = 2 8-byte programming: N = 4 16-byte programming: N = 8	N+3	0xE8	0x02 (=N) 0x04 (=N) 0x08 (=N)	WD1 to WDN	0xD0
Block Erase (user area 8K/32K Bytes)	2	0x20	0xD0	—	—
Block Erase (data area 64 bytes)	2	0x20	0xD0	—	—
Multi block erase (data area 64/128/256 bytes)	2	0x21	0xD0	—	—
P/E suspend	1	0xB0	—	—	—
P/E resume	1	0xD0	—	—	—
Status Clear	1	0x50	—	—	—
Forced Stop	1	0xB3	—	—	—
Blank Check	2	0x71	0xD0	—	—
Configuration set N = 8	11	0x40	0x08 (=N)	WD1 to WD8	0xD0

Note: WDN (N = 1, 2, …): Nth 16-bit data to be programmed.

The flash sequencer clears the FSTATR.FRDY bit to 0 at the start of a command processing other than the Status Clear command, and sets this bit to 1 on completion.

If the FRDYIE.FRDYIE bit setting is 1, a flash ready (FRDY) interrupt is generated when the FSTATR.FRDY bit is set to 1.

50.9.2 Relationship between the Flash Sequencer State and FACI Commands

The FACI commands are accepted according to the mode/state of the flash sequencer. FACI commands should be issued after transitioning of the flash sequencer to the code flash P/E mode or data flash P/E mode and after checking the state of the flash sequencer.

Use the FSTATR and FASTAT registers to check the state of the flash sequencer. In addition, the occurrence of errors in general can be checked by reading the CMDLK bit in the FASTAT register. The value of the CMDLK bit is the logical OR of the following bits in the FSTATR register:

- ILGLERR
- ILGCOMERR
- FESETERR
- SECERR

- OTERR
- ERSERR
- PRGERR
- FLWEERR.

Table 50.16 lists the available FACI commands in each operating mode.

Table 50.16 Operating mode and available FACI commands

Operating mode	FENTRYR	Available FACI commands
Read mode	0x0000	None
Code flash P/E mode	0x0001	Program Block erase P/E suspend P/E resume Status Clear Forced Stop Configuration set
Data flash P/E mode	0x0080	Program Block erase Multi block erase P/E suspend P/E resume Status Clear Forced Stop Blank Check

Table 50.17 shows the state of the flash sequencer and acceptable FACI commands. An appropriate mode is assumed to have been set before the commands are executed.

Table 50.17 Acceptable FACI commands and state of the flash sequencer (1 of 2)

	Program, block erase or multi block erase command processing	Configuration set command processing	Program, block erase or multi block erase command suspension processing	Blank check command processing	Programming suspended	Erasure suspended	Programming while erasure is suspended	Command-locked state (FRDY = 1)	Command-locked state (FRDY = 0)	Processing of forced stop command	Other state
FRDY bit	0	0	0	0	1	1	0	1	0	0	1
SUSRDY bit	1	0	0	0	0	0	0	0	0	0	0
ERSSPD bit	0	0	0/1	0/1	0	1	1	0/1	0/1	0	0
PRGSPD bit	0	0	0/1	0/1	1	0	0	0/1	0/1	0	0
CMDLK bit	0	0	0	0	0	0	0	1	1	0	0
Program	X	X*4	X	X	X	O*3	X	X	X	X	O
Block erase or multi block erase	X	X*4	X	X	X	X	X	X	X	X	O
P/E suspend	O	X*4	X	X	X	X	X	—	X	X	—

Table 50.17 Acceptable FACI commands and state of the flash sequencer (2 of 2)

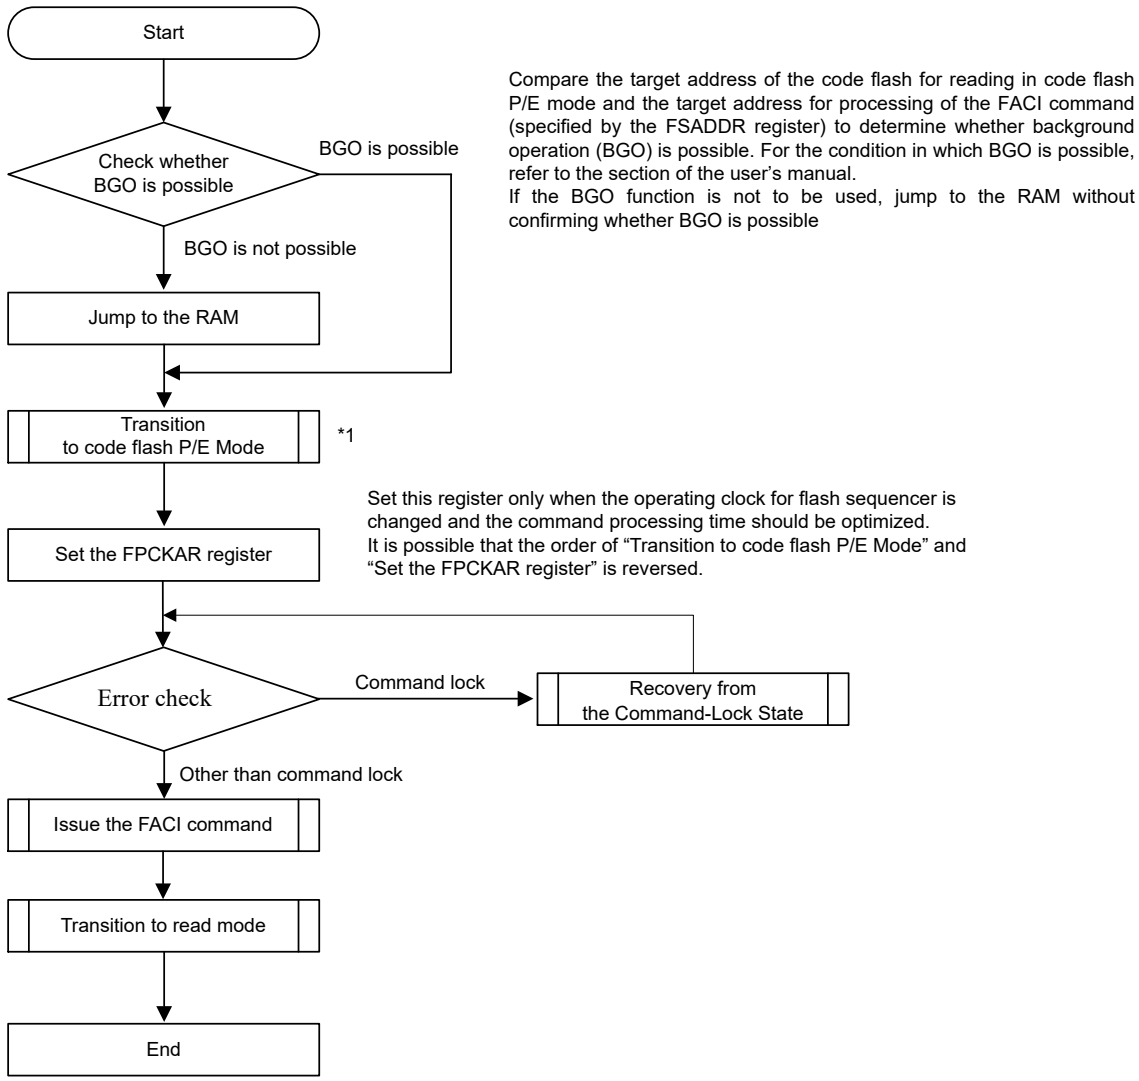
	Program, block erase or multi block erase command processing	Configuration set command processing	Program, block erase or multi block erase command suspension processing	Blank check command processing	Programming suspended	Erasure suspended	Programming while erasure is suspended	Command-locked state (FRDY = 1)	Command-locked state (FRDY = 0)	Processing of forced stop command	Other state
P/E resume	X	X*4	X	X	O	O	X	X	X	X	X
Status clear	X	X*4	X	X	O	O	X	O	X	X	O
Forced stop	O	O*4	O	O	O	O	O	O	O	O	O
Blank check	X	X*4	X	X	O*1	O*1	X	X	X	X	O*1
Configuration set	X	X*4	X	X	X	X	X	X	X	X	O*2

Note: O: Acceptable
X: Not acceptable (places the sequencer in the command-locked state)
—: Ignored
Note 1. Only acceptable in data flash P/E mode.
Note 2. Only acceptable in code flash P/E mode
Note 3. Acceptable when programming area is other than erase suspending block.
Note 4. When configuration set is processing and when FSTATR.DBFULL bit is 1, do not issue this command.

50.9.3 Usage of FACI Commands

50.9.3.1 Overview of Command Usage in Code Flash P/E Mode

Figure 50.8 show an overview of FACI command usage in code flash P/E mode. For the available commands in code flash P/E mode, see Table 50.16.

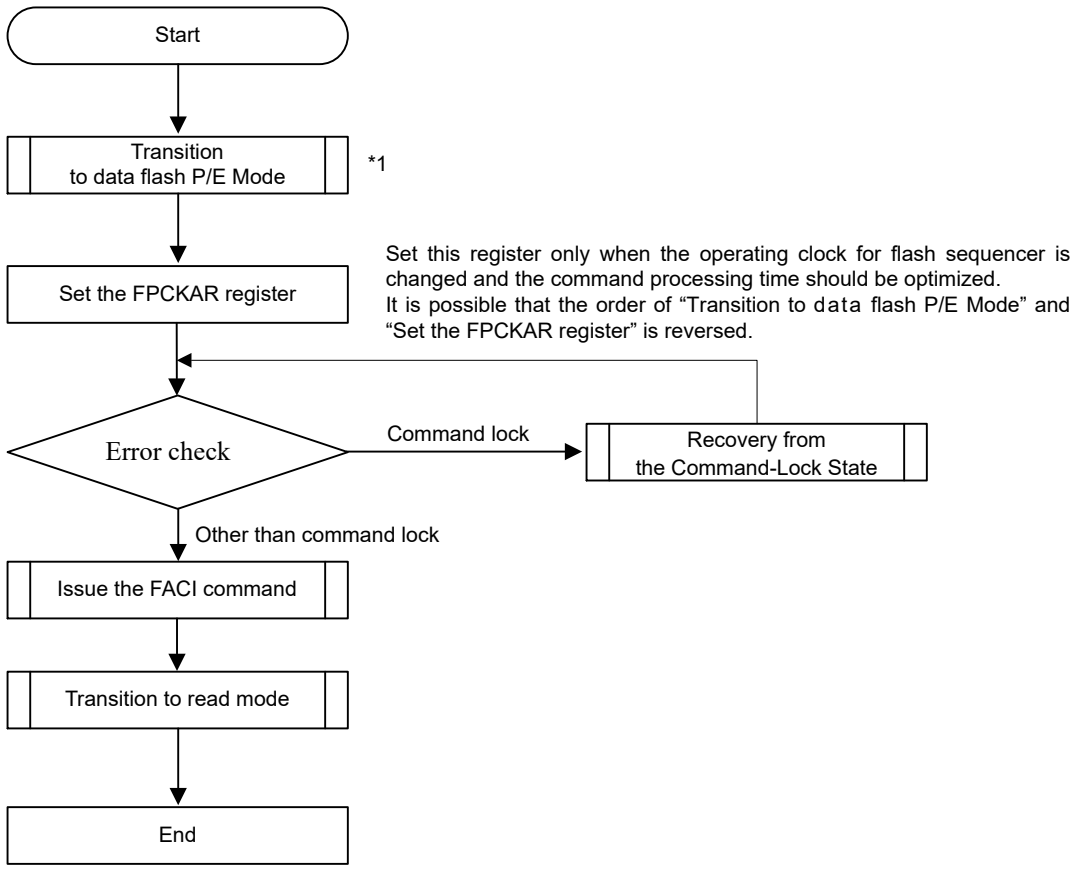


Note 1. See section 50.9.3.3. Transition to Code Flash P/E Mode

Figure 50.8 Overview of command usage in code flash P/E mode

50.9.3.2 Overview of Command Usage in Data Flash P/E Mode

Figure 50.9 shows an overview of FACI command usage in data flash P/E and Table 50.16 lists the available commands in data flash P/E mode.



Note 1. See section 50.9.3.4. Transition to Data Flash P/E Mode

Figure 50.9 Overview of command usage in data flash P/E mode

50.9.3.3 Transition to Code Flash P/E Mode

To issue FACI commands for the code flash memory, a transition to code flash P/E mode is required by setting the FENTRYC bit in the FENTRYR register to 1.

Figure 50.10 shows the procedure to transition to code flash P/E mode.

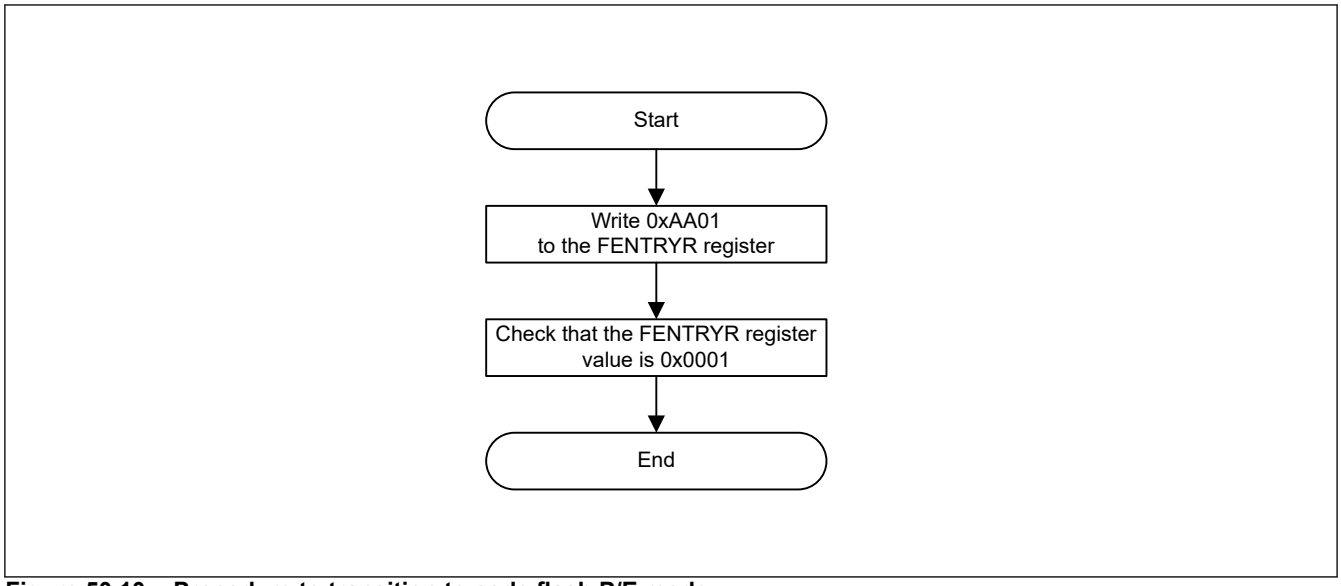


Figure 50.10 Procedure to transition to code flash P/E mode

50.9.3.4 Transition to Data Flash P/E Mode

To issue FACI commands for the data flash memory, a transition to data flash P/E mode is required by setting the FENTRYD bit in the FENTRYR register to 1.

Figure 50.11 shows the procedure to transition to data flash P/E mode.

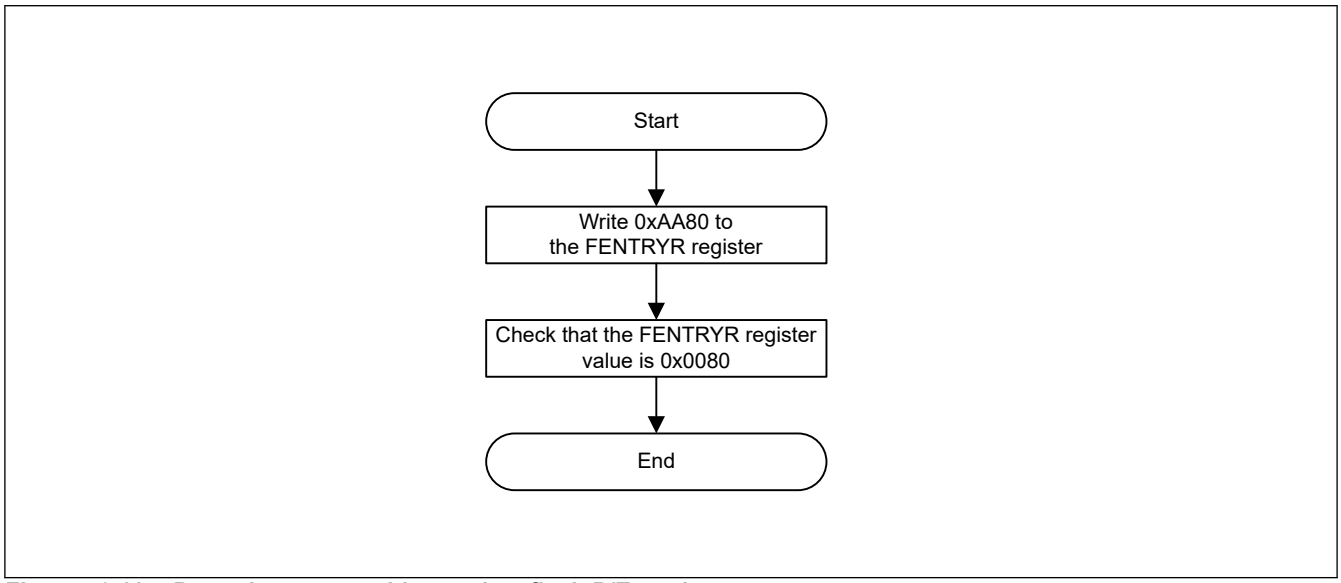

Figure 50.11 Procedure to transition to data flash P/E mode

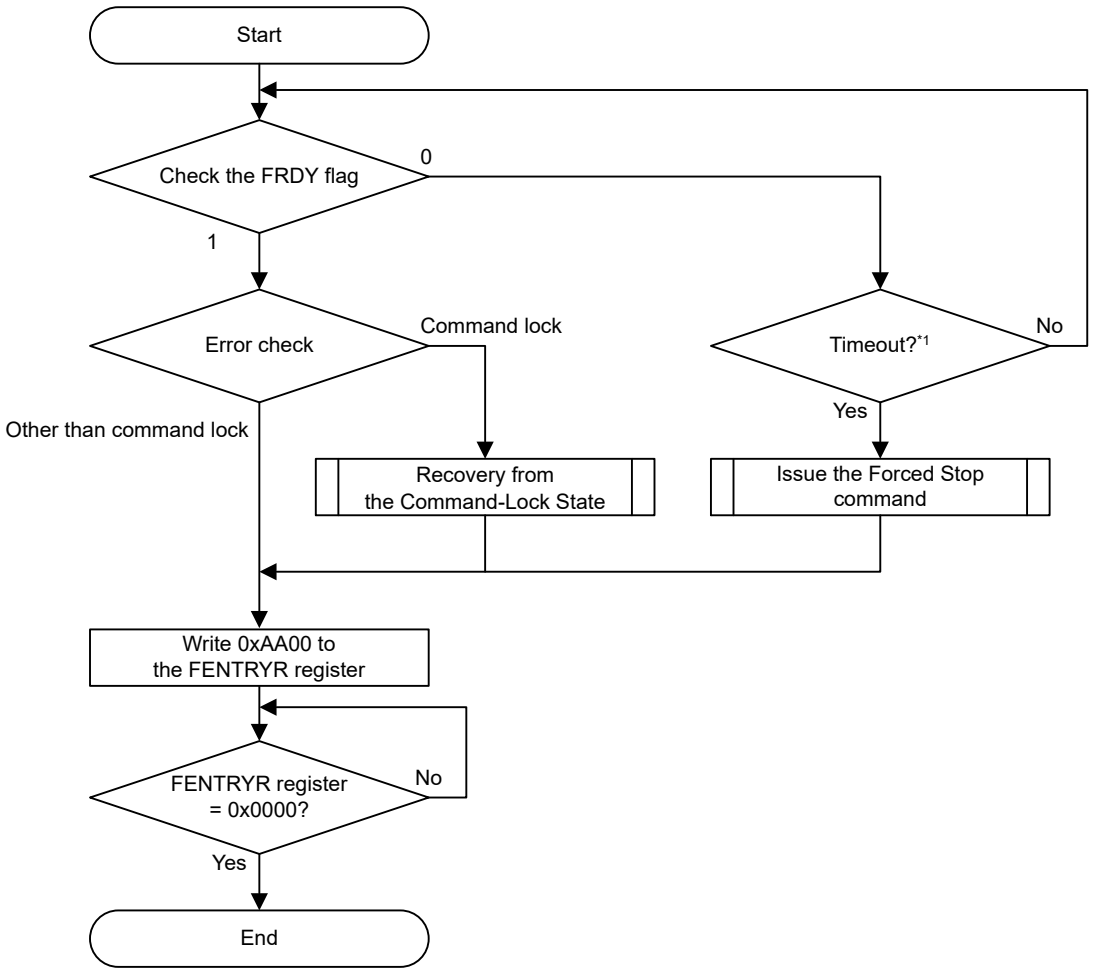
50.9.3.5 Transition to Read Mode

To read the flash memory, a transition to read mode is required by setting the FENTRYR register to 0x0000. The transition to read mode should be made after the flash sequencer completes the processing and while operation is not in the command-locked state.

Figure 50.12 shows the procedure to transition to read mode.



Note 1. Judgment of the timeout is based on 1.1 times the maximum time for processing of the FACI command that is in progress (see section 53, Electrical Characteristics)

Figure 50.12 Procedure to transition to read mode

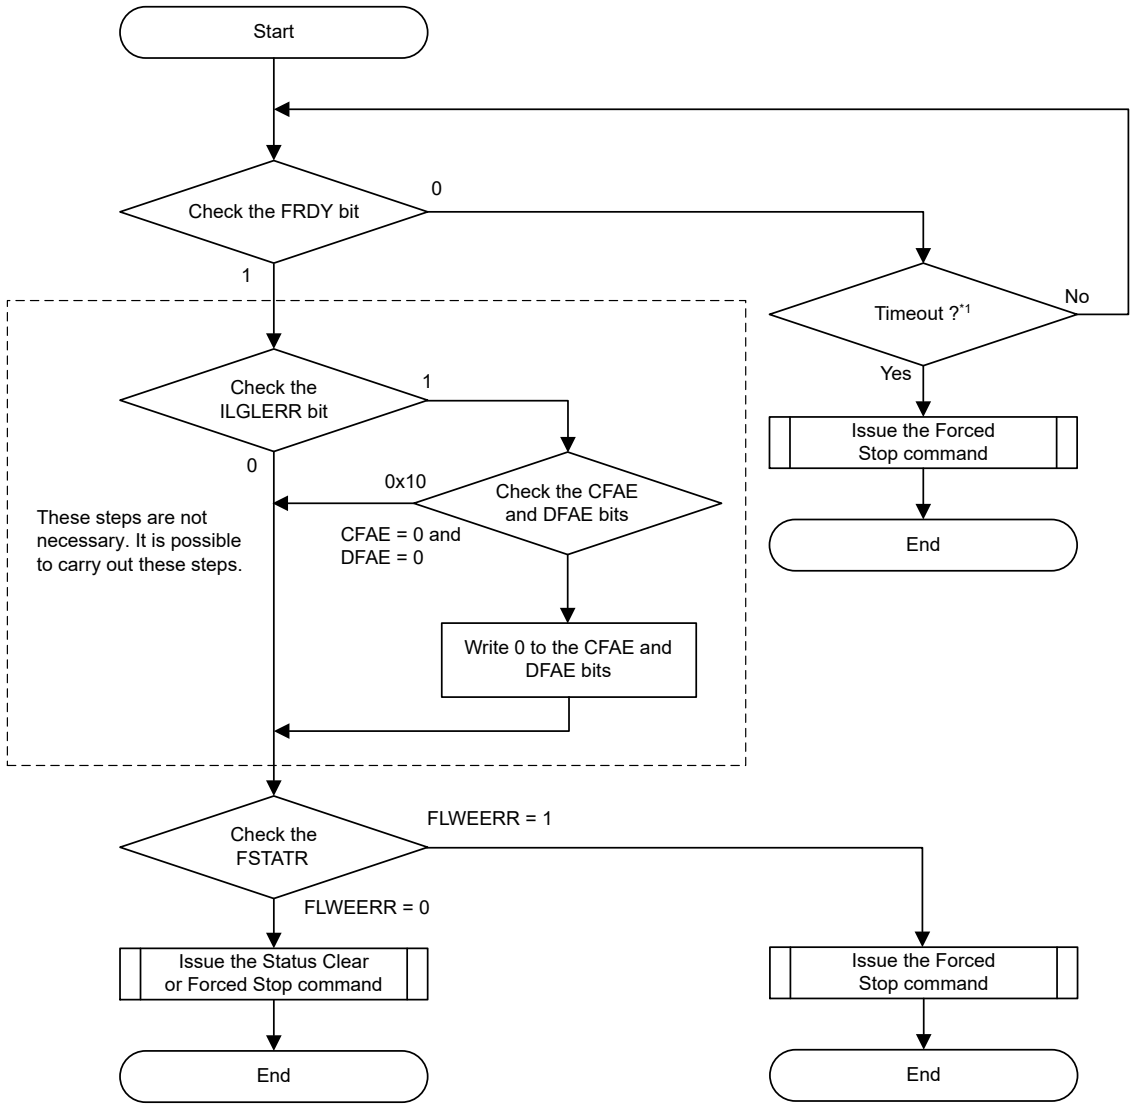
50.9.3.6 Recovery from the Command-Locked State

When the flash sequencer enters the command-locked state, FACI commands cannot be accepted. To release the sequencer from the command-locked state, use the status clear command, forced stop command, or FASTAT register.

When the command-locked state is detected by checking for an error before issuing the P/E suspend command, the FRDY bit in the FSTATR register might be 0 even though command processing has not completed. If processing is not complete by the maximum programming/erasure time specified in the electrical characteristics, this is a timeout and the flash sequencer must be stopped with the forced stop command.

The FLWEERR bit in the FSTATR register does not change from 1 to 0 with the status clear command. When these bits are set to 1, use the forced stop command to release from the command-locked state. Bits other than FRDY and FLWEERR in FSTATR register that indicate the command-locked state can be changed from 1 to 0 with the status clear or forced stop command.

Figure 50.13 shows the recovery flow from the command-locked state.



Note 1. Judgment of the timeout is based on 1.1 times the maximum time for processing of the FACI command that is in progress (see section 53, Electrical Characteristics)

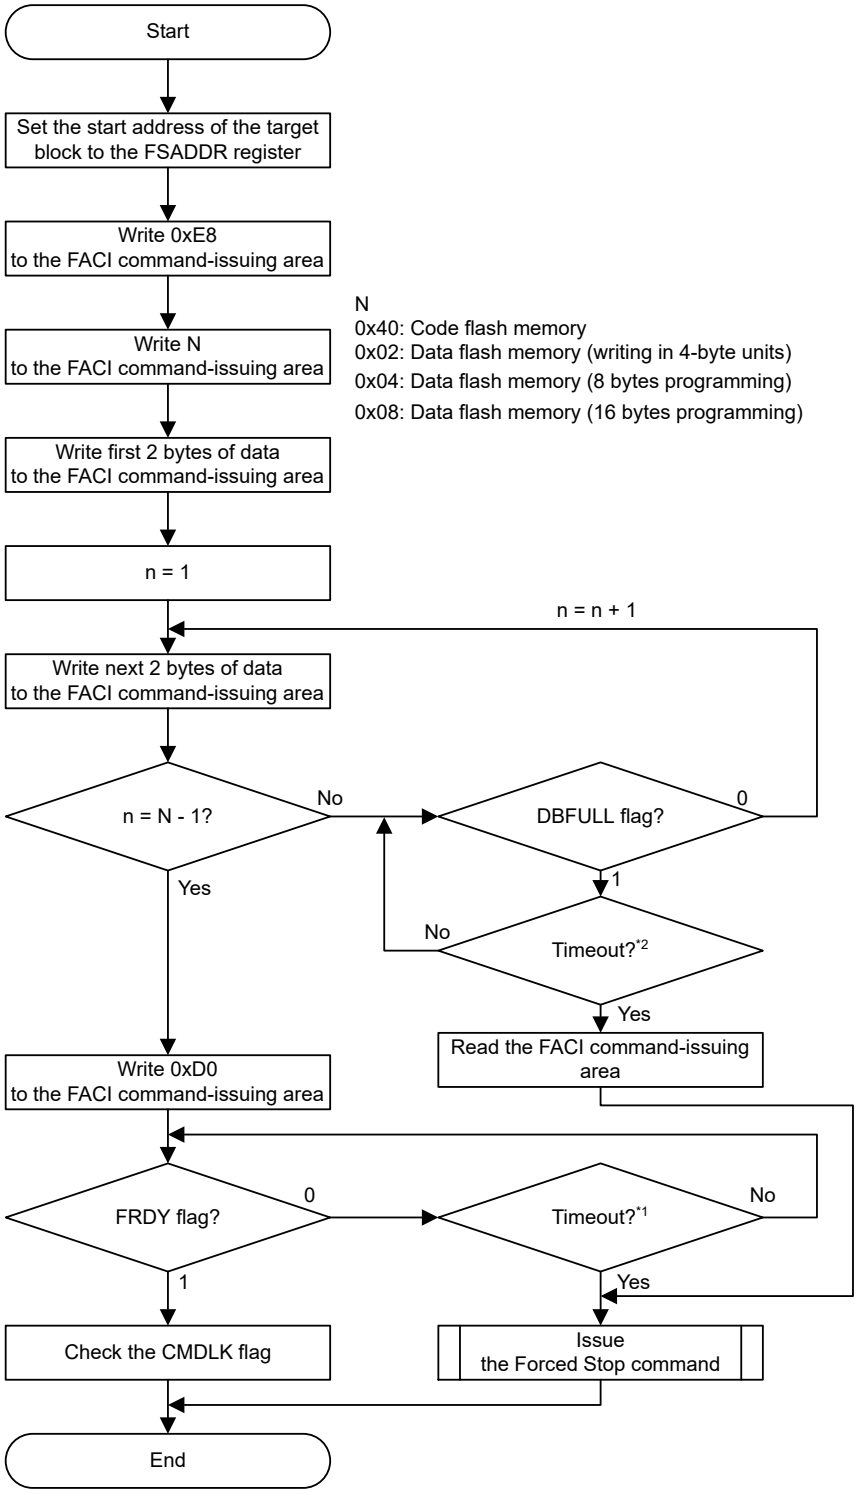
Figure 50.13 Recovery flow from the command-locked state

50.9.3.7 Program Command

The program command is used for writing to the user area and data area. Before issuing the FACI program command, set the first address of the target block in the FSADDR register. Writing 0xD0 at the final access of the FACI command-issuing area starts the program command processing. If the target area of program command processing contains area that are not for writing, write 0xFFFF to the corresponding area.

Issuing the program command while the FACI internal data buffer is full leads to a wait on the peripheral bus that might affect communications performance of other peripheral modules. To avoid a wait, set the DBFULL bit in the FSTATR register to 0 when issuing the FACI command. Writing to the data area does not lead to the data buffer becoming full.

Figure 50.14 shows the usage of the program command.



Note 1. Judgment of the timeout is based on 1.1 times the maximum time of programming. See section 53, Electrical Characteristics about those time

Note 2. 1.4 µs (f_{FCLK} ≥ 20 MHz)

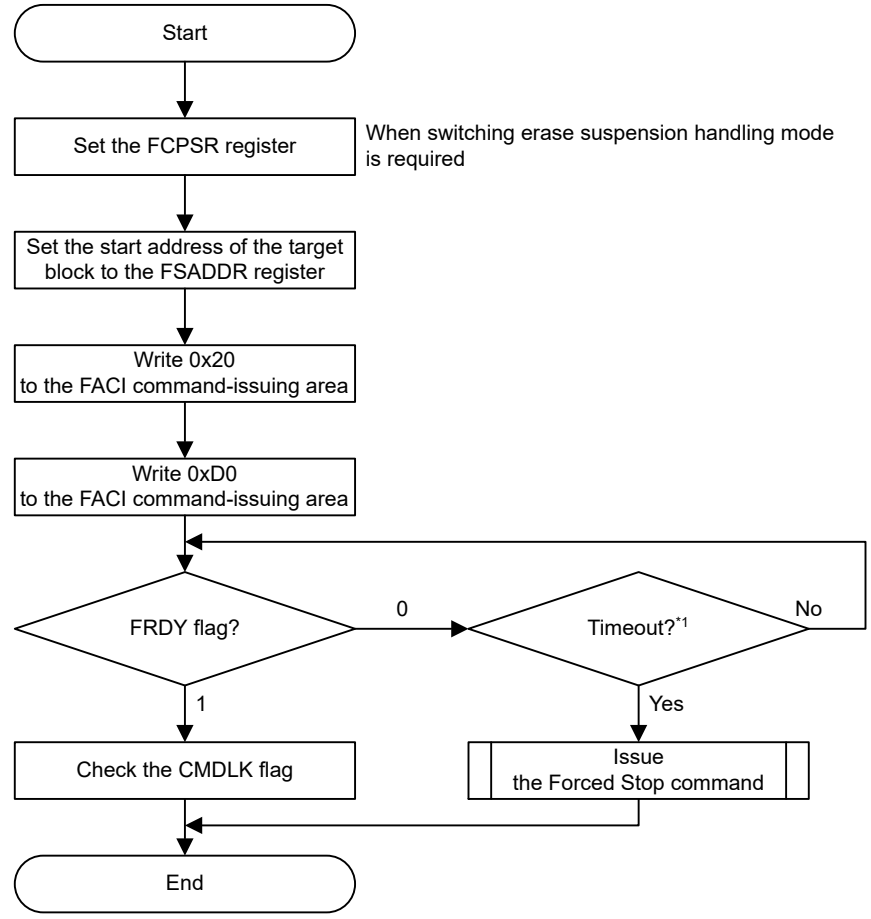
Figure 50.14 Usage flow of the program command

50.9.3.8 Block Erase Command

The block erase command is used for erasing user area or data area. The erase unit is one block. Before issuing a block erase command, set the first address of the target block to FSADDR register. Writing 0xD0 at the second write access of the FACI command triggers the FACI to start the block erase command processing. Completion of command processing can be confirmed with the FRDY bit of FSTATR register.

Set the FCPSR registers before issuing the block erase command. Additionally, FCPSR must be set when the erasure-suspended mode is to be switched.

Figure 50.15 shows the usage of the block erase command.



Note 1. Judgment of the timeout is based on 1.1 times the maximum time of erasure. See section 53, Electrical Characteristics.

Figure 50.15 Usage flow of the block erase command

50.9.3.9 Multi Block Erase Command

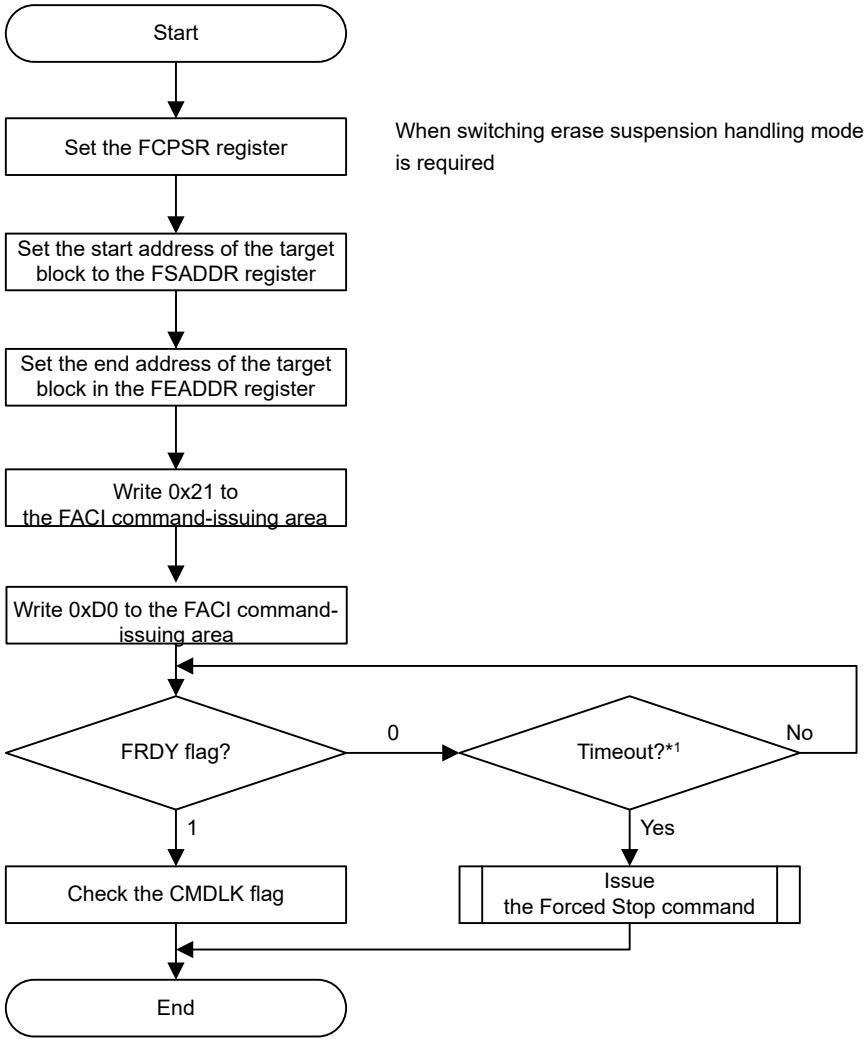
The multi block erase command is used for erasing data area. The erase unit is 64, 128, or 256 bytes. Before issuing the multi block erase command, set the start address to FSADDR register and the end address to FEADDR register. Writing 0xD0 at the second write access of the FACI command triggers FACI to start the multi block erase command processing. Completion of command processing can be confirmed with the FRDY bit of FSTATR register.

Set the FCPSR registers before issuing the multi block erase command. Additionally, FCPSR must be set when the erasure-suspended mode is to be switched.

The erase size is specified by both the FSADDR and FEADDR settings. Table 50.18 describes how to set the FSADDR and FEADDR.

Table 50.18 Settings for the erase size

Erase size	FSADDR	FEADDR
64 bytes	FSA0 to FSA5 = 0 (64 byte-boundary)	FSADDR + 0x3C
128 bytes	FSA0 to FSA6 = 0 (128 byte-boundary)	FSADDR + 0x7C
256 bytes	FSA0 to FSA7 = 0 (256 byte-boundary)	FSADDR + 0xFC



Note 1. Judgment of the timeout is based on 1.1 times the maximum time of erasure. See section 53, Electrical Characteristics.

Figure 50.16 Usage flow of the multi block command

50.9.3.10 P/E Suspend Command

The P/E suspend command is used to suspend programming/erasure. Before issuing a P/E suspend command, check that the CMDLK bit in the FASTAT register is 0, and that the execution of programming/erasure is performed normally. To confirm that the P/E suspend command can be received, check that the SUSRDY bit in the FSTATR register is 1. After issuing a P/E suspend command, read the CMDLK bit to confirm that no error occurs.

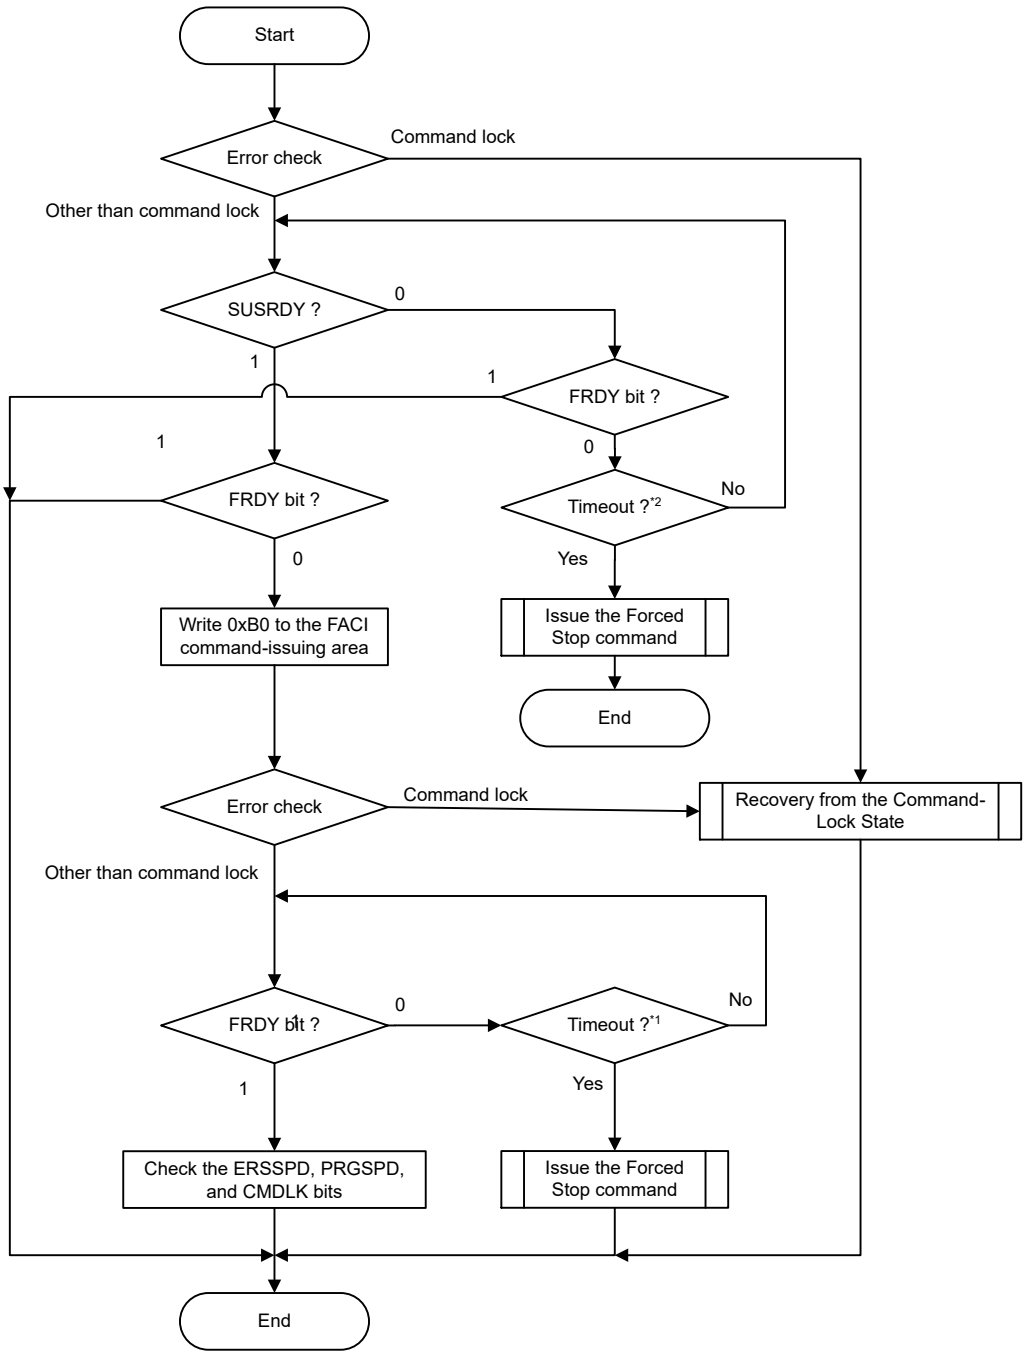
If an error occurs during programming/erasure, the CMDLK bit is set to 1. When programming/erasure processing has finished from the time when the SUSRDY bit is 1 to when the P/E suspend command is received, no error occurs and the

suspended state is not entered (the FRDY bit in the FSTATR register is 1 and the ERSSPD and PRGSPD bits in FSTATR are 0).

When a P/E suspend command is received and the programming/erasure suspend processing finishes normally, the flash sequencer enters the suspended state, the FRDY bit is set to 1, and the ERSSPD or PRGSPD bit is 1. After issuing a P/E suspend command, check that the ERSSPD or PRGSPD bit is 1 and the suspended state is entered, then proceed with the subsequent flow. If a P/E resume command is issued in the subsequent flow even when the suspended state is not entered, an illegal command error occurs and the flash sequencer shifts to the command-locked state (see section 50.11.2. Error Protection).

If the erasure suspended state is entered, programming to blocks other than an erasure target block can be performed. Additionally, the programming and erasure suspended states can shift to read mode by clearing the FENTRYR register.

Figure 50.17 shows the usage of the P/E suspend command.



Note 1. Judgment of the timeout is based on 1.1 times the maximum time of suspend delay during erasure for both code flash and data flash.
See section 53, Electrical Characteristics.
Note 2. 4.4µs (f_{FCLK} >= 20MHz)

Figure 50.17 Usage flow of the P/E suspend command

(1) Suspension during Programming

When issuing a P/E suspend command during flash memory programming, the flash sequencer suspends programming processing. Figure 50.18 shows the suspend programming operation. When receiving programming-related command, the flash sequencer clears the FRDY bit in the FSTATR register to 0 to start programming. If the flash sequencer enters the state

in which the P/E suspend command can be received after programming starts, it sets the SUSRDY bit in the FSTATR register to 1.

When a P/E suspend command is issued, the flash sequencer receives the command and clears the SUSRDY bit to 0. If the flash sequencer receives a P/E suspend command while a programming pulse is applied, the flash sequencer continues with the pulse. After the specified pulse application time, the flash sequencer finishes pulse application, starts the programming suspend processing, and sets the PRGSPD bit in the FSTATR register to 1.

When a suspended processing finishes, the flash sequencer sets the FRDY bit to 1 to enter the programming suspended state. When receiving a P/E resume command in the programming suspended state, the flash sequencer clears the FRDY and PRGSPD bits to 0 and resumes programming.

Figure 50.18 shows the timing for suspension during programming.

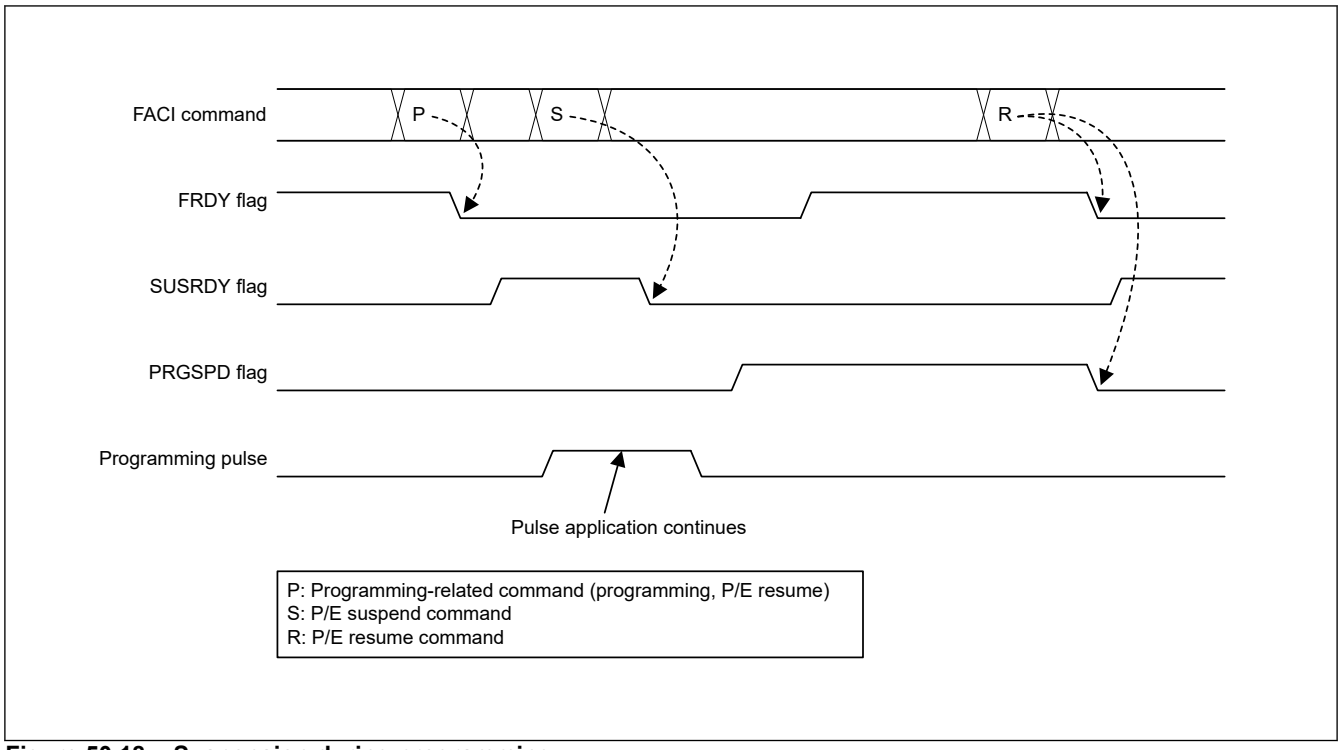


Figure 50.18 Suspension during programming

(2) Suspension during Erasure (Suspension Priority Mode)

The flash sequencer has a suspension priority mode for the suspension of erasure. Figure 50.19 shows the suspend operation of erasure when the erasure suspend mode is set to the suspension priority mode (the ESUSPMD bit in the FCPSR register is 0).

When receiving an erasure-related command, the flash sequencer clears the FRDY bit in the FSTATR register to 0 to start erasure. If the flash sequencer enters the state in which the P/E suspend command can be received after erasure starts, it sets the SUSRDY bit in the FSTATR register to 1.

When a P/E suspend command is issued, the flash sequencer receives the command and clears the SUSRDY bit to 0.

When receiving a suspend command during erasure, the flash sequencer starts the suspend processing and sets the ERSSPD bit in the FSTATR register to 1 even when it is applying an erasure pulse. When the suspended processing finishes, the flash sequencer sets the FRDY bit to 1 to enter the erasure suspended state. When receiving a P/E resume command in the erasure suspended state, the flash sequencer clears the FRDY and ERSSPD bits to 0 and resumes erasure. Operations of the FRDY, SUSRDY, and ERSSPD bits at the suspension and resumption of erasure are the same, regardless of the erasure suspend mode.

The setting of the erasure suspend mode affects the control method of erasure pulses. In suspension priority mode, when receiving a P/E suspend command while erasure pulse A that has not been previously suspended is being applied, the flash sequencer suspends the application of erasure pulse A and enters the erasure suspended state. When receiving a P/E suspend command while reapplying erasure pulse A after erasure is resumed with a P/E resume command, the flash sequencer

continues to apply erasure pulse A. After the specified pulse application time, the flash sequencer finishes erasure pulse application and enters the erasure suspended state.

When the flash sequencer receives a P/E resume command next and erasure pulse B is being applied, the flash sequencer receives a P/E suspend command again, and the application of erasure pulse B is then suspended. In suspension priority mode, delays due to suspension can be minimized because the application of an erasure pulse is suspended once per pulse, and priority is given to the suspend processing.

If the interval of suspension after resume is longer than t_{REST1} (Resume time: priority on suspension, resume after the 1st suspend for the same pulse), suspend delay will be always t_{SESD1} (Suspend delay: priority on suspension, the 1st suspend for the same pulse).

If the interval of suspension after resume is shorter than t_{REST1}, suspend delay becomes either t_{SESD1} or t_{SESD2} (Suspend delay: priority on suspension, the 2nd suspend for the same pulse).

(The value of t_{REST1} / t_{SESD1} / t_{SESD2}, see section 53, Electrical Characteristics.)

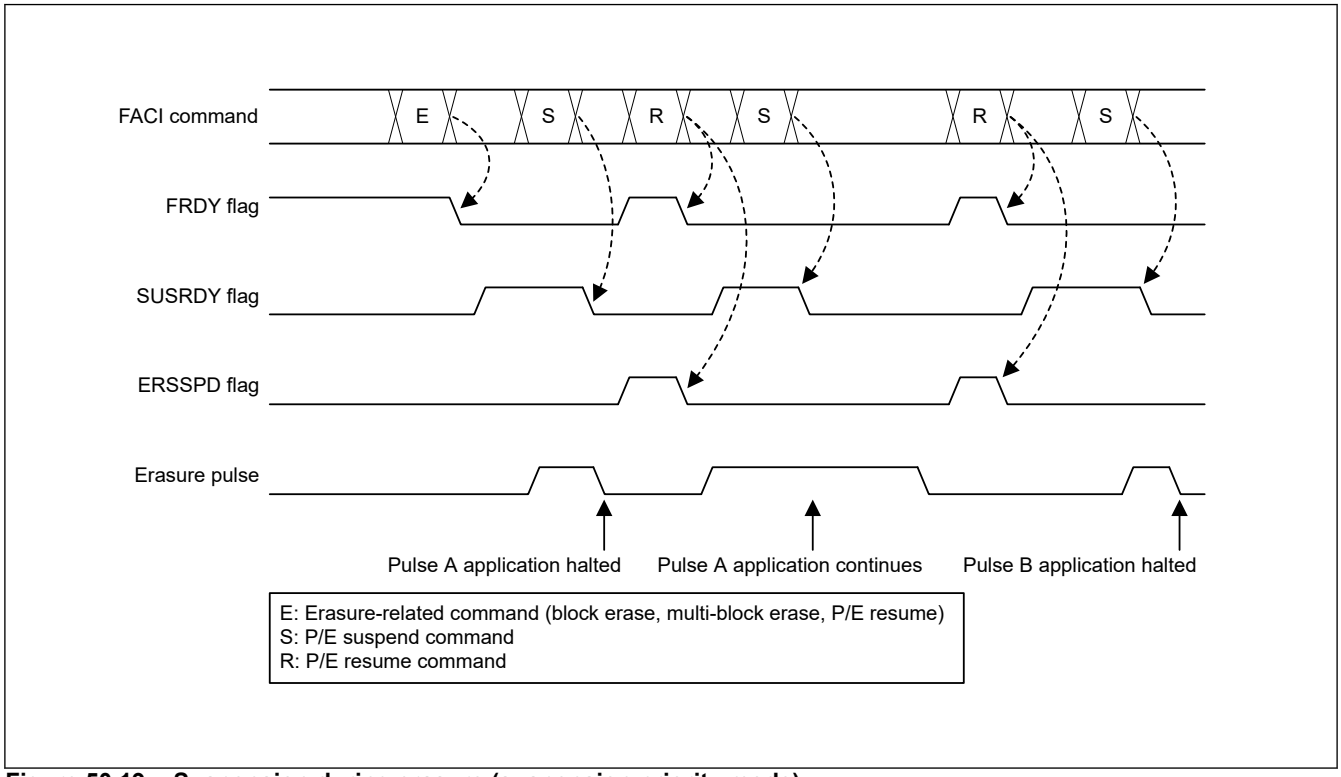

Figure 50.19 Suspension during erasure (suspension priority mode)

(3) Suspension during Erasure (Erasure Priority Mode)

The flash sequencer has an erasure priority mode for the suspension of erasure. Figure 50.20 shows the suspend operation of erasure when the erasure suspend mode is set to the erasure priority mode (the ESUSPMD bit in the FCPSR register is 1). The control method of erasure pulses in erasure priority mode is the same as that of programming pulses for the programming suspend processing.

If the flash sequencer receives a P/E suspend command while an erasure pulse is applied, the flash sequencer continues to apply the pulse. In this mode, the required time for the erasure processing can be reduced compared to the suspension priority mode because the re-application of erasure pulses does not occur when a P/E resume command is issued.

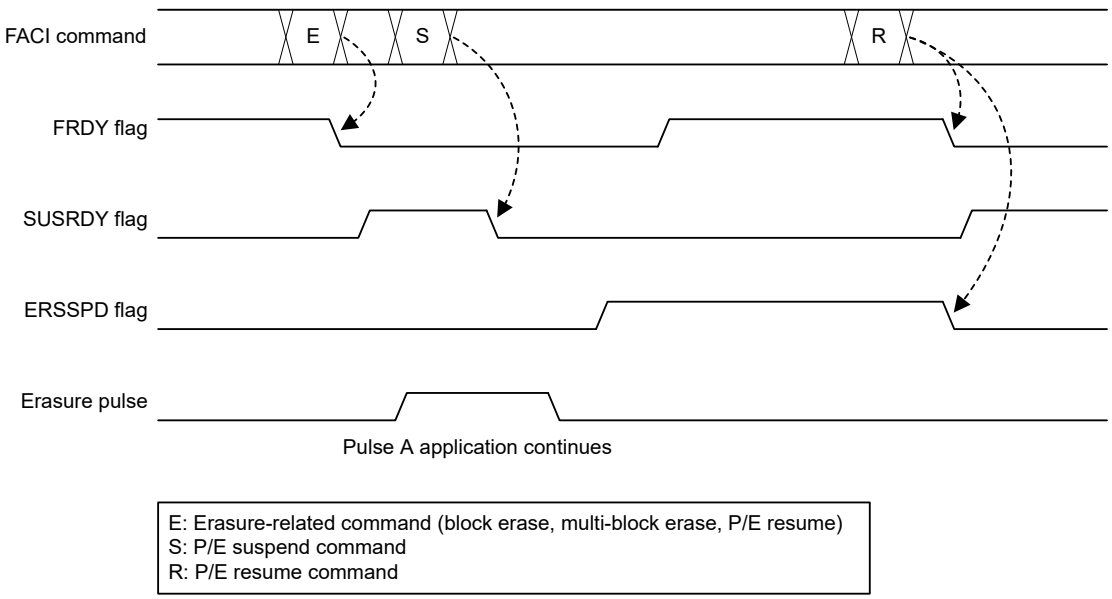

Figure 50.20 Suspension during erasure (erasure priority mode)

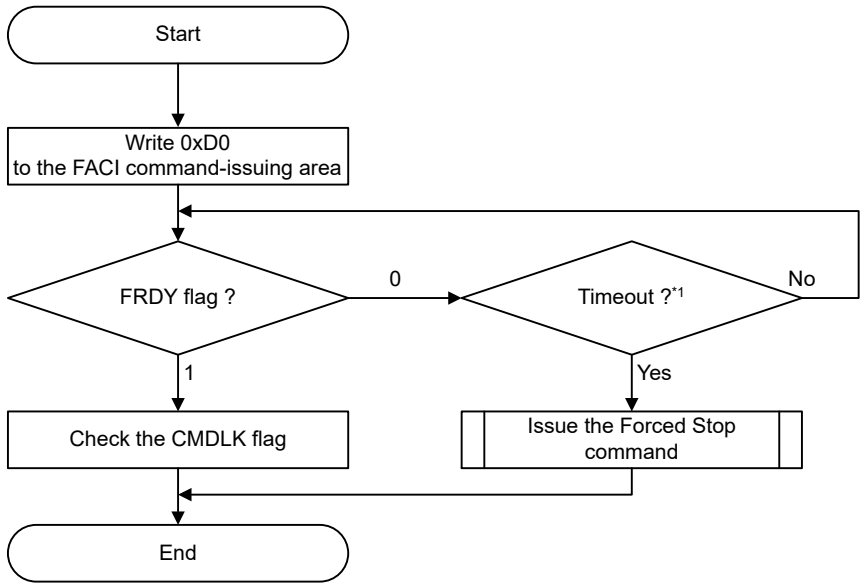
50.9.3.11 P/E Resume Command

The P/E resume command is used to resume suspended programming or erasure. If the FENTRYR setting has been modified during suspension, issue a P/E resume command only after resetting FENTRYR to the previous value that was held before the P/E suspend command was issued. Figure 50.21 shows usage of the P/E resume command.



Note 1. Judgment of the timeout is based on 1.1 times the maximum time for halted processing of the FACI command. See section 53, Electrical Characteristics.

Figure 50.21 Usage flow of the P/E resume command

50.9.3.12 Status Clear Command

The status clear command is used to clear the command-locked state (see section 50.9.3.6. Recovery from the Command-Locked State).

You can use the status clear command to clear the following bits in the FSTATR register in the command-locked state:

- ILGLERR
- ILGCOMERR
- FESETERR
- SECERR
- OTERR
- ERSERR
- PRGERR

Figure 50.22 shows usage of the status clear command.

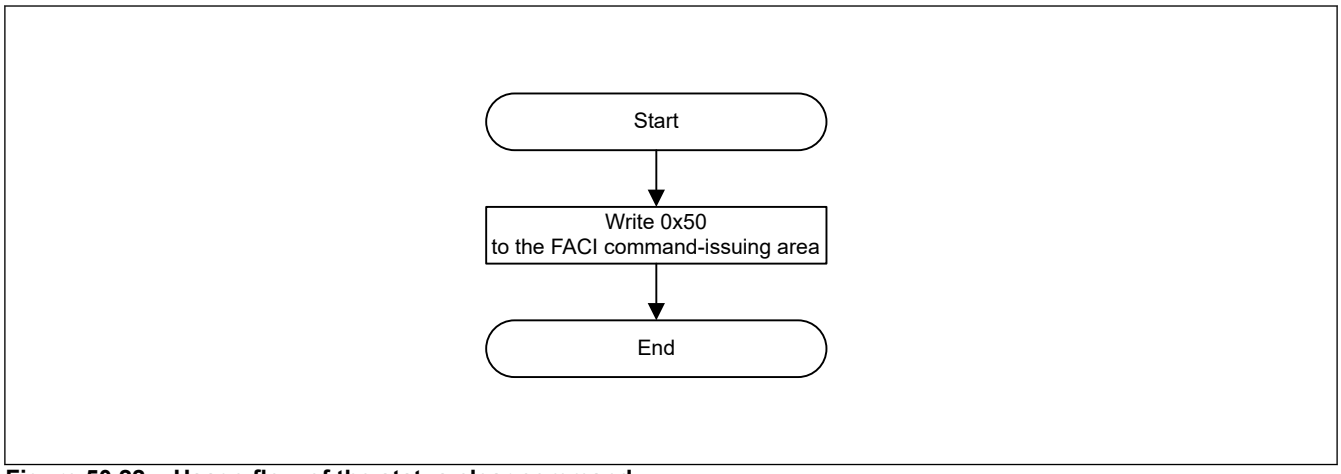


Figure 50.22 Usage flow of the status clear command

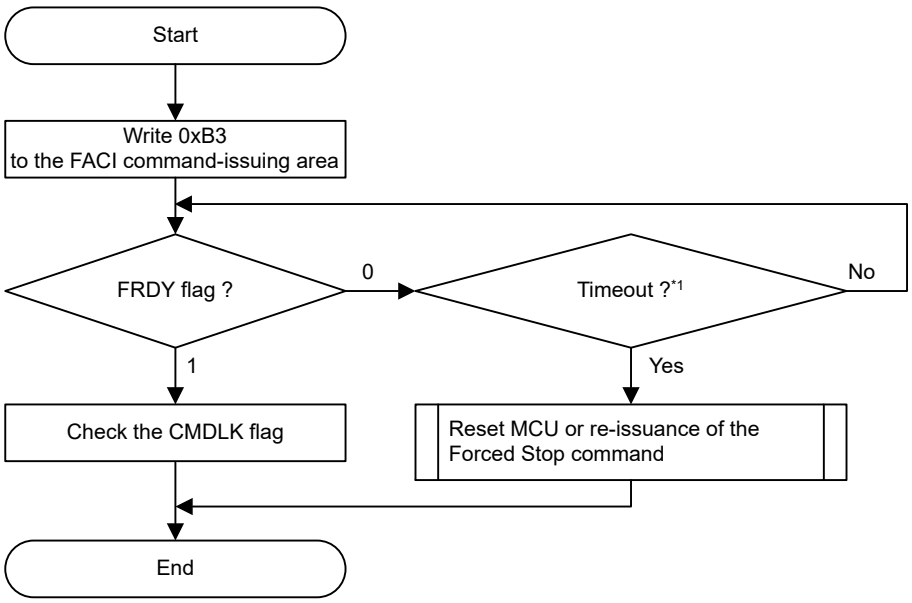
50.9.3.13 Forced Stop Command

The forced stop command is used to forcibly end command processing by the flash sequencer. Although this command halts command processing more quickly than the P/E suspension command, values from the programming or erasure that are in progress are not guaranteed. Additionally, resumption of processing is not possible. Processing of programming or erasure that is halted by the forced stop command is also defined as one programming round.

Executing the forced stop command also initializes part of the FACI, the whole FCU, the FSTATR and FASTAT registers. This command can be used in the procedure for recovery from the command-locked state and for processing in response to a timeout of the flash sequencer (see section 50.9.3.6. Recovery from the Command-Locked State).

Figure 50.23 shows usage of the forced stop command.



Note 1. Judgment of the timeout is based on 1.1 times the maximum time of the Forced Stop command latency. See section 53, Electrical Characteristics.

Figure 50.23 Usage flow of the forced stop command

(1) Notes on Using the Forced Stop Command during Command Issue

When using the forced stop command at the timeout occurrence by DBFULL bit of the program command, writing in the FACI command-issuing area is sometimes processed as writing in data of the program command. See Table 50.4 in section 50.3. Address Space for information on the FACI command-issuing area to force a command lock. Then issue a forced stop command with return method from the command lock status (see Figure 50.14). Locking commands is possible in any case where the unit for reading the FACI command issuing area is 8, 16, or 32 bits.

50.9.3.14 Blank Check Command

The blank check command is used to confirm that an area is in the non-programmed state. Values read from the data flash memory that have been erased but not yet programmed again that is in the non-programmed state, are undefined.

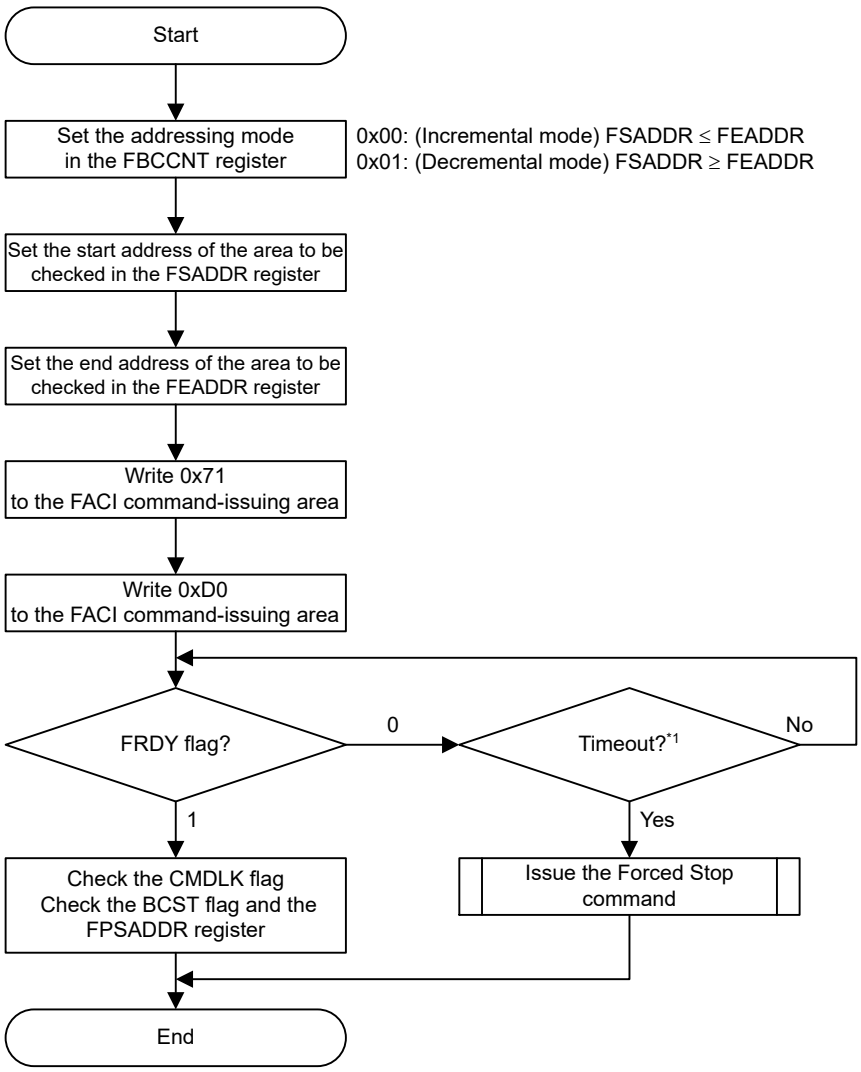
Before issuing the Blank Check command, set addressing mode, start address, and end address of the target area for Blank Check to the FBCCNT, FSADDR, and FEADDR registers. When Blank Check addressing mode is set to decremental mode (i.e. FBCCNT.BCDIR = 1), address specified in FSADDR should be equal to or larger than address in FEADDR.

On the other hand, the address in FSADDR should be equal to or smaller than address in FEADDR when Blank Check addressing mode is set to incremental mode (i.e. FBCCNT.BCDIR = 0).

If the settings of the BCDIR bit, FSADDR, and FEADDR are inconsistent, the flash sequencer enters the command-locked state. The size of the target area for Blank Check is in the range from 4 bytes to the data flash memory capacity and is set in units of 4 bytes.

Write 0x71 and 0xD0 to the FACI command-issuing area to start Blank Check. Completion of processing can be confirmed by the FRDY bit of the FSTATR register. At the end of processing, the result of Blank Check is stored in the BCST bit in the FBCSTAT register. If non-programmed data exists within the target area for Blank Check, flash sequencer stops Blank Check command operation. In this case, address of non-programmed data is indicated to FPSADDR register.

Figure 50.24 shows usage of the blank check command.



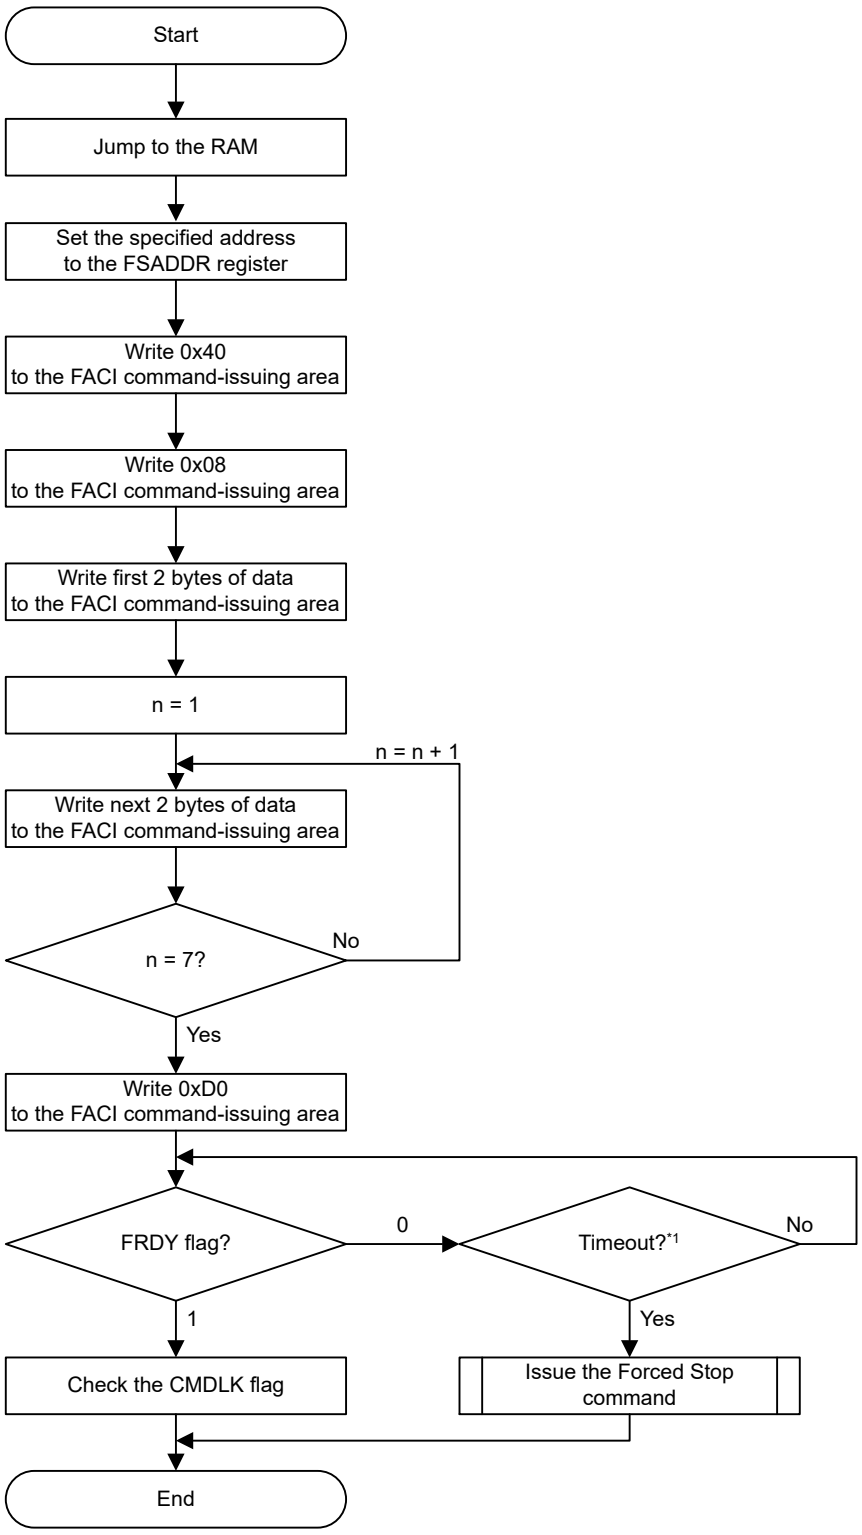
Note 1. Judgment of the timeout is based on 1.1 times the maximum time of Blank Checking for the whole target range. See section 53, Electrical Characteristics.

Figure 50.24 Usage flow of the blank check command

50.9.3.15 Configuration Set Command

The Configuration set command is used to set option-setting memory. Before issuing the Configuration set command, set the specified address (shown in Table 50.19) in the FSADDR register. Writing 0xD0 to the FACI command-issuing area in the final access for issuing the FACI command starts FACI processing of the Configuration set command.

Figure 50.25 shows usage of the configuration set command.



Note 1. Judgment of the timeout is based on 1.1 times the maximum time of programing in option-setting memory. See section 53, Electrical Characteristics.

Figure 50.25 Usage flow of the configuration set command

The correspondence between the possible target data for configuration setting and the address value set in the FSADDR register is shown in Table 50.19. For details, see section 50.4.12. FSADDR : FACI Command Start Address Register.

Table 50.19 Address Used by Configuration Set Command

Address	FSADDR Register Value	Setting Data	Operation of additional writing		Timing when the Setting is Enabled
			SAS.FSPR bit is 1	SAS.FSPR bit is 0	
0x0100_A100	0x0100_A100	Option Function Select Register 0 (OFS0)	Writable	Writable	At a reset
0x0100_A110	0x0100_A110	Dual Mode Select Register (DULSEL)	Writable	Writable	At a reset
0x0100_A134	0x0100_A130	Start-up Area Setting Register (SAS)	Writable	Not writable*1	When a reset or command is executed
0x0100_A180	0x0100_A180	Option Function Select Register 1 (OFS1)	Writable	Writable	At a reset
0x0100_A190	0x0100_A190	Bank Select Register (BANKSEL)	Writable	Writable	At a reset
0x0100_A1C0	0x0100_A1C0	Block Protect Setting Register (BPS)	Writable*2	Writable*2	When a reset or command is executed
0x0100_A1E0	0x0100_A1E0	Permanent Block Protect Setting Register (PBPS)	Writable*3 (from 1 to 0 only)	Writable*3 (from 1 to 0 only)	When a reset or command is executed
0x0100_A200	0x0100_A200	Option Function Select Register 1 Secure (OFS1_SEC)	Writable	Writable	At a reset
0x0100_A210	0x0100_A210	Bank Select Register Secure (BANKSEL_SEC)	Writable	Writable	At a reset
0x0100_A240	0x0100_A240	Block Protect Setting Register Secure (BPS_SEC)	Writable*4	Writable*4	When a reset or command is executed
0x0100_A260	0x0100_A260	Permanent Block Protect Setting Register Secure (PBPS_SEC)	Writable*5 (from 1 to 0 only)	Writable*5 (from 1 to 0 only)	When a reset or command is executed
0x0100_A280	0x0100_A280	Option Function Select Register 1 Select (OFS1_SEL)	Writable	Writable	At a reset
0x0100_A290	0x0100_A290	Bank Select Register Select (BANKSEL_SEL)	Writable	Writable	At a reset
0x0100_A2C0	0x0100_A2C0	Block Protect Setting Register Select (BPS_SEL)	Writable	Writable	At a reset

Note 1. The SAS.FSPR bit cannot be restored to 1 by using the Configuration set command once it is set to 0. Therefore, setting the start-up area select flags again becomes impossible. (when the Configuration set command is issued to the address of 0x0100A134, the command is locked.) Exercise extra caution when handling the SAS.FSPRbit.
Note 2. Once PBPS[n] bit is set to 0, the BPS[n] bit cannot be restored to 1 by using the Configuration set command.
Note 3. Once these bits are set to 0, the bits cannot be restored to 1 by using the Configuration set command. The PBPS[n] bit cannot be set to 0 by using the Configuration set command when the BPS[n] bit is 1.
Note 4. Once PBPS_SEC[n] bit is set to 0, the BPS_SEC[n] bit cannot be restored to 1 by using the Configuration set command.
Note 5. Once these bits are set to 0, the bits cannot be restored to 1 by using the Configuration set command. The PBPS_SEC[n] bit cannot be set to 0 by using the Configuration set command when the BPS_SEC[n] bit is 1.

50.10 Suspend Operation

Reading from the flash memory is not possible during programming or erasure if the conditions for background operation given in Table 50.35 are not satisfied. When a P/E suspend command is issued to suspend the programming or erasure of the flash memory, reading from the flash memory is enabled. Regarding P/E suspend commands, there are one suspend command mode for programming and two suspend command modes for erasure (suspension priority mode and erasure priority mode). To resume suspended programming or erasure, the P/E resume command is available. For details on the suspend operation, see Figure 50.17.

50.11 Protection Function

50.11.1 Software Protection

Software protection disables programming and erasure of the code flash memory through the settings of control registers and block protect setting in the user area. If an attempt is made to issue an FACI command against software protection, the flash sequencer enters the command-locked state.

50.11.1.1 Protection through FWEPROR

Unless the FWEPROR.FLWE[1:0] bits are set to 01b, programming cannot proceed in any mode.

50.11.1.2 Protection by FENTRYR

When the FENTRYR register is set to 0x0000, the flash sequencer enters read mode. In read mode, FACI commands cannot be accepted. If an attempt is made to issue an FACI command in read mode, the flash sequencer enters the command-locked state.

50.11.1.3 Protection by Block Protect Setting

Each block in user area has the block protect setting (BPS or BPS_SEC). When the FBPROT0 or FBPROT1 register is 0x0000 and the block protect bit is 0, issuing the Program or Block Erase command to user area of the code flash causes the command-locked state. To program or erase the block whose block protect bit is 0, set the FBPROT0 or FBPROT1 register to 0x0001.

The block protect setting can be locked by the permanent block protect setting (PBPS or PBPS_SEC). When the permanent block protect setting and the block protect setting are 0, issuing a Program or Block erase command to user area of the code flash causes the flash sequencer to enter the command-locked state regardless of the FBPROT0 and FBPROT1 register settings.

Valid block protect setting (BPS or BPS_SEC) depends on the Block Protect Select bit (BPS_SEL).

See section 50.12.2. Permanent Block Protect Setting for details of the block protect setting and permanent block protect setting. See section 50.4.15. FBPROT0 : Flash Block Protection Register and section 50.4.16. FBPROT1 : Flash Block Protection for Secure Register for more information.

For details of block protect setting (BPS or BPS_SEC) and block protect select (BPS_SEL), see section 6, Option-Setting Memory.

The protected area by the block protect setting is always determined by the address of the FSADDR register setting regardless of the address swapping function setting (the startup area select, the block swap in linear mode, and the startup bank select in dual mode). Table 50.20 to Table 50.25 show the relation of user area and the block protect setting in each function setting.

(1) In case of the linear mode

- BPS[0] to BPS[n] or BPS_SEC[0] to BPS_SEC[n] are assigned to the block of user area (for example, address is 0x00_0000 to the last block address).
- BPS[0]/BPS_SEC[0] and BPS[1]/BPS_SEC[1] are assigned to the block of user area depending on the startup area select setting (SAS.BTFLG bit). (See section 50.11.3. Start-Up Program Protection).
- The second half of FLI user area is assigned to block protect setting depending on the block swap select setting (BANKSEL.BLCKSWP[2:0] bits). See section 50.11.5. Block Swap Function.

Table 50.20 shows the block protect setting when the startup area select is disabled (not swapping).

Table 50.21 show example of the block protect setting when the address conversion function is used.

Table 50.20 Example of Block Protect setting when SAS.BTFLG is 1 (1 of 2)

FSADDR[23:0]	Block size	Block protect setting	User area block number	Notes
The last block address	32 KB	BPS[n] or BPS_SEC[n]	Block n	—

(2) In case of the dual mode (DUALSEL.BANKMD[2:0] = 000b)

- BPS[0] to BPS[n] or BPS_SEC[0] to BPS_SEC[n] are assigned the block of bank 0 user area (for example, address is 0x00000000 to the last block address in the lower side bank).
- BPS[70] to BPS[70 + n] or BPS_SEC[70] to BPS_SEC[70 + n] are assigned to the block of bank 1 user area (for example, address is 0x00200000 to the last block address in the upper side bank).

Bank0 is upper side bank (BANKSEL.BANKSWP[2:0] = 000b)

- BPS[0] to BPS[n] or BPS_SEC[0] to BPS_SEC[n] are assigned to the block of bank1 user area (e.g. Address is 0x00_0000 to The last block address in lower side bank).
- BPS[70] to BPS[70+n] or BPS_SEC[70] to BPS_SEC[70+n] are assigned to the block of bank0 user area (e.g. Address is 0x20_0000 to The last block address in upper side bank).

Table 50.24 and Table 50.25 show example of the block protect setting in the dual mode. See section 50.11.4. Dual Bank Function for details of dual bank function (DUALSEL.BANKMD[2:0] and BANKSEL.BANKSWP[2:0] bits).

Table 50.24 Example of Block Protect setting when BANKSEL.BANKSWP[2:0] is 111b

FSADDR[23:0]	Block size	Block protect setting	User area block number	Notes

0x20_2000 to 0x20_3FFF	8 KB	BPS[71] or BPS_SEC[71]	Block 1	
0x20_0000 to 0x20_1FFF	8 KB	BPS[70] or BPS_SEC[70]	Block 0	

Table 50.25 Relation of User area and Block Protect setting when BANKSEL.BANKSWP[2:0] is 000b (2 of 2)

FSADDR[23:0]	Block size	Block protect setting	User area block number	Notes
The last block address in the lower side bank	32 KB	BPS[n] or BPS_SEC[n]	Block 70 + n	Swap bank 0 and bank 1 in this startup bank switch setting
⋮	⋮	⋮	⋮	
0x01_8000 to 0x01_FFFF	32 KB	BPS[9] or BPS_SEC[9]	Block 79	
0x01_0000 to 0x01_7FFF	32 KB	BPS[8] or BPS_SEC[8]	Block 78	
0x00_E000 to 0x00_FFFF	8 KB	BPS[7] or BPS_SEC[7]	Block 77	
0x00_C000 to 0x00_DFFF	8 KB	BPS[6] or BPS_SEC[6]	Block 76	
⋮	⋮	⋮	⋮	
0x00_2000 to 0x00_3FFF	8 KB	BPS[1] or BPS_SEC[1]	Block 71	
0x00_0000 to 0x00_1FFF	8 KB	BPS[0] or BPS_SEC[0]	Block 70	

50.11.2 Error Protection

Error protection detects the issuing of illegal FACI commands, illegal access, and flash sequencer malfunction. FACI command acceptance is disabled (command-locked state) in response to the detection of these errors. The flash memory cannot be programmed or erased while the flash sequencer is in the command-locked state. For release from the command-locked state, issue the Status Clear or Forced Stop command. The Status Clear command can only be used while the FRDY bit in the FSTATR register is 1. The Forced Stop command can be used regardless of the value of the FRDY bit. While the CMDLKIE bit in the FAEINT register is 1, a flash access error (FIFERR) interrupt is generated if the flash sequencer enters the command-locked state (the CMDLK bit in the FASTAT register is set to 1).

If the flash sequencer enters the command-locked state in response to a command other than the P/E suspend command during programming or erasure processing, the flash sequencer continues the processing for programming or erasure. In this state, the P/E suspend command cannot be used to suspend the processing for programming or erasure. If a command is issued in the command-locked state, the ILGLERR bit becomes 1 and the other bits retain the values set from previous error detection.

Table 50.26 shows the error protection types and status bit values after error detections.

Table 50.26 Error protection type (1 of 3)

Error type	Description	ILGCOMERR	FESETERR	SECERR	OTERR	ILGLERR	ERSERR	PRGERR	FLWEERR	CFAE	DFAE
FENTRYR setting error	The value set in FENTRYR is not 0x0000, 0x0001, or 0x0080	0	1	0	0	1	0	0	0	0	0
	The FENTRYR setting at suspension is different from that at resumption	0	1	0	0	1	0	0	0	0	0

Table 50.26 Error protection type (2 of 3)

Error type	Description	ILGCOMERR	FESETERR	SECERR	OTERR	ILGLERR	ERSERR	PRGERR	FLWEERR	CFAE	DFAE
Illegal command error	An undefined size is specified in the first cycle of the command. (not byte-write)	1	0	0	0	1	0	0	0	0	0
	An undefined code is written in the first access of the FACI command	1	0	0	0	1	0	0	0	0	0
	The value specified in the last access of the multiple-access FACI command is not 0xD0	1	0	0	0	1	0	0	0	0	0
	The value (N) specified in the second write access of the FACI command in the program or configuration set command is wrong	1	0	0	0	1	0	0	0	0	0
	Blank Check command is issued with inconsistent BCDIR, FSADDR, and FEADDR settings (see section 50.4.13. FEADDR : FACI Command End Address Register)	1	0	0	0	1	0	0	0	0	0/1 *1
	A multi block erase command is issued with inconsistent FSADDR and FEADDR settings. ● FSADDR > FEADDR ● FEADDR is set to reserved area.	1	0	0	0	1	0	0	0	0	0/1 *1
	An FACI command not acceptable in each mode is issued (see Table 50.16)	1	0	0	0	1	0	0	0	0	0
	An FACI command is issued when command acceptance conditions are not satisfied (see Table 50.17)	0/1	0/1	0/1	0/1	1	0/1	0/1	0/1	0/1	0/1
	A program or block erase command is issued against the area protected by the block protect setting (see section 50.11.1.3. Protection by Block Protect Setting)	1	0	0	0	1	0	0	0	0	0
	A program command is issued against the erase area in erase suspend	1	0	0	0	1	0	0	0	0	0
Erasure error	An error occurs during erasure	0	0	0	0	0	1	0	0	0	0
Programming error	An error occurs during programming	0	0	0	0	0	0	1	0	0	0
Code flash memory access violation	An FACI command is issued to the reserved portion of the user area in code flash P/E mode	0	0	0	0	1	0	0	0	1	0
	Configuration set command is issued to the reserved option-setting memory	0	0	0	0	1	0	0	0	1	0
	Configuration set command of non-secure access is issued to the secure region of TrustZone in the code flash	0	0	0	0	1	0	0	0	1	0
	Program or block erase command of non-secure access is issued to the secure region of user area.	0	0	0	0	1	0	0	0	1	0

Table 50.26 Error protection type (3 of 3)

Error type	Description	ILGCOMERR	FESETERR	SECERR	OTERR	ILGLERR	ERSERR	PRGERR	FLWEERR	CFAE	DFAE
Data flash memory access violation	A program or block erase command is issued to the reserved data area in data flash P/E mode	0	0	0	0	1	0	0	0	0	1
	A multi block erase command is issued to the reserved data area in data flash P/E mode. (FSADDR is set to reserved data area).	1	0	0	0	1	0	0	0	0	1
	Blank Check command is issued to reserved data area in data flash P/E mode. (FSADDR is set to reserved data area).	1	0	0	0	1	0	0	0	0	1
	A program, block erase, multi block erase, or blank check command of non-secure access is issued to the secure region of data area.	0	0	0	0	1	0	0	0	0	1
Security error	Configuration set command for the SAS.BTFLG bit setting is issued when the SAS.FSPR bit is 0 (see section 50.9.3.15. Configuration Set Command)	0	0	1	0	1	0	0	0	0	0
Others	An FACI command-issuing area is accessed in read mode	0	0	0	1	1	0	0	0	0	0
	An FACI command-issuing area is read in code flash P/E mode or data flash P/E mode	0	0	0	1	1	0	0	0	0	0
Flash write erase protection error	A flash memory write protection error is detected by the FWEPROR register setting*2 during command processing by the flash sequencer	0	0	0	0	0	0/1	0/1	1	0	0

Note 1. DFAE value depends on the FSADDR setting.
Note 2. For details on the FWEPROR register, see section 50.4.8. FWEPROR : Flash P/E Protect Register.

50.11.3 Start-Up Program Protection

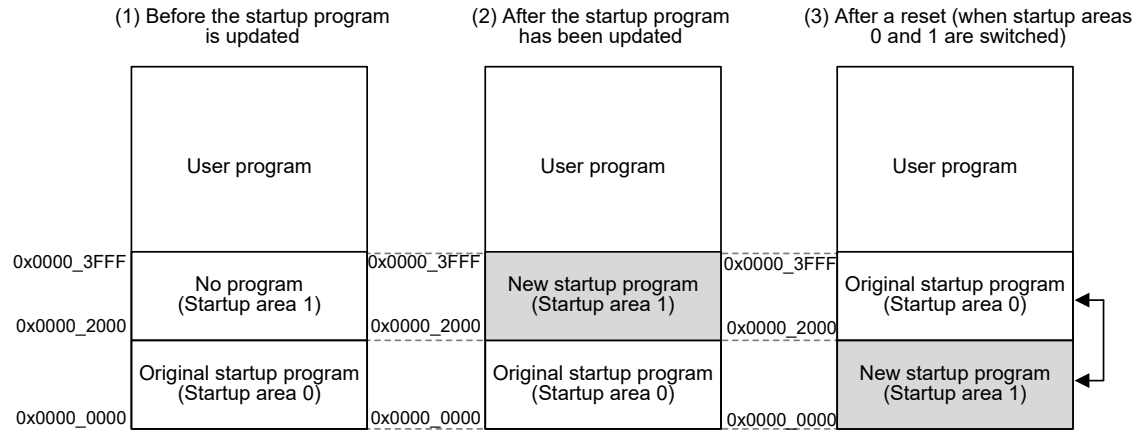
Protection of the startup program is for protection of the program to be started after a reset (the startup program). This function provides a way to safely update the startup program when rewriting is suspended during a reset.

The startup area is 8 Kbytes in size and is assigned to the user area in the code flash memory. This function uses the values of the SAS.BTFLG bit and the FSUACR.SAS[1:0] bits to change the area where the startup program is stored in block units (see Figure 50.26 to Figure 50.29).

In protection of the startup program, the state of the selection of the startup area can be fixed by the FSPR bit. However, the SAS.FSPR bit never be restored to 1 once the flag is set to 0. Exercise extra caution when handling the SAS.FSPR bit.

In addition, this protection cannot be used when dual mode is selected by the bank mode switching function (when the BANKMD[2:0] bits are 000b).

For details of SAS.FSPR bit and DUALSEL.BANKMD[2:0] bits, see section 6, Option-Setting Memory.



Note: The addresses are used for reading, programming, and erasure. Startup area 0 is erased when Block Erase command is issued for the address 0x00000000 with allocation shown under 3.

1. Before the startup program is updated
   When the SAS.BTFLG bit is 1 and the FSUACR.SAS[1:0] bits are 0xb, the address range from 0x00002000 to 0x00003FFF is selected as startup area 1 and the address range from 0x00000000 to 0x00001FFF is selected as startup area 0.
2. After the startup program has been updated
   A new startup program can be written to startup area 1. At this time, startup area 0 will still contain the previous startup program, so rewriting by starting up from startup area 0 remains possible if rewriting to the startup area 1 fails.
3. After a reset (when startup areas 0 and 1 are switched)
   When rewriting startup area 1 is successfully completed, switch the assignment of startup areas 0 and 1 by rewriting the startup area selection bit (the SAS.BTFLG bit) with Configuration set command. Afterwards, the program is started up from startup area 1 after a reset.

Figure 50.26 Concept of Protection of the Startup Program

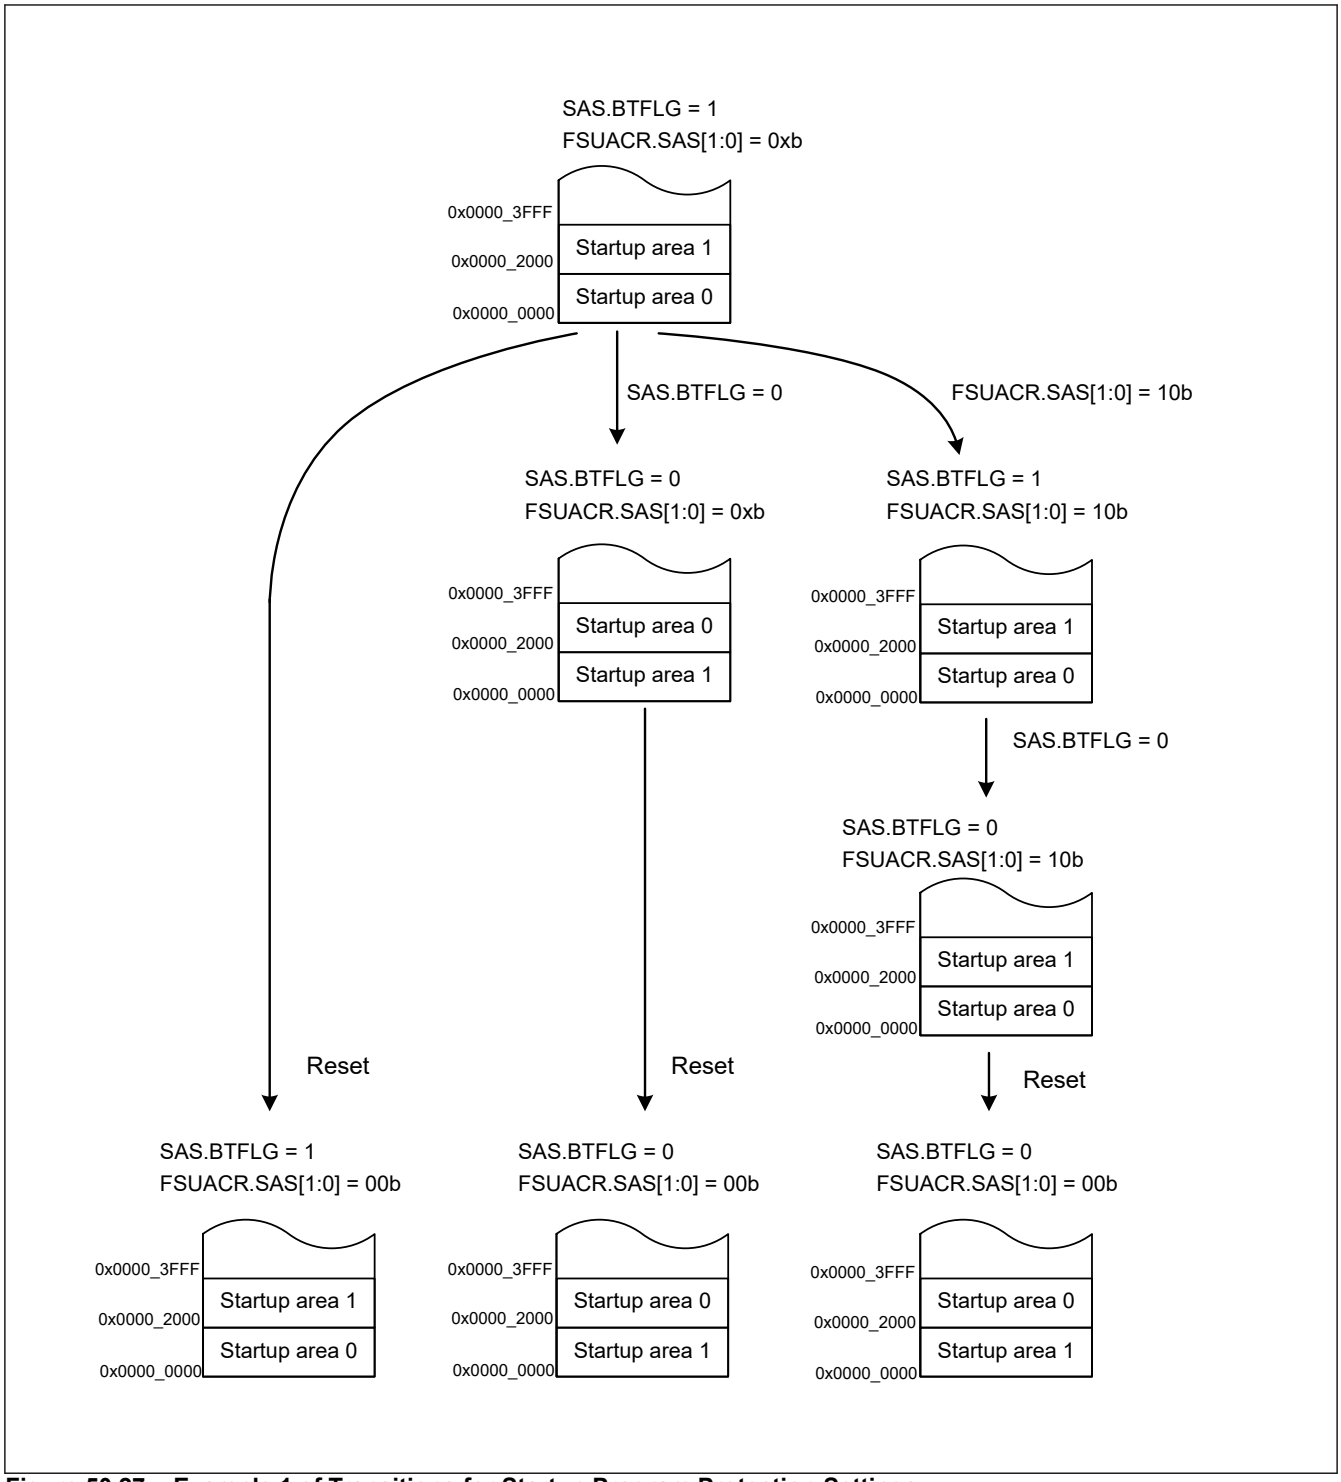


Figure 50.27 Example 1 of Transitions for Startup Program Protection Settings

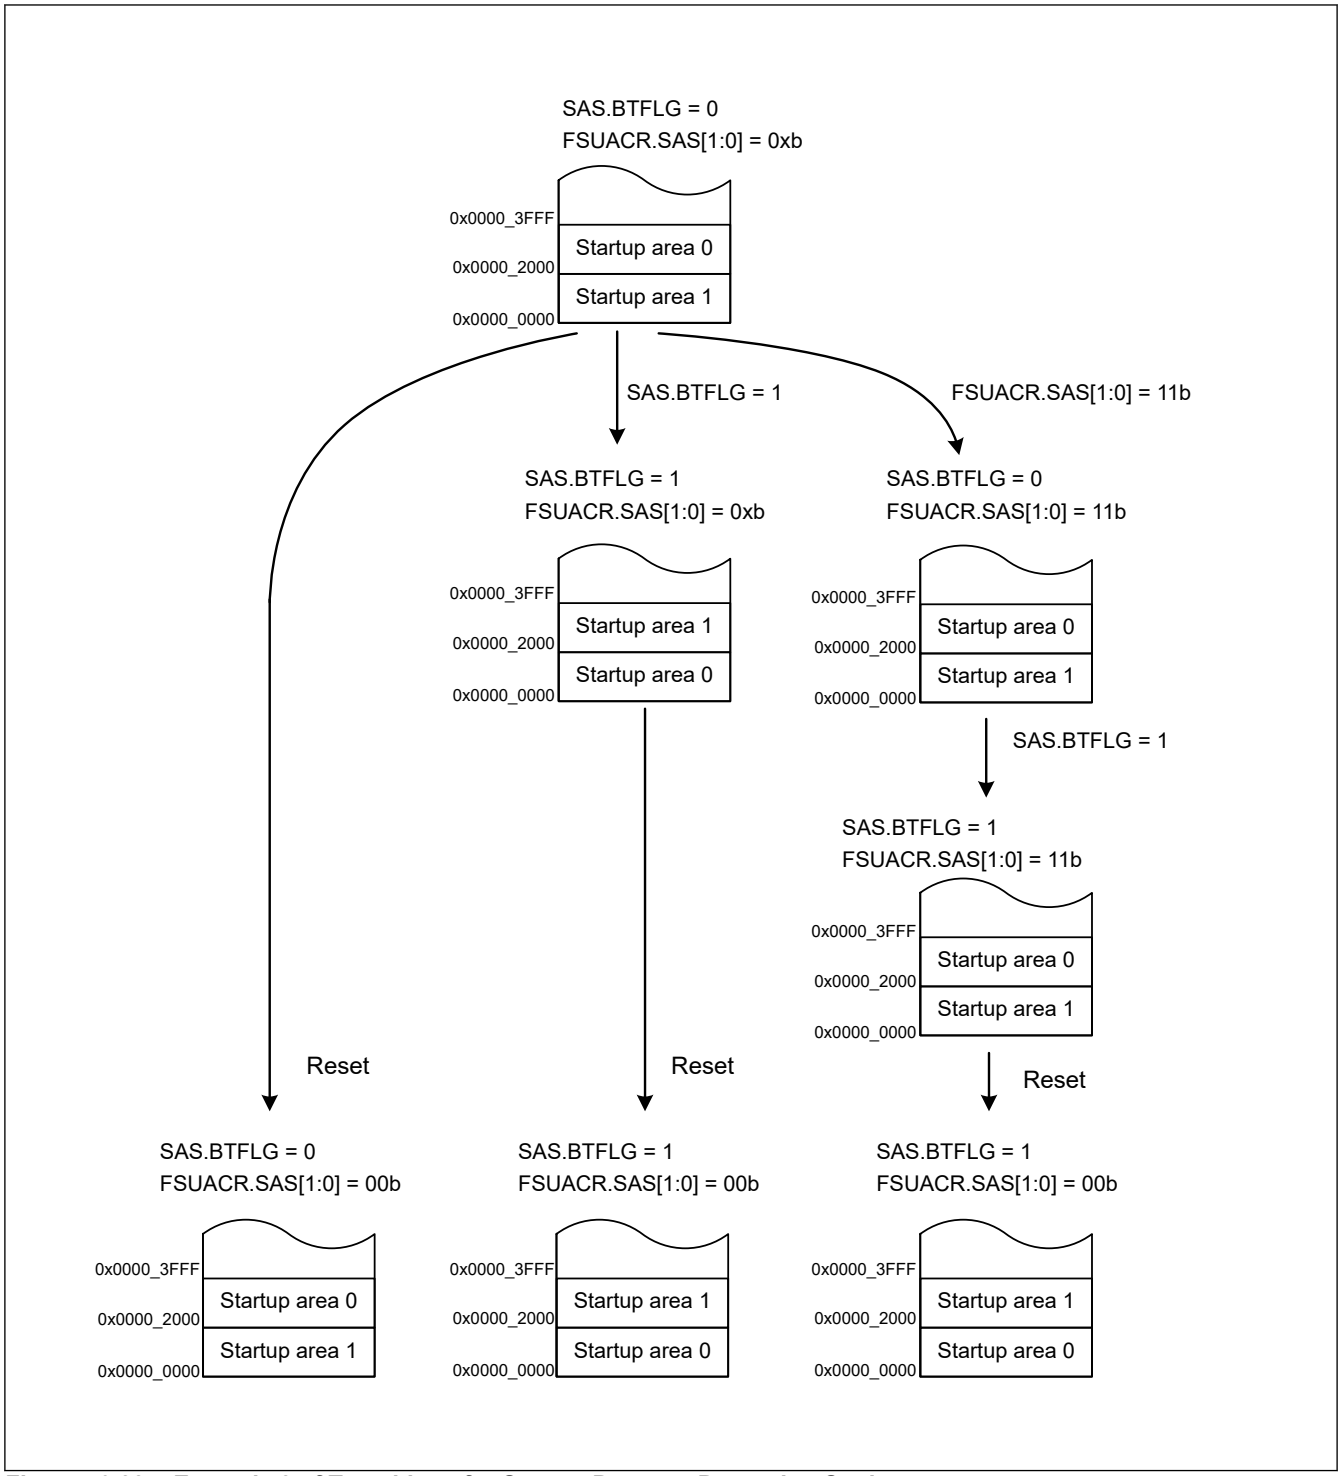

Figure 50.28 Example 2 of Transitions for Startup Program Protection Settings

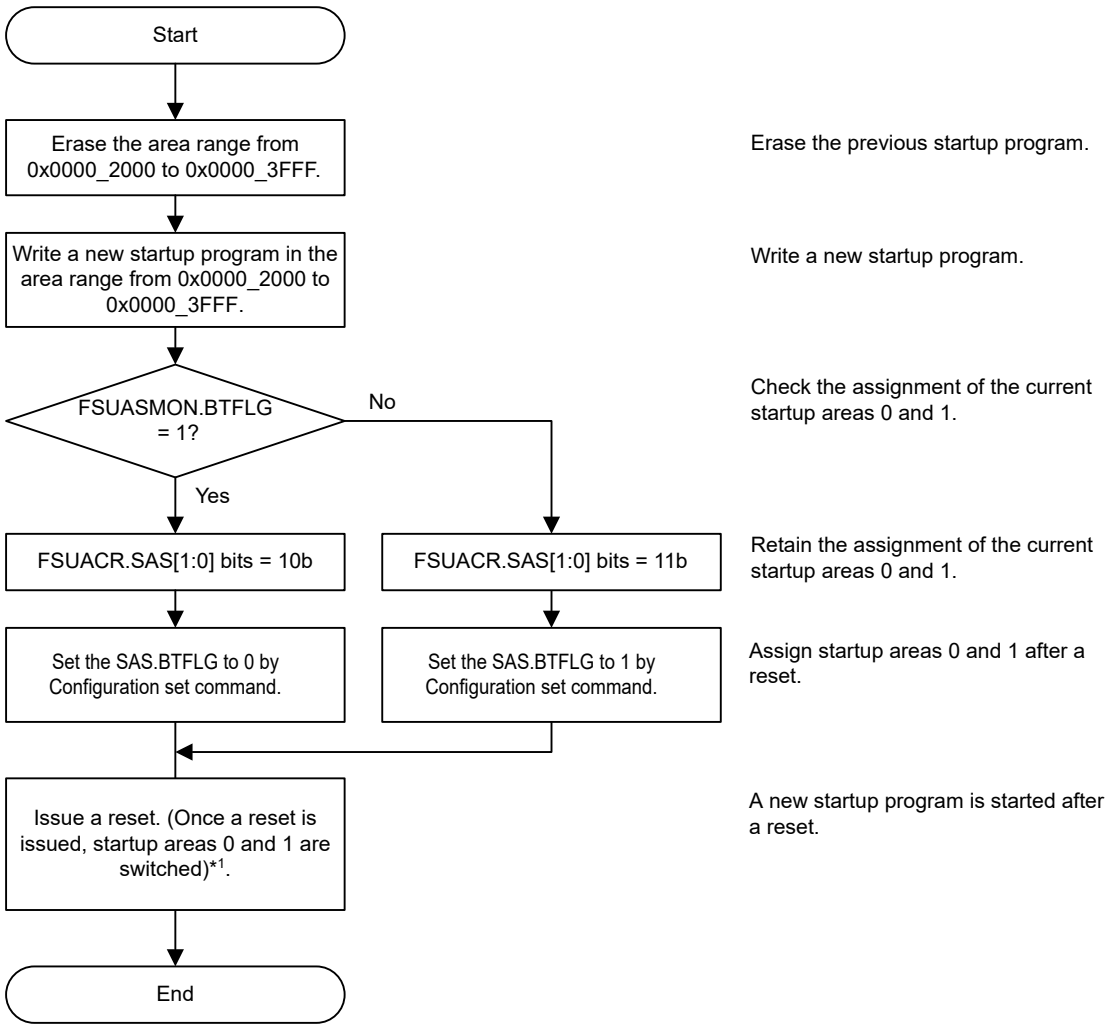

Note 1. For details, see Figure 50.27 and Figure 50.28.

Figure 50.29 Concept of Protection of the Startup Program

50.11.4 Dual Bank Function

This protection uses the functions of bank mode switching and startup bank selection to update a program while a user program is running and to provide a safe method of updating in cases where programming is suspended during a reset.

50.11.4.1 Switching Bank Modes

The bank mode switching function selects either linear mode in which the user area in the code flash memory is used as one area, or dual mode in which the user area is divided into two bank areas. Figure 50.30 shows an example of flow of switching bank modes. A reset after setting the DUALSEL.BANKMD[2:0] bits in the option setting memory determines the mode of the bank mode switching function. Selecting dual mode enables the startup bank selection function.

When dual mode is selected by bank mode switching function (the DUALSEL.BANKMD[2:0] bits are 000b), start-up program protection function cannot be used.

For details of DUALSEL.BANKMD[2:0] bits, see section 6, Option-Setting Memory.

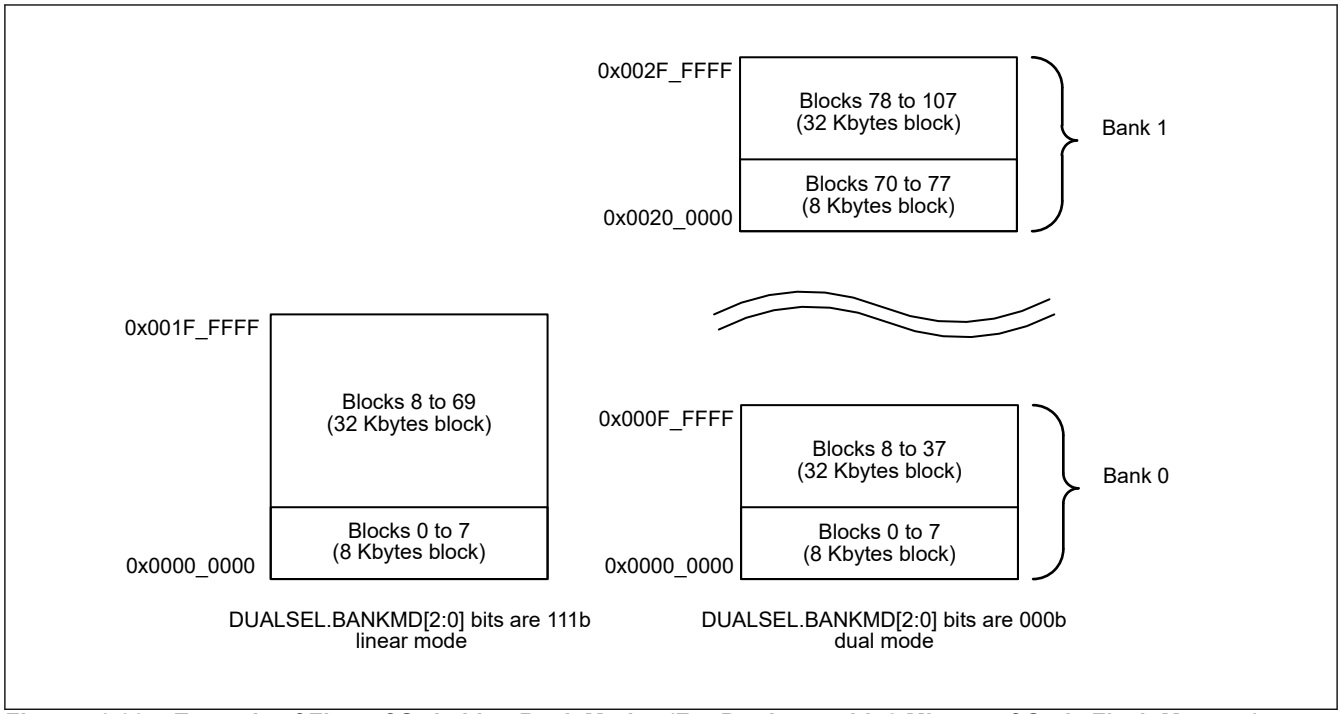

Figure 50.30 Example of Flow of Switching Bank Modes (For Products with 2 Mbytes of Code Flash Memory)

50.11.4.2 Selecting the Startup Bank

Startup bank selection provides a way to safely update the program by selecting a bank area to be started in dual mode (when the DUALSEL.BANKMD[2:0] bits are 000b) when programming is suspended during a reset. Figure 50.31 is a schematic view of startup bank selection and Table 50.27 shows an example of the flow of startup bank selection. A reset after setting the value of the BANKSEL.BANKSWP[2:0] bits in the option-setting memory changes the addresses of banks 0 and 1 and booting up a program proceeds from the updated area. When the address is switched by using startup bank selection, the programming/erasure target for the FACI commands is also switched. This function is invalid in linear mode.

For details of DUALSEL.BANKMD[2:0] bits and BANKSEL.BANKSWP[2:0] bits, see section 6, Option-Setting Memory.

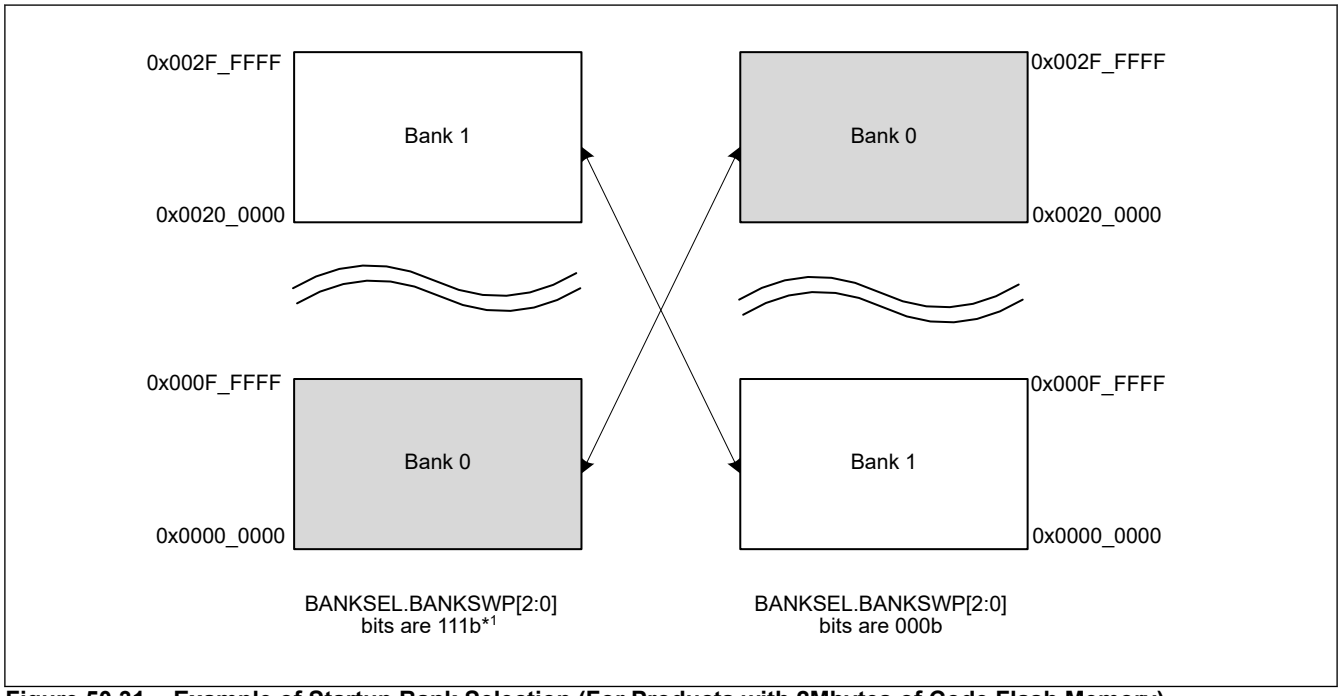

Figure 50.31 Example of Startup Bank Selection (For Products with 2Mbytes of Code Flash Memory)

Table 50.27 Example of Startup Bank Selection Flow (For Products with 2 Mbytes of Code Flash Memory)

No.	Step Name	Description
1	Erase block	Erase blocks to be programed in the address range from 0x0020_0000 to 0x002F_FFFF
2	Program a new software	Program a new software in the address range from 0x0020_0000 to 0x002F_FFFF
3	Read the value	Read the value of the BANKSEL.BANKSWP[2:0] bits.
4	Write an inverted value	Write an inverted value in the BANKSEL.BANKSWP[2:0] bits*1.
5	Issue a reset	Issue a reset (A reset switches the banks.)

Note 1. Set the inverse of the read value of the BANKSEL.BANKSWP[2:0] bits (000b or 111b).

50.11.5 Block Swap Function

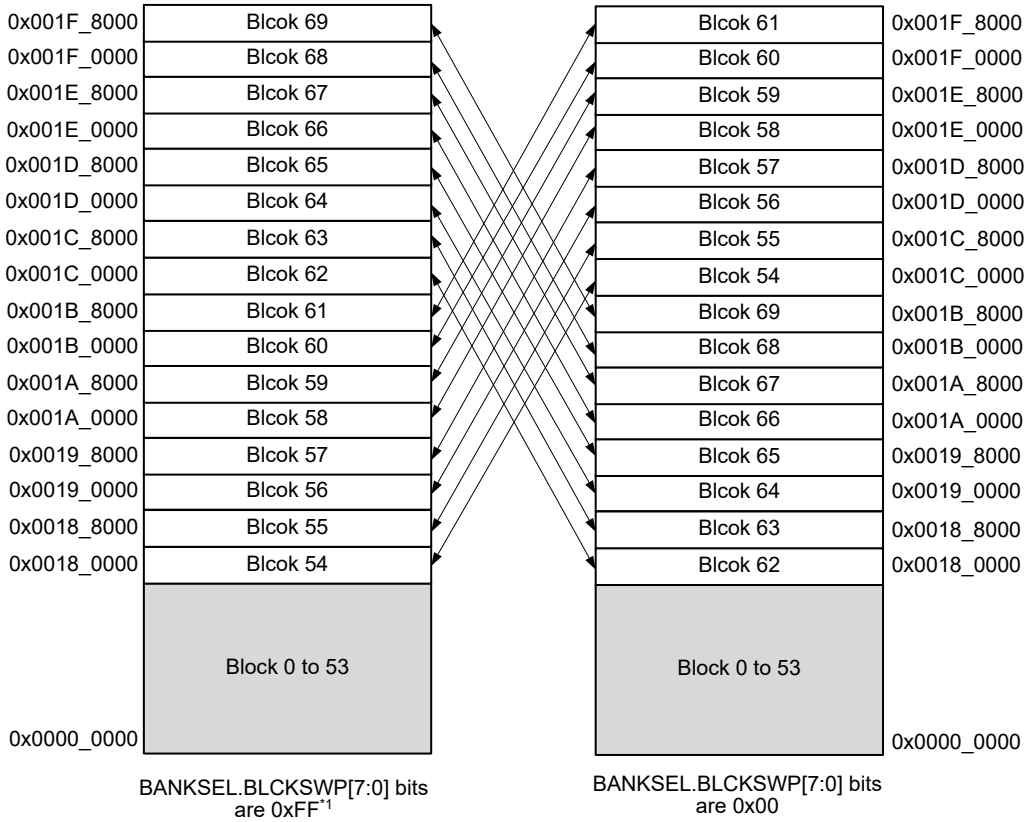
This protection uses the functions of block swap selection to update a program while a user program is running and to provide a safe method of updating in cases where programming is suspended during a reset.

50.11.5.1 Selecting the Block Swap

Block swap selection provides a way to safely update the program when programming is suspended during a reset. Figure 50.32 is a schematic view of block swap selection and Figure 50.33 shows an example of the flow of block swap selection. A reset after setting the value of the BANKSEL.BLCKSWP bit in the option-setting memory changes the addresses of block A and B. When the address is switched, the Programming/erasure target for the FACI commands is also switched.

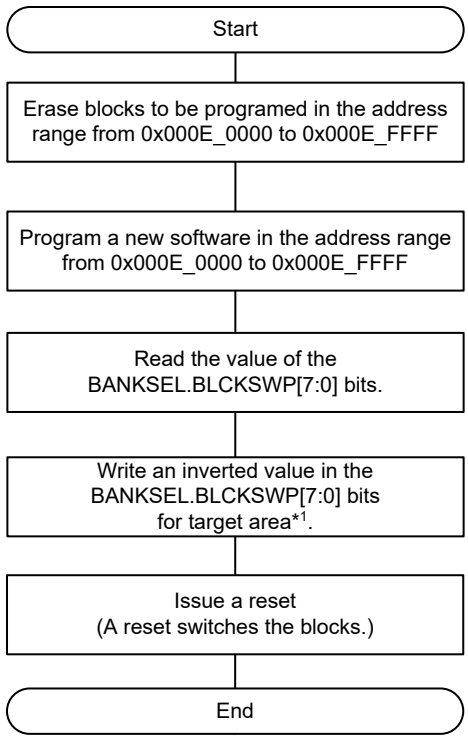
In addition, this protection cannot be used when dual mode is selected by the bank mode switching function (when the DUALSEL.BANKMD[2:0] bits are 000b).

For details of DUALSEL.BANKMD[2:0] bits and BANKSEL.BLCKSWP bit, see section 6, Option-Setting Memory.



Note 1. For products without setting of the option-setting memory, the BANKSEL.BLCKSWP[7:0] bits are 1111b

Figure 50.32 Example of Block Swap Selection (For Products with 2 Mbytes of Code Flash Memory)



Note 1. See Table 6.2 for the correspondence between the target region and the BANKSEL.BLCKSWP[7:0] bit.

Figure 50.33 Example of Block Swap Selection Flow (For Products with 2 Mbytes of Code Flash Memory)

50.12 Security Function

The flash sequencer supports the following security functions:

- Security flag for startup area
- Permanent block protect setting
- Flash memory protection for TrustZone

50.12.1 Security Flag for Startup Area Select

The security flag (SAS.FSPR) for the startup area is located in the option-setting memory.

When the SAS.FSPR bit is 0, issuing the configuration set command to change the SAS.BTFLG bit causes the flash sequencer to be in the command-locked state. Also, when the SAS.FSPR bit is 0, it is invalid to write to the Startup Area Select bits SAS[1:0] in the FSUACR register. The SAS.FSPR bit enables protection.

50.12.2 Permanent Block Protect Setting

The permanent block protect setting is the clear protection for the block protection setting. User area cannot be permanently updated by the FACI command when the permanent block protect setting is enabled. See section 50.11.1.3. Protection by Block Protect Setting for more details.

The block protect setting and the permanent block protect setting have the write/clear protection against the configuration set command. The flash sequencer does not detect an error when the configuration set command is issued to the write/clear protected settings.

Figure 50.34 and Table 50.28 show the write/clear protection against the block protect setting (BPS[n]) and the permanent protect setting (PBPS[n]). Figure 50.35 and Table 50.29 show the write/clear protection against the block protect setting for secure (BPS_SEC[n]) and permanent protect setting for secure (PBPS_SEC[n]).

Effective permanent block protect setting (PBPS or PBPS_SEC) depends on block protect select (BPS_SEL). For details of permanent block protect setting (PBPS or PBPS_SEC) and block protect select (BPS_SEL), see section 6, Option-Setting Memory.

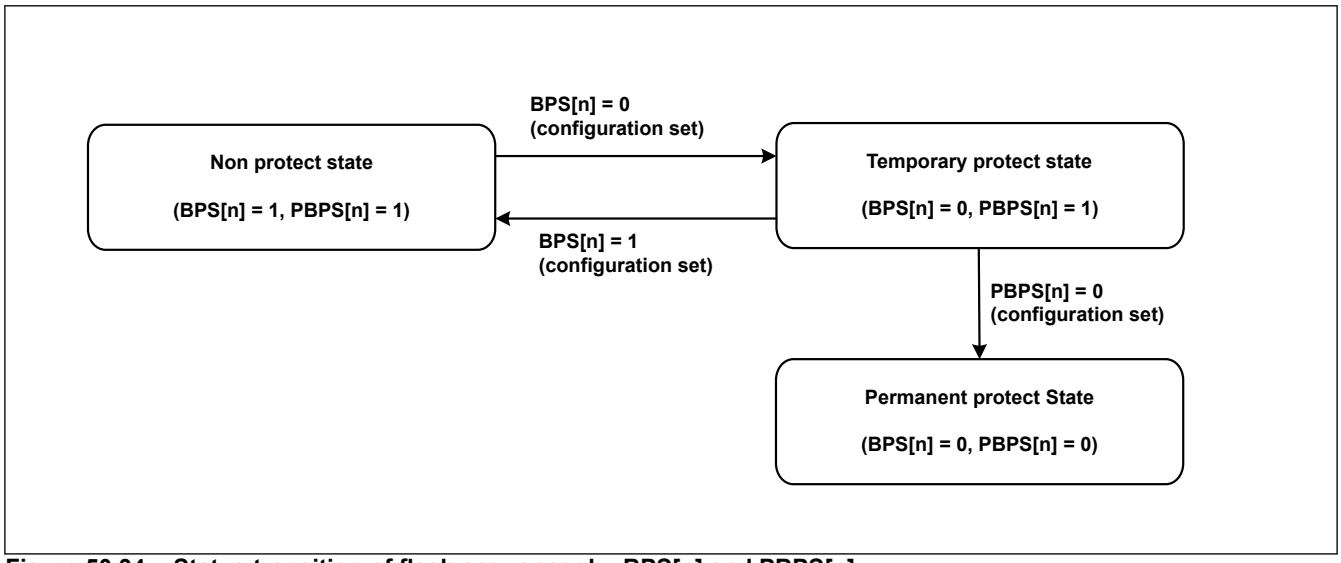


Figure 50.34 Status transition of flash sequencer by BPS[n] and PBPS[n]

Table 50.28 Write/clear protection of BPS[n] and PBPS[n]

Current state		Updatable state by configuration set command			
BPS[n]	PBPS[n]	BPS[n] = 1	BPS[n] = 0	PBPS[n] = 1	PBPS[n] = 0
1	1	✓	✓	✓	X
1	0	—	—	—	—
0	1	✓	✓	✓	✓
0	0	X	✓	X	✓

Note:
- ✓ indicates updatable by configuration set command.
- X indicates not updatable by configuration set command (error does not occur).
- — indicates not reaching to this state.

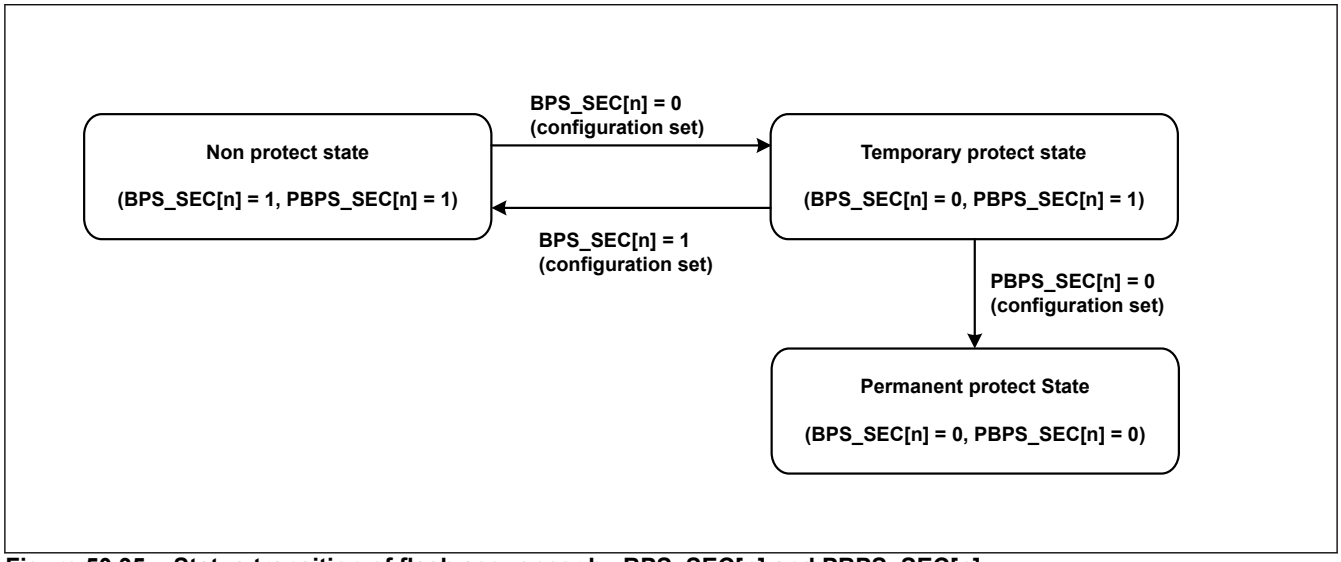

Figure 50.35 Status transition of flash sequencer by BPS_SEC[n] and PBPS_SEC[n]

Table 50.29 Write/clear protection of BPS_SEC[n] and PBPS_SEC[n]

Current state		Updatable state by configuration set command			
BPS_SEC[n]	PBPS_SEC[n]	BPS_SEC[n] = 1	BPS_SEC[n] = 0	PBPS_SEC[n] = 1	PBPS_SEC[n] = 0
1	1	✓	✓	✓	X
1	0	—	—	—	—
0	1	✓	✓	✓	✓
0	0	X	✓	X	✓

Note:
- ✓ indicates updatable by configuration set command.
- X indicates not updatable by configuration set command (error does not occur).
- — indicates not reaching to this state.

50.12.3 Flash Memory Protection for TrustZone

Information in this section focuses on the flash sequencer operation.

The flash memory provides the following types of protect function against non-secure access:

- Protection for flash memory area (P/E)
- Protection for flash memory area (read)
- Protection for registers
- Protection during FACI command operation
- Code flash P/E mode entry protection

50.12.3.1 Protection for Flash Memory Area (P/E)

This function protects the secure region of the code flash and data flash from FACI commands of non-secure access. The condition of protection depends on the FACI command, the access attribution, and the memory boundary setting.

For details of secure region, see section 52, Security Features .

See Table 50.30 for information on protection of the flash memory area (P/E).

Table 50.30 Protection for the flash memory area (P/E)

FACI command	Target area		Issuing of FACI command by non-secure access	Issuing of FACI command by secure access
Program Block erase	Code flash memory	User area (non-secure area)	✓	✓
		User area (secure area)	X	✓
	Data flash memory	Data area (non-secure area)	✓	✓
		Data area (secure area)	X	✓
Multi block erase Blank check	Data flash memory	Data area (non-secure area)	✓	✓
		Data area (secure area)	X	✓
Configuration set	Code flash memory	option-setting memory (non-secure area)	✓	✓
		option-setting memory (secure area)	X	✓

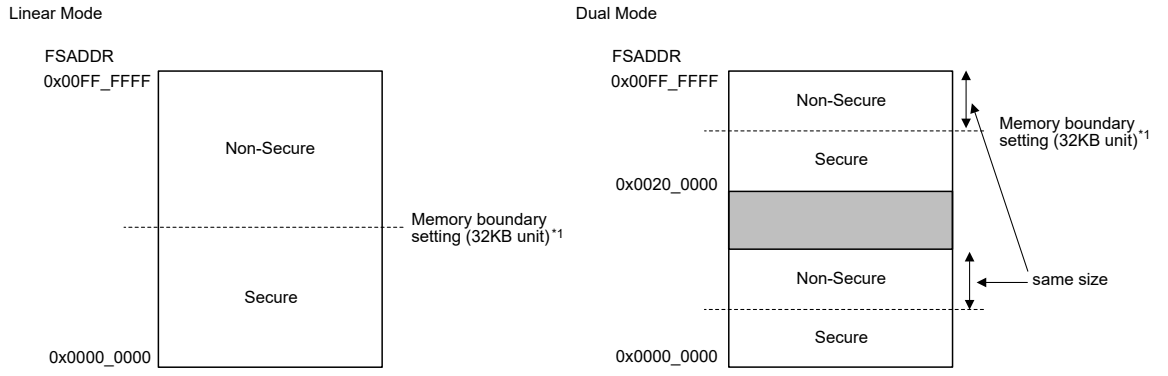
Note:
- ✓ indicates FACI command operation is not prohibited.
- X indicates FACI command operation is prohibited. Error occurs when the area is selected, and the FACI command is executed.

When the target area of FACI command is the user area of code flash, the flash sequencer compares the FSADDR register setting with the memory boundary setting of the code flash and determines whether the target area is in the secure region.

In linear mode, the memory boundary can be set to 0x0000_0000 to 0x00FF_8000 in 32 KB unit.

In dual mode, the memory boundary can be set to 0x0000_0000 to 0x0020_0000 in 32 KB unit. When the memory boundary is set to 0x0020_0000 or greater in the dual mode, the entire user area is defined as the secure region.

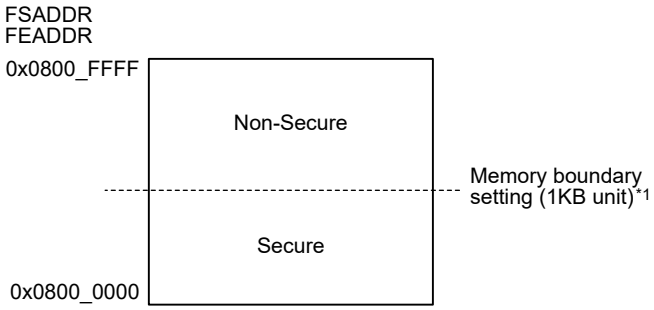
Figure 50.36 shows details of the non-secure/secure attribute of user area in the code flash.



Note 1. Comparing FSADDR with memory boundary setting of user area and judges whether the target area is in secure area.

Figure 50.36 Secure/non-secure region in user area

When the target area of the issuing FACI command is the data area of data flash, the flash sequencer compares the FSADDR/FEADDR register setting with the memory boundary setting of the data flash and determines whether the target area is in secure region. The memory boundary can be set to 0x0800_0000 to 0x0800_FC00 in 1 KB unit. Figure 50.37 shows details of the non-secure/secure attribute of data area in the data flash.



Note 1. Comparing FSADDR/FEADDR with memory boundary setting of data area and judges whether the target area is in secure area.

Figure 50.37 Secure/non-secure region in data area

See Figure 50.38 for details of non-secure/secure region of option-setting memory. The flash sequencer judges that target area is secure region from the FSADDR register setting.

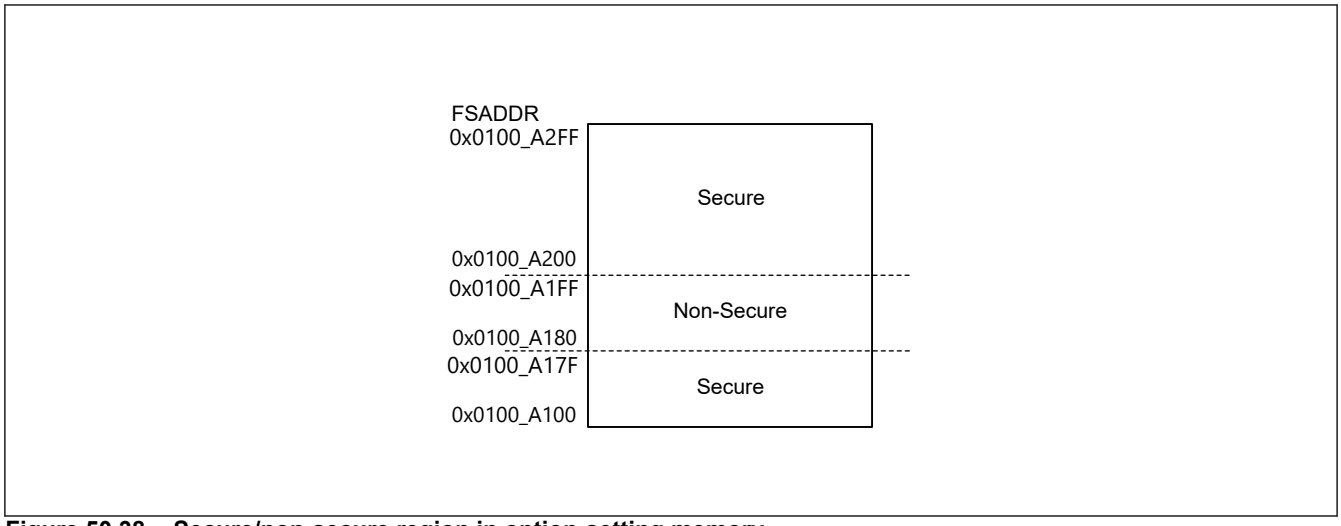


Figure 50.38 Secure/non-secure region in option-setting memory

50.12.3.2 Protection for Flash Memory Area (Read)

This function protects the secure region of code flash and data flash from non-secure bus access.

For details of secure region, see section 52, Security Features .

50.12.3.3 Protection for Register

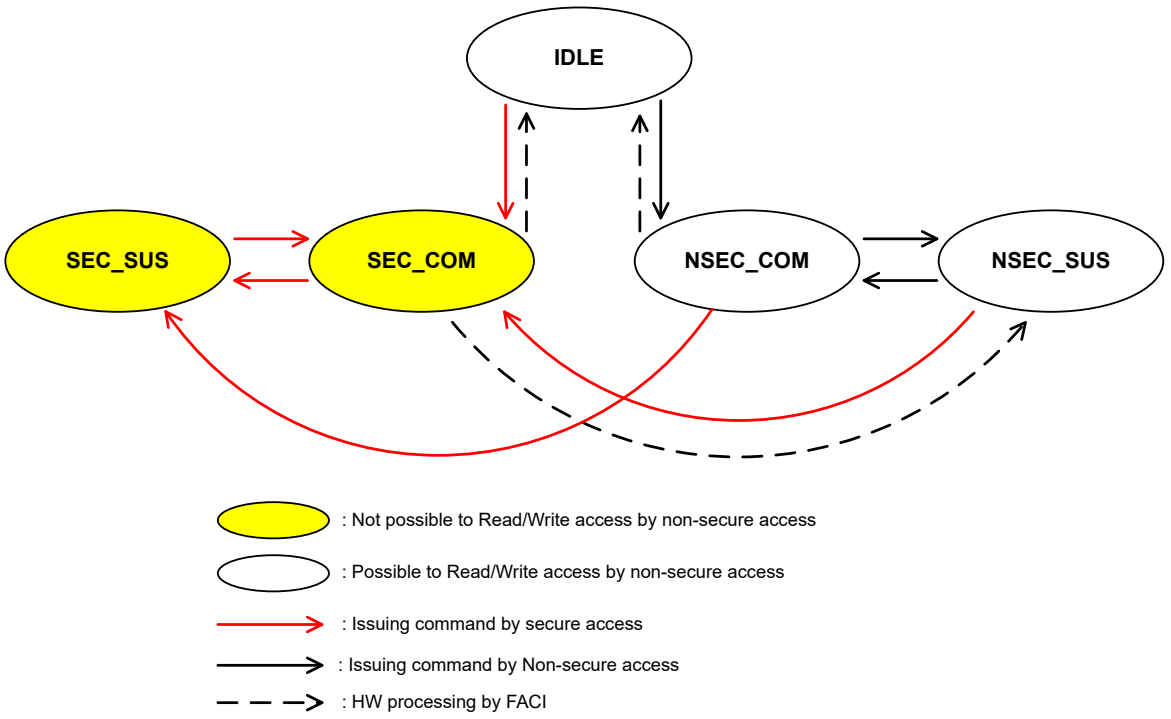
The flash sequencer registers have write-access protection against non-secure access. Table 50.31 shows details of the protected registers of the flash sequencer.

Table 50.31 Protected registers of the flash sequencer for TrustZone

Protection target register	Security attribute setting	Notes
FCKMHZ	Security attribution register setting (FSAR.FCKMHZSA)	See section 50.4.4. FSAR : Flash Security Attribution Register
FMEPROT	Always secure	See section 50.4.14. FMEPROT : Flash P/E Mode Entry Protection Register
FBPROT1	Always secure	See section 50.4.16. FBPROT1 : Flash Block Protection for Secure Register
FSUACR	Always secure	See section 50.4.27. FSUACR : Flash Startup Area Control Register
FACI command-issuing area and all registers of FACI (Base address is FACI) and FWEPROR register	During FACI command processing by secure access	See section 50.12.3.4. Protection during FACI Command Operation

50.12.3.4 Protection during FACI Command Operation

This function protects read/write access to the FACI command-issuing area, including all registers of FACI (Base address is FACI) and FWEPROR register by the non-secure access during the FACI command processing of the secure access. The protect condition includes the suspending period of the program, block erase, or multi block erase command by the P/E suspend command of the secure access. See Figure 50.39 and Table 50.32 for details of the protection during the FACI command operation.



Note: IDLE: State of not executing FACI command
SEC_COM: State of executing FACI command by secure access
SEC_SUS: State of "P/E Suspend" by secure access
NSEC_COM: State of executing FACI command by non-secure access
NSEC_SUS: State of P/E Suspend by non-secure access

Figure 50.39 State of protection during FACI command operation

Table 50.32 Protection during FACI command operation

	Flash sequencer is not operating	Program, Block erase, Multi block erase, Blank check, or Configuration set command processing		Command lock state		Forced stop command processing		While suspend Program, Block erase, or Multi block erase command		Program command processing while suspend Block erase or Multi block erase command by secure access		Program command processing while suspend Block erase or Multi block erase command by non-secure access		P/E resume command processing while suspend Program, Block erase, or Multi block erase command by secure access		P/E Resume command processing while suspend Program, Block erase, or Multi block erase command by non-secure access	
FACI command attribute	—	S	NS	S	NS	S	NS	S	NS	S	NS *1	S	NS	S	NS *1	S	NS
FRDY bit	1	0	0	1	1	0	0	1	1	0	0	0	0	1	1	0	0
PRGSPD or ERSSPD bit	0	0	0	0	0	0	0	1	1	1	1	1	1	0	0	0	0
CMDLK bit	0	0	0	1	1	1/0	1/0	1/0	1/0	0	0	0	0	0	0	0	0
Non-secure access	✓	X	✓	✓	✓	X	✓	X	✓	X	✓	X	✓	X	✓	X	✓

Note:
- S indicates the FACI command by the secure access.
- NS indicates the FACI command by the non-secure access.
- ✓ indicates read/write access is possible by the non-secure access.
- X indicates read/write access is not possible by the non-secure access. Write data is ignored and read data is always 0.

Note 1. The FACI command issued by the non-secure access is not allowed.

Code flash programming/erasure can be protected by the FMEPROT register of secure function. Therefore, it does not assume that secure function issues P/E suspend command during code flash programming/erasure of non-secure function.

Data flash programming/erasure of non-secure can be suspended by secure function. If secure function issues P/E suspend command during data flash programming/erasure of non-secure function, secure function should issue P/E resume command. When secure function issues P/E resume command, secure function should notify non-secure function that data flash programming/erasure is complete and return to non-secure function. See Figure 50.40 and Figure 50.41 in example of issuing P/E suspend of secure function during programming/erasure of non-secure function.

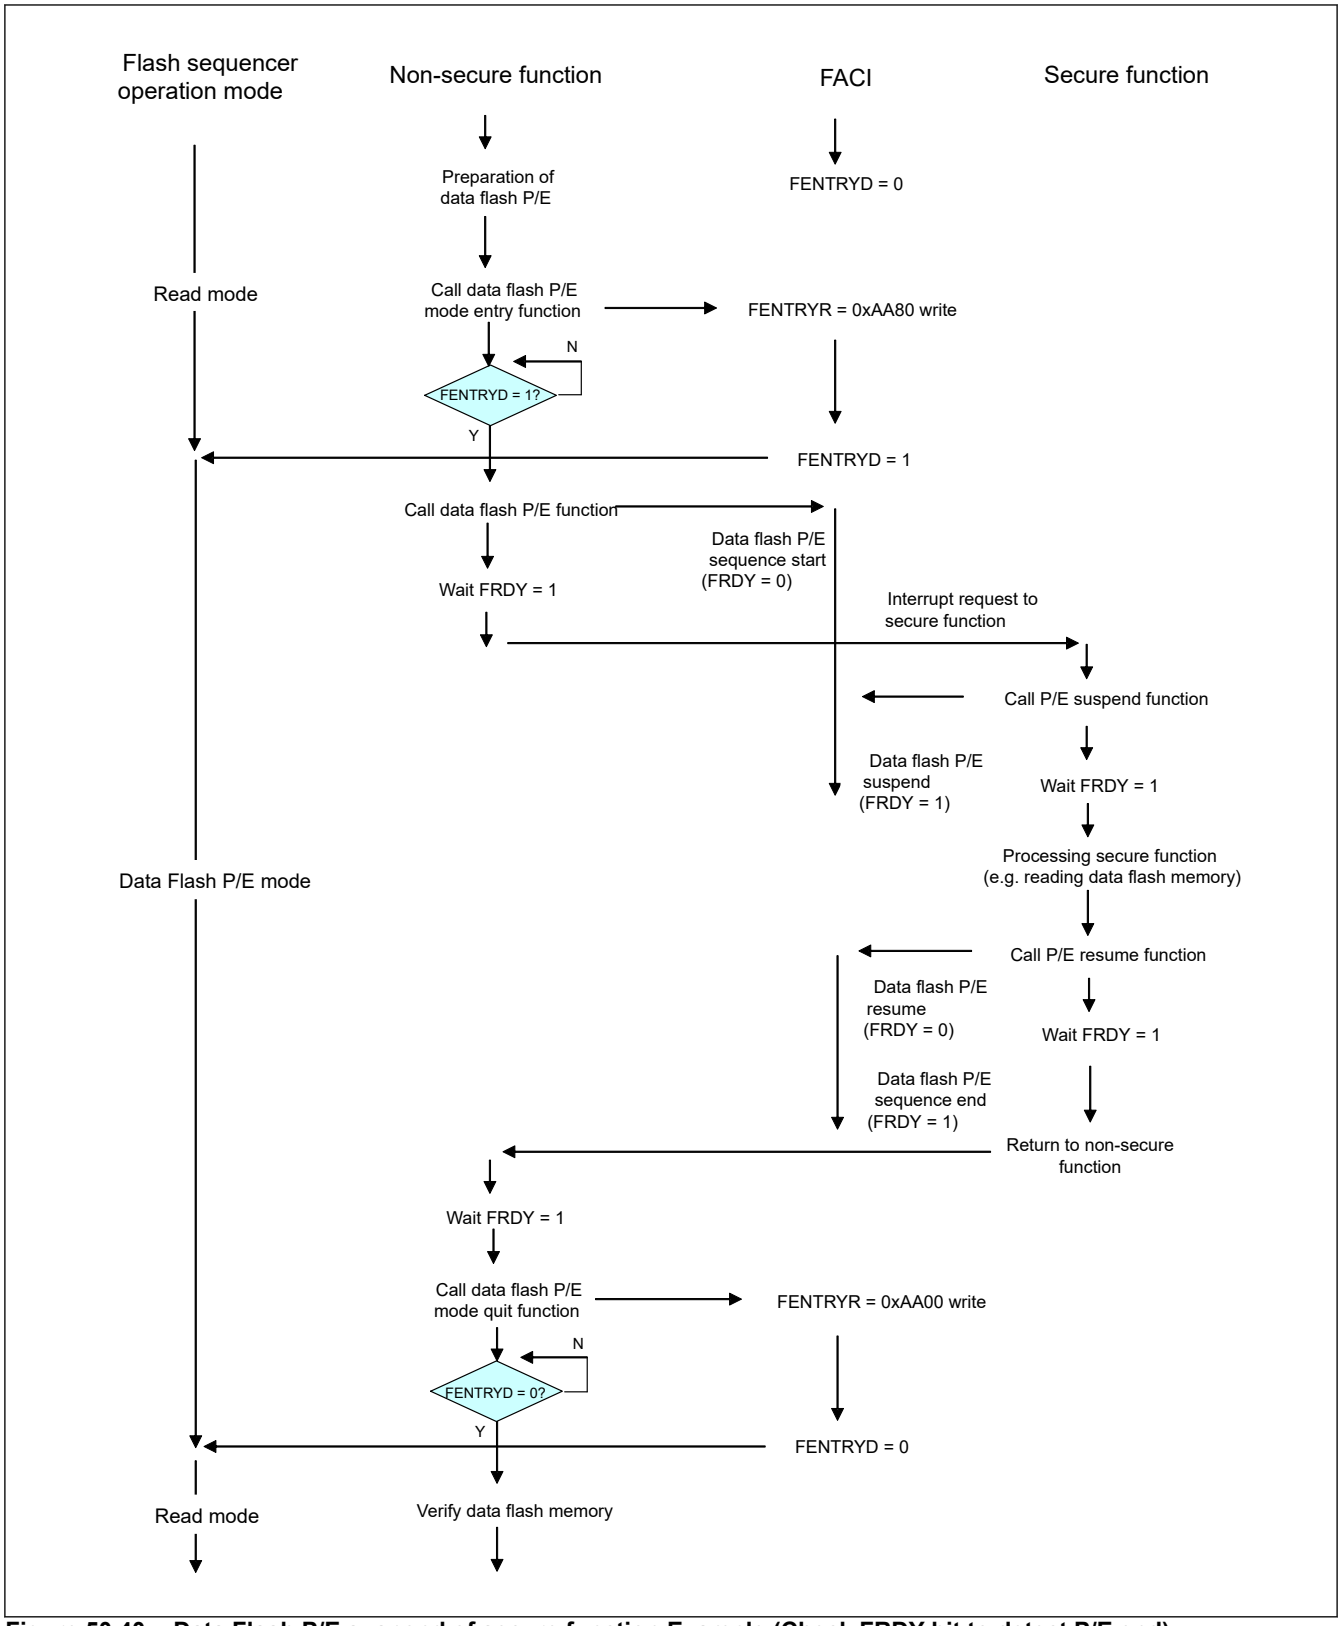


Figure 50.40 Data Flash P/E suspend of secure function Example (Check FRDY bit to detect P/E end)

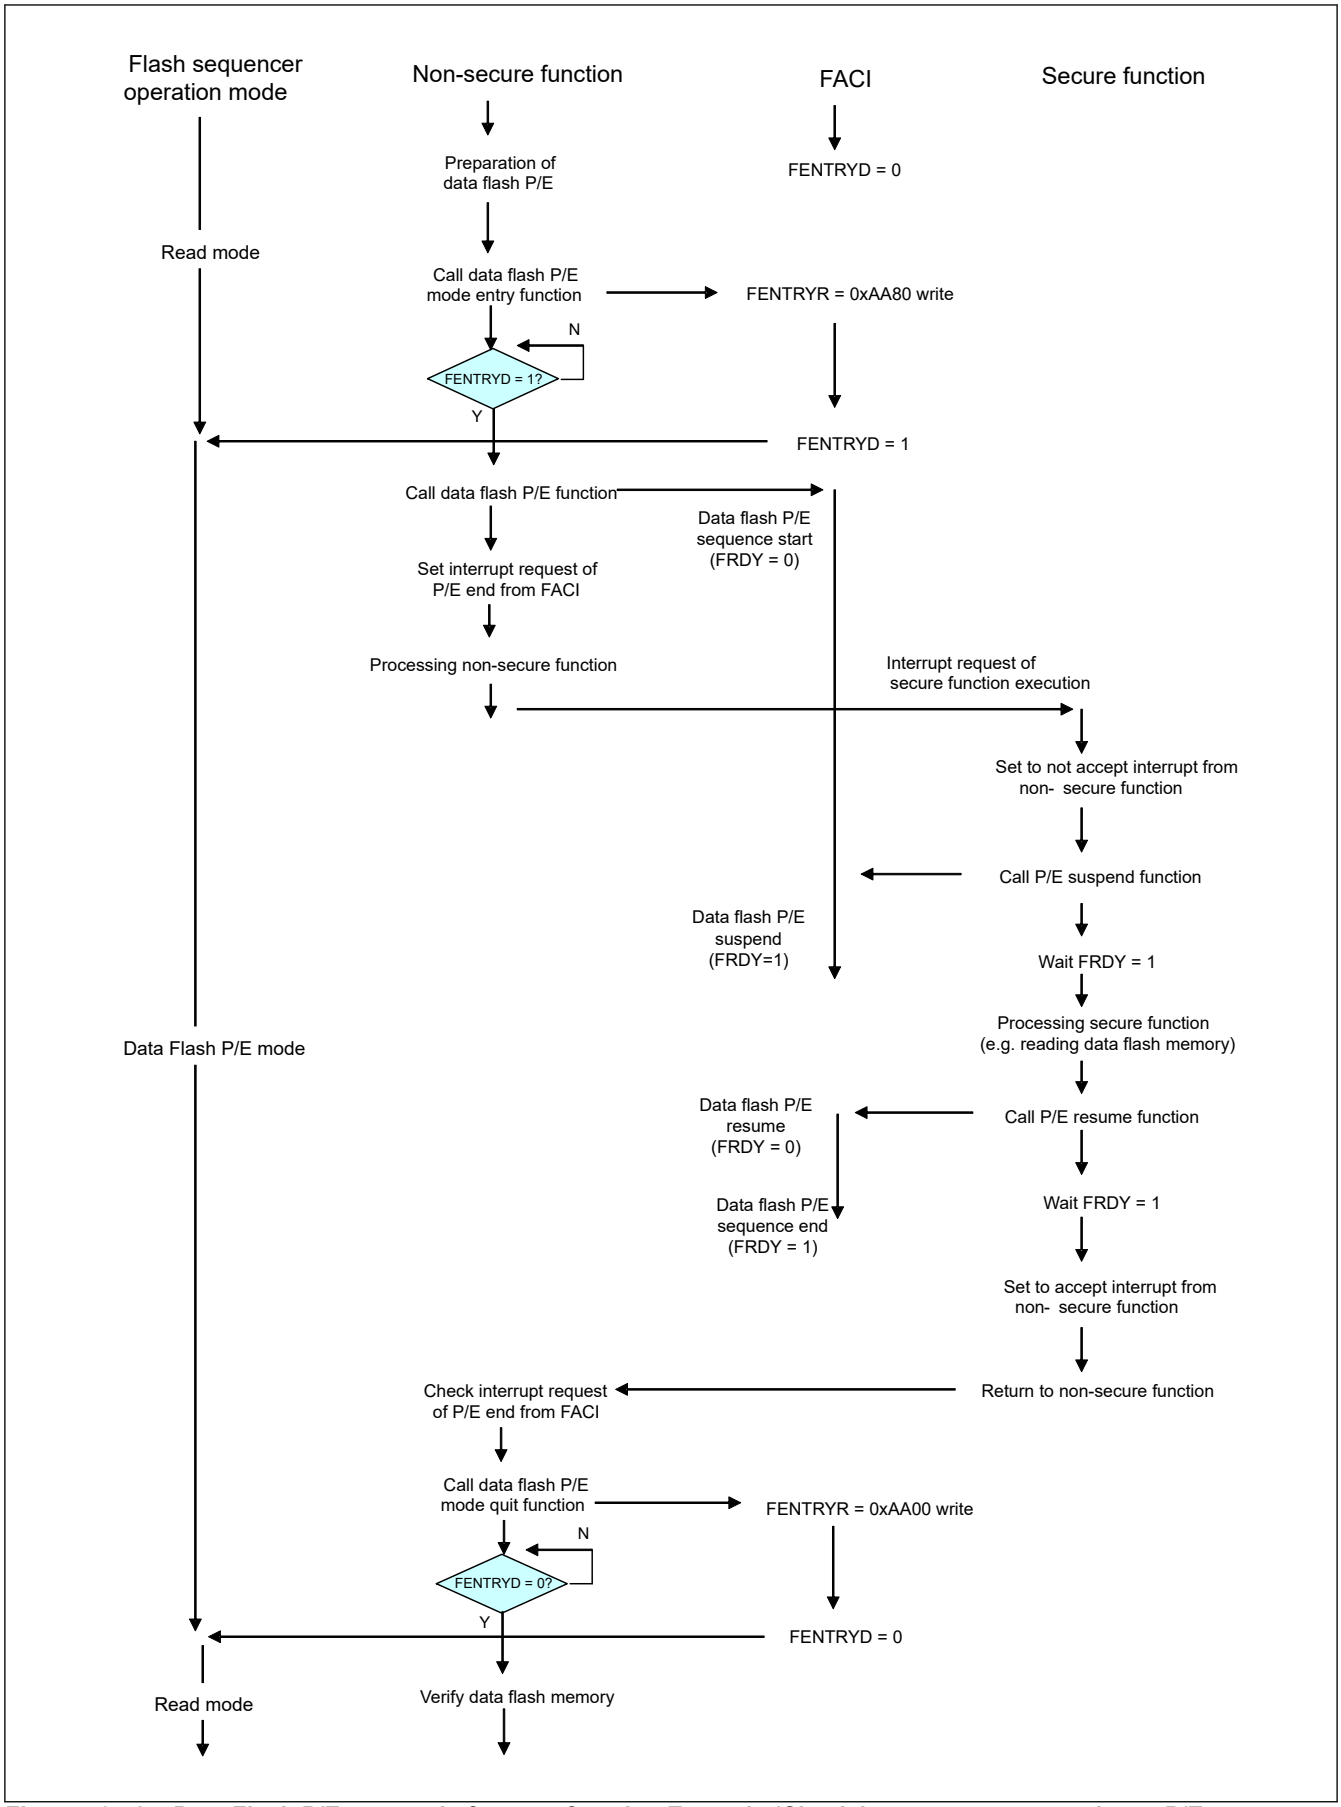

Figure 50.41 Data Flash P/E suspend of secure function Example (Check interrupt request to detect P/E end)

50.12.3.5 Code Flash P/E Mode Entry Protection

The flash sequencer has protection function of code flash P/E by the FMEPROT register for the secure developer. Secure function can prevent disturbance of reading code flash memory by this protection function. See section 50.4.14. FMEPROT : Flash P/E Mode Entry Protection Register.

For applications that do not require non-secure region programming/erasure other than from secure function, it is recommended to always disable non-secure function of code flash programming/erasure by enabling the protection function of FMEPROT register.

For details, see Figure 50.42 of the code flash P/E sequence example by non-secure function.

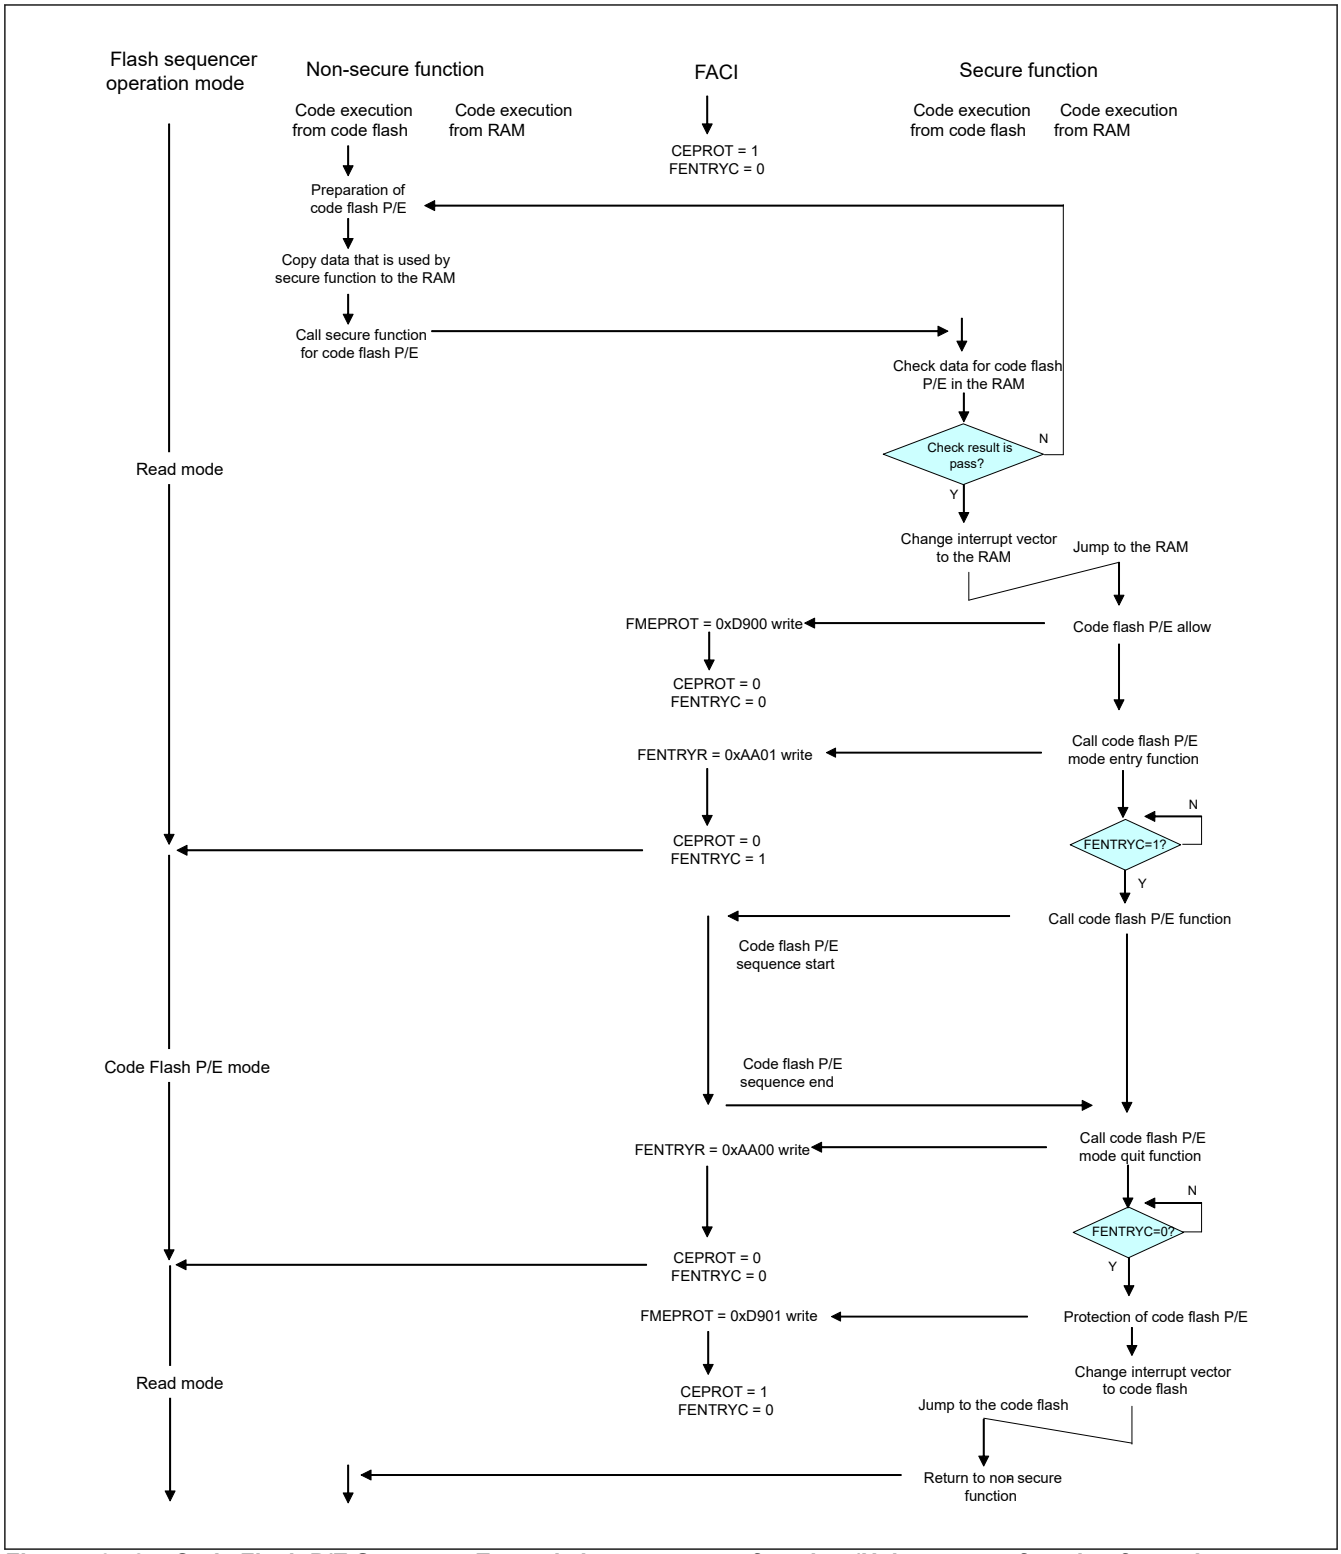

Figure 50.42 Code Flash P/E Sequence Example by non-secure function (Using secure function for code flash P/E)

50.13 Boot Mode

There are two serial programming modes; the boot mode (for the SCI interface) with SCI9 and the boot mode (for the USB interface) with USBFS. Table 50.33 lists the I/O pins used in boot mode. Table 50.34 lists the available communication interface used in the boot mode.

Table 50.33 I/O Pins Used in Boot Mode

Pin Name	I/O	Mode to be Used	Use
MD	Input	Boot mode (for the SCI interface) Boot mode (for the USB interface)	Selection of operating mode
P110/RXD9	Input	Boot mode (for the SCI interface)	For host communication (to receive data through SCI)
P109/TXD9	Output		For host communication (to transmit data through SCI)
USB_DP, USB_DM	I/O	Boot mode (for the USB interface)	Data input/output of USB
USB_VBUS	Input		Detection of connection and disconnection of USB cables

Table 50.34 Available Communication Interface Used in Boot Mode

Main clock oscillator or external clock is connected	Yes	No	No
Sub clockoscillator is connected*1	Yes or No	Yes	No
Available interface	SCI or USB	SCI or USB	SCI
Tool connection time*2	Up to 1 second	Up to 2 seconds	Up to 3 seconds

Note 1. The drive capability of the sub clock oscillator is set to standard by SOMCR.SODRV bit. Note that if you use the crystal corresponding the low drive capability on your board, the crystal may not oscillate in the boot mode.
Note 2. See the boot firmware manual for the detail connection time.

50.13.1 Boot Mode (for the SCI Interface)

In boot mode (for the SCI interface), the host sends control commands and data for programming, and the flash memory is programmed or erased accordingly. An on-chip SCI handles transfer between the host and this MCU in asynchronous mode. Tools for transmission of control commands and the data for programming must be prepared in the host.

When this MCU is activated in boot mode (for the SCI interface), the program on the dedicated area the MCU is executed. The boot program automatically adjusts the bit rate of the SCI and controls programming/erasure by receiving control commands from the host.

Figure 50.43 shows the system configuration for operations in boot mode (for the SCI interface).

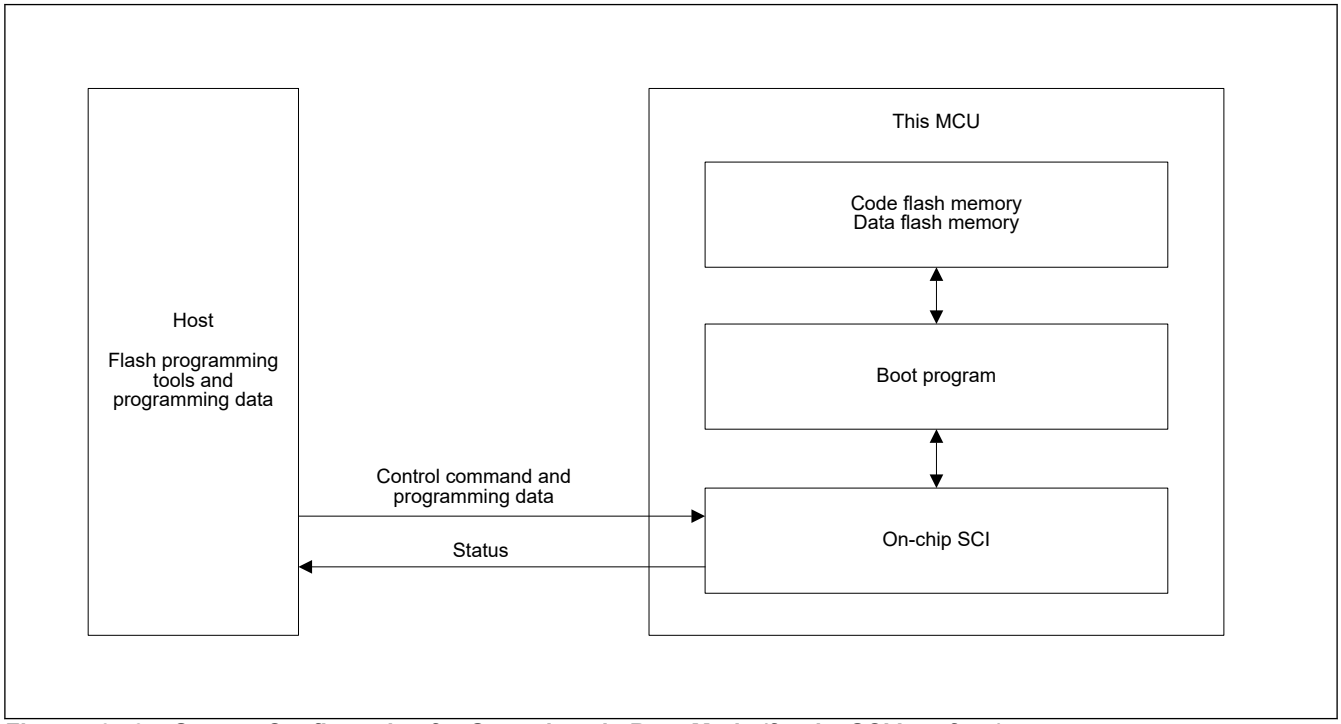

Figure 50.43 System Configuration for Operations in Boot Mode (for the SCI Interface)

50.13.2 Boot Mode (for the USB Interface)

In boot mode (with the USB interface), the flash memory can be programmed or erased by sending control commands and program data from the host. An on-chip USB is used for communications between the host and this MCU. The host requires tools for sending control commands and data for programming. Figure 50.44 shows the configuration of a system for use in boot mode (for the USB interface). The USB cable must be connected on reset release.

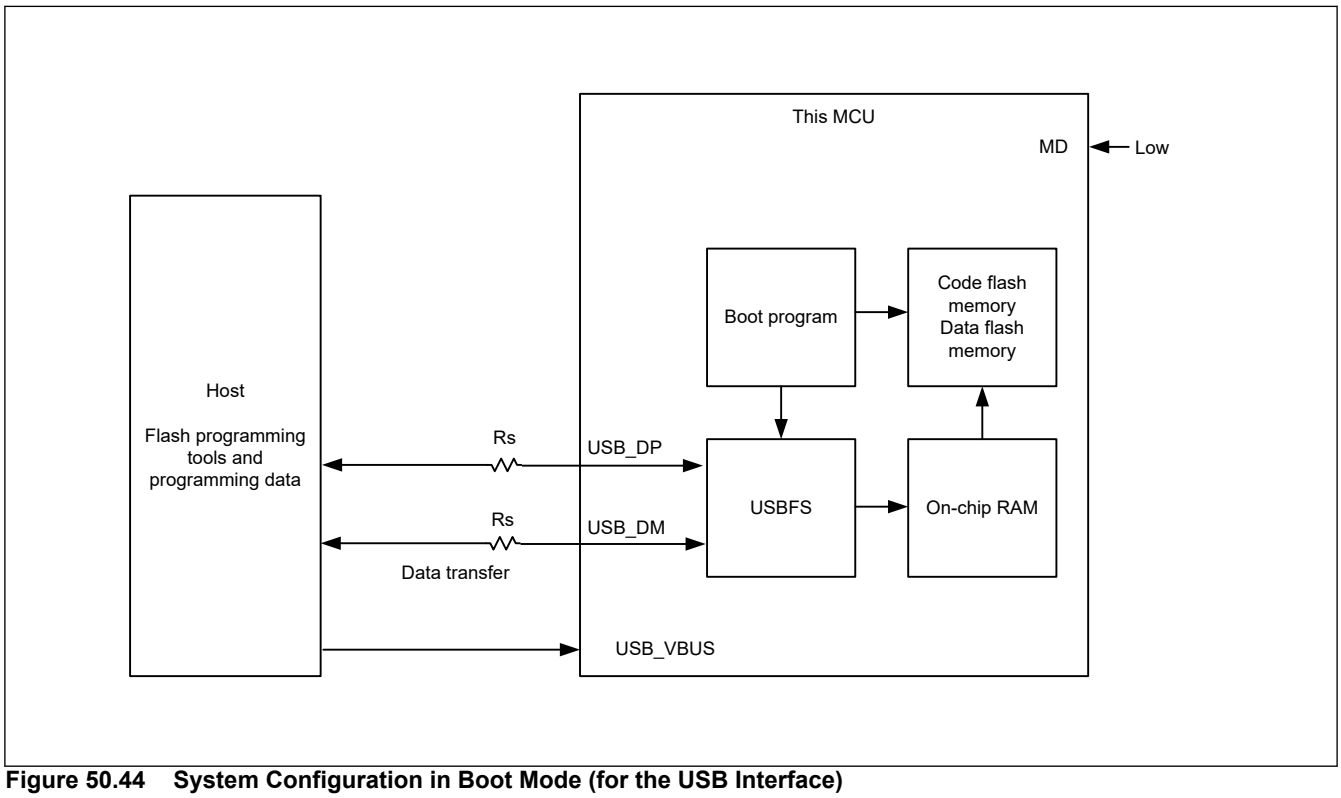

Figure 50.44 System Configuration in Boot Mode (for the USB Interface)

50.14 Using the Serial Programmer for Rewriting

A serial programmer can be used to rewrite flash memory in boot mode.

(1) Serial Programming

This MCU is mounted on the system board at the time of serial programming. Providing a connector to the board enables rewriting of this MCU by the serial programmer to proceed.

50.14.1 Environments for Serial Programming

The recommended environments for rewriting the flash memory of the MCU with data are described below.

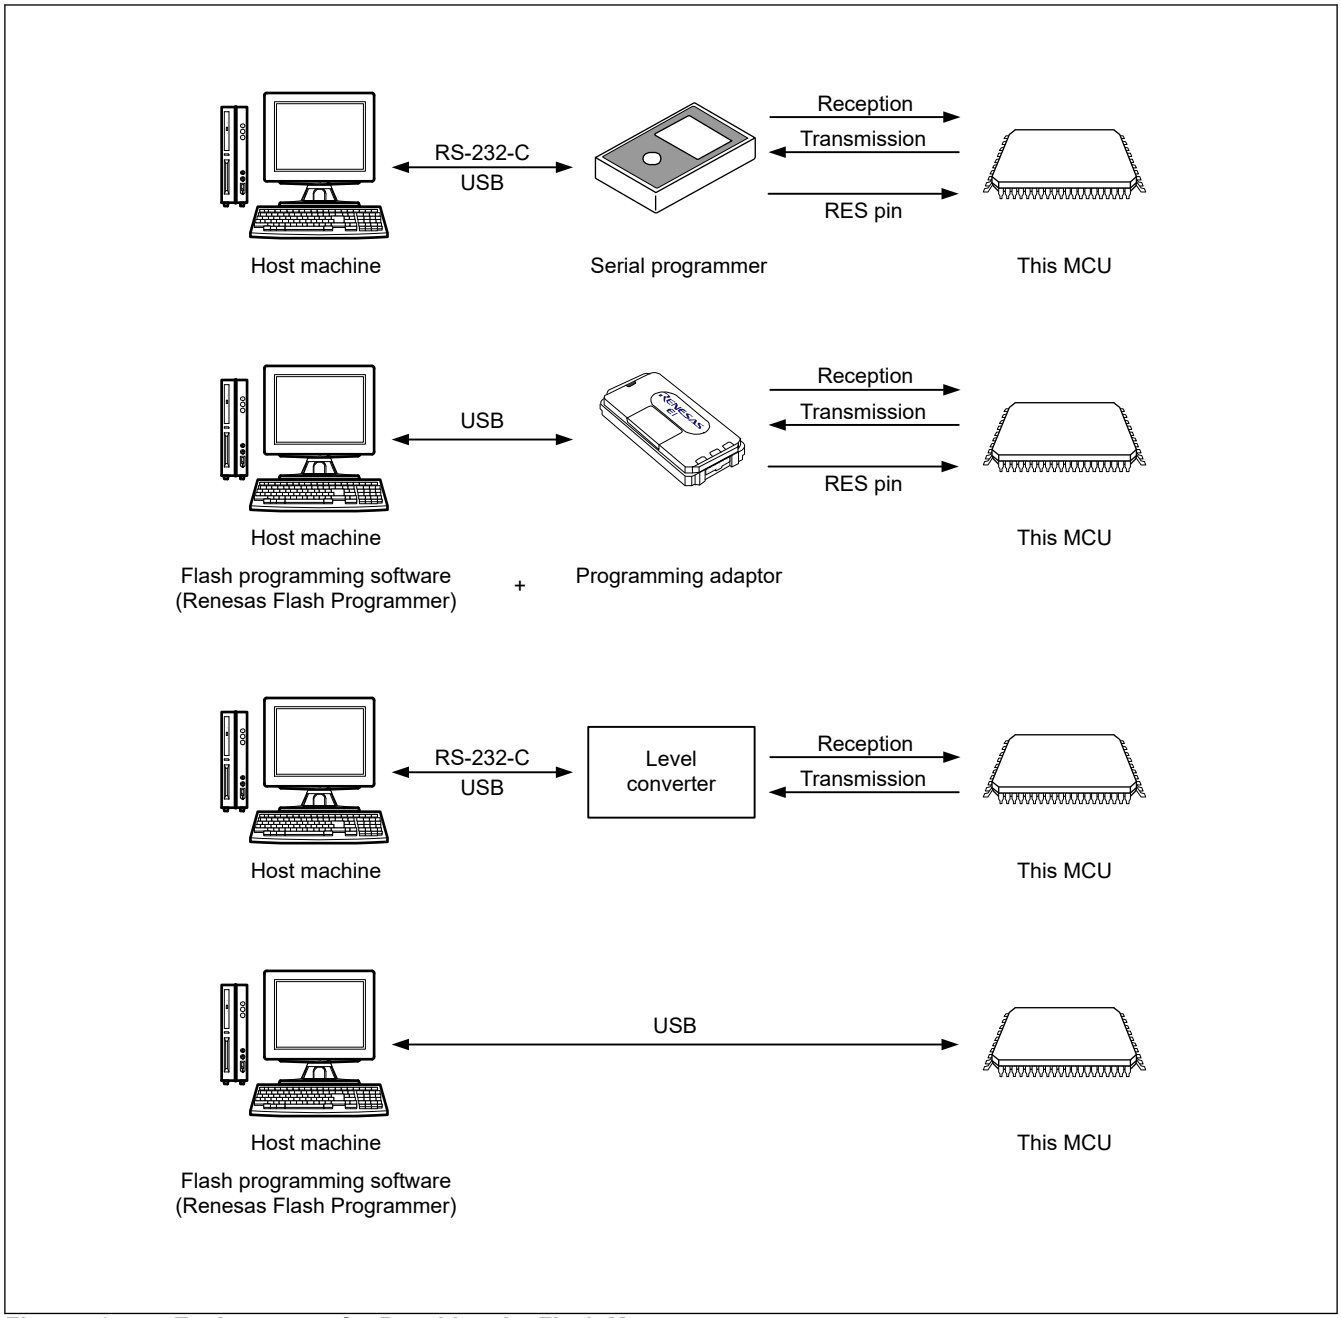

Figure 50.45 Environments for Rewriting the Flash Memory

50.15 Programming through Self-Programming

50.15.1 Overview

This MCU supports programming of the flash memory by the user program itself. The FACI commands can be used with user programs for writing to the flash memory. This allows upgrading of user programs and rewriting of constant data fields.

The program for rewriting must be transferred to the internal RAM or external memory in advance when the BGO is not available or when rewriting the option-setting memory.

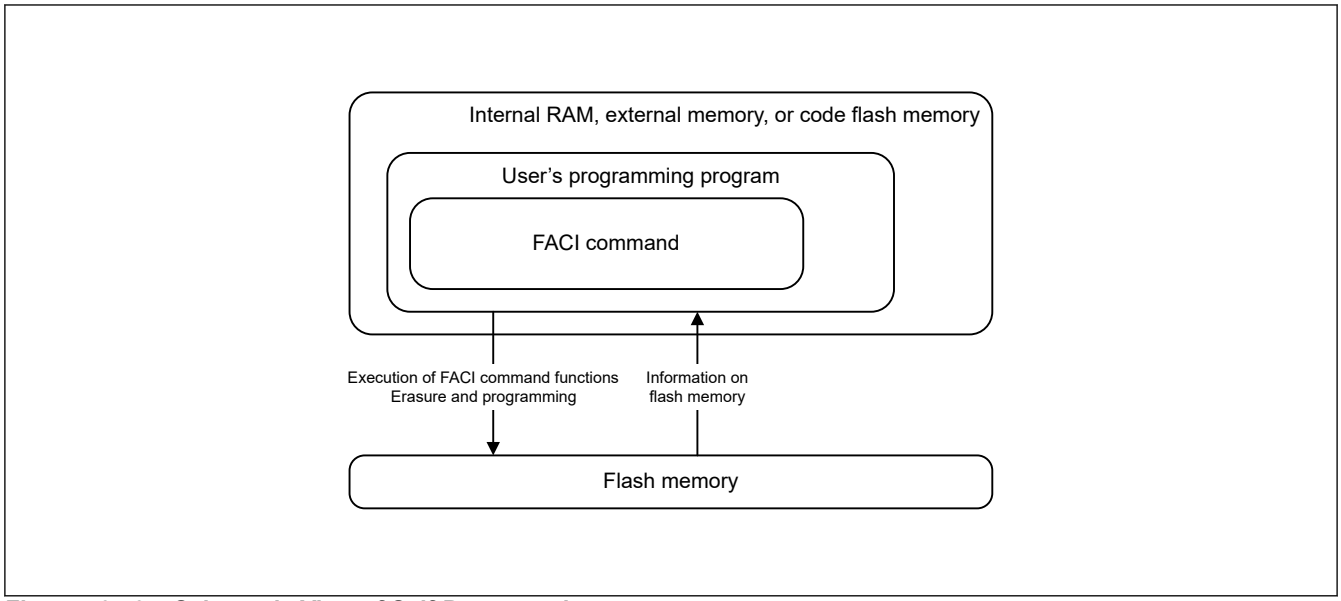

Figure 50.46 Schematic View of Self-Programming

For comprehensive information on the self-programming, see section 50.9. FACI Commands.

50.15.2 Background Operation

The background operation (BGO) can be used to execute the flash rewrite routine on the code flash memory when the data flash memory or other area of code flash memory is rewritten.

Background operations can be used when the combination of the flash memory for rewriting and the flash memory for reading is any of those listed below.

Table 50.35 Conditions under which Background Operation is Usable (1 of 2)

		Range for rewriting	Range for reading
Common to linear and dual modes		Code flash memory	Data flash memory
		Data flash memory	Code flash memory
Liner mode	Products with 2 Mbytes of code flash memory	First half (1 Mbytes) of the code flash memory (addresses 0x0000_0000 to 0x000F_FFFF)	Second half (1 Mbytes) of the code flash memory (addresses 0x0010_0000 to 0x001F_FFFF)
		Second half (1 Mbytes) of the code flash memory (addresses 0x0010_0000 to 0x001F_FFFF)	First half (1 Mbytes) of the code flash memory (addresses 0x0000_0000 to 0x000F_FFFF)
Liner mode	Products with 1.5 Mbytes of code flash memory	First half (0.75 Mbytes) of the code flash memory (addresses 0x0000_ 0000 to 0x000B_FFFF)	Second half (0.75 Mbytes) of the code flash memory (addresses 0x000C_0000 to 0x0017_FFFF)
		Second half (0.75 Mbytes) of the code flash memory (addresses 0x000C_0000 to 0x0017_FFFF)	First half (0.75 Mbytes) of the code flash memory (addresses 0x0000_0000 to 0x000B_FFFF)
Liner mode	Products with 1 Mbytes of code flash memory	First half (0.5 Mbytes) of the code flash memory (addresses 0x0000_0000 to 0x0007_FFFF)	Second half (0.5 Mbytes) of the code flash memory (addresses 0x0008_0000 to 0x000F_FFFF)
		Second half (0.5 Mbytes) of the code flash memory (addresses 0x0008_0000 to 0x000F_FFFF)	First half (0.5 Mbytes) of the code flash memory (addresses 0x0000_0000 to 0x0007_FFFF)

Table 50.35 Conditions under which Background Operation is Usable (2 of 2)

		Range for rewriting	Range for reading
Dual mode	When the BANKSEL.BANKSWP[2:0] bits are 111b	Bank 1 area of the code flash memory	Bank 0 area of the code flash memory
	When the BANKSEL.BANKSWP[2:0] bits are 000b	Bank 0 area of the code flash memory	Bank 1 area of the code flash memory

50.16 Reading Flash Memory

50.16.1 Reading Code Flash Memory

Special settings are not required to read code flash memory after release from the reset state. Data can simply be read out through access to addresses in the code flash memory.

When reading code flash memory that has been erased but not yet been programming again (i.e. that is in the non-programmed state), all bits are read as 1.

50.16.2 Reading Data Flash Memory

Special settings are not required to read data flash memory after release from the reset state. Data can simply be read out through access to addresses in the data flash memory.

Values read from data flash memory that has been erased but not yet been programming again (i.e. that is in the non-programmed state) are undefined. Use blank checking when you need to confirm that an area is in the non-programmed state.

50.16.3 Access Cycle

When the CPU cache is hit, access is one cycle.

For the CPU cache is missed while CPU cache operation is enabled, or CPU cache is disabled. (This operation only guarantees the first read access of a wrapping burst in AHB protocol. Otherwise, access wait occurs until the CPU cache is filled.)

Table 50.36 Code Flash Memory

Flash Cache Operation	FLWT Register Setting	Read cycle (ICLK)
enable and hit	—	3
disable or miss	0x00	3
	0x01	4
	0x02	5
	0x03	6

Table 50.37 Data Flash Memory (1 of 2)

FCKMHZ Register Setting	Read (cycle)
0x00 to 0x09	Min: 2 ICLK + 3 FCLK Max: (n + 1) ICLK + 3 FCLK
0x0A to 0x13	Min: 2 ICLK + 4 FCLK Max: (n + 1) ICLK + 4 FCLK
0x14 to 0x1D	Min: 2 ICLK + 5 FCLK Max: (n + 1) ICLK + 5 FCLK
0x1E to 0x27	Min: 2 ICLK + 6 FCLK Max: (n + 1) ICLK + 6 FCLK
0x28 to 0x31	Min: 2 ICLK + 7 FCLK Max: (n + 1) ICLK + 7 FCLK

Table 50.37 Data Flash Memory (2 of 2)

FCKMHZ Register Setting	Read (cycle)
0x32	Min: 2 ICLK + 8 FCLK Max: (n + 1) ICLK + 8 FCLK

Note: When the frequency ratio of ICLK : FCLK is n : 1

50.17 Usage Notes

(1) Reading Area Where Programming/Erasure was Interrupted and Area Targeted for Suspension

The data stored in the area where programming or erasure has been suspended or the area where programming or erasure has been suspended by using the suspend command are undefined. To avoid faulty operation caused by reading undefined data, take care not to fetch instructions or read data from areas where programming or erasure was suspended and where programming or erasure was suspended by using the suspend command.

(2) Suspension During Programming/Erasure

When processing of programming/erasure is stopped by issuing the P/E suspend command, the programming/erasure processing can be resumed by issuing the P/E resume command. If the flash sequencer enters the command-locked state for any reason and issues the forced stop command after the suspended processing is normally completed and the ERSSPD flag or PRGSPD flag is set to 1, the suspended processing cannot be resumed. In addition, the values in the area where the processing was suspended are not guaranteed. Erase that area

(3) Prohibition of Additional Programming

Programming a given area of the code flash memory or data flash memory twice is not possible. To program the code flash memory or data flash memory where has been programed, erase the target area. Programming can be added to the option-setting memory.

(4) Resets During Programming/Erasure, or Blank Checking

In the case of a reset due to the signal on the RES pin during programming/erasure, or blank checking of the flash memory, wait for at least t_{RESW} (see section 53, Electrical Characteristics) of the reset input period once the operating voltage is within the range stipulated in the electrical characteristics, then release the device from the reset state.

(5) Allocation of Vectors for Interrupts and Other Exceptions During Programming/Erasure

Generation of an interrupt or other exception during programming/erasure may lead to fetching of the vector from the code flash memory. Under conditions where BGO cannot be used, set the address of the vector to an address that is not in the code flash memory. Alternatively, make sure that no handling of interrupts or exceptions proceeds during programming/erasure.

(6) Items Prohibited During Programming/Erasure, or Blank Checking

High voltage is applied to the flash memory during programming/erasure, or blank checking. To prevent damage to the flash memory, do not perform the following operations.

- Have the operating voltage from the power supply go beyond the permitted range.
- Change the FWEPROR.FLWE[1:0]bits.
- Change the OPCCR.OPCM[2:0] and SOPCCR.SOPCM bits.
- Change the SCKDIVCR.FCK[2:0]bits.
- Change the SCKSCR.CKSEL[2:0]bits.
- Transition to the software standby mode, or Deep Software Standby mode.

(7) Programming/Erasure in Low-Speed Modes and Subosc-Speed Mode

Do not programming/erasure the flash memory when low-speed mode or subosc-speed mode is selected with the operating power control register (OPCCR or SOPCCR).

(8) Setting dual bank mode and programming in Boot Mode

The initial mode of the MCU shipped from Renesas is linear mode. In customer's factory when programming dual bank mode and customer's applications on MCU set in linear mode, it is recommended that only area1 in Figure 50.47 is programed in boot mode and area2 is kept blank. After reset, MCU starts in dual mode and the application is in bank0. Use self-programming when programming area2 for updating in the field. See section 52.5. Field Updating in Dual Mode for details

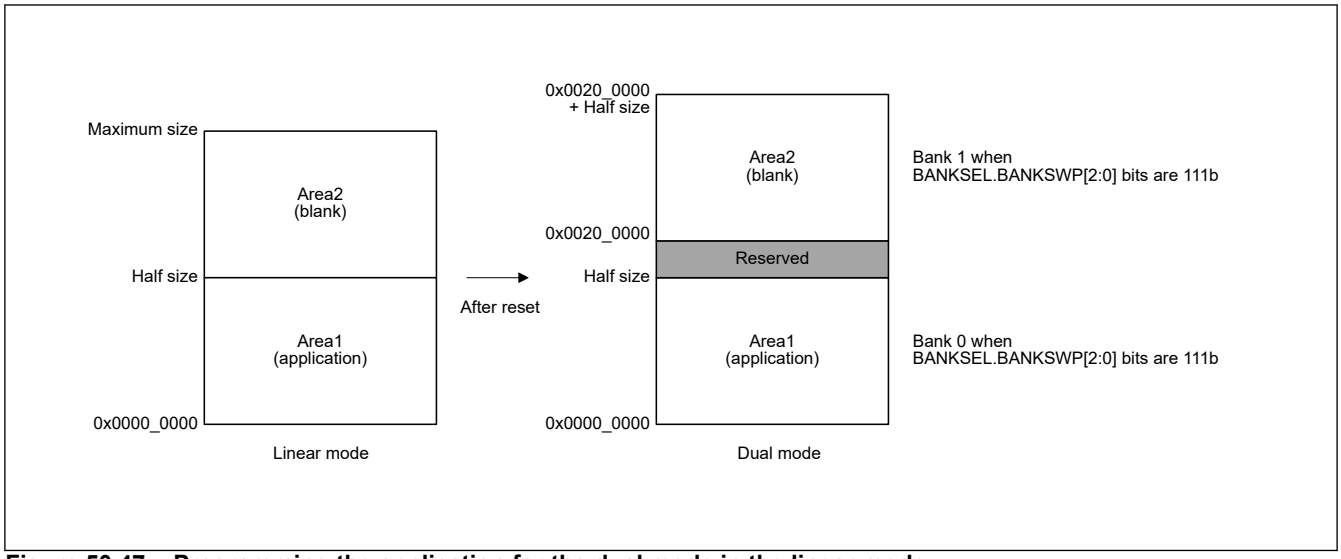

Figure 50.47 Programming the application for the dual mode in the linear mode

(9) Emulator Connection

Renesas provides the emulator which supports both debugging using SWD or JTAG communication and serial programming using SCI communication. This emulator makes it easy to switch between debugging and serial programming.

Table 50.38 shows the pinout of 10 pin or 20 pin socket pinouts when using this emulator. The pinout of SWD and JTAG is ARM standard, and MD, TXD, RXD pins are added for the serial programming using SCI communication.

The serial programming interface must be used to program the TrustZone IDAU boundary register settings.

It is recommended to connect P300/SWCLK/TCK and P201/MD pins using wired OR circuit on the board to use both debugging and serial programming

Table 50.38 Pin assign for emulator (1 of 2)

Pin No.	SWD	JTAG	Serial Programming using SCI
1	VCC	VCC	VCC
2	P108/SWDIO	P108/TMS	NC
4	P300/SWCLK Wired OR with P201/MD	P300/TCK Wired OR with P201/MD	P201/MD
6	P109/SWO/TXD9	P109/TDO/TXD9	P109/TXD9
8	P110/RXD9	P110/TDI/RXD9	P110/RXD9
9	GNDdetect	GNDdetect	GNDdetect
10	nRESET	nRESET	nRESET
12	P214/TCLK	P214/TCLK	NC
14	P211/TDATA[0]	P211/TDATA[0]	NC
16	P210/TDATA[1]	P210/TDATA[1]	NC
18	P209/TDATA[2]	P209/TDATA[2]	NC
20	P208/TDATA[3]	P208/TDATA[3]	NC

Table 50.38 Pin assign for emulator (2 of 2)

Pin No.	SWD	JTAG	Serial Programming using SCI
3, 5, 15, 17, 19	GND	GND	GND
7	NC	NC	NC
11, 13	NC	NC	NC

51. Internal Voltage Regulator

51.1 Overview

The MCU includes one internal voltage regulator:

- Linear regulator (LDO)

This regulator supplies voltage to all internal circuits and memory except for I/O, analog, USB, and battery backup power domains.

51.2 Operation

Table 51.1 lists the LDO mode pin settings, and Figure 51.1 shows the LDO mode settings. In LDO mode, the internal voltage is generated from VCC.

Table 51.1 LDO mode pin

Pins	Setting descriptions
All VCC	• Connect each pin to the system power supply. • Connect each pin to VSS through a 0.1-μF multilayer ceramic capacitor. Place the capacitor close to the pin.
VCL, VCL0	Connect the each pin to VSS through a 0.1-μF multilayer ceramic capacitor. Place the capacitor close to the pin.

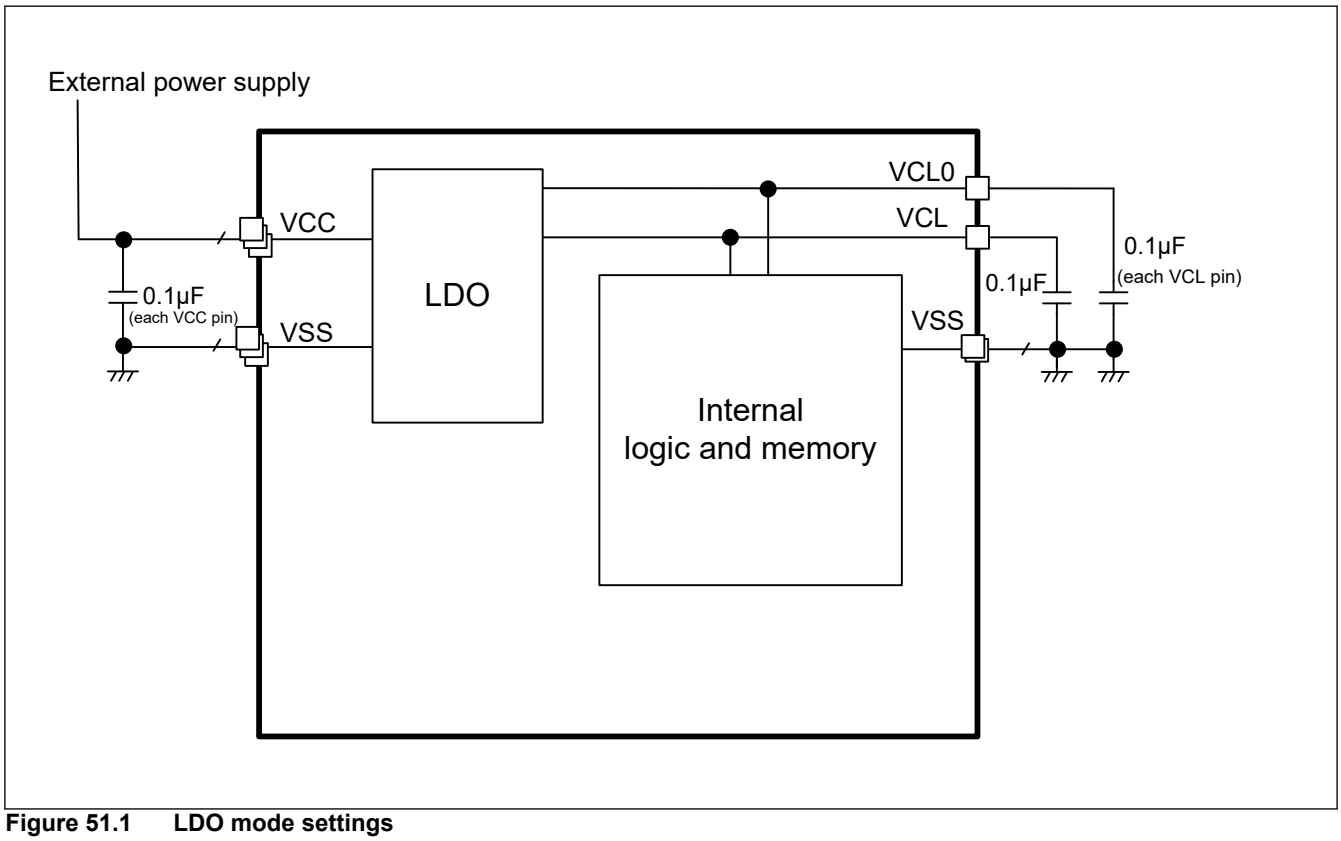

Figure 51.1 LDO mode settings

52. Security Features

52.1 Features

- ARMv8-M TrustZone security
  - Eight regions IDAU for memory space
    - Up to three or six regions for the code flash, depending on the bank mode
    - Up to two regions for the data flash
    - Up to three regions for the SRAM
    - IDAU setting is common for the CPU, DMAC, and DTC
  - SAU is not implemented
  - Secure or Non-secure region for the Standby SRAM
  - Secure or Non-secure region for the VBATT backup registers
  - Individual Secure or Non-secure security attribution for each peripheral
  - Some peripherals support both Secure and Non-secure security attributions
- Device lifecycle management
- Three debug access levels
  - DBG2: The debugger connection is allowed, and no restriction to access memories and peripherals
  - DBG1: The debugger connection is allowed, and restricted to access only non-secure memory regions and peripherals
  - DBG0: The debugger connection is not allowed
- Key injection
- Cryptographic accelerator
  - See section 42, Secure Cryptographic Engine (SCE9)
- Secure pin multiplexing
  - All I/O port pins can be configured individually as secure or non-secure
  - Pin functions of SCI3, SPI0, IIC0, GPT321 and GPT165 can be configured as secure pin
  - See section 19, I/O Ports

52.2 Arm TrustZone Security

52.2.1 Arm TrustZone Technology

Arm TrustZone technology divides the system and the application into Secure and Non-secure domains. Secure application can access both Secure and Non-secure memory and resources. Non-secure application can only access Non-secure memory and resources.

The system starts up in Secure state by default. The security state of CPU can be either Secure or Non-secure.

52.2.2 Memory Security Attribution

The code flash, the data flash, and the SRAM are divided into Secure (S), Non-secure (NS) and Non-secure callable (NSC) regions. These memory security attributions are set into the nonvolatile memory by the serial programming command when the device lifecycle is SSD state. These memory security attributions are loaded into the IDAU and the memory controller before application execution. These memory security attributions cannot be updated by application but can be through the dedicated registers.

The code flash can be divided in up to three regions in the linear mode and six regions in the dual mode. The area of three regions is same between bank0 and bank1 in the dual mode. The data flash can be divided in up to two regions. The SRAM can be divided in up to three regions. Figure 52.1 shows the memory mapping. Table 52.1 shows the size of memory region.

Note: It is prohibited to place Secure or Non-secure callable regions in a block swappable area in the linear mode because the secure application will be placed in the non-secure region after block swapping.

Note: The contents in Secure or Non-secure callable regions must be same in both bank0 and bank1 in the dual mode. Otherwise, the contents of secure or non-secure regions may not be latest by the field updating of non-secure region. See section 52.5. Field Updating in Dual Mode.

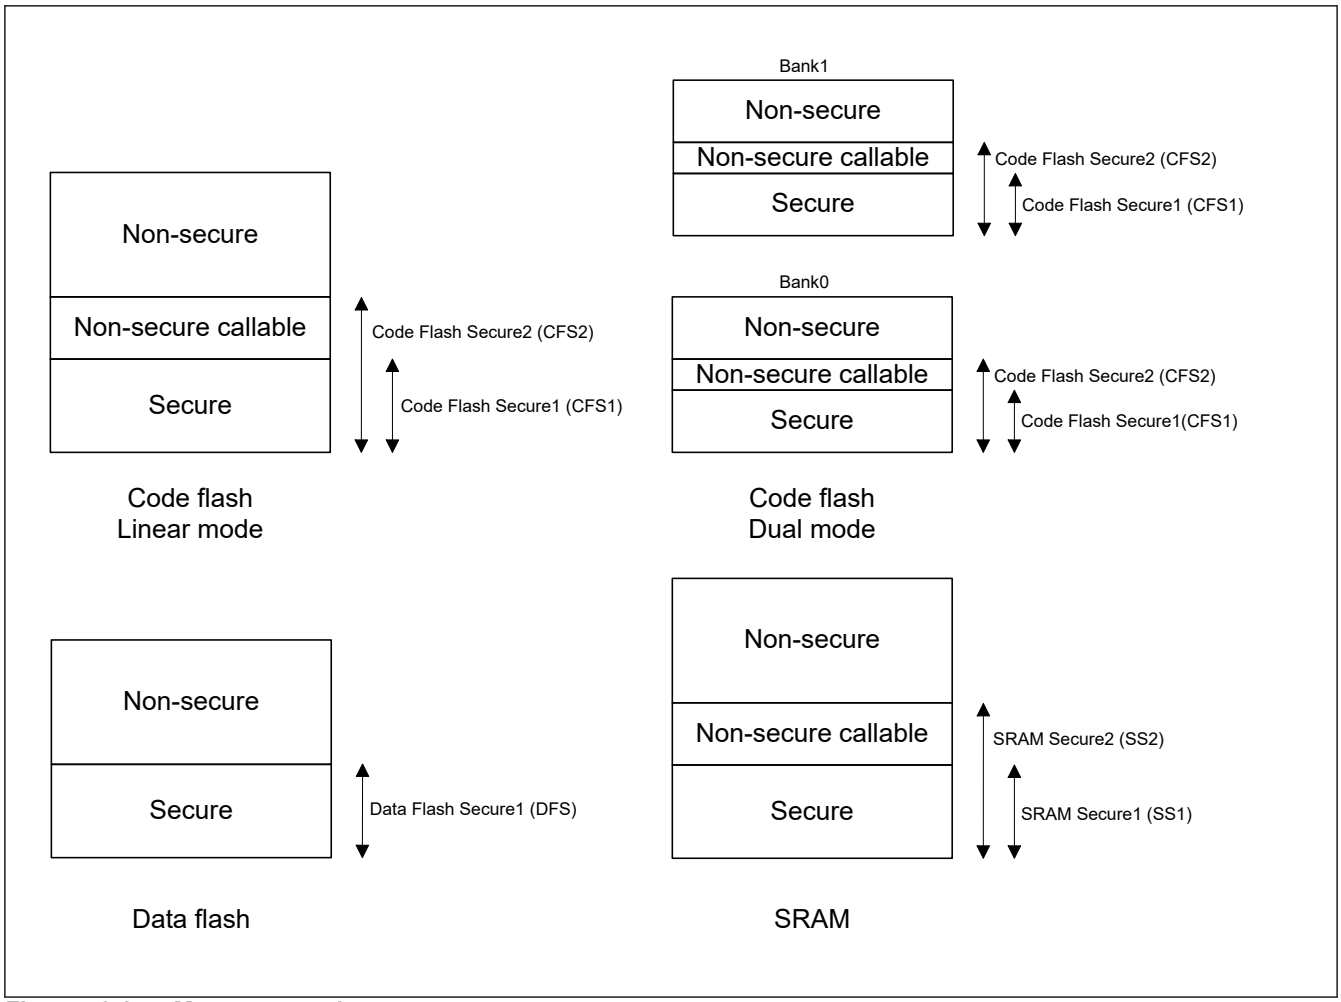

Figure 52.1 Memory mapping

Table 52.1 Memory Region Size (1 of 2)

Memory region		Start address	Size
Linear mode	Code flash secure	0x0000_0000	CFS1 × 1 KB
	Code flash non-secure callable	CFS1 × 1 KB	CFS2 × 32 KB - CFS1 × 1 KB
	Code flash non-secure	CFS2 × 32 KB	Code flash size - CFS2 × 32 KB
Dual mode	Code flash bank0 secure	0x0000_0000	CFS1 × 1 KB
	Code flash bank0 non-secure callable	CFS1 × 1 KB	CFS2 × 32 KB - CFS1 × 1 KB
	Code flash bank0 non-secure	CFS2 × 32 KB	Code flash size/2 - CFS2 × 32 KB
	Code flash bank1 secure	0x0020_0000	CFS1 × 1 KB
	Code flash bank1 non-secure callable	0x0020_0000 + CFS1 × 1 KB	CFS2 × 32 KB - CFS1 × 1 KB
	Code flash bank1 non-secure	0x0020_0000 + CFS2 × 32 KB	Code flash size/2 - CFS2 × 32 KB
Data flash secure		0x0800_0000	DFS × 1 KB

Table 52.1 Memory Region Size (2 of 2)

Memory region	Start address	Size
Data flash non-secure	0x0800_0000 + DFS × 1 KB	Data flash size - DFS × 1 KB
SRAM secure	0x2000_0000	SS1 × 1 KB
SRAM non-secure callable	0x2000_0000 + SS1 × 1 KB	SS2 × 8 KB - SS1 × 1 KB
SRAM non-secure	0x2000_0000 + SS2 × 8 KB	SRAM size - SS2 × 8 KB

The Standby SRAM is divided 8 regions. Security attribution can be set for each region, but both secure region and non-secure region must be contiguous. In other words, the Standby SRAM can have one contiguous secure region and one contiguous non-secure region. The Standby SRAM security attribution is set to the dedicated register by the secure application. See section 49, Standby SRAM for the details.

The VBATT backup register is divided 8 regions. Security attribution can be set for each region, but both secure region and non-secure region must be contiguous. In other words, the VBATT backup register can have one contiguous Secure region and one contiguous Non-secure region. The VBATT backup register security attribution is set to the dedicated register by the secure application. See section 11, Battery Backup Function for the details.

Table 52.2 shows the access permission of the memory.

Table 52.2 Access Permission of Memory

Memory	Secure access	Non-secure access
Code flash, Data flash, SRAM configured as Secure or Non-secure callable	allowed	Write ignored / Read ignored TrustZone Access error is generated
Code flash, Data flash, SRAM configured as non-secure	allowed	allowed
Standby SRAM, VBATT backup register configured as Secure	allowed	Write ignored / Read 0x00 TrustZone Access error is not generated
Standby SRAM, VBATT backup register configured as Non-secure	allowed	allowed

52.2.3 Peripheral Security Attribution

Each peripheral can be configured to be Secure or Non-secure.

Peripherals are divided into two types.

Type-1 peripherals has the one security attribution. Access to all registers is controlled by one security attribution. Type-1 peripheral security attribution is set to the PSARx (x = B to E) register by the secure application.

Type-2 peripherals has the security attribution for each register or for each bit. Access to each register or bit field is controlled according to these security attributions. Type-2 peripheral security attribution is set to the Security Attribution register in each module by the secure application. For the Security Attribution register, see sections in the user manual for each peripheral.

Table 52.3 shows the classification of peripheral type.

Table 52.3 Peripheral Type Classification

Type	Peripheral
Type-1	SCI, SPI, USBFS, USBHS, CANFD, IIC, CEC, SCE9, DOC, SDHI, SSIE, CTSU, CRC, CAC, TSN, ADC12, DAC12, POEG, AGT, GPT, RTC, IWDT, WDT
Type-2	System control (Resets, LVD, Clock Generation Circuit, Low Power Modes, Battery Backup Function), FLASH CACHE, SRAM controller, CPU CACHE, DMAC, DTC, ICU, MPU, BUS, Security setting, ELC, I/O ports
Always Non-secure	CS Area Controller, QSPI, OSPI, ETHERC, EDMAC

Table 52.4 shows the access permission of type-1 peripherals. The access permission of type-2 peripherals is different by peripherals. See section Register Description of each peripherals.

Table 52.4 The access permission of type-1 peripherals

Permission	Secure access	Non-secure access
Peripheral configured as secure	allowed	Write ignored / Read ignored TrustZone Access error is generated
Peripheral configured as non-secure	allowed	allowed

52.2.4 Flash Sequencer Security Attribution

The flash sequencer is used to program or erase the flash.

The flash sequencer has the special security attribution. Table 52.5 shows the access permission of flash sequencer.

Table 52.5 Access Permissions of Flash Sequencer

	Secure access	Non-secure access
FACI command issuing area	allowed	When the FACI command is issued to the secure region of code flash, data flash and option-setting memory ● Issued FACI command is invalid ● Flash sequencer error is generated When the FACI command is issued to the non-secure region of code flash, data flash and option-setting memory ● Issued FACI command is valid
FBPROT1, FSUACR, FMEPROT registers	allowed	Write ignored / Readable TrustZone Access error is not generated
FCKMHZ register	allowed	Configured by Flash Security Attribution register When configured as Secure, ● Write ignored / Readable ● TrustZone Access error is not generated. When configured as Non-secure ● allowed
Other registers	allowed	During programming/erasure or during suspend programming/erasure by secure application ● Write ignored / Read 0x00 ● TrustZone Access error is not generated In other state ● allowed

52.2.5 Address Space Security Attribution

Table 52.6 shows the security attribution of the address space.

Table 52.6 Address Space Security Attribution

Region	Attribution
Code flash secure	Secure
Code flash non-secure callable	Non-secure callable
Code flash non-secure	Non-secure
Data flash secure	Secure
Data flash non-secure	Non-Secure
SRAM secure	Secure
SRAM non-secure callable	Non-secure callable
SRAM non-secure	Non-secure
Peripherals	Exempt
External address space	Exempt
Other area	Exempt

Note: Exempt: No check will be done. All bus transactions are propagated.

52.2.6 TrustZone Access Error

Table 52.7 shows the behavior when TrustZone access error. The behavior varies depending on the master or slave area to be accessed.

Table 52.7 The Behavior When TrustZone Access Error

Area	CPU	DMAC/DTC	EDMAC
Code flash, Data flash, SRAM	Detect SecureFault exception*2	• Transfer does not start • Occur NMI or reset*1 • Occur interrupt (DMA_TRANSERR)	• Occur NMI or reset*1 • Occur interrupt (ETHER_EINT0)*3
Other area	• Detect BusFault exception*2 *4 • Occur NMI or reset*1*2 *4	• Stop transfer*5 • Occur NMI or reset*1 *5 • Occur interrupt (DMA_TRANSERR)*5	No TrustZone access error occurs

Note 1. NMI or reset is selected with TZFOAD.OAD bit.
Note 2. When TrustZone access error occurs by the debugger access, exception, NMI, or reset does not occurs. Only the error response is returned.
Note 3. Address error flag in EESR.ADE bit is set. The interrupt occurs when interrupt is enabled in EESIPR.ADEIP bit.
Note 4. These error behaviors does not occur for write access to the PHBIU or PLBIU address space which memory attribute is set to "Early Write Acknowledgment" by the ARM MPU.
Note 5. These error behaviors does not occer for write access from DMAC to the PHBIU or PLBIU address space when the bufferable write is enabled by DMBWR.BWE.

52.3 Device Lifecycle Management

Device lifecycle identifies the current phase of the device and controls the capabilities of the debug interface, the serial programming interface and Renesas test mode. Figure 52.2 is the illustration of the device lifecycle. Table 52.8 shows the lifecycle definition and capability in each lifecycle.

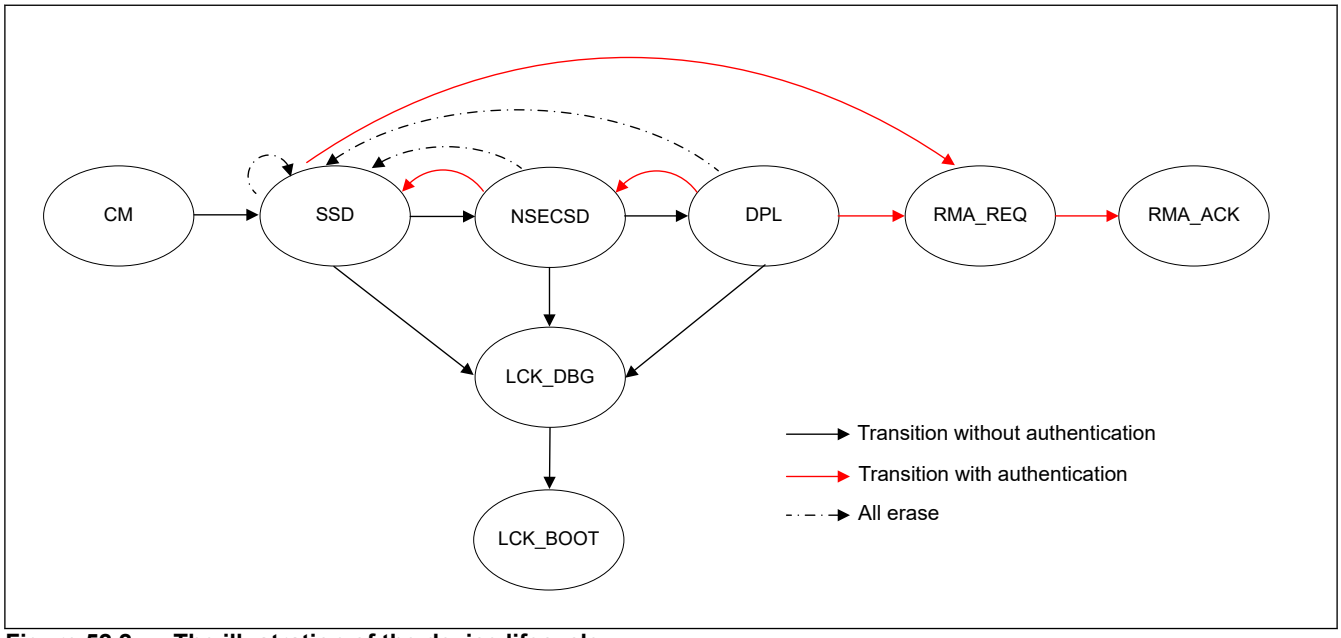

Figure 52.2 The illustration of the device lifecycle

Table 52.8 The lifecycle definition and the capability can be used in each lifecycle (1 of 2)

Lifecycle	Definition	Debug level	Serial programming	Renesas test mode
CM	"Chip Manufacturing" The device is in Renesas factory. The state when the customer received the device.	DBG2	Available cannot access code/data flash area	Not available

Table 52.8 The lifecycle definition and the capability can be used in each lifecycle (2 of 2)

Lifecycle	Definition	Debug level	Serial programming	Renesas test mode
SSD	“Secure Software Development” The secure part of application is being developed.	DBG2	Available can program/erase/read all code/data flash area	Not available
NSECSD	“Non-SECure Software Development” The non-secure part of application is being developed.	DBG1	Available can program/erase/read only non-secure code/data flash area	Not available
DPL	“DePLoyed” The device is in-field.	DBG0	Available cannot access code/data flash area	Not available
LCK_DBG	“LoCKed DeBuG” The debug interface is permanently disabled.	DBG0	Available cannot access code/data flash area	Not available
LCK_BOOT	“LoCKed BOOT interface” The debug interface and the serial programming interface are permanently disabled.	DBG0	Not available	Not available
RMA_REQ	“Return Material Authorization REQuest” Request for RMA. The customer must send the device to Renesas in this state.	DBG0	Available cannot access code/data flash area	Not available
RMA_ACK	“Return Material Authorization ACKnowledged” Failure analysis in Renesas	DBG2	Available cannot access code/data flash area	Available

52.3.1 Changing the Lifecycle State

Use the serial programming commands to change the device lifecycle state. See the boot firmware application note for the detail of command. The lifecycle cannot be updated by application but can read through the dedicated registers.

As shown in Figure 52.2, there are three types lifecycle transition.

The first one is to change to lower debug access level or restrict the serial programming mode. This change can be done with no restriction.

Note: The debug interface is permanently disabled in LCK_DBG. After changed to LCK_DBG, the debug interface cannot be used forever.

Note: The debug interface and serial programming interface are permanently disabled in LCK_BOOT. After changed to LCK_BOOT, the debug interface and the serial programming interface cannot be used forever.

The second one is to change to higher debug access level or request for RMA. This change needs key authentication. The key length is 128 bits. The secure developer needs to inject two keys when the lifecycle is SSD state. One is “SECDBG_KEY” which is used to authentication to change the lifecycle from NSECSD to SSD. Other one is “RMA_KEY” which is used to authentication to change the lifecycle from SSD or DPL to RMA_REQ. The non-secure developer needs to inject one key when the lifecycle is NSECSD state. This is “NONSECDBG_KEY” which is used to authentication to change the lifecycle from DPL to NSECSD. See section 52.4. Key Injection for the detail of how to inject the key. The key authentication uses a challenge and response authentication or authentication using the unique ID. The authentication using the unique ID is available only transition to RMA_REQ. The following is the process of how to calculate the response, challenge and response authentication, or the authentication code using unique ID.

Response = HMAC-SHA256 (KEY, 128bits challenge || fixed value (256bits))

Authentication code = HMAC-SHA256 (KEY, 128bits unique ID || fixed value (256 bits))

fixed value = 9e56dc41 cf0c9648 1b811141 f8f9ba1e 4dd77746 6d403593 17f46d64 fe64fdf6

Note: That "||" represents concatenation, not logical or.

Note: In case the key is not injected, these lifecycle changes cannot be done.

Note: In the lifecycle transition from NSECSD to SSD or form DPL to NSECSD, the contents on the flash memory are not erased.

Note: MCU does not respond after changing to higher debug access level or RMA_REQ. If you continue to use the serial programming commands, need to re-enter the boot mode after a reset. See the boot firmware application note for the detail.

Note: In the lifecycle transition to RMA_REQ, the contents on the flash memory except permanently locked block or setting or BPS_SEL register are erased. The contents in the permanently locked block or register can be read by Renesas at failure analysis. Permanently locked block means the block which programming and erasure is disabled permanently by PBPS, PBPS_SEC and BPS_SEL register. Permanently locked register means SAS register which programming and erasure is disabled permanently by FSPR bit.

The third one is all erase. This is done by an initialize command unless an initialize command itself is disabled. The lifecycle is back to SSD and the contents on the flash memory is erased. If there is permanently locked block or register, an initialize command does not execute. In case of the all bits of PBPS and PBPS_SEC register are 1 and FSPR bit is1, an initialize command is executable.

Note: The initialize command can be issued by everyone, so contents on the flash memory are easily erased. Developers who do not want this can invalidate the initialize command permanently by parameter setting command.

Note: MCU does not respond after executing the initialize command. If you continue to use the serial programming commands, need to re-enter the boot mode after a reset. See the boot firmware application note for the detail.

52.3.2 Debug access level

There are three debug access levels, and the debug access level changes according to the lifecycle state.

- DBG2: The debugger connection is allowed, and no restriction to access memories and peripherals
- DBG1: The debugger connection is allowed, and restricted to access only non-secure memory regions and peripherals
- DBG0: The debugger connection is not allowed

52.3.3 Serial Programming

Whether a serial programmer can be connected and the range of flash memory that can be accessed depends on the lifecycle state as shown in Table 52.8. And the accepted serial programming command differs depending on the lifecycle state. See the boot firmware application note for the detail of command.

52.3.4 Lifecycle changing example

The following is a typical lifecycle changing example.

Secure developer

- Change the lifecycle from CM to SSD by using the serial programming command.
- Set the memory security attribution of the code flash, data flash and SRAM by using the serial programming command.
- Program the secure application by using the serial programming interface and debug the secure application. Debug is possible if the lifecycle is CM, but it is impossible to set the memory security attribution in CM state. If the memory security attribution is not set, all area of the code flash, data flash and SRAM is Secure.

Note: Need to configure the registers listed in Table 52.10 as Non-secure only in NSECSD state. See section 52.7.1. Restrictions on setting the security attribution for details.

- Inject “SECDBG_KEY” and “RMA_KEY” by using the serial programming command (if need).
- Inject AES, RSA, ECC, HMAC keys listed in Table 52.9 (if need).
- Disable the all erase by using the serial programming command (if need).
- Change the lifecycle from SSD to NSECSD by using the serial programming command.

Non-secure developer

- Program the Non-secure application by using the serial programming interface and debug the Non-secure application.
- Inject “NONSECDBG_KEY” by using the serial programming command (if need).
- Inject AES, RSA, ECC, HMAC keys listed in Table 52.9 (if need).
- Disable the all erase by using the serial programming command (if need).
- Change the lifecycle to DPL by using the serial programming command.

52.3.5 Failure analysis

If the customer requests the failure analysis to Renesas, it is necessary to send the device after changing the lifecycle to RMA_REQ. If the lifecycle is not RMA_REQ, Renesas cannot do the failure analysis. Because RMA_REQ is permanent state, it cannot back to the another state after changing to RMA_REQ. It is assumed to change to SSD or NSECSD and analyze before changing to RMA_REQ.

Devices sent to Renesas will not be returned to customers. The device will be discarded.

Note: As described in the section 52.3.1. Changing the Lifecycle State, RMA_KEY is needed to change the lifecycle to RMA_REQ. If the customer forgets the RMA_KEY, Renesas cannot do the failure analysis.

52.4 Key Injection

There are three steps required to inject a user key into the MCU.

First, the customer needs to create the 256 bits installation key. This key is called User Factory Programming Key (UFPK) and used to encrypt a user key. The customer gets the key of the wrapped version (W-UFPK) through the Renesas Key Wrapping Service.

Second the customer encrypts the user key using UFPK as the AES key.

Last the customer sends W-UFPK and the encrypted user key to the MCU by using serial programming interface. The sent user key is decrypted, wrapped with the hardware unique key, and then stored in the nonvolatile memory.

Figure 52.3 is the illustration of key injection. Table 52.9 shows the keys that can be injected by serial programming interface.

User Key is used for authentication during the life cycle transition.

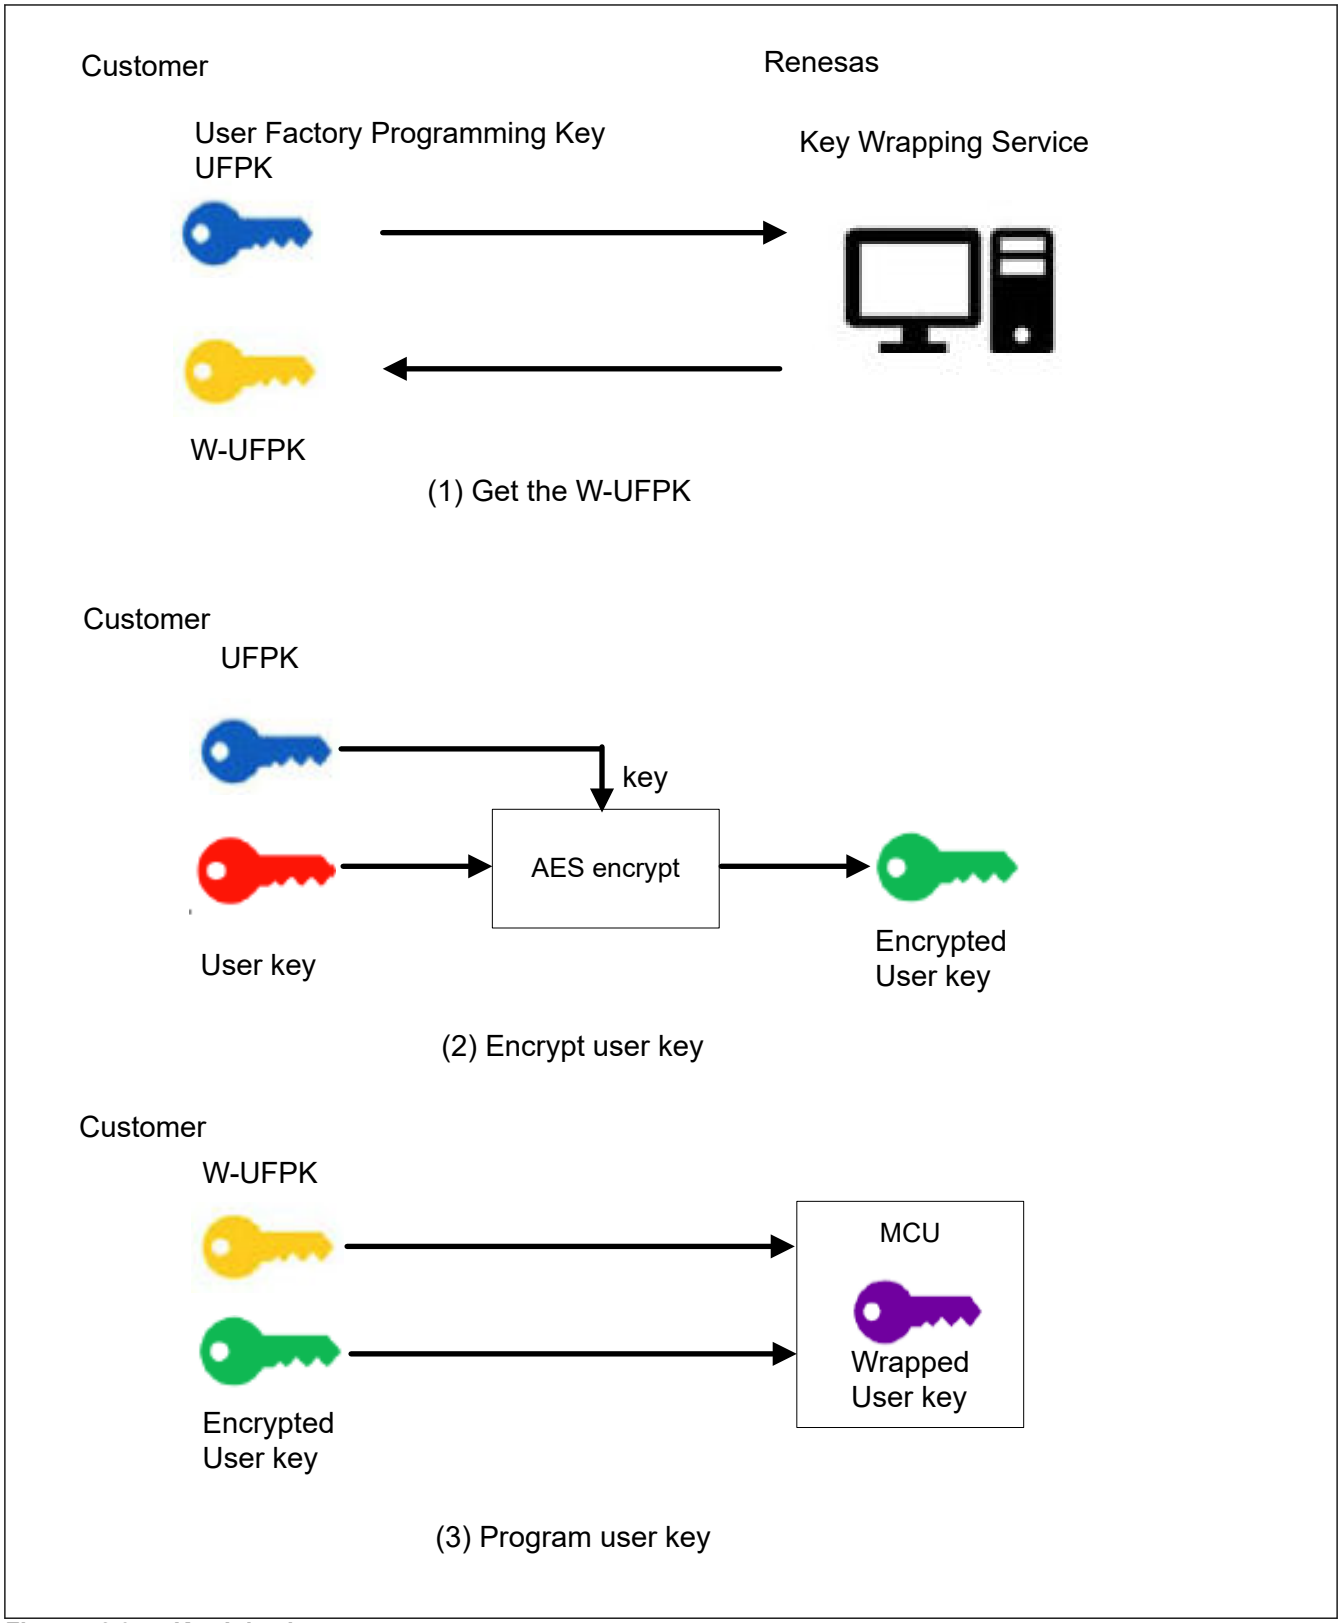

Figure 52.3 Key Injection

Table 52.9 The keys that can be injected by serial programming (1 of 2)

Lifecycle transition	SECDBG_KEY, NONSECDBG_KEY, RMA_KEY
AES	AES-128, AES-192, AES-256, AES-XTS-128, AES-XTS-256
RSA	RSA-1024, RSA-2048, RSA-3072, RSA-4096 (Public and Private)

Table 52.9 The keys that can be injected by serial programming (2 of 2)

ECC	ECC P192, ECC P224, ECC P256, ECC P384, ECC P512 (Public and Private)
HMAC	HMAC-SHA224, HMAC-SHA256

52.5 Field Updating in Dual Mode

Be careful when performing in-field update of information to keep the contents of secure or non-secure regions after bank swapping in the dual mode. Figure 52.4 and Figure 52.5 shows the performing in-field update of information flow of secure or non-secure regions in the dual mode.

In this example of Figure 52.4, BANK0 is valid, and Version 1 information is stored in NS and S or NSC.

BANK1 is blank. To update the S or NSC information in the field to Version 2, first copy the version 1 information of BANK0 to NS, update the S or NSC to Version 2, and then execute the Bank swap.

In this example of Figure 52.5, BANK0 is valid, and Version 1 information is stored in NS and S or NSC. BANK1 is blank.

To update the NS information in the field and set it to Version 2, First of all, non-secure users should have the Secure user copy the version 1 information of BANK0 to BANK1.

After that, Non secure user should update NS information to Version 2 and execute BANK swap.

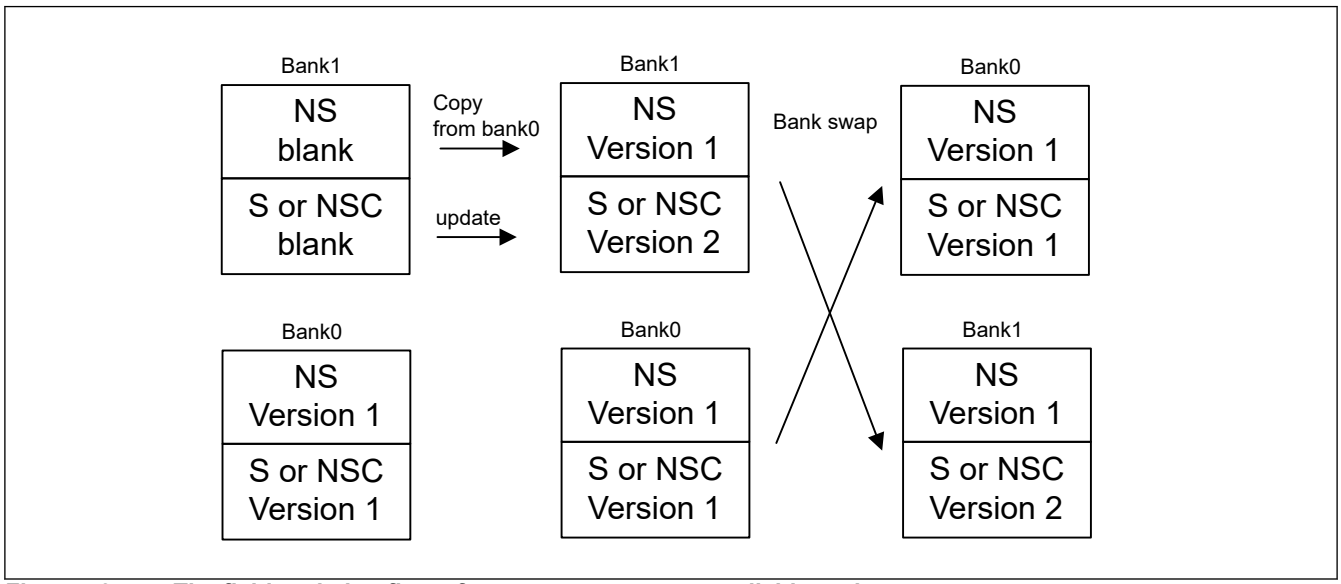

Figure 52.4 The field updating flow of secure or non-secure callable regions

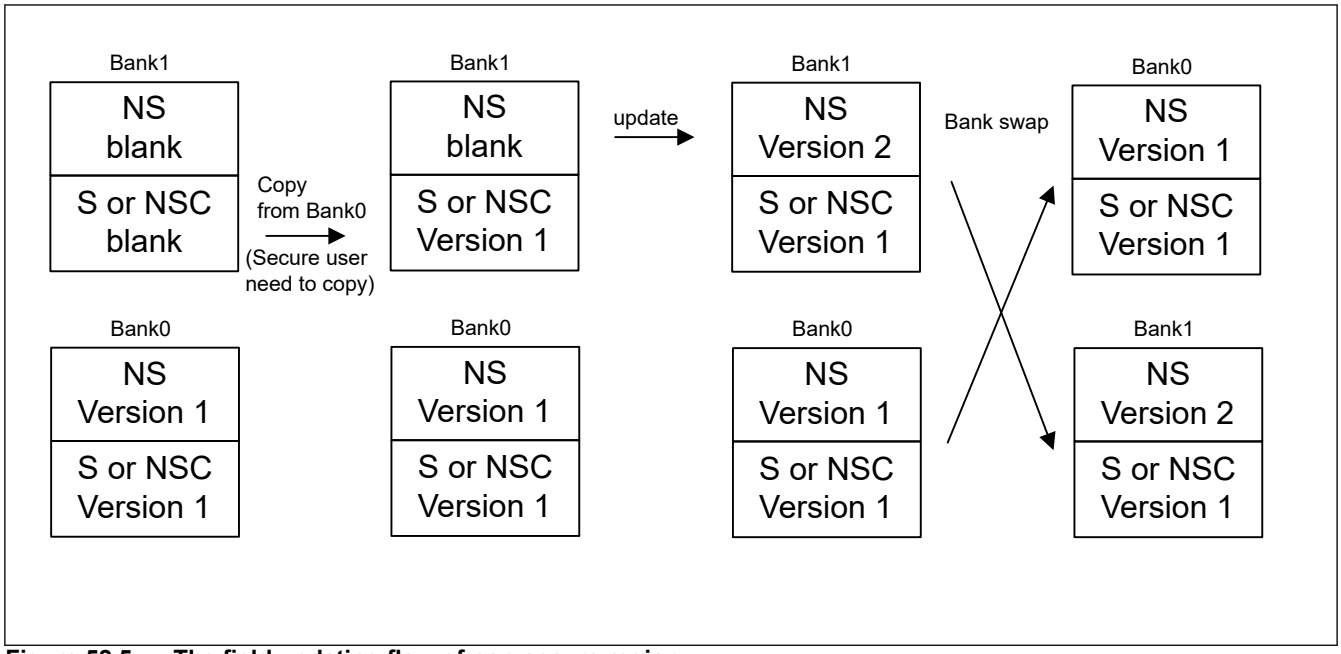

Figure 52.5 The field updating flow of non-secure region

52.6 Register Description

52.6.1 PSARB : Peripheral Security Attribution Register B

Base address: PSCU = 0x400E_0000

Offset address: 0x04

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	PSARB31	PSARB30	PSARB29	PSARB28	PSARB27	PSARB26	PSARB25	PSARB24	PSARB23	PSARB22	—	—	PSARB19	PSARB18	—	PSARB16
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	PSARB15	—	—	PSARB12	PSARB11	—	PSARB9	PSARB8	PSARB7	PSARB6	—	—	PSARB3	—	—	—
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
0	—	This bit is read as 1. The write value should be 1.	R/W
1	—	This bit is read as 1. The write value should be 1.	R/W
2	—	This bit is read as 1. The write value should be 1.	R/W
3	PSARB3	CEC and the MSTPCRB.MSTPB3 bit security attribution 0: Secure 1: Non-secure	R/W
5:4	—	These bits are read as 1. The write value should be 1.	R/W
6	PSARB6	QSPI and the MSTPCRB.MSTPB6 bit security attribution This bit is read as 1 (non-secure).	R
7	PSARB7	IIC2 and the MSTPCRB.MSTPB7 bit security attribution 0: Secure 1: Non-secure	R/W

Bit	Symbol	Function	R/W
8	PSARB8	IIC1 and the MSTPCRB.MSTPB8 bit security attribution 0: Secure 1: Non-secure	R/W
9	PSARB9	IIC0 and the MSTPCRB.MSTPB9 bit security attribution 0: Secure 1: Non-secure	R/W
10	—	This bit is read as 1. The write value should be 1.	R/W
11	PSARB11	USBFS and the MSTPCRB.MSTPB11 bit security attribution 0: Secure 1: Non-secure	R/W
12	PSARB12	USBHS and the MSTPCRB.MSTPB12 bit security attribution 0: Secure 1: Non-secure	R/W
14:13	—	These bits are read as 1. The write value should be 1.	R/W
15	PSARB15	ETHER0/EDMAC0, the MSTPCRB.MSTPB15 bit and the PFENET.PHYMODE0 bit security attribution This bit is read as 1 (non-secure).	R
16	PSARB16	OSPI and the MSTPCRB.MSTPB16 bit security attribution This bit is read as 1 (non-secure).	R
17	—	This bit is read as 1. The write value should be 1.	R/W
18	PSARB18	SPI1 and the MSTPCRB.MSTPB18 bit security attribution 0: Secure 1: Non-secure	R/W
19	PSARB19	SPI0 and the MSTPCRB.MSTPB19 bit security attribution 0: Secure 1: Non-secure	R/W
21:20	—	These bits are read as 1. The write value should be 1.	R/W
22	PSARB22	SCI9 and the MSTPCRB.MSTPB22 bit security attribution 0: Secure 1: Non-secure	R/W
23	PSARB23	SCI8 and the MSTPCRB.MSTPB23 bit security attribution 0: Secure 1: Non-secure	R/W
24	PSARB24	SCI7 and the MSTPCRB.MSTPB24 bit security attribution 0: Secure 1: Non-secure	R/W
25	PSARB25	SCI6 and the MSTPCRB.MSTPB25 bit security attribution 0: Secure 1: Non-secure	R/W
26	PSARB26	SCI5 and the MSTPCRB.MSTPB26 bit security attribution 0: Secure 1: Non-secure	R/W
27	PSARB27	SCI4 and the MSTPCRB.MSTPB27 bit security attribution 0: Secure 1: Non-secure	R/W
28	PSARB28	SCI3 and the MSTPCRB.MSTPB28 bit security attribution 0: Secure 1: Non-secure	R/W
29	PSARB29	SCI2 and the MSTPCRB.MSTPB29 bit security attribution 0: Secure 1: Non-secure	R/W
30	PSARB30	SCI1 and the MSTPCRB.MSTPB30 bit security attribution 0: Secure 1: Non-secure	R/W

Bit	Symbol	Function	R/W
31	PSARB31	SCI0 and the MSTPCRB.MSTPB31 bit security attribution 0: Secure 1: Non-secure	R/W

Note: A bit undefined in this table is reserved bit. The reserved bit should be kept the initial value.
Note: Only secure access can write to this register. Both secure access and Non-secure read access are allowed but Non-secure write access is not allowed and TrustZone access error is not generated.
Note: This register is write-protected by PRCR register.

The PSARB specifies the security attribution for each module and the corresponding bit in Module Stop Control Register.

52.6.2 PSARC : Peripheral Security Attribution Register C

Base address: PSCU = 0x400E_0000

Offset address: 0x08

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	PSARC31	—	—	—	PSARC27	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	PSARC13	PSARC12	—	—	—	PSARC8	—	—	—	—	PSARC3	—	PSARC1	PSARC0
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
0	PSARC0	CAC and the MSTPCRC.MSTPC0 bit security attribution 0: Secure 1: Non-secure	R/W
1	PSARC1	CRC and the MSTPCRC.MSTPC1 bit security attribution 0: Secure 1: Non-secure	R/W
2	—	This bit is read as 1. The write value should be 1.	R/W
3	PSARC3	CTSU and the MSTPCRC.MSTPC3 bit security attribution 0: Secure 1: Non-secure	R/W
7:4	—	These bits are read as 1. The write value should be 1.	R/W
8	PSARC8	SSIE0 and the MSTPCRC.MSTPC8 bit security attribution 0: Secure 1: Non-secure	R/W
11:9	—	These bits are read as 1. The write value should be 1.	R/W
12	PSARC12	SDHI0 and the MSTPCRC.MSTPC12 bit security attribution 0: Secure 1: Non-secure	R/W
13	PSARC13	DOC and the MSTPCRC.MSTPC13 bit security attribution 0: Secure 1: Non-secure	R/W
19:14	—	These bits are read as 1. The write value should be 1.	R/W
20	—	This bit is read as 1. The write value should be 1.	R/W
21	—	This bit is read as 1. The write value should be 1.	R/W
26:22	—	These bits are read as 1. The write value should be 1.	R/W
27	PSARC27	CANFD0 and the MSTPCRC.MSTPC27 bit security attribution 0: Secure 1: Non-secure	R/W

Bit	Symbol	Function	R/W
30:28	—	These bits are read as 1. The write value should be 1.	R/W
31	PSARC31	SCE9 and the MSTPCRC.MSTPC31 bit security attribution 0: Secure 1: Non-secure	R/W

Note: Only secure access can write to this register. Both secure access and Non-secure read access are allowed but Non-secure write access is not allowed and TrustZone access error is not generated.
Note: This register is write-protected by PRCR register.

The PSARC specifies the security attribution for each module and the corresponding bit in Module Stop Control Register.

52.6.3 PSARD : Peripheral Security Attribution Register D

Base address: PSCU = 0x400E_0000

Offset address: 0x0C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	PSARD22	—	PSARD20	—	—	—	PSARD16
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	PSARD15	PSARD14	PSARD13	PSARD12	PSARD11	—	—	—	—	—	—	—	PSARD3	PSARD2	PSARD1	PSARD0
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
0	PSARD0	AGT3 and the MSTPCRD.MSTPD0 bit security attribution 0: Secure 1: Non-secure	R/W
1	PSARD1	AGT2 and the MSTPCRD.MSTPD1 bit security attribution 0: Secure 1: Non-secure	R/W
2	PSARD2	AGT1 and the MSTPCRD.MSTPD2 bit security attribution 0: Secure 1: Non-secure	R/W
3	PSARD3	AGT0 and the MSTPCRD.MSTPD3 bit security attribution 0: Secure 1: Non-secure	R/W
10:4	—	These bits are read as 1. The write value should be 1.	R/W
11	PSARD11	POEG Group D and the MSTPCRD.MSTPD11 bit security attribution 0: Secure 1: Non-secure	R/W
12	PSARD12	POEG Group C and the MSTPCRD.MSTPD12 bit security attribution 0: Secure 1: Non-secure	R/W
13	PSARD13	POEG Group B and the MSTPCRD.MSTPD13 bit security attribution 0: Secure 1: Non-secure	R/W
14	PSARD14	POEG Group A and the MSTPCRD.MSTPD14 bit security attribution 0: Secure 1: Non-secure	R/W
15	PSARD15	ADC121 and the MSTPCRD.MSTPD15 bit security attribution 0: Secure 1: Non-secure	R/W

Bit	Symbol	Function	R/W
16	PSARD16	ADC120 and the MSTPCRD.MSTPD16 bit security attribution 0: Secure 1: Non-secure	R/W
19:17	—	These bits are read as 1. The write value should be 1.	R/W
20	PSARD20	DAC12 and the MSTPCRD.MSTPD20 bit security attribution 0: Secure 1: Non-secure	R/W
21	—	This bit is read as 1. The write value should be 1.	R/W
22	PSARD22	TSN and the MSTPCRD.MSTPD22 bit security attribution 0: Secure 1: Non-secure	R/W
31:23	—	These bits are read as 1. The write value should be 1.	R/W

Note: Only secure access can write to this register. Both secure access and Non-secure read access are allowed but Non-secure write access is not allowed and TrustZone access error is not generated.
Note: This register is write-protected by PRCR register.

The PSARD specifies the security attribution for each module and the corresponding bit in Module Stop Control Register.

52.6.4 PSARE : Peripheral Security Attribution Register E

Base address: PSCU = 0x400E_0000

Offset address: 0x10

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	PSARE31	PSARE30	PSARE29	PSARE28	PSARE27	PSARE26	PSARE25	PSARE24	PSARE23	PSARE22	—	—	—	—	—	—
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	PSARE15	PSARE14	—	—	—	—	—	—	—	—	—	—	—	PSARE2	PSARE1	PSARE0
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
0	PSARE0	WDT security attribution 0: Secure 1: Non-secure	R/W
1	PSARE1	IWDT security attribution 0: Secure 1: Non-secure	R/W
2	PSARE2	RTC security attribution 0: Secure 1: Non-secure	R/W
13:3	—	These bits are read as 1. The write value should be 1.	R/W
14	PSARE14	AGT5 and the MSTPCRE.MSTPE14 bit security attribution 0: Secure 1: Non-secure	R/W
15	PSARE15	AGT4 and the MSTPCRE.MSTPE15 bit security attribution 0: Secure 1: Non-secure	R/W
21:16	—	These bits are read as 1. The write value should be 1.	R/W
22	PSARE22	GPT9 and the MSTPCRE.MSTPE22 bit security attribution 0: Secure 1: Non-secure	R/W

Bit	Symbol	Function	R/W
23	PSARE23	GPT8 and the MSTPCRE.MSTPE23 bit security attribution 0: Secure 1: Non-secure	R/W
24	PSARE24	GPT7 and the MSTPCRE.MSTPE24 bit security attribution 0: Secure 1: Non-secure	R/W
25	PSARE25	GPT6 and the MSTPCRE.MSTPE25 bit security attribution 0: Secure 1: Non-secure	R/W
26	PSARE26	GPT5 and the MSTPCRE.MSTPE26 bit security attribution 0: Secure 1: Non-secure	R/W
27	PSARE27	GPT4 and the MSTPCRE.MSTPE27 bit security attribution 0: Secure 1: Non-secure	R/W
28	PSARE28	GPT3 and the MSTPCRE.MSTPE28 bit security attribution 0: Secure 1: Non-secure	R/W
29	PSARE29	GPT2 and the MSTPCRE.MSTPE29 bit security attribution 0: Secure 1: Non-secure	R/W
30	PSARE30	GPT1 and the MSTPCRE.MSTPE30 bit security attribution 0: Secure 1: Non-secure	R/W
31	PSARE31	GPT0, GPT_OPS and the MSTPCRE.MSTPE31 bit security attribution 0: Secure 1: Non-secure	R/W

Note: Only secure access can write to this register. Both secure access and Non-secure read access are allowed but Non-secure write access is not allowed and TrustZone access error is not generated.
Note: This register is write-protected by PRCR register.

The PSARE specifies the security attribution for each module and the corresponding bit in Module Stop Control Register.

52.6.5 MSSAR : Module Stop Security Attribution Register

Base address: PSCU = 0x400E_0000

Offset address: 0x14

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	MSSAR3	MSSAR2	MSSAR1	MSSAR0
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
0	MSSAR0	The MSTPCRC.MSTPC14 bit security attribution 0: Secure 1: Non-secure	R/W
1	MSSAR1	The MSTPCRA.MSTPA22 bit security attribution 0: Secure 1: Non-secure	R/W

Bit	Symbol	Function	R/W
2	MSSAR2	The MSTPCRA.MSTPA7 bit security attribution 0: Secure 1: Non-secure	R/W
3	MSSAR3	The MSTPCRA.MSTPA0 bit security attribution 0: Secure 1: Non-secure	R/W
31:4	—	These bits are read as 1. The write value should be 1.	R/W

Note: Only secure access can write to this register. Both secure access and Non-secure read access are allowed but Non-secure write access is not allowed and TrustZone access error is not generated.
Note: This register is write-protected by PRCR register.

The MSSAR specifies the security attribution for the corresponding bit in Module Stop Control Register.

52.6.6 CFSAMONA : Code Flash Security Attribution Monitor Register A

Base address: PSCU = 0x400E_0000

Offset address: 0x18

Bit position:	31								23								15								0
Bit field:	—	—	—	—	—	—	—	—	CFS2[8:0]								—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	The value set by user								0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
14:0	—	These bits are read as 0.	R
23:15	CFS2[8:0]	Code Flash Secure area 2 Indicate the total area of secure region and non-secure callable region for code flash.	R
31:24	—	These bits are read as 0.	R

Note: The CFSAMONA does not have security attribution.

52.6.7 CFSAMONB : Code Flash Security Attribution Monitor Register B

Base address: PSCU = 0x400E_0000

Offset address: 0x1C

Bit position:	31								23								10								0
Bit field:	—	—	—	—	—	—	—	—	CFS1[13:0]								—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	The value set by user								0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
9:0	—	These bits are read as 0.	R
23:10	CFS1[13:0]	Code Flash Secure area 1 Indicate the area of secure region for code flash.	R
31:24	—	These bits are read as 0.	R

Note: The CFSAMONB does not have security attribution.

52.6.8 DFSAMON : Data Flash Security Attribution Monitor Register

Base address: PSCU = 0x400E_0000

Offset address: 0x20

Bit position:	31															15		10									0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DFS[5:0]			—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	The value set by user			0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
9:0	—	These bits are read as 0.	R
15:10	DFS[5:0]	Data flash Secure area Indicate the area of Secure region for data flash.	R
31:16	—	These bits are read as 0.	R

Note: The DFSAMON does not have security attribution.

52.6.9 SSAMONA : SRAM Security Attribution Monitor Register A

Base address: PSCU = 0x400E_0000

Offset address: 0x24

Bit position:	31											20					13										0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	SS2[7:0]						—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	The value set by user						0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
12:0	—	These bits are read as 0.	R
20:13	SS2[7:0]	SRAM Secure area 2 Indicate the total area of Secure region and non-secure callable region for SRAM.	R
31:21	—	These bits are read as 0.	R

Note: The SSAMONA does not have security attribution.

52.6.10 SSAMONB : SRAM Security Attribution Monitor Register B

Base address: PSCU = 0x400E_0000

Offset address: 0x28

Bit position:	31											20							10								0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	SS1[10:0]								—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	The value set by user								0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
9:0	—	These bits are read as 0.	R
20:10	SS1[10:0]	SRAM secure area 1 Indicate the area of secure region for SRAM.	R
31:21	—	These bits are read as 0.	R

Note: The SSAMONB does not have security attribution.

52.6.11 DLMMON : Device Lifecycle Management State Monitor Register

Base address: PSCU = 0x400E_0000

Offset address: 0x2C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	DLMMON[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	DLM status value			

Bit	Symbol	Function	R/W
3:0	DLMMON[3:0]	Device Lifecycle Management State Monitor 0x1: CM 0x2: SSD 0x3: NSECSD 0x4: DPL 0x5: LCK_DBG 0x6: LCK_BOOT 0x7: RMA_REQ 0x8: RMA_ACK Others: Reserved	R
31:4	—	These bits are read as 0. The write value should be 0.	R

Note: The DLMMON does not have security attribution.

52.6.12 TZFSAR : TrustZone Filter Security Attribution Register

Base address: CPSCU = 0x4000_8000

Offset address: 0x180

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TZFSA0
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	0

Bit	Symbol	Function	R/W
0	TZFSA0	Security attributes of registers for TrustZone Filter 0: Secure 1: Non-secure	R/W
31:1	—	These bits are read as 1.	R

Note: Only secure access can write to this register. Both secure access and Non-secure read access are allowed but Non-secure write access is not allowed and TrustZone access error is not generated.

Note: This register is write-protected by PRCR register.

TZFSA0 bit (Security attributes of registers for TrustZone Filter)

Security attributes of register for TZFOAD and TZFPT registers.

52.6.13 TZFOAD : TrustZone Filter Operation After Detection Register

Base address: TZF = 0x4000_0E00

Offset address: 0x00

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	KEY[7:0]								—	—	—	—	—	—	—	OAD
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	OAD	Operation after detection 0: Non-maskable interrupt 1: Reset	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W
15:8	KEY[7:0]	KeyCode This bit is used to enable or disable writing of the OAD bit.	W

Note: If the security attribution is configured as secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

OAD bit (Operation after detection)

The OAD bit is specified to generate either reset or non-maskable interrupt when the access to the protect region is detected by the TrustZone Filter.

When the OAD bit is set, write 0xA5 in the KEY[7:0] bits at the same time.

KEY[7:0] bits (KeyCode)

The KEY[7:0] bits are used to enable or disable writing of the OAD bit. When writing the OAD bit, write 0xA5 in the KEY[7:0] bits at the same time.

When the KEY[7:0] bits value except 0xA5 is written in, the OAD bit is not updated.

The KEY[7:0] bits are read always as 0x00.

52.6.14 TZFPT : TrustZone Filter Protect Register

Base address: TZF = 0x4000_0E00

Offset address: 0x04

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	KEY[7:0]								—	—	—	—	—	—	—	PROTECT
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PROTECT	Protection of register 0: All Bus TrustZone Filter register writing is protected. Read is possible. 1: All Bus TrustZone Filter register writing is possible.	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W
15:8	KEY[7:0]	KeyCode This bit is used to enable or disable writing of the PROTECT bit.	W

Note: If the security attribution is configured as secure:
- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:
- Secure and Non-secure access are allowed.

PROTECT bit (Protection of register)

The PROTECT bit controls enable or disable writing to the corresponding registers to be protected. TZFOAD register is protected by PROTECT.

When the PROTECT bit is set, write 0xA5 in the KEY[7:0] bits at the same time.

KEY[7:0] bits (KeyCode)

The KEY[7:0] bits are used to enable or disable writing of the PROTECT bit. When writing the PROTECT bit, write 0xA5 in the KEY[7:0] bits at the same time.

When the KEY[7:0] bits value except 0xA5 is written in, the PROTECT bit is not updated.

The KEY[7:0] bits are read always as 0x00.

52.7 Usage Notes

52.7.1 Restrictions on setting the security attribution

To set the software breakpoint, the debugger need to re-program the flash. Table 52.10 shows the registers that the debugger sets to re-program the flash. If the security attribution of the register listed in Table 52.10 is configured as secure, the debugger cannot set the software breakpoint in NSECSD state because the debugger cannot change the register setting. Secure developper need to configure the registers listed in Table 52.10 as non-secure only in NSECSD state.

Table 52.10 The registers that the debugger sets to re-program the flash

Function name	Register name
Clock Generation Circuit	SCKDIVCR, SCKCR, PLLCCR, PLLCR, HOCOCR, MOCOCR
Low-Power modes	OPCCR, SOPCCR

52.7.2 SAU setting

After reset, all of address space is marked as Secure by SAU default setting. SAU_CTRL register should be set to 0x2 to enable the IDAU security attribution. That is, after setting SAU_CTRL register to 0x2, the address space security attribution becomes as shown in Table 52.6.

52.7.3 Non-secure exception during the setting of FACI registers

As shown in Table 52.5, the registers related to FACI are protected from non-secure access only during programming/erasure or during suspend programming/erasure. Outside of this state, the access from non-secure region is not protected. For example, when programming by the secure user, the non-secure user can rewrite the FSADDR if a non-secure exception occurs immediately after “Set the start address of the target block to the FSADDR register” flow in Figure 50.14. If the FACI command is issued after the non-secure exception processing is completed and the CPU state returns to the secure state, data will be programmed to an address not intended by the secure user.

To prevent such a things, secure user needs to set not to accept the non-secure exception during the following period.

- Set not to accept the non-secure exeption before setting FWEPROR to 0x01 or setting FENTRYR to other than 0x0000, that is before lereasing the protection of FWEPROR or FENTRYR.
- Set to accept the non-secure exception after all write access to the FACI command-issuing area is completed.

52.7.4 FCU interrupt usage

It is recommended that secure users do not use the FCU interrupts, but rather use the register polling. Because non-secure users can program/erase the data flash without calling the secure gateway, if secure user uses FCU interrupts, the unintentional exception handliing may be exeuted when data flash is programmed/erased by a non-secure user.

53. Electrical Characteristics

Supported peripheral functions and pins differ from one product name to another.

Unless otherwise specified, the electrical characteristics of the MCU are defined under the following conditions:

- VCC = AVCC0 = VCC_USB = VBATT = 2.7 to 3.6 V, VCC_USBHS = AVCC_USBHS = 3.0 to 3.6 V
- 2.7 ≤ VREFH0/VREFH ≤ AVCC0
- VSS = AVSS0 = VREFL0/VREFL = VSS_USB = VSS1_USBHS = VSS2_USBHS = AVSS_USBHS = PVSS_USBHS = 0 V
- $T_a = T_{opr}$

Figure 53.1 shows the timing conditions.

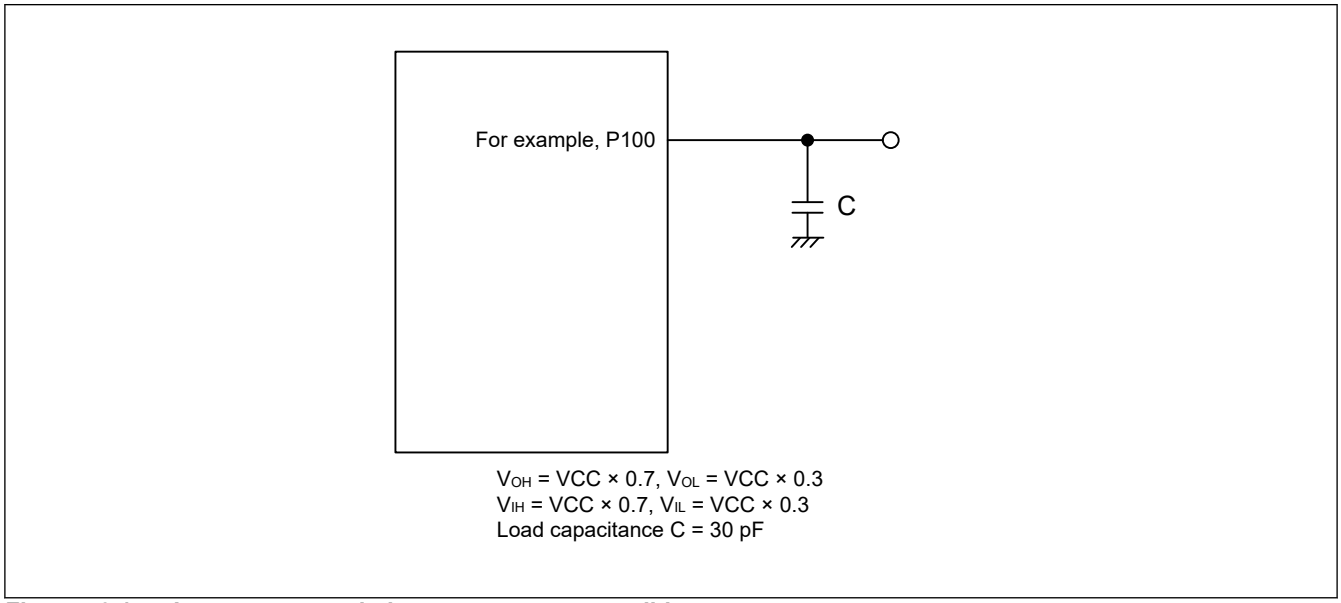

Figure 53.1 Input or output timing measurement conditions

The recommended measurement conditions for the timing specification of each peripheral provided are for the best peripheral operation. Make sure to adjust the driving abilities of each pin to meet your conditions.

53.1 Absolute Maximum Ratings

Table 53.1 Absolute maximum ratings

Parameter	Symbol	Value	Unit
Power supply voltage	VCC, VCC_USB*2	–0.3 to +4.0	V
VBATT power supply voltage	VBATT	–0.3 to +4.0	V
Input voltage (except for 5 V-tolerant ports*1)	V_{in}	–0.3 to VCC + 0.3	V
Input voltage (5 V-tolerant ports*1)	V_{in}	–0.3 to + VCC + 4.0 (max. 5.8)	V
Reference power supply voltage	VREFH/VREFH0	–0.3 to VCC + 0.3	V
USBHS power supply voltage	VCC_USBHS	–0.3 to +4.0	V
USBHS analog power supply voltage	AVCC_USBHS	–0.3 to +4.0	V
Analog power supply voltage	AVCC0*2	–0.3 to +4.0	V
Analog input voltage	V_{AN}	–0.3 to AVCC0 + 0.3	V
Operating temperature*3 *4	T_{opr}	–40 to +105	°C
Storage temperature	T_{stg}	–55 to +125	°C

Note 1. Ports P205, P206, P400, P401, P407 to P415, P511, P512, and P708 to P713 are 5 V tolerant.

Note 2. Connect AVCC0 and VCC_USB to VCC.
Note 3. See section 53.2.1. Tj/Ta Definition.
Note 4. Contact a Renesas Electronics sales office for information on derating operation when Ta = +85°C to +105°C. Derating is the systematic reduction of load for improved reliability.

Caution: Permanent damage to the MCU might result if absolute maximum ratings are exceeded.

Table 53.2 Recommended operating conditions

Parameter	Symbol	Value	Min	Typ	Max	Unit
Power supply voltages	VCC	When USB/USBHS is not used	2.7	—	3.6	V
		When USB/USBHS is used	3.0	—	3.6	V
	VSS		—	0	—	V
USB power supply voltages	VCC_USB, VCC_USBHS		—	VCC	—	V
	VSS_USB, AVSS_USBHS, PVSS_USBHS, VSS1_USBHS, VSS2_USBHS		—	0	—	V
VBATT power supply voltage	VBATT		1.65*2	—	3.6	V
Analog power supply voltages	AVCC0*1		—	VCC	—	V
	AVSS0		—	0	—	V

Note 1. Connect AVCC0 to VCC. When the A/D converter and the D/A converter are not in use, do not leave the AVCC0, VREFH/VREFH0, AVSS0, and VREFL/VREFL0 pins open. Connect the AVCC0 and VREFH/VREFH0 pins to VCC, and the AVSS0 and VREFL/VREFL0 pins to VSS, respectively.
Note 2. Low CL crystal cannot be used below VBATT = 1.8V.

53.2 DC Characteristics

53.2.1 Tj/Ta Definition

Table 53.3 DC characteristics

Parameter	Symbol	Typ	Max	Unit	Test conditions
Permissible junction temperature	T_j	—	125	°C	High-speed mode Low-speed mode Subosc-speed mode
			105*1		

Note: Make sure that $T_j = T_a + \theta ja \times$ total power consumption (W), where total power consumption = $(VCC - V_{OH}) \times \Sigma I_{OH} + V_{OL} \times \Sigma I_{OL} + I_{CC}max \times VCC$.
Note 1. The upper limit of operating temperature is 85°C or 105°C, depending on the product. For details, see section 1.3. Part Numbering. If the part number shows the operation temperature to 85°C, then T_j max is 105°C, otherwise, 125°C.

53.2.2 I/O V_{IH}, V_{IL}

Table 53.4 I/O V_{IH}, V_{IL} (1 of 2)

Parameter			Symbol	Min	Typ	Max	Unit
Input voltage (except for Schmitt trigger input pins)	Peripheral function pin	EXTAL (external clock input), WAIT, SPI (except RSPCK), OSPI (except ECS)	V_{IH}	VCC × 0.8	—	—	V
			V_{IL}	—	—	VCC × 0.2	
		D00 to D15	V_{IH}	VCC × 0.7	—	—	
			V_{IL}	—	—	VCC × 0.3	
		ETHERC	V_{IH}	2.3	—	—	
			V_{IL}	—	—	VCC × 0.2	
		IIC (SMBus)	V_{IH}	2.1	—	VCC + 3.6 (max 5.8)	
			V_{IL}	—	—	0.8	

Table 53.4 I/O V_{IH}, V_{IL} (2 of 2)

Parameter					Symbol	Min	Typ	Max	Unit
Schmitt trigger input voltage	Peripheral function pin	IIC (except for SMBus)			V_{IH}	VCC × 0.7	—	VCC + 3.6 (max 5.8)	V
					V_{IL}	—	—	VCC × 0.3	
					ΔV_T	VCC × 0.05	—	—	
		5 V-tolerant ports*1 *5			V_{IH}	VCC × 0.8	—	VCC + 3.6 (max 5.8)	
					V_{IL}	—	—	VCC × 0.2	
					ΔV_T	VCC × 0.05	—	—	
		RTCIC0, RTCIC1, RTCIC2	When using the Battery Backup Function	When VBATT power supply is selected	V_{IH}	V_{BATT} × 0.8	—	V_{BATT} + 0.3	
					V_{IL}	—	—	V_{BATT} × 0.2	
					ΔV_T	V_{BATT} × 0.05	—	—	
				When VCC power supply is selected	V_{IH}	VCC × 0.8	—	Higher voltage either VCC + 0.3 V or V_{BATT} + 0.3 V	
					V_{IL}	—	—	VCC × 0.2	
					ΔV_T	VCC × 0.05	—	—	
			When not using the Battery Backup Function		V_{IH}	VCC × 0.8	—	VCC + 0.3	
					V_{IL}	—	—	VCC × 0.2	
					ΔV_T	VCC × 0.05	—	—	
		Other input pins*2			V_{IH}	VCC × 0.8	—	—	
					V_{IL}	—	—	VCC × 0.2	
					ΔV_T	VCC × 0.05	—	—	
	Ports	5 V-tolerant ports*3 *5			V_{IH}	VCC × 0.8	—	VCC + 3.6 (max 5.8)	V
					V_{IL}	—	—	VCC × 0.2	
		Other input pins*4			V_{IH}	VCC × 0.8	—	—	
					V_{IL}	—	—	VCC × 0.2	

Note 1. RES and peripheral function pins associated with P205, P206, P400, P401, P407 to P415, P511, P512, P708 to P713 (total 22 pins).
Note 2. All input pins except for the peripheral function pins already described in the table.
Note 3. P205, P206, P400, P401, P407 to P415, P511, P512, P708 to P713 (total 21 pins).
Note 4. All input pins except for the ports already described in the table.
Note 5. When VCC is less than 2.7 V, the input voltage of 5 V-tolerant ports should be less than 3.6 V, otherwise breakdown may occur because 5 V-tolerant ports are electrically controlled so as not to violate the break down voltage.

53.2.3 I/O I_{OH}, I_{OL}

Table 53.5 I/O I_{OH}, I_{OL} (1 of 2)

Parameter			Symbol	Min	Typ	Max	Unit
Permissible output current (average value per pin)	Ports P000 to P010, P014, P015, P201	—	I_{OH}	—	—	–2.0	mA
			I_{OL}	—	—	2.0	mA
	Ports P205, P206, P407 to P415, P708 to P713, PB01 (total 18 pins)	Low drive*1	I_{OH}	—	—	–2.0	mA
			I_{OL}	—	—	2.0	mA
		Middle drive*2	I_{OH}	—	—	–4.0	mA
			I_{OL}	—	—	4.0	mA
		High drive*3	I_{OH}	—	—	–20	mA
			I_{OL}	—	—	20	mA
	Ports P100 to P107, P208 to P211, P214, P600, P601 (total 15 pins)	Low drive*1	I_{OH}	—	—	–2.0	mA
			I_{OL}	—	—	2.0	mA
		Middle drive*2	I_{OH}	—	—	–4.0	mA
			I_{OL}	—	—	4.0	mA
		High drive*3	I_{OH}	—	—	–16	mA
			I_{OL}	—	—	16	mA
		High spped high drive*4	I_{OH}	—	—	–20	mA
			I_{OL}	—	—	20	mA
	Other output pins*5	Low drive*1	I_{OH}	—	—	–2.0	mA
			I_{OL}	—	—	2.0	mA
		Middle drive*2	I_{OH}	—	—	–4.0	mA
			I_{OL}	—	—	4.0	mA
		High drive*3	I_{OH}	—	—	–16	mA
			I_{OL}	—	—	16	mA

Table 53.5 I/O I_{OH}, I_{OL} (2 of 2)

Parameter			Symbol	Min	Typ	Max	Unit
Permissible output current (max value per pin)	Ports P000 to P010, P014, P015, P201	—	I_{OH}	—	—	–4.0	mA
			I_{OL}	—	—	4.0	mA
	Ports P205, P206, P407 to P415, P708 to P713, PB01 (total 18 pins)	Low drive*1	I_{OH}	—	—	–4.0	mA
			I_{OL}	—	—	4.0	mA
		Middle drive*2	I_{OH}	—	—	–8.0	mA
			I_{OL}	—	—	8.0	mA
		High drive*3	I_{OH}	—	—	–40	mA
			I_{OL}	—	—	40	mA
	Ports P100 to P107, P208 to P211, P214, P600, P601 (total 15 pins)	Low drive*1	I_{OH}	—	—	–4.0	mA
			I_{OL}	—	—	4.0	mA
		Middle drive*2	I_{OH}	—	—	–8.0	mA
			I_{OL}	—	—	8.0	mA
		High drive*3	I_{OH}	—	—	–32	mA
			I_{OL}	—	—	32	mA
		High spped high drive*4	I_{OH}	—	—	–40	mA
			I_{OL}	—	—	40	mA
	Other output pins*5	Low drive*1	I_{OH}	—	—	–4.0	mA
			I_{OL}	—	—	4.0	mA
		Middle drive*2	I_{OH}	—	—	–8.0	mA
			I_{OL}	—	—	8.0	mA
		High drive*3	I_{OH}	—	—	–32	mA
			I_{OL}	—	—	32	mA
Permissible output current (maxvalue of total of all pins)	Maximum of all output pins		$\Sigma I_{OH\ (max)}$	—	—	–80	mA
			$\Sigma I_{OL\ (max)}$	—	—	80	mA

Note 1. This is the value when low driving ability is selected in the Port Drive Capability bit in the PmnPFS register. The selected driving ability is retained in Deep Software Standby mode.
Note 2. This is the value when middle driving ability is selected in the Port Drive Capability bit in the PmnPFS register. The selected driving ability is retained in Deep Software Standby mode.
Note 3. This is the value when high driving ability is selected in the Port Drive Capability bit in the PmnPFS register. The selected driving ability is retained in Deep Software Standby mode.
Note 4. This is the value when high speed high driving ability is selected in the Port Drive Capability in the PmnPFS register. The selected driving ability is retained in Deep Software Standby mode.
Note 5. Except for P200, which is an input port.

Caution: To protect the reliability of the MCU, the output current values should not exceed the values in this table. The average output current indicates the average value of current measured during 100 µs.

53.2.4 I/O V_{OH}, V_{OL}, and Other Characteristics

Table 53.6 I/O V_{OH}, V_{OL}, and other characteristics

Parameter		Symbol	Min	Typ	Max	Unit	Test conditions
Output voltage	IIC	V_{OL}	—	—	0.4	V	I_{OL} = 3.0 mA
		V_{OL}	—	—	0.6		I_{OL} = 6.0 mA
	IIC*1	V_{OL}	—	—	0.4		I_{OL} = 15.0 mA (ICFER.FMPE = 1)
		V_{OL}	—	0.4	—		I_{OL} = 20.0 mA (ICFER.FMPE = 1)
	ETHERC	V_{OH}	VCC – 0.5	—	—		I_{OH} = –1.0 mA
		V_{OL}	—	—	0.4		I_{OL} = 1.0 mA
	Ports P205, P206, P407 to P415, P708 to P713, PB01 (total of 18 pins)*2	V_{OH}	VCC – 1.0	—	—		I_{OH} = –20 mA VCC = 3.3 V
		V_{OL}	—	—	1.0		I_{OL} = 20 mA VCC = 3.3 V
	Other output pins	V_{OH}	VCC – 0.5	—	—		I_{OH} = –1.0 mA
		V_{OL}	—	—	0.5		I_{OL} = 1.0 mA
Input leakage current	RES	$\|I_{in}\|$	—	—	5.0	µA	V_{in} = 0 V V_{in} = 5.5 V
	Port P200		—	—	1.0		V_{in} = 0 V V_{in} = VCC
Three-state leakage current (off state)	5 V-tolerant ports	$\|I_{TSI}\|$	—	—	5.0	µA	V_{in} = 0 V V_{in} = 5.5 V
	Other ports (except for port P200)		—	—	1.0		V_{in} = 0 V V_{in} = VCC
Input pull-up MOS current	Ports P0 to PB	I_p	–300	—	–10	µA	VCC = 2.7 to 3.6 V V_{in} = 0 V
Input capacitance	USB_DP, USB_DM, and ports P014, P015, P400, P401, P511, P512	C_{in}	—	—	16	pF	Vbias = 0 V Vamp = 20 mV f = 1 MHz Ta = 25°C
	Other input pins		—	—	8		

Note 1. SCL0_A, SDA0_A (total 2 pins).
Note 2. This is the value when high driving ability is selected in the Port Drive Capability bit in the PmnPFS register. The selected driving ability is retained in Deep Software Standby mode.

53.2.5 Operating and Standby Current

Table 53.7 Operating and standby current (1 of 2)

Parameter				Symbol	Min	Typ	Max	Unit	Test conditions
Supply current[*1]	High-speed mode	Maximum[*2]		I_{CC}[*3]	—	—	143	mA	ICLK = 200 MHz PCLKA = 100 MHz PCLKB = 50 MHz PCLKC = 50 MHz PCLKD = 100 MHz FCLK = 50 MHz BCLK = 100 MHz
		Maximum (without USBHS)			—	—	130		
		CoreMark®[*5 *6]			—	22	—		
		Normal mode	All peripheral clocks enabled, while (1) code executing from flash[*4]		—	32	—		
			All peripheral clocks disabled, while (1) code executing from flash[*5 *6]		—	18	—

	ADC12 unit 1 in standby modes			—	0.07	0.8	μA	—
USB operating current	Low speed	USB	$I_{CCUSBLS}$	—	3.5	6.5	mA	VCC_USB
		USBHS		—	10.5	13.5	mA	VCC_USBHS = AVCC_USBHS (PHYSET.HSEB = 0)
		USBHS		—	2.8	3.6	mA	VCC_USBHS = AVCC_USBHS (PHYSET.HSEB = 1)
	Full speed	USB	$I_{CCUSBFS}$	—	4.0	10.0	mA	VCC_USB
		USBHS		—	14	22	mA	VCC_USBHS = AVCC_USBHS (PHYSET.HSEB = 0)
		USBHS		—	6.5	13.0	mA	VCC_USBHS = AVCC_USBHS (PHYSET.HSEB = 1)
	High speed	USBHS	$I_{CCUSBHS}$	—	50	65	mA	VCC_USBHS = AVCC_USBHS
	Standby mode (direct power down)	USBHS	$I_{CCUSBSBY}$	—	0.5	4.5	μA	VCC_USBHS = AVCC_USBHS

Note 1. Supply current values are with all output pins unloaded and all input pull-up MOSs in the off state.
Note 2. Measured with clocks supplied to the peripheral functions. This does not include the BGO operation.
Note 3. I_{CC} depends on f (ICLK) as follows.
I_{CC} Max. = 0.34 × f + 58 (max. operation in high-speed mode)
I_{CC} Typ. = 0.07 × f + 3.7 (normal operation in high-speed mode, all peripheral clocks disabled)
I_{CC} Typ. = 0.2 × f + 1.7 (low-speed mode)
I_{CC} Max. = 0.035 × f + 58 (sleep mode)
Note 4. This does not include the BGO operation.
Note 5. Supply of the clock signal to peripherals is stopped in this state. This does not include the BGO operation.
Note 6. FCLK, BCLK, PCLKA, PCLKB, PCLKC, and PCLKD are set to divided by 64 (3.125 MHz).
Note 7. Reference value
Note 8. When the MCU is in Software Standby mode or the MSTPCRD.MSTPD16 (12-Bit A/D Converter 0 Module Stop bit) and MSTPCRD.MSTPD15 (12-bit A/D converter 1 module stop bit) are in the module-stop state.
Note 9. FCLK, BCLK, PCLKA, PCLKB, PCLKC, and PCLKD are set to divided by 64 (15.6 kHz).
Note 10. BCLK, PCLKA, PCLKB, PCLKC, and PCLKD are set to divided by 64 (512 Hz). FCLK is the same frequency as that of ICLK.

Table 53.8 Coremark and normal mode current

Parameter			Symbol	Typ	Unit	Test conditions
Supply Current*1	Coremark		I_{CC}	107	µA/MHz	ICLK = 200MHz PCLKA = PCLKB = PCLKC = PCLKD = FCLK = BCLK = 3.125MHz
	Normal mode	All peripheral clocks disabled, cache on, while (1) code executing from flash*2		104		
		All peripheral clocks disabled, cache off, while (1) code executing from flash*2		87		

Note 1. Supply current values are with all output pins unloaded and all input pull-up MOSs in the off state.
Note 2. Supply of the clock signal to peripherals is stopped in this state. This does not include the BGO operation.

53.2.6 VCC Rise and Fall Gradient and Ripple Frequency

Table 53.9 Rise and fall gradient characteristics

Parameter		Symbol	Min	Typ	Max	Unit	Test conditions
VCC rising gradient	Voltage monitor 0 reset disabled at startup	SrVCC	0.0084	—	20	ms/V	—
	Voltage monitor 0 reset enabled at startup		0.0084	—	—		—
	SCI/USB boot mode*1		0.0084	—	20		—
VCC falling gradient*2		SfVCC	0.0084	—	—	ms/V	—

Note 1. At boot mode, the reset from voltage monitor 0 is disabled regardless of the value of the OFS1.LVDAS bit.
Note 2. This applies when VBATT is used.

Table 53.10 Rising and falling gradient and ripple frequency characteristics

The ripple voltage must meet the allowable ripple frequency $f_{r(VCC)}$ within the range between the VCC upper limit (3.6 V) and lower limit (2.7 V). When the VCC change exceeds VCC ±10%, the allowable voltage change rising and falling gradient dt/dVCC must be met.

Parameter	Symbol	Min	Typ	Max	Unit	Test conditions
Allowable ripple frequency	$f_{r\ (VCC)}$	—	—	10	kHz	Figure 53.6 $V_{r\ (VCC)} \leq VCC \times 0.2$
		—	—	1	MHz	Figure 53.6 $V_{r\ (VCC)} \leq VCC \times 0.08$
		—	—	10	MHz	Figure 53.6 $V_{r\ (VCC)} \leq VCC \times 0.06$
Allowable voltage change rising and falling gradient	dt/dVCC	1.0	—	—	ms/V	When VCC change exceeds VCC ±10%

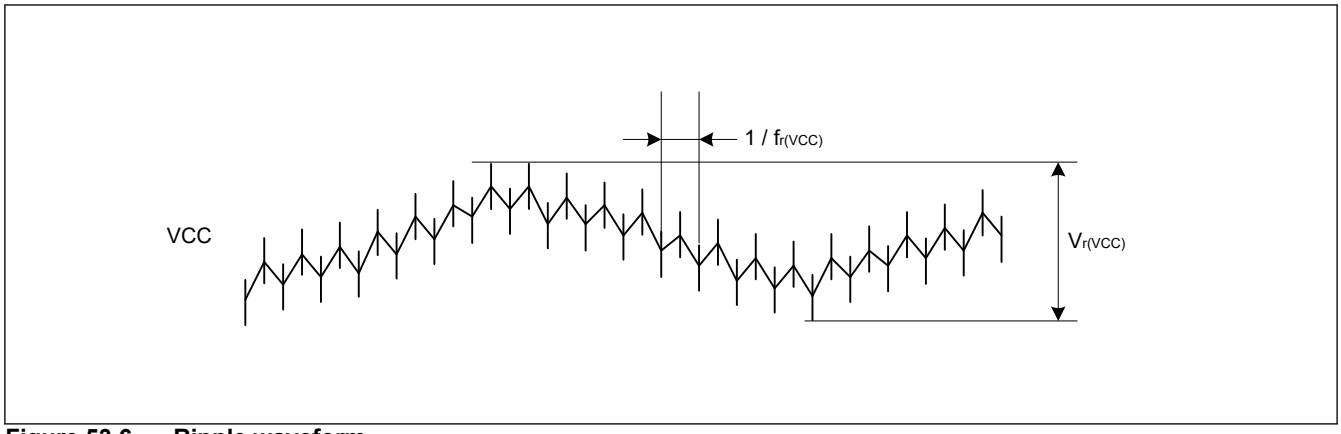

Figure 53.6 Ripple waveform

53.2.7 Thermal Characteristics

Maximum value of junction temperature (Tj) must not exceed the value of "section 53.2.1. Tj/Ta Definition".

Tj is calculated by either of the following equations.

- Tj = Ta + θja × Total power consumption
- Tj = Tt + Ψjt × Total power consumption
  - Tj : Junction Temperature (°C)
  - Ta : Ambient Temperature (°C)
  - Tt : Top Center Case Temperature (°C)
  - θja : Thermal Resistance of "Junction"-to-"Ambient" (°C/W)
  - Ψjt : Thermal Resistance of "Junction"-to-"Top Center Case" (°C/W)
- Total power consumption = Voltage × (Leakage current + Dynamic current)
- Leakage current of IO = Σ (I_{OL} × V_{OL}) /Voltage + Σ ($|I_{OH}|$ × |VCC – V_{OH}|) /Voltage
- Dynamic current of IO = Σ IO (C_{in} + C_{load}) × IO switching frequency × Voltage
  - C_{in}: Input capacitance
  - C_{load}: Output capacitance

Regarding θja and Ψjt, see Table 53.11.

Table 53.11 Thermal Resistance

Parameter	Package	Symbol	Value*1	Unit	Test conditions
Thermal Resistance	100-pin LQFP (PLQP0100KB-B)	θja	35.0	°C/W	JESD 51-2 and 51-7 compliant
	144-pin LQFP (PLQP0144KA-B)		33.0		
	176-pin LQFP (PLQP0176KB-C)		32.3		
	144-pin BGA (PLBG0144KB-A)		36.3		JESD 51-2 and 51-9 compliant
	176-pin BGA (PLBG0176GF-A)		35.4		
	100-pin LQFP (PLQP0100KB-B)	Ψjt	0.76	°C/W	JESD 51-2 and 51-7 compliant
	144-pin LQFP (PLQP0144KA-B)		0.63		
	176-pin LQFP (PLQP0176KB-C)		0.48		
	144-pin BGA (PLBG0144KB-A)		0.49		JESD 51-2 and 51-9 compliant
	176-pin BGA (PLBG0176GF-A)		0.52		

Note 1. The values are reference values when the 4-layer board is used. Thermal resistance depends on the number of layers or size of the board. For details, refer to the JEDEC standards.

53.2.7.1 Calculation guide of I_{CC}max

Table 53.12 shows the power consumption of each unit.

Table 53.12 Power consumption of each unit

Dynamic current/ Leakage current	MCU Domain	Category	Item	Frequency [MHz]	Current [uA/MHz]	Current*1 [mA]
Leakage current	Analog	LDO and Leak*2	Ta = 75 °C*3	—	—	28.6
			Ta = 85 °C*3	—	—	34.0
			Ta = 95 °C*3	—	—	41.1
			Ta = 105 °C*3	—	—	50.5
Dynamic current	CPU	Operation with Flash and SRAM	Coremark	200	90.786	18.16
	Peripheral Unit	Timer	GPT16 (6ch)*4	100	5.101	0.51
			GPT32 (4ch)*4	100	3.990	0.40
			POEG (4 Groups)*4	50	1.364	0.07
			AGT (6ch)*4	50	11.852	0.59
			RTC	50	4.872	0.24
			WDT	50	0.740	0.04
			IWDT	50	0.282	0.01
		Communication interfaces	ETHERC	100	8.307	0.83
			USBFS	50	9.631	0.48
			USBHS	50	23.571	1.18
			SCI (10ch)*4	100	12.631	1.26
			IIC (2ch)*4	50	4.210	0.21
			CAN/CANFD (2ch)*4	50	23.346	1.17
			CEC	100	0.336	0.03
			SPI (2ch)*4	100	7.503	0.75
			OSPI	50	33.444	1.67
			QSPI	100	2.511	0.25
			SSIE	50	3.480	0.17
			SDHI	50	7.781	0.39
		Analog	ADC12 (2 Units)*4	100	4.725	0.47
			DAC12 (2ch)*4	100	3.630	0.36
			TSN	50	0.161	0.01
		Human machine interfaces	CTSU	50	0.761	0.04
		Event link	ELC	50	1.002	0.05
		Security	SCE9	100	218.100	21.81
		Data processing	CRC	100	0.569	0.06
			DOC	100	0.441	0.04
		System	CAC	50	0.990	0.05
		DMA	DMAC	200	4.519	0.90
			DTC	200	4.427	0.89

Note 1. The values are guaranteed by design.

Note 2. LDO and Leak are internal voltage regulator's current and MCU's leakage current.
It is selected according to the temperature of Ta.
Note 3. Δ(Tj-Ta) = 20 °C is considered to measure the current.
Note 4. To determine the current consumption per channel or unit, divide Current [mA] by the number of channels, groups or units.

Table 53.13 shows the outline of operation for each unit.

Table 53.13 Outline of operation for each unit (1 of 2)

Peripheral	Outline of operation
GPT	Operating modes is set to saw-wave PWM mode. GPT is operating with PCLKD.
POEG	Only clear module stop bit.
AGT	AGT is operating with PCLKB.
RTC	RTC is operating with LOCO.
WDT	WDT is operating with PCLKB.
IWDT	IWDT is operating with IWDTCLK.
ETHERC	Operation modes is set to full-duplex mode. ETHERC is operating using Reduced Media Independent Interface (RMII).
USBFS	Transfer types is set to bulk transfer. USBFS is operating using Full-speed transfer (12 Mbps).
USBHS	Transfer types is set to bulk transfer. USBHS is operating using High-speed transfer.
SCI	SCI is transmitting data in clock synchronous mode.
IIC	Communication format is set to I2C-bus format. IIC is transmitting data in master mode.
CANFD	CANFD is transmitting and receiving data in self-test mode 1.
SPI	SPI mode is set to SPI operation (4-wire method). SPI master/slave mode is set to master mode. SPI is transmitting 8-bit width data.
OSPI	Transfer mode is single continuous write mode. OSPI is issuing memory write command to OctaRAM.
QSPI	QSPI is issuing Fast Read Quad I/O Instruction.
SSIE	Communication mode is set to Master. System word length is set to 32 bits. Data word length is set to 20 bits. SSIE is transmitting data using I2S format.
CEC	CEC operation clock is set to CECCLK. CEC is transmitting and receiving header block and data block.
SDHI	Transfer bus mode is set to 4-bit wide bus mode. SDHI is issuing CMD24 (single-block write).
ADC12	Resolution is set to 12-bit accuracy. Data registers is set to A/D-converted value addition mode. ADC12 is converting the analog input in continuous scan mode.
DAC12	DAC12 is outputting the conversion result while updating the value of data register.
TSN	TSN is operating.
CTSU	CTSU is operating in self-capacitance single scan mode.
ELC	Only clear module stop bit.
SCE9	SCE9 is executing built-in self test.
CRC	CRC is generating CRC code using 32-bit CRC32-C polynomial.
DOC	DOC is operating in data addition mode.
CAC	Measurement target clocks is set to PCLKB. Measurement reference clocks is set to PCLKB. CAC is measuring the clock frequency accuracy.

Table 53.13 Outline of operation for each unit (2 of 2)

Peripheral	Outline of operation
DMAC	Bit length of transfer data is set to 32 bits. Transfer mode is set to block transfer mode. DMAC is transferring data from SRAM0 to SRAM0.
DTC	Bit length of transfer data is set to 32 bits. Transfer mode is set to block transfer mode. DTC is transferring data from SRAM0 to SRAM0.

53.2.7.2 Example of T_j calculation

Assumption :

- Package 176-pin LQFP : θja = 32.3 °C/W
- Ta = 100 °C
- I_{CC}max = 70 mA
- VCC = 3.5 V (VCC = AVCC0 = AVCC_USBHS = VCC_USB = VCC_USBHS)
- I_{OH} = 1 mA, V_{OH} = VCC – 0.5 V, 12 Outputs
- I_{OL} = 20 mA, V_{OL} = 1.0 V, 8 Outputs
- I_{OL} = 1 mA, V_{OL} = 0.5 V, 12 Outputs
- C_{in} = 8 pF, 32 pins, Input frequency = 10 MHz
- C_{load} = 30 pF, 32 pins, Output frequency = 10 MHz

Leakage current of IO = Σ (V_{OL} × I_{OL}) / Voltage + Σ ((VCC - V_{OH}) × I_{OH}) / Voltage
= (20 mA × 1 V) × 8 / 3.5 V + (1 mA × 0.5 V) × 12 / 3.5 V + ((VCC - (VCC - 0.5 V)) × 1 mA) × 12 / 3.5 V
= 45.7 mA + 1.71 mA + 1.71 mA
= 49.1 mA

Dynamic current of IO = Σ IO (C_{in} + C_{load}) × IO switching frequency × Voltage
= ((8 pF × 32) × 10 MHz + (30 pF × 32) × 10 MHz) × 3.5 V
= 42.6 mA

Total power consumption = Voltage × (Leakage current + Dynamic current)
= (70 mA × 3.5 V) + (49.1 mA + 42.6 mA) × 3.5 V
= 566 mW (0.566 W)

Tj = Ta + θja × Total power consumption
= 100 °C + 32.3 °C/W × 0.566W
= 118.7 °C

53.3 AC Characteristics

53.3.1 Frequency

Table 53.14 Operation frequency value in high-speed mode

Parameter		Symbol	Min	Typ	Max	Unit
Operation frequency	System clock (ICLK*2)	f	—	—	200	MHz
	Peripheral module clock (PCLKA)*2		—	—	100	
	Peripheral module clock (PCLKB)*2		—	—	50	
	Peripheral module clock (PCLKC)*2		—*3	—	50	
	Peripheral module clock (PCLKD)*2		—	—	100	
	Flash interface clock (FCLK)*2		—*1	—	50	
	External bus clock (BCLK)*2		—	—	100	
	EBCLK pin output		—	—	50	

Note 1. FCLK must run at a frequency of at least 4 MHz when programming or erasing the flash memory.
Note 2. See section 8, Clock Generation Circuit for the relationship between the ICLK, PCLKA, PCLKB, PCLKC, PCLKD, FCLK, and BCLK frequencies.
Note 3. When the ADC12 is used, the PCLKC frequency must be at least 1 MHz.

Table 53.15 Operation frequency value in low-speed mode

Parameter		Symbol	Min	Typ	Max	Unit
Operation frequency	System clock (ICLK)*2	f	—	—	1	MHz
	Peripheral module clock (PCLKA)*2		—	—	1	
	Peripheral module clock (PCLKB)*2		—	—	1	
	Peripheral module clock (PCLKC)*2 *3		—*3	—	1	
	Peripheral module clock (PCLKD)*2		—	—	1	
	Flash interface clock (FCLK)*1 *2		—	—	1	
	External bus clock (BCLK)		—	—	1	
	EBCLK pin output		—	—	1	

Note 1. Programming or erasing the flash memory is disabled in low-speed mode.
Note 2. See section 8, Clock Generation Circuit for the relationship between the ICLK, PCLKA, PCLKB, PCLKC, PCLKD, FCLK, and BCLK frequencies.
Note 3. When the ADC12 is used, the PCLKC frequency must be set to at least 1 MHz.

Table 53.16 Operation frequency value in Subosc-speed mode

Parameter		Symbol	Min	Typ	Max	Unit
Operation frequency	System clock (ICLK)*2	f	29.4	—	36.1	kHz
	Peripheral module clock (PCLKA)*2		—	—	36.1	
	Peripheral module clock (PCLKB)*2		—	—	36.1	
	Peripheral module clock (PCLKC)*2 *3		—	—	36.1	
	Peripheral module clock (PCLKD)*2		—	—	36.1	
	Flash interface clock (FCLK)*1 *2		29.4	—	36.1	
	External bus clock (BCLK)*2		—	—	36.1	
	EBCLK pin output		—	—	36.1	

Note 1. Programming or erasing the flash memory is disabled in Subosc-speed mode.
Note 2. See section 8, Clock Generation Circuit for the relationship between the ICLK, PCLKA, PCLKB, PCLKC, PCLKD, FCLK, and BCLK frequencies.
Note 3. The ADC12 cannot be used.

53.3.2 Clock Timing

Table 53.17 Clock timing except for sub-clock oscillator

Parameter		Symbol	Min	Typ	Max	Unit	Test conditions
EBCLK pin output cycle time		t_{Bcyc}	20	—	—	ns	Figure 53.7
EBCLK pin output high pulse width		t_{CH}	3.3	—	—	ns	
EBCLK pin output low pulse width		t_{CL}	3.3	—	—	ns	
EBCLK pin output rise time		t_{Cr}	—	—	5.0	ns	
EBCLK pin output fall time		t_{Cf}	—	—	5.0	ns	
EXTAL external clock input cycle time		t_{EXcyc}	41.66	—	—	ns	Figure 53.8
EXTAL external clock input high pulse width		t_{EXH}	15.83	—	—	ns	
EXTAL external clock input low pulse width		t_{EXL}	15.83	—	—	ns	
EXTAL external clock rise time		t_{EXr}	—	—	5.0	ns	
EXTAL external clock fall time		t_{EXf}	—	—	5.0	ns	
Main clock oscillator frequency		f_{MAIN}	8	—	24	MHz	—
Main clock oscillation stabilization wait time (crystal)*1		$t_{MAINOSCWT}$	—	—	—*1	ms	Figure 53.9
LOCO clock oscillation frequency		f_{LOCO}	29.4912	32.768	36.0448	kHz	—
LOCO clock oscillation stabilization wait time		t_{LOCOWT}	—	—	60.4	µs	Figure 53.10
ILOCO clock oscillation frequency		f_{ILOCO}	13.5	15	16.5	kHz	—
MOCO clock oscillation frequency		f_{MOCO}	6.8	8	9.2	MHz	—
MOCO clock oscillation stabilization wait time		t_{MOCOWT}	—	—	15.0	µs	—
HOCO clock oscillator oscillation frequency	Without FLL	f_{HOCO16}	15.78	16	16.22	MHz	–20 ≤ Ta ≤ 105°C
		f_{HOCO18}	17.75	18	18.25		
		f_{HOCO20}	19.72	20	20.28		
		f_{HOCO16}	15.71	16	16.29		–40 ≤ Ta ≤ –20°C
		f_{HOCO18}	17.68	18	18.32		
		f_{HOCO20}	19.64	20	20.36		
	With FLL	f_{HOCO16}	15.960	16	16.040		–40 ≤ Ta ≤ 105°C Sub-clock frequency accuracy is ±50 ppm.
		f_{HOCO18}	17.955	18	18.045		
		f_{HOCO20}	19.950	20	20.050		
HOCO clock oscillation stabilization wait time*2		t_{HOCOWT}	—	—	64.7	µs	—
HOCO period jitter		—	—	—	±85	ps	—
FLL stabilization wait time		t_{FLLWT}	—	—	1.8	ms	—
PLL clock frequency		f_{PLL}	120	—	200	MHz	—
PLL2 clock frequency		f_{PLL2}	120	—	240	MHz	—
PLL/PLL2 clock oscillation stabilization wait time		t_{PLLWT}	—	—	174.9	µs	Figure 53.11
PLL/PLL2 period jitter		—	—	—	±100	ps	—
PLL/PLL2 long term jitter		—	—	—	±300	ps	Term: 1µs, 10µs

Note 1. When setting up the main clock oscillator, ask the oscillator manufacturer for an oscillation evaluation, and use the results as the recommended oscillation stabilization time. Set the MOSCWTCR register to a value equal to or greater than the recommended value.
After changing the setting in the MOSCCR.MOSTP bit to start main clock operation, read the OSCSF.MOSCSF flag to confirm that it is 1, and then start using the main clock oscillator.

Note 2. This is the time from release from reset state until the HOCO oscillation frequency (f_{HOCO}) reaches the range for guaranteed operation.

Table 53.18 Clock timing for the sub-clock oscillator

Parameter	Symbol	Min	Typ	Max	Unit	Test conditions
Sub-clock frequency	f_{SUB}	—	32.768	—	kHz	—
Sub-clock oscillation stabilization wait time	$t_{SUBOSCWT}$	—	—	—*1	s	Figure 53.12

Note 1. When setting up the sub-clock oscillator, ask the oscillator manufacturer for an oscillation evaluation and use the results as the recommended oscillation stabilization time.
After changing the setting in the SOSCCR.SOSTP bit to start sub-clock operation, only start using the sub-clock oscillator after the sub-clock oscillation stabilization time elapses with an adequate margin. A value that is two times the value shown is recommended.

53.3.4 Wakeup Timing

Table 53.20 Timing of recovery from low power modes (1 of 2)

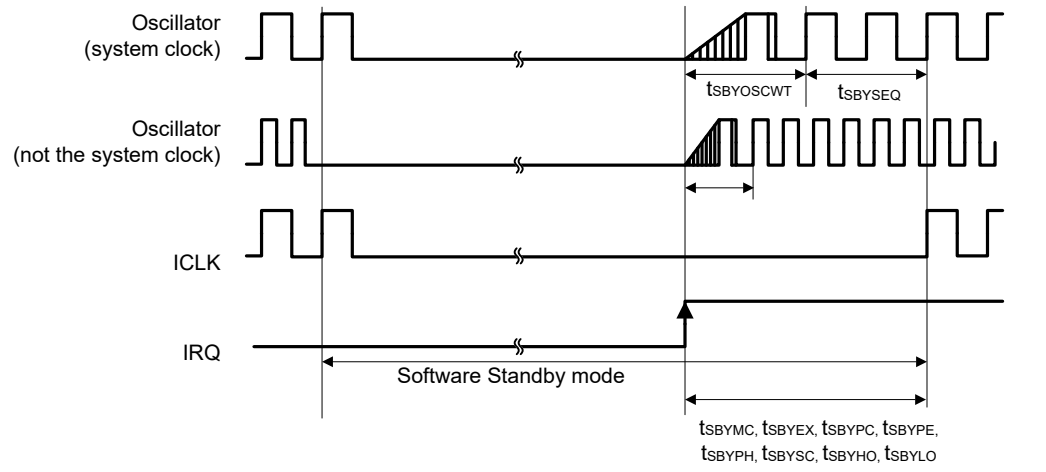
Parameter			Symbol	Min	Typ	Max	Unit	Test conditions
Recovery time from Software Standby mode*1	Crystal resonator connected to main clock oscillator	System clock source is main clock oscillator*2	t_{SBYMC}*13	—	2.1	2.4	ms	Figure 53.15 The division ratio of all oscillators is 1.
		System clock source is PLL with main clock oscillator*3	t_{SBYPC}*13	—	2.2	2.6	ms	
	External clock input to main clock oscillator	System clock source is main clock oscillator*4	t_{SBYEX}*13	—	45	125	µs	
		System clock source is PLL with main clock oscillator*5	t_{SBYPE}*13	—	170	255	µs	
	System clock source is sub-clock oscillator*6 *11		t_{SBYSC}*13	—	0.7	0.8	ms	
	System clock source is LOCO*7 *11		t_{SBYLO}*13	—	0.7	0.9	ms	
	System clock source is HOCO clock oscillator*8		t_{SBYHO}*13	—	55	130	µs	
	System clock source is PLL with HOCO*9		t_{SBYPH}*13	—	175	265	µs	
	System clock source is MOCO clock oscillator*10		t_{SBYMO}*13	—	35	65	µs	

Table 53.20 Timing of recovery from low power modes (2 of 2)

Parameter		Symbol	Min	Typ	Max	Unit	Test conditions
Recovery time from Deep Software Standby mode	DPSBYCR.DEEPCUT[1] = 0 and DPSWCR.WTSTS[5:0] = 0x0E	t_{DSBY}	—	0.38	0.54	ms	Figure 53.16
	DPSBYCR.DEEPCUT[1] = 1 and DPSWCR.WTSTS[5:0] = 0x19	t_{DSBY}	—	0.55	0.73	ms	
Wait time after cancellation of Deep Software Standby mode		t_{DSBYWT}	56	—	57	t_{cyc}	
Recovery time from Software Standby mode to Snooze mode	High-speed mode when system clock source is HOCO (20 MHz)	t_{SNZ}	—	35*12	70*12	µs	Figure 53.17
	High-speed mode when system clock source is MOCO (8 MHz)	t_{SNZ}	—	11*12	14*12	µs	

Note 1. The recovery time is determined by the system clock source. When multiple oscillators are active, the recovery time can be determined with the following equation:
Total recovery time = recovery time for an oscillator as the system clock source + the longest tSBYOSCWT in the active oscillators - tSBYOSCWT for the system clock + 2 LOCO cycles (when LOCO is operating) + Subosc is oscillating and MSTPC0 = 0 (CAC module stop))
Note 2. When the frequency of the crystal is 24 MHz (Main Clock Oscillator Wait Control Register (MOSCWTCR) is set to 0x05) and the greatest value of the internal clock division setting is 1.
Note 3. When the frequency of PLL is 200 MHz (Main Clock Oscillator Wait Control Register (MOSCWTCR) is set to 0x05) and the greatest value of the internal clock division setting is 4.
Note 4. When the frequency of the external clock is 24 MHz (Main Clock Oscillator Wait Control Register (MOSCWTCR) is set to 0x00) and the greatest value of the internal clock division setting is 1.
Note 5. When the frequency of PLL is 200 MHz (Main Clock Oscillator Wait Control Register (MOSCWTCR) is set to 0x00) and the greatest value of the internal clock division setting is 4.
Note 6. The Sub-clock oscillator frequency is 32.768 KHz and the greatest value of the internal clock division setting is 1.
Note 7. The LOCO frequency is 32.768 kHz and the greatest value of the internal clock division setting is 1.
Note 8. The HOCO frequency is 20 MHz and the greatest value of the internal clock division setting is 1.
Note 9. The PLL frequency is 200 MHz and the greatest value of the internal clock division setting is 4.
Note 10. The MOCO frequency is 8 MHz and the greatest value of the internal clock division setting is 1.
Note 11. In Subosc-speed mode, the sub-clock oscillator or LOCO continues oscillating in Software Standby mode.
Note 12. When the SNZCR.RXDREQEN bit is set to 0, the following time is added as the power supply recovery time: 16 µs (typical), 48 µs (maximum).
Note 13. The recovery time can be calculated with the equation of tSBYOSCWT + tSBYSEQ. And they can be determined with the following value and equation. For n, the greatest value is selected from among the internal clock division settings.

Wakeup time	TYP		MAX		Unit
	tSBYOSCWT	tSBYSEQ	tSBYOSCWT	tSBYSEQ	
tSBYMC	(MSTS[7:0]*32 + 3) / 0.262	35 + 18 / fICLK + 4n / fMAIN	(MSTS[7:0]*32 + 14 / 0.236	62 + 18 / fICLK + 4n / fMAIN	µs
tSBYPC	(MSTS[7:0]*32 + 34) / 0.262	35 + 18 / fICLK + 4n / fPLL	(MSTS[7:0]*32 + 45) / 0.236	62 + 18 / fICLK + 4n / fPLL	µs
tSBYEX	10	35 + 18 / fICLK + 4n / fEXMAIN	62	62 + 18 / fICLK + 4n / fEXMAIN	µs
tSBYPE	135	35 + 18 / fICLK + 4n / fPLL	192	62 + 18 / fICLK + 4n / fPLL	µs
tSBYSC	0	35 + 18 / fICLK + 4n / fSUB	0	62 + 18 / fICLK + 4n / fSUB	µs
tSBYLO	0	35 + 18 / fICLK + 4n / fLOCO	0	62 + 18 / fICLK + 4n / fLOCO	µs
tSBYHO	20	35 + 18 / fICLK + 4n / fHOCO	67	62 + 18 / fICLK + 4n / fHOCO	µs
tSBYPH	140	35 + 18 / fICLK + 4n / fPLL	202	62 + 18 / fICLK + 4n / fPLL	µs
tSBYMO	0	35 + 18 / fICLK + 4n / fMOCO	0	62 + 18 / fICLK + 4n / fMOCO	µs



When stabilization of the system clock oscillator is slower

53.3.5 NMI and IRQ Noise Filter

Table 53.21 NMI and IRQ noise filter

Parameter	Symbol	Min	Typ	Max	Unit	Test conditions	
NMI pulse width	t_{NMIW}	200	—	—	ns	NMI digital filter disabled	$t_{Pcyc} \times 2 \leq 200$ ns
		$t_{Pcyc} \times 2$*1	—	—			$t_{Pcyc} \times 2 > 200$ ns
		200	—	—		NMI digital filter enabled	$t_{NMICK} \times 3 \leq 200$ ns
		$t_{NMICK} \times 3.5$*2	—	—			$t_{NMICK} \times 3 > 200$ ns
IRQ pulse width	t_{IRQW}	200	—	—	ns	IRQ digital filter disabled	$t_{Pcyc} \times 2 \leq 200$ ns
		$t_{Pcyc} \times 2$*1	—	—			$t_{Pcyc} \times 2 > 200$ ns
		200	—	—		IRQ digital filter enabled	$t_{IRQCK} \times 3 \leq 200$ ns
		$t_{IRQCK} \times 3.5$*3	—	—			$t_{IRQCK} \times 3 > 200$ ns

Note: 200 ns minimum in Software Standby mode.
Note: If the clock source is switched, add 4 clock cycles of the switched source.
Note 1. t_{Pcyc} indicates the PCLKB cycle.
Note 2. t_{NMICK} indicates the cycle of the NMI digital filter sampling clock.
Note 3. t_{IRQCK} indicates the cycle of the IRQi digital filter sampling clock.

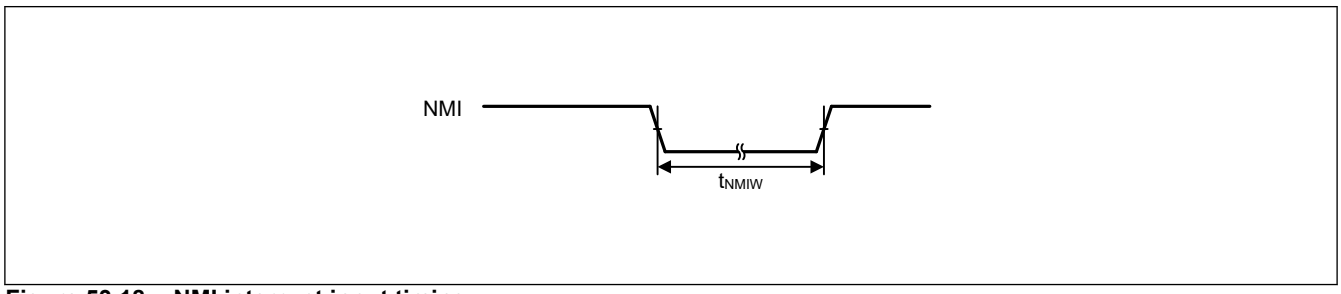

Figure 53.18 NMI interrupt input timing

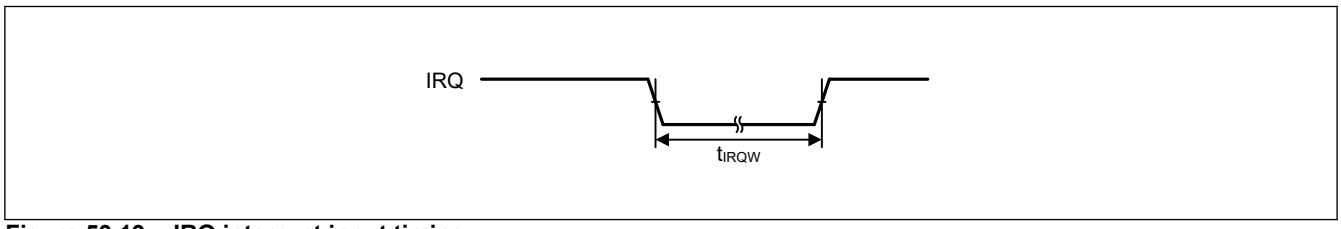

Figure 53.19 IRQ interrupt input timing

53.3.6 Bus Timing

Table 53.22 Bus timing

Condition:
Output load conditions: VOH = VCC × 0.5, VOL = VCC × 0.5, C = 30 pF.
EBCLK: High drive output is selected in the Port Drive Capability bit in the PmnPFS register.
Others: Middle drive output is selected in the Port Drive Capability bit in the PmnPFS register.

Parameter	Symbol	Min	Max	Unit	Test conditions
Address delay	t_{AD}	—	12.5	ns	Figure 53.22 to Figure 53.25
Byte control delay	t_{BCD}	—	12.5	ns	
CS delay	t_{CSD}	—	12.5	ns	
ALE delay time	t_{ALED}	—	12.5	ns	
RD delay	t_{RSD}	—	12.5	ns	
Read data setup time	t_{RDS}	12.5	—	ns	
Read data hold time	t_{RDH}	0	—	ns	
WR/WRn delay	t_{WRD}	—	12.5	ns	
Write data delay	t_{WDD}	—	12.5	ns	
Write data hold time	t_{WDH}	0	—	ns	
WAIT setup time	t_{WTS}	12.5	—	ns	Figure 53.26
WAIT hold time	t_{WTH}	0	—	ns

53.3.7 I/O Ports, POEG, GPT, AGT, and ADC12 Trigger Timing

Table 53.23 I/O ports, POEG, GPT, AGT, and ADC12 trigger timing (1 of 2)

GPT32 Conditions:
High drive output is selected in the Port Drive Capability bit in the PmnPFS register.
AGT Conditions:
Middle drive output is selected in the Port Drive Capability bit in the PmnPFS register.

Parameter			Symbol	Min	Max	Unit	Test conditions
I/O ports	Input data pulse width		t_{PRW}	1.5	—	t_{Pcyc}	Figure 53.27
POEG	POEG input trigger pulse width		t_{POEW}	3	—	t_{Pcyc}	Figure 53.28
GPT	Input capture pulse width	Single edge	t_{GTICW}	1.5	—	t_{PDcyc}	Figure 53.29
		Dual edge		2.5	—		
	GTIOCxY output skew (x = 0 to 3, Y = A or B)	Middle drive buffer	t_{GTISK}*1	—	4	ns	Figure 53.30
		High drive buffer		—	4		
	GTIOCxY output skew (x = 4 to 9, Y = A or B)	Middle drive buffer		—	4		
		High drive buffer		—	4		
	GTIOCxY output skew (x = 0 to 9, Y = A or B)	Middle drive buffer		—	6		
		High drive buffer		—	6		
	OPS output skew GTOUUP, GTOULO, GTOVUP, GTOVLO, GTOWUP, GTOWLO		t_{GTOSK}	—	5	ns	Figure 53.31

Table 53.23 I/O ports, POEG, GPT, AGT, and ADC12 trigger timing (2 of 2)

GPT32 Conditions:
High drive output is selected in the Port Drive Capability bit in the PmnPFS register.
AGT Conditions:
Middle drive output is selected in the Port Drive Capability bit in the PmnPFS register.

Parameter		Symbol	Min	Max	Unit	Test conditions
AGT	AGTIO, AGTEE input cycle	t_{ACYC} *2	100	—	ns	Figure 53.32
	AGTIO, AGTEE input high width, low width	t_{ACKWH}, t_{ACKWL}	40	—	ns	
	AGTIO, AGTO, AGTOA, AGTOB output cycle	t_{ACYC2}	62.5	—	ns	
ADC12	ADC12 trigger input pulse width	t_{TRGW}	1.5	—	t_{Pcyc}	Figure 53.33

Note: t_{Pcyc}: PCLKB cycle, t_{PDcyc}: PCLKD cycle.
Note 1. This skew applies when the same driver I/O is used. If the I/O of the middle and high drivers is mixed, operation is not guaranteed.
Note 2. Constraints on input cycle:
When not switching the source clock: $t_{Pcyc} \times 2 < t_{ACYC}$ should be satisfied.
When switching the source clock: $t_{Pcyc} \times 6 < t_{ACYC}$ should be satisfied.

53.3.8 CAC Timing

Table 53.24 CAC timing

Parameter			Symbol	Min	Typ	Max	Unit	Test conditions
CAC	CACREF input pulse width	$t_{PBcyc} \leq t_{cac}$ *1	t_{CACREF}	$4.5 \times t_{cac} + 3 \times t_{PBcyc}$	—	—	ns	—
		$t_{PBcyc} > t_{cac}$ *1		$5 \times t_{cac} + 6.5 \times t_{PBcyc}$	—	—	ns	

Note: t_{PBcyc}: PCLKB cycle.
Note 1. t_{cac}: CAC count clock source cycle.

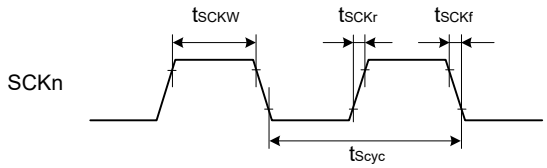
53.3.9 SCI Timing

Table 53.25 SCI timing (1)

Conditions: High drive output is selected in the Port Drive Capability bit in the PmnPFS register.

Parameter			Symbol	Min	Max	Unit	Test conditions
SCI	Input clock cycle	Asynchronous	t_{Scyc}	4	—	t_{Pcyc}	Figure 53.34
		Clock synchronous		6	—		
	Input clock pulse width		t_{SCKW}	0.4	0.6	t_{Scyc}	
	Input clock rise time		t_{SCKr}	—	5	ns	
	Input clock fall time		t_{SCKf}	—	5	ns	
	Output clock cycle	Asynchronous	t_{Scyc}	6 (other than SCI1, SCI2) 8 (SCI1, SCI2)	—	t_{Pcyc}	
		Clock synchronous		4	—		
	Output clock pulse width		t_{SCKW}	0.4	0.6	t_{Scyc}	
	Output clock rise time		t_{SCKr}	—	5	ns	
	Output clock fall time		t_{SCKf}	—	5	ns	
	Transmit data delay	Clock synchronous master mode (internal clock)	t_{TXD}	—	5	ns	Figure 53.35
		Clock synchronous slave mode (external clock)	t_{TXD}	—	25	ns	
	Receive data setup time	Clock synchronous master mode (internal clock)	t_{RXS}	15	—	ns	
		Clock synchronous slave mode (external clock)	t_{RXS}	5	—	ns	
	Receive data hold time	Clock synchronous	t_{RXH}	5	—	ns	

Note: t_{Pcyc}: PCLKA cycle.



Note: n = 0 to 9

53.3.13 IIC Timing

Table 53.31 IIC timing (1) (1 of 2)

(1) Conditions: Middle drive output is selected in the Port Drive Capability bit in the PmnPFS register for the following pins: SDA0_B, SCL0_B, SDA1_B, SCL1_B, SDA2, SCL2.
(2) The following pins do not require setting: SCL0_A, SDA0_A, SCL1_A, SDA1_A.
(3) Use pins that have a letter appended to their names, for instance "_A" or "_B", to indicate group membership. For the IIC interface, the AC portion of the electrical characteristics is measured for each group.

Parameter		Symbol	Min	Max	Unit	Test conditions
IIC (Standard mode, SMBus) ICFER.FMPE = 0	SCL input cycle time	t_{SCL}	6 (12) × t_{IICcyc} + 1300	—	ns	Figure 53.57
	SCL input high pulse width	t_{SCLH}	3 (6) × t_{IICcyc} + 300	—	ns	
	SCL input low pulse width	t_{SCLL}	3 (6) × t_{IICcyc} + 300	—	ns	
	SCL, SDA rise time	t_{Sr}	—	1000	ns	
	SCL, SDA fall time	t_{Sf}	—	300	ns	
	SCL, SDA input spike pulse removal time	t_{SP}	0	1 (4) × t_{IICcyc}	ns	
	SDA input bus free time when wakeup function is disabled	t_{BUF}	3 (6) × t_{IICcyc} + 300	—	ns	
	SDA input bus free time when wakeup function is enabled	t_{BUF}	3 (6) × t_{IICcyc} + 4 × t_{Pcyc} + 300	—	ns	
	START condition input hold time when wakeup function is disabled	t_{STAH}	t_{IICcyc} + 300	—	ns	
	START condition input hold time when wakeup function is enabled	t_{STAH}	1 (5) × t_{IICcyc} + t_{Pcyc} + 300	—	ns	
	Repeated START condition input setup time	t_{STAS}	1000	—	ns	
	STOP condition input setup time	t_{STOS}	1000	—	ns	
	Data input setup time	t_{SDAS}	t_{IICcyc} + 50	—	ns	
	Data input hold time	t_{SDAH}	0	—	ns	
	SCL, SDA capacitive load	C_b	—	400	pF	

Table 53.31 IIC timing (1) (2 of 2)

(1) Conditions: Middle drive output is selected in the Port Drive Capability bit in the PmnPFS register for the following pins: SDA0_B, SCL0_B, SDA1_B, SCL1_B, SDA2, SCL2.
(2) The following pins do not require setting: SCL0_A, SDA0_A, SCL1_A, SDA1_A.
(3) Use pins that have a letter appended to their names, for instance "_A" or "_B", to indicate group membership. For the IIC interface, the AC portion of the electrical characteristics is measured for each group.

Parameter		Symbol	Min	Max	Unit	Test conditions
IIC (Fast mode)	SCL input cycle time	t_{SCL}	6 (12) × t_{IICcyc} + 600	—	ns	Figure 53.57
	SCL input high pulse width	t_{SCLH}	3 (6) × t_{IICcyc} + 300	—	ns	
	SCL input low pulse width	t_{SCLL}	3 (6) × t_{IICcyc} + 300	—	ns	
	SCL, SDA rise time	t_{Sr}	20 × (external pullup voltage/5.5V)*1	300	ns	
	SCL, SDA fall time	t_{Sf}	20 × (external pullup voltage/5.5V)*1	300	ns	
	SCL, SDA input spike pulse removal time	t_{SP}	0	1 (4) × t_{IICcyc}	ns	
	SDA input bus free time when wakeup function is disabled	t_{BUF}	3 (6) × t_{IICcyc} + 300	—	ns	
	SDA input bus free time when wakeup function is enabled	t_{BUF}	3 (6) × t_{IICcyc} + 4 × t_{Pcyc} + 300	—	ns	
	START condition input hold time when wakeup function is disabled	t_{STAH}	t_{IICcyc} + 300	—	ns	
	START condition input hold time when wakeup function is enabled	t_{STAH}	1 (5) × t_{IICcyc} + t_{Pcyc} + 300	—	ns	
	Repeated START condition input setup time	t_{STAS}	300	—	ns	
	STOP condition input setup time	t_{STOS}	300	—		
	Data input setup time	t_{SDAS}	t_{IICcyc} + 50	—	ns	
	Data input hold time	t_{SDAH}	0	—	ns	
	SCL, SDA capacitive load	C_b	—	400	pF	

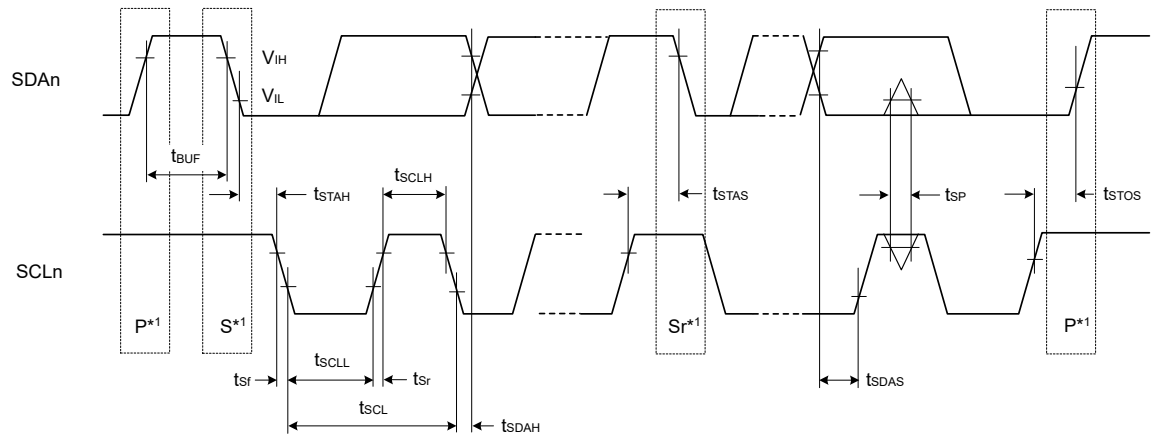
Note: t_{IICcyc}: IIC internal reference clock (IICφ) cycle, t_{Pcyc}: PCLKB cycle.
Note: Values in parentheses apply when ICMR3.NF[1:0] is set to 11b while the digital filter is enabled with ICFER.NFE set to 1.
Note: Must use pins that have a letter appended to their name, for instance "_A", "_B", to indicate group membership. For the IIC interface, the AC portion of the electrical characteristics is measured for each group.
Note 1. Only supported for SCL0_A, SDA0_A, SCL1_A, and SDA1_A.

Table 53.32 IIC timing (2)

Setting of the SCL0/1_A, SDA0/1_A pins is not required with the Port Drive Capability bit in the PmnPFS register.

Parameter		Symbol	Min	Max	Unit	Test conditions
IIC (Fast-mode+) ICFER.FMPE = 1	SCL input cycle time	t_{SCL}	6 (12) × t_{IICcyc} + 240	—	ns	Figure 53.57
	SCL input high pulse width	t_{SCLH}	3 (6) × t_{IICcyc} + 120	—	ns	
	SCL input low pulse width	t_{SCLL}	3 (6) × t_{IICcyc} + 120	—	ns	
	SCL, SDA rise time	t_{Sr}	—	120	ns	
	SCL, SDA fall time	t_{Sf}	20 × (external pullup voltage/ 5.5V)	120	ns	
	SCL, SDA input spike pulse removal time	t_{SP}	0	1 (4) × tIICcyc	ns	
	SDA input bus free time when wakeup function is disabled	t_{BUF}	3 (6) × t_{IICcyc} + 120	—	ns	
	SDA input bus free time when wakeup function is enabled	t_{BUF}	3 (6) × t_{IICcyc} + 4 × t_{Pcyc} + 120	—	ns	
	Start condition input hold time when wakeup function is disabled	t_{STAH}	t_{IICcyc} + 120	—	ns	
	START condition input hold time when wakeup function is enabled	t_{STAH}	1 (5) × t_{IICcyc} + t_{Pcyc} + 120	—	ns	
	Restart condition input setup time	t_{STAS}	120	—	ns	
	Stop condition input setup time	t_{STOS}	120	—	ns	
	Data input setup time	t_{SDAS}	t_{IICcyc} + 30	—	ns	
	Data input hold time	t_{SDAH}	0	—	ns	
	SCL, SDA capacitive load	C_b *1	—	550	pF	

Note: t_{IICcyc}: IIC internal reference clock (IICφ) cycle, t_{Pcyc}: PCLKB cycle.
Note: Values in parentheses apply when ICMR3.NF[1:0] is set to 11b while the digital filter is enabled with ICFER.NFE set to 1.
Note 1. Cb indicates the total capacity of the bus line.



Note 1. S, P, and Sr indicate the following conditions:
S: Start condition
P: Stop condition
Sr: Restart condition

Figure 53.57 I²C bus interface input/output timing

53.3.14 SSIE Timing

Table 53.33 SSIE timing

(1) High drive output is selected with the Port Drive Capability bit in the PmnPFS register.
(2) Use pins that have a letter appended to their names, for instance "_A" , "_B" or "_C" to indicate group membership. For the SSIE interface, the AC portion of the electrical characteristics is measured for each group.

Parameter			Symbol	Target specification		Unit	Comments
				Min.	Max.		
SSIBCK0	Cycle	Master	t_O	80	—	ns	Figure 53.58
		Slave	t_I	80	—	ns	
	High level/ low level	Master	t_{HC}/t_{LC}	0.35	—	t_O	
		Slave		0.35	—	t_I	
	Rising time/ falling time	Master	t_{RC}/t_{FC}	—	0.15	t_O / t_I	
		Slave		—	0.15	t_O / t_I	
SSILRCK0/ SSIFS0, SSITXD0, SSIRXD0, SSIDATA0	Input set up time	Master	t_{SR}	12	—	ns	Figure 53.60, Figure 53.61
		Slave		12	—	ns	
	Input hold time	Master	t_{HR}	8	—	ns	
		Slave		15	—	ns	
	Output delay time	Master	t_{DTR}	-10	5	ns	
		Slave		0	20	ns	Figure 53.60, Figure 53.61
	Output delay time from SSILRCK0/ SSIFS0 change	Slave	t_{DTRW}	—	20	ns	Figure 53.62*1
GTIOC2A, AUDIO_CLK	Cycle		t_{EXcyc}	20	—	ns	Figure 53.59
	High level/ low level		t_{EXL}/t_{EXH}	0.4	0.6	t_{EXcyc}	

Note 1. For slave-mode transmission, SSIE has a path, through which the signal input from the SSILRCK0/SSIFS0 pin is used to generate transmit data, and the transmit data is logically output to the SSITXD0 or SSIDATA0 pin.

53.3.15 SD/MMC Host Interface Timing

Table 53.34 SD/MMC Host Interface signal timing

Conditions: High drive output is selected in the Port Drive Capability bit in the PmnPFS register.
Clock duty ratio is 50%.

Parameter	Symbol	Min	Max	Unit	Test conditions
SDCLK clock cycle	T_{SDCYC}	20	—	ns	Figure 53.63
SDCLK clock high pulse width	T_{SDWH}	6.5	—	ns	
SDCLK clock low pulse width	T_{SDWL}	6.5	—	ns	
SDCLK clock rise time	T_{SDLH}	—	3	ns	
SDCLK clock fall time	T_{SDHL}	—	3	ns	
SDCMD/SDDAT output data delay	T_{SDODLY}	–7	4	ns	
SDCMD/SDDAT input data setup	T_{SDIS}	4.5	—	ns	
SDCMD/SDDAT input data hold	T_{SDIH}	1.5	—	ns	

Note: Must use pins that have a letter appended to their name, for instance “_A”, “_B”, to indicate group membership. For the SD/MMC Host interface, the AC portion of the electrical characteristics is measured for each group.

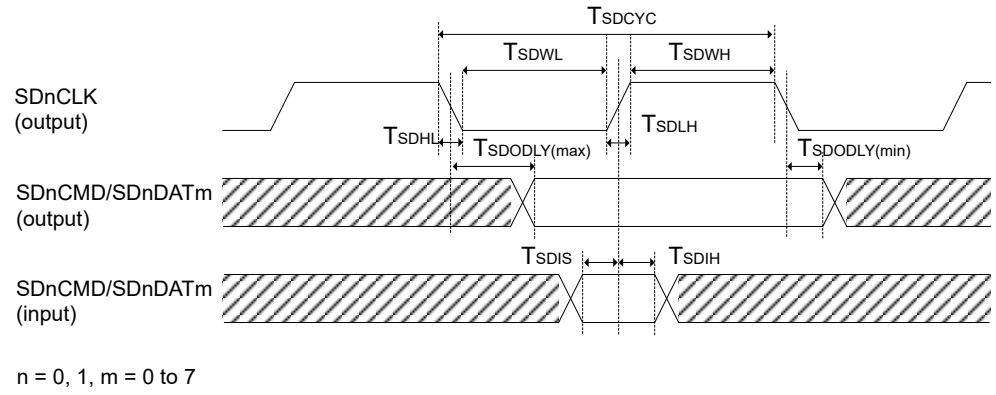

Figure 53.63 SD/MMC Host Interface signal timing

53.3.16 ETHERC Timing

Table 53.35 ETHERC timing (1 of 2)

Conditions: ETHERC (RMII): Middle drive output is selected in the Port Drive Capability bit in the PmnPFS register for the following pins: ET0_MDC, ET0_MDIO.
For other pins, high drive output is selected in the Port Drive Capability bit in the PmnPFS register.
ETHERC (MII): Middle drive output is selected in the Port Drive Capability bit in the PmnPFS register.

Parameter		Symbol	Min	Max	Unit	Test conditions
ETHERC (RMII)	REF50CK0 cycle time	T_{ck}	20	—	ns	Figure 53.64 to Figure 53.67
	REF50CK0 frequency, typical 50 MHz	—	—	50 + 100 ppm	MHz	
	REF50CK0 duty	—	35	65	%	
	REF50CK0 rise/fall time	$T_{ckr/ckf}$	0.5	3.5	ns	
	RMII_xxxx*1 output delay	T_{co}	2.5	12.0	ns	
	RMII_xxxx*2 setup time	T_{su}	3	—	ns	
	RMII_xxxx*2 hold time	T_{hd}	1	—	ns	
	RMII_xxxx*1, *2 rise/fall time	T_r/T_f	0.5	4	ns	
	ET0_WOL output delay	t_{WOLd}	1	23.5	ns	Figure 53.68

Table 53.35 ETHERC timing (2 of 2)

Conditions: ETHERC (RMII): Middle drive output is selected in the Port Drive Capability bit in the PmnPFS register for the following pins: ET0_MDC, ET0_MDIO.
For other pins, high drive output is selected in the Port Drive Capability bit in the PmnPFS register.
ETHERC (MII): Middle drive output is selected in the Port Drive Capability bit in the PmnPFS register.

Parameter		Symbol	Min	Max	Unit	Test conditions
ETHERC (MII)	ET0_TX_CLK cycle time	t_{Tcyc}	40	—	ns	—
	ET0_TX_EN output delay	t_{TENd}	1	20	ns	Figure 53.69
	ET0_ETXD0 to ET_ETXD3 output delay	t_{MTDd}	1	20	ns	
	ET0_CRS setup time	t_{CRSs}	10	—	ns	
	ET0_CRS hold time	t_{CRSh}	10	—	ns	
	ET0_COL setup time	t_{COLs}	10	—	ns	Figure 53.70
	ET0_COL hold time	t_{COLh}	10	—	ns	
	ET0_RX_CLK cycle time	t_{TRcyc}	40	—	ns	—
	ET0_RX_DV setup time	t_{RDVs}	10	—	ns	Figure 53.71
	ET0_RX_DV hold time	t_{RDVh}	10	—	ns	
	ET0_ERXD0 to ET_ERXD3 setup time	t_{MRDs}	10	—	ns	
	ET0_ERXD0 to ET_ERXD3 hold time	t_{MRDh}	10	—	ns	
	ET0_RX_ER setup time	t_{RERs}	10	—	ns	Figure 53.72
	ET0_RX_ER hold time	t_{RESh}	10	—	ns	
	ET0_WOL output delay	t_{WOLd}	1	23.5	ns	Figure 53.73

Note: The following pins must use pins that have a letter appended to their name, for instance "_A", "_B", to indicate group membership. For the ETHERC (RMII) Host interface, the AC portion of the electrical characteristics is measured for each group. REF50CK0_A, REF50CK0_B, RMII0_xxxx_A, RMII0_xxxx_B.
Note 1. RMII_TXD_EN, RMII_TXD1, RMII_TXD0.
Note 2. RMII_CRS_DV, RMII_RXD1, RMII_RXD0, RMII_RX_ER.

Table 53.46 A/D internal reference voltage characteristics

Parameter	Min	Typ	Max	Unit	Test conditions
A/D internal reference voltage	1.13	1.18	1.23	V	—
Sampling time	4.15	—	—	µs	—

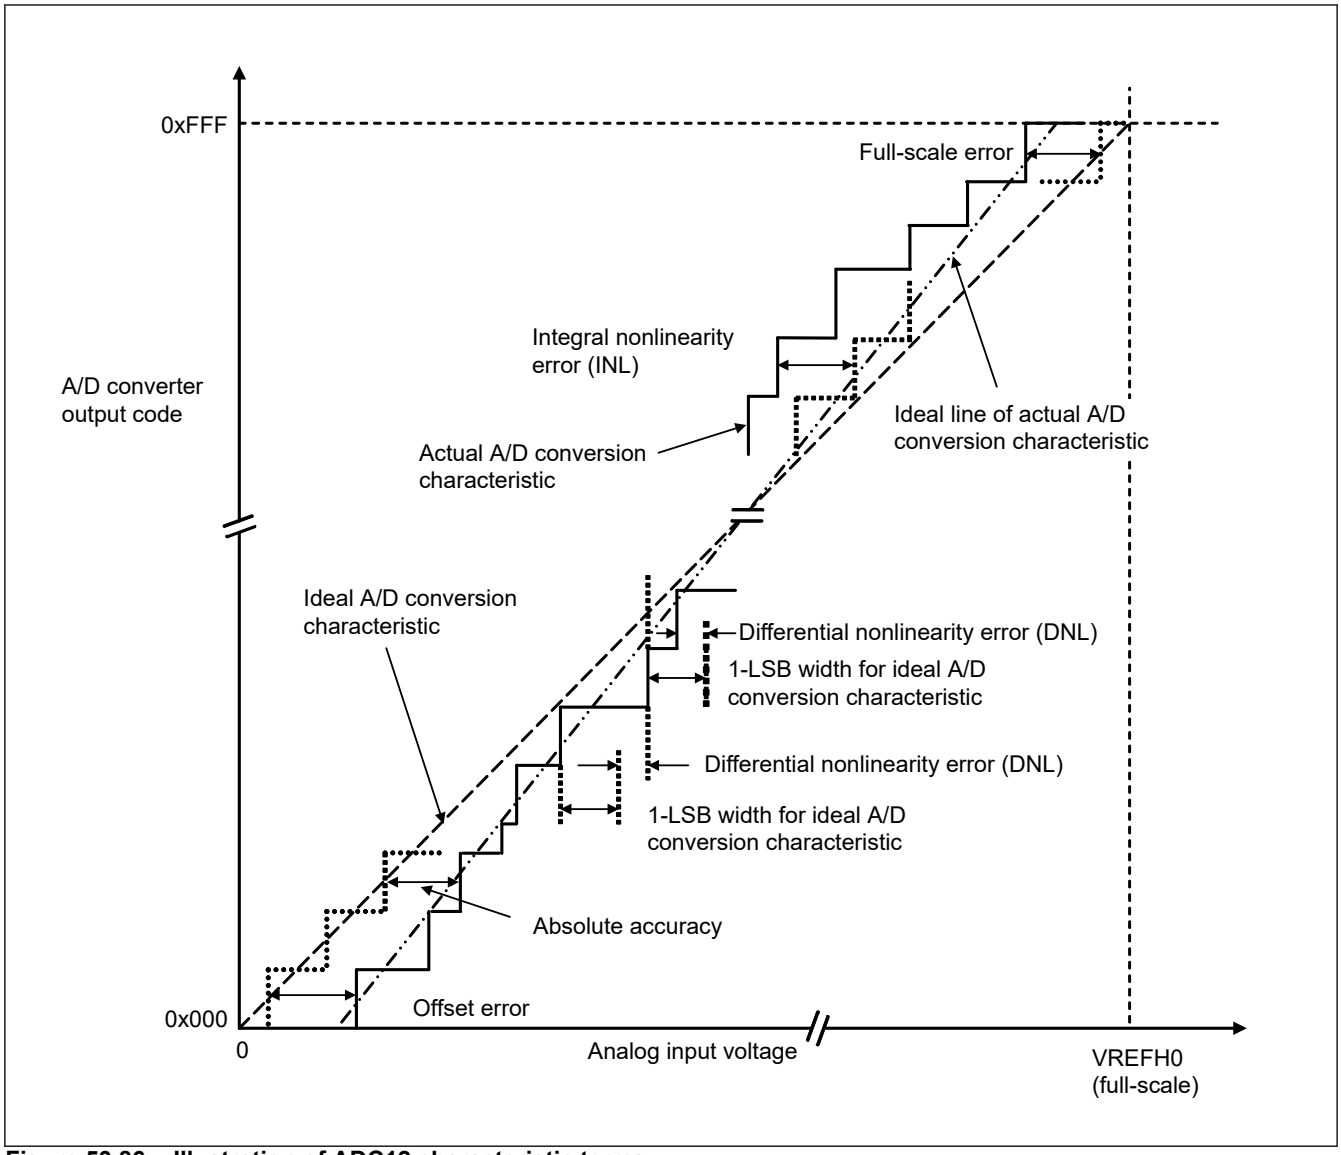

Figure 53.86 Illustration of ADC12 characteristic terms

Absolute accuracy

Absolute accuracy is the difference between output code based on the theoretical A/D conversion characteristics, and the actual A/D conversion result. When measuring absolute accuracy, the voltage at the midpoint of the width of the analog input voltage (1-LSB width), which can meet the expectation of outputting an equal code based on the theoretical A/D conversion characteristics, is used as an analog input voltage. For example, if 12-bit resolution is used and the reference voltage VREFH0 = 3.072 V, then the 1-LSB width becomes 0.75 mV, and 0 mV, 0.75 mV, and 1.5 mV are used as the analog input voltages. If the analog input voltage is 6 mV, an absolute accuracy of ±5 LSB means that the actual A/D conversion result is in the range of 0x003 to 0x00D, though an output code of 0x008 can be expected from the theoretical A/D conversion characteristics.

Integral nonlinearity error (INL)

Integral nonlinearity error is the maximum deviation between the ideal line when the measured offset and full-scale errors are zeroed, and the actual output code.

Differential nonlinearity error (DNL)

Differential nonlinearity error is the difference between the 1-LSB width based on the ideal A/D conversion characteristics and the width of the actual output code.

Offset error

Offset error is the difference between the transition point of the ideal first output code and the actual first output code.

Full-scale error

Full-scale error is the difference between the transition point of the ideal last output code and the actual last output code.

53.6 DAC12 Characteristics

			30*2 *3	—	—	30*2 *3	—	—		Ta = +85°C

Note 1. This is the minimum number of times to guarantee all the characteristics after reprogramming. The guaranteed range is from 1 to the minimum value.
Note 2. This indicates the minimum value of the characteristic when reprogramming is performed within the specified range.
Note 3. This result is obtained from reliability testing.
Note 4. The reprogram/erase cycle is the number of erasures for each block. When the reprogram/erase cycle is n times (n = 10,000), erasing can be performed n times for each block. For example, when 128-byte programming is performed 64 times for different addresses in 8-KB blocks, and then the entire block is erased, the reprogram/erase cycle is counted as one. However, programming the same address several times as one erasure is not enabled. Overwriting is prohibited.
Note 5. Time for resumption includes time for reapplying the erasing pulse (up to one full pulse) that was cut off at the time of suspension.
Note 6. The reference value at VCC = 3.3V and room temperature.

USBHS	USBHS_OVRCURx/ USBHS_VBUS	Hi-Z	Keep-O*2		Keep*3	Hi-Z	Keep
	USBHS_DP/ USBHS_DM	Hi-Z	Keep-O*4		Keep*5	Hi-Z	Keep
RTC	RTCICx	Hi-Z	Keep-O*2		Keep*3	Hi-Z	Keep
	RTCOUT	Hi-Z	[RTCOUT selected] RTCOUT output		Keep	Hi-Z	Keep
CLKOUT	CLKOUT	Hi-Z	[CLKOUT selected] CLKOUT output		Keep	Hi-Z	Keep
DAC	DAn	Hi-Z	[DAn output (DAOE = 1)] D/A output retained		Keep	Hi-Z	Keep
External bus (CS area)	EBCLK	Hi-Z	[EBCLK output] H		Keep	Hi-Z	Keep
	Dx	Hi-Z	[Dx output] Hi-Z		Keep	Hi-Z	Keep
	Ax	Hi-Z	[Ax output] Hi-Z	[Ax output] Keep-O	Keep	Hi-Z	Keep
	BCx/CSx/RD/WRx	Hi-Z	[BCx/CSx/RD/WRx output] Hi-Z	[BCx/CSx/RD/WRx output] H	Keep	Hi-Z	Keep
	ALE	Hi-Z	[ALE output] Hi-Z	[ALE output] L	Keep	Hi-Z	Keep
Others	—	Hi-Z	Keep-O		Keep	Hi-Z	Keep

Note: H: High-level
L: Low-level
Hi-Z: High-impedance
Keep-O: Output pins retain their previous values. Input pins go to high-impedance.
Keep: Pin states are retained during periods in Software Standby mode.

Note 1. Retains the I/O port state until the DPSBYCR.IOKEEP bit is cleared to 0.
Note 2. Input is enabled if the pin is specified as the Software Standby canceling source while it is used as an external interrupt pin.
Note 3. Input is enabled if the pin is specified as the Deep Software Standby canceling source.
Note 4. Input is enabled while the pin is used as an input pin.
Note 5. For host operation, set the USBHS.SYSCFG.DRPD bit to 1 to enable the USBHS_DP and USBHS_DM pull-down resistors. For device operation, set the USBHS.SYSCFG.DPRPU bit to 1 to enable the DP pull-up resistor.

Appendix 2. Package Dimensions

Information on the latest version of the package dimensions or mountings is displayed in “Packages” on the Renesas Electronics Corporation website.

JEITA Package Code	RENESAS Code	MASS (Typ.) [g]
P-LFQFP176-24×24-0.50	PLQP0176KB-C	1.8

Appendix 3. I/O Registers

This appendix describes I/O register address and access cycles by function.

3.1 Peripheral Base Addresses

This section provides the base addresses for peripherals described in this manual. Table 3.1 shows the name, description, and the base address of each peripheral.

Table 3.1 Peripheral base address (1 of 3)

Name	Description	Base address
RMPU	Renesas Memory Protection Unit	0x4000_0000
TZF	TrustZone Filter	0x4000_0E00
SRAM	SRAM Control	0x4000_2000
BUS	BUS Control	0x4000_3000
DMAC0	Direct memory access controller 0	0x4000_5000
DMAC1	Direct memory access controller 1	0x4000_5040
DMAC2	Direct memory access controller 2	0x4000_5080
DMAC3	Direct memory access controller 3	0x4000_50C0
DMAC4	Direct memory access controller 4	0x4000_5100
DMAC5	Direct memory access controller 5	0x4000_5140
DMAC6	Direct memory access controller 6	0x4000_5180
DMAC7	Direct memory access controller 7	0x4000_51C0
DMA	DMAC Module Activation	0x4000_5200
DTC	Data Transfer Controller	0x4000_5400
ICU	Interrupt Controller	0x4000_6000
CACHE	CACHE	0x4000_7000
CPSCU	CPU System Security Control Unit	0x4000_8000
DBG	Debug Function	0x400_1B000
FCACHE	Flash Cache	0x400_1C100
SYSC	System Control	0x4001_E000
PORT0	Port 0 Control Registers	0x4008_0000
PORT1	Port 1 Control Registers	0x4008_0020

Note: Name = Peripheral name
Description = Peripheral functionality
Base address = Lowest reserved address or address used by the peripheral

3.2 Access Cycles

This section provides access cycle information for the I/O registers described in this manual.

- Registers are grouped by associated module.
- The number of access cycles indicates the number of cycles based on the specified reference clock.
- In the internal I/O area, reserved addresses that are not allocated to registers must not be accessed, otherwise operations cannot be guaranteed.
- The number of I/O access cycles depends on bus cycles of the internal peripheral bus, divided clock synchronization cycles, and wait cycles of each module. Divided clock synchronization cycles differ depending on the frequency ratio between ICLK and PCLK.
- When the frequency of ICLK is equal to that of PCLK, the number of divided clock synchronization cycles is always constant.
- When the frequency of ICLK is greater than that of PCLK, at least 1 PCLK cycle is added to the number of divided clock synchronization cycles.
- The number of write access cycles indicates the number of cycles obtained by non-bufferable write access.

Note: This applies to the number of cycles when access from the CPU does not conflict with the instruction fetching to the external memory or bus access from other bus masters such as DTC or DMAC.

Table 3.2 Access cycles (1 of 3)

Peripherals	Address		Number of access cycles				Cycle Unit	Related function
			ICLK = PCLK		ICLK > PCLK*1			
	From	To	Read	Write	Read	Write

Table 3.2 Access cycles (3 of 3)

Peripherals	Address		Number of access cycles					
			ICLK = FCLK		ICLK > FCLK*1		Cycle Unit	Related function
	From	To	Read	Write	Read	Write		
FLAD, FACI	0x407F_C000	0x407F_EFFF	5	4	2 to 5	2 to 4	FCLK	Data Flash, Flash Application Command Interface

Note 1. If the number of PCLK or FCLK cycles is non-integer (for example 1.5), the minimum value is without the decimal point, and the maximum value is rounded up to the decimal point. For example, 1.5 to 2. 5 is 1 to 3.
Note 2. BWAIT is the number of waits (not cycles) described in the USBHS.BUSWAIT register.
Note 3. When accessing a 16-bit register (FTDRHL, FRDRHL, FCR, FDR, LSR, and CDR), access is 2 cycles more than the value shown in Table 3.2. When accessing an 8-bit register (including FTDRH, FTDRL, FRDRH, and FRDRL), the access cycles are as shown in Table 3.2.
Note 4. When accessing the 32-bit register (SPDR), access is 2 cycles more than the value in Table 3.2. When accessing an 8-bit or 16-bit register (SPDR_HA), the access cycles are as shown in Table 3.2.
Note 5. The access cycles depend on the QSPI bus cycles.

Revision History

Revision 1.10 — Mar 31, 2021

First edition, issued

Revision 1.20 — Dec 6, 2022

1. Overview:
- Fixed the ADC12 functional description in Table 1.9 Analog.
- Added Table 1.13 I/O ports to 1.1 Function Outline.
- Merged and fixed Figure 1.2 and Figure 1.3 Part numbering scheme.
- Added the row of PLBG0144KB-A to Table 1.14 and Table 1.15 Product list.
- Merged Table 1.14 and Table 1.15 Product list.
- Added the column of BGA 144-pin to Table 1.15 Function Comparison.
- Fixed the row of ADC12 in Table 1.15 Function Comparison.
- Added the row of I/O ports to Table 1.15 Function Comparison.
- Added Note 2 to Table 1.15 Function Comparison.
- Added Figure 1.6 Pin assignment for BGA 144-pin.
- Added the column of BGA 144-pin to Table 1.17 Pin list.
- Changed from SSISCK0_B to SSIBCK0_B in Table 1.17 Pin list.

2. CPU:
- Fixed 2.13.2.3 Connecting sequence and JTAG/SWD authentication.

6. Option-Setting Memory:
- Fixed 6.2.1 OFS0.
- Fixed Note of the HOCOEN bit in 6.2.4 OFS1, OFS1_SEC, OFS1_SEL.
- Fixed address in 6.2.6 BPS, BPS_SEC, BPS_SEL.

7. Low Voltage Detection:
- Fixed Note in Figure 7.4 Example of voltage monitor 0 reset operation.
- Fixed the function of the LVD1LVL[4:0] bits in 7.2.2 LVD1CMPCR.
- Fixed the function of the LVD2LVL[2:0] bits in 7.2.3 LVD2CMPCR.

8. Clock Generation Circuit:
- Added the sentence in 8.7.5 USB Clock (USBCLK).
- Fixed the sentence in 8.7.10 CANFD Clock (CANFDCLK).
- Fixed Figure 8.1 Clock generation circuit block diagram.
- Fixed 8.2.9 MOSCCR.
- Fixed 8.2.18 OSTDSR.
- Fixed Figure 8.10 Timing of clock source switching.
- Fixed 8.8.5 Notes on Using Sub-Clock Oscillator.

10. Low Power Modes:
- Fixed the DPFSAn bits in 10.2.2 DPFSAR.
- Fixed 10.5.1 Setting Operating Power Control Mode.
- Fixed Figure 10.7 Setting example of using SCI0 in Snooze mode entry.
- Fixed 10.8.4 Snooze Operation Example.

11. Battery Backup Function:
- Fixed the cross-reference to 19.5.5 I/O Buffer Specification in 11.2.6 VBTICTLR.

13. Interrupt Controller Unit:
- Fixed 13.2.10 IRQCRi.
- Fixed 13.2.17 SELSR0.

14. Buses:
- Added the sentence to the description of the EMODE bit in 14.3.3 CSnCR.
- Fixed Note 1 in Table 14.9 Cache specifications.

19. I/O Ports:
- Fixed Table 19.10 Register settings for input/output pin function (PORT5).

21. General PWM Timer:
- Fixed the setting condition of the TCFPU flag in 21.2.16 GTST.
- Fixed 21.2.12 GTCR.
- Fixed Note 1 in Table 21.4 Settings of GTIOA[4:0] and GTIOB[4:0] bits.
- Fixed Table 21.21 Example setting for automatic dead time setting function in saw-wave one-shot pulse mode, and triangle-wave PWM mode 3.

Revision 1.20 — Dec 6, 2022

22. Low Power Asynchronous General Purpose Timer:
- Fixed the cross-reference to 19.5.5 I/O Buffer Specification in Table 22.2 AGT I/O pins.
- Fixed Note 5 in 22.2.5 AGTMR1.
- Fixed Figure 22.12 Operation example in compare match function (TOPOLA = 0, TOPOLB = 0).
- Fixed 22.4.3 When Changing Mode.

23. Realtime Clock:
- Removed the redundant phrase in 23.2.29 RTCCRn.

24. Watchdog Timer:
- Fixed Figure 24.1 WDT block diagram.
- Fixed 24.2.2 WDTCR.
- Fixed 24.2.4 WDTRCR.
- Fixed 24.2.5 WDTCSTPR.
- Fixed 24.3.1.1 Register start mode.
- Fixed 24.3.1.2 Auto start mode.
- Fixed 24.3.2 Controlling Writes to the WDTCR, WDTRCR, and WDTCSTPR Registers.
- Fixed 24.3.3 Refresh Operation.
- Fixed 24.3.8 Association between Option Function Select Register 0 (OFS0) and WDT Registers.
- Fixed 24.5.1 ICU Event Link Setting Register n (IELSRn) Setting.

25. Independent Watchdog Timer:
- Fixed Figure 25.1 IWDT block diagram.
- Fixed 25.2.3 OFS0.
- Fixed 25.3.1 Auto Start Mode.
- Fixed 25.3.2 Refresh Operation.
- Fixed Figure 25.4 IWDT refresh operation waveforms when OFS0.IWDTCKS[3:0] = 0000b, OFS0.IWDTTOPS[1:0] = 11b.
- Fixed Figure 25.5 Processing for reading IWDT counter value when OFS0.IWDTCKS[3:0] = 0000b, OFS0.IWDTTOPS[1:0] = 11b.

26. Ethernet MAC Controller:
- Fixed the cross-reference to Figure 26.2 in 26.1 Overview.

28. USB 2.0 Full-Speed Module:
- Fixed the specifications of features in Table 28.1 USBFS specifications.
- Fixed 28.2.3 DVSTCTR0.
- Fixed 28.2.7 DnFIFOSEL.
- Fixed 28.2.17 INTSTS1.
- Fixed 28.2.29 DCPMAXP.
- Fixed 28.2.35 PIPEnCTR.

29. USB 2.0 High-Speed Module:
- Fixed the specifications of features in Table 29.1 USBHS specifications.
- Added CFIFO to 29.2.7 CFIFO, DnFIFO.

30. Serial Communications Interface:
- Removed the sentence from the description of the DRES bit in 30.2.29 FCR.

31. I^2C Bus Interface:
- Fixed Note 1 in Table 31.1 IIC specifications.
- Fixed the sentence in 31.10.1 Master Arbitration-Lost Detection (MALE Bit).

32. CANFD:
- Fixed the symbol in Table 32.2 CANFD Registers.
- Fixed the bit specification table in 32.2.26 CFDRFCCn.
- Removed the sentence from the description of the DRES bit in 30.2.29 FCR.

36. Octa Serial Peripheral Interface:
- Fixed the function of the DV0SZ[29:0] bits in 36.2.4 DSR0.
- Fixed the sentence in 36.3.2 Address Map.

38. Serial Sound Interface Enhanced:
- Fixed Note of the AUCKE bit in 38.4.3 SSIFCR.
- Fixed the sentence in Figure 38.43 SSIE state transition.
- Fixed 38.11.1.1 SSIBCK control.
- Fixed 38.11.2.1 AUCKE control.
- Fixed the list No.3 in 38.11.3.4 Switching transfer modes.

Revision 1.20 — Dec 6, 2022

43. 12-Bit A/D Converter:
- Fixed the introduction in 43.1 Overview.
- Fixed the row of input channels in Table 43.1 ADC12 specifications.
- Added Note 4 to Table 43.1 ADC12 specifications.
- Added Note 3 to Table 43.2 ADC12 functions.
- Added Note 1 to Table 43.3 ADC12 I/O pins (unit 0).
- Added Note 1 to Table 43.4 ADC12 I/O pins (unit 1).
- Updated Table 43.18 Settable combinations of ADADC register.
- Fixed the CMPBE bit in 43.2.21 ADCMPCR.

46. Capacitive Touch Sensing Unit:
- Fixed 46.2.20 CTSUERRS.

48. SRAM:
- Fixed the function of the OAD bit in 48.2.2 PARIOAD.

50. Flash Memory:
- Fixed the cross-reference to Table 1.14 Product list in 50.4.6 PNRn.

52. Security Features:
- Fixed the sentence in 52.4 Key Injection.

53. Electrical Characteristics:
- Fixed Table 53.3 DC characteristics.
- Fixed Table 53.11 Thermal Resistance.

Appendix:
- Added Figure 2.2 BGA 176-pin to Appendix 2. Package Dimensions.
- Fixed Figure 2.4 BGA 144-pin in Appendix 2. Package Dimensions.
